Amazon CloudWatch

Amazon CloudWatch: User Guide

Table of Contents

What is Amazon CloudWatch?

Amazon CloudWatch monitors your Amazon Web Services (Amazon) resources and the applications you run on Amazon in real time, and offers many tools to give you system-wide observability of your application performance, operational health, and resource utilization.

Topics

Operational visibility with metrics, alarms, and dashboards

Metrics collect and track key performance data at user-defined intervals. Many Amazon services automatically report metrics into CloudWatch, and you can also publish custom metrics in CloudWatch from your applications.

Dashboards offer a unified view of your resources and applications with visualizations of your metrics and logs in a single location. You can also share dashboards across accounts and Regions for enhanced operational awareness. CloudWatch provides curated automatic dashboards for many Amazon services, so that you don't have to build them yourself.

You can set up alarms that continuously monitor CloudWatch metrics against user-defined thresholds. They can automatically alert you to breaches of the thresholds, and can also automatically respond to changes in your resources' behavior by triggering automated actions.

Application performance monitoring (APM)

With Application Signals you can automatically detect and monitor your applications' key performance indicators like latency, error rates, and request rates without manual instrumentation or code changes. Application Signals also provides curated dashboards so you can begin monitoring with a minimum of setup.

CloudWatch Synthetics complements this by enabling you to proactively monitor your endpoints and APIs through configurable scripts called *canaries* that simulate user behavior and alert you to availability issues or performance degradation before they impact real users. You can also use CloudWatch RUM to gather performance data from real user sessions.

Use Service Level Objectives (SLOs) in CloudWatch to define, track, and alert on specific reliability targets for your applications, helping you maintain service quality commitments by setting error budgets and monitoring SLO compliance over time.

Infrastructure monitoring

Many Amazon services automatically send basic metrics to CloudWatch for free. Services that send metrics are listed here. Additionally, CloudWatch provides additional monitoring capabilities for several key pieces of Amazon infrastructure:

- Database Insights allows you to monitor database performance metrics in real time, analyze SQL query performance, and troubleshoot database load issues for Amazon database services.
- Lambda Insights provides system-level metrics for Lambda functions, including memory and CPU utilization tracking, and cold start detection and analysis.
- Container Insights allows you to collect and analyze metrics from containerized applications, on Amazon ECS clusters, Amazon EKS clusters, and self-managed Kubernetes clusters on Amazon EC2.

Collect, store, and query logs

CloudWatch Logs offers a suite of powerful features for comprehensive log management and analysis. Logs ingested from Amazon services and custom applications are stored in log groups and streams for easy organization. Use CloudWatch Logs Insights to perform interactive, fast queries on your log data, with a choice of three query languages including SQL and PPL. Use log anomaly detection to find unusual patterns in log events in a log group, which can indicate issues. Create metric filters to extract numerical values from logs and generate CloudWatch metrics, which you can use for alerting and dashboards. Set up subscription filters to process and analyze logs in real-time or route them to other services like Amazon S3 or Firehose.

Use the CloudWatch agent to gather metrics, logs, and traces from Amazon EC2 fleets

Use the CloudWatch agent to collect detailed system metrics about processes, CPU, memory, disk usage, and network performance from your fleets of Amazon EC2 instances and on-premises servers. You can also collect and monitor custom metrics from your applications, aggregate logs from multiple sources, and configure alarms based on the collected data. You can also use the agent to gather GPU metrics. The agent supports both Windows and Linux operating systems and can integrate with Systems Manager for centralized configuration management.

Cross-account monitoring

CloudWatch cross-account observability lets you set up a central monitoring account to monitor and troubleshoot applications that span multiple accounts. From the central account, you can view metrics, logs, and traces from source accounts across your organization. This centralized approach enables you to create cross-account dashboards, set up alarms that watch metrics from multiple accounts, and perform root-cause analysis across account boundaries. With CloudWatch cross-account observability, you can link source accounts either individually or link them automatically through Amazon Organizations.

Solutions catalog

CloudWatch offers a catalog of readily available configurations to help you quickly implement monitoring for various Amazon services and common workloads, such as Java Virtual Machines (JVM), NVIDIA GPU, Apache Kafka, Apache Tomcat, and NGINX. These solutions provide focused guidance, including instructions for installing and configuring the CloudWatch agent, deploying pre-defined custom dashboards, and setting up related alarms.

Network and internet monitoring

CloudWatch provides comprehensive network and internet monitoring capabilities through CloudWatch Network Monitoring.

Internet Monitor uses Amazon global networking data to analyze internet performance and availability between your applications and end users. With an internet monitor, you can identify or get notifications for increased latency or regional disruptions that impact your customers. Internet monitors work by analyzing your VPC flow logs to provide automated insights about network traffic patterns and performance. You can also get suggestions for how to optimize application performance for your clients.

Network Flow Monitor displays network performance information gathered by lightweight software agents that you install on your instances. Using a flow monitor, you can quickly visualize packet loss and latency of your network connections over a time frame that you specify. Each monitor also generates a network health indicator (NHI), which tells you whether there were Amazon network issues for the network flows tracked by your monitor during the time period that you're evaluating.

When you connect by using Amazon Direct Connect, you can use synthetic monitors in Network Synthetic Monitor to proactively monitor network connectivity by running synthetic tests between a VPC and on-premises endpoints. When you create a synthetic monitor, you specify probes by providing a VPC subnet and on-premises IP addresses. Amazon creates and manages the infrastructure in the background that is required to perform round-trip time and packet loss measurements with the probes. These tests detect issues with connectivity, DNS, and latency before they impact your applications, so that you can take action to improve your end users' experience.

Billing and costs

For complete information about CloudWatch pricing, see Amazon CloudWatch Pricing.

For information that can help you analyze your bill and possibly optimize and reduce costs, see Analyzing, optimizing, and reducing CloudWatch costs.

Amazon CloudWatch resources

The following related resources can help you as you work with this service.

Resource	Description
Amazon CloudWatch FAQs	The FAQ covers the top questions developers have asked about this product.

Resource	Description
Amazon Developer Center	A central starting point to find documentation, code examples, release notes, and other information to help you build innovative applications with Amazon.
Amazon Web Services Management Console	The console allows you to perform most of the functions of Amazon CloudWatch and various other Amazon offerings without programming.
Amazon CloudWatch Discussion Forums	Community-based forum for developers to discuss technical questions related to Amazon CloudWatch.
Amazon Web Services Support	The hub for creating and managing your Amazon Web Services Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and Amazon Trusted Advisor.
Amazon CloudWatch product i nformation	The primary web page for information about Amazon CloudWatch.
Contact Us	A central contact point for inquiries concerning Amazon billing, account, events, abuse, etc.

Getting set up

To use Amazon CloudWatch you need an Amazon account. Your Amazon account allows you to use services (for example, Amazon EC2) to generate metrics that you can view in the CloudWatch console, a point-and-click web-based interface. In addition, you can install and configure the Amazon command line interface (CLI).

Sign up for an Amazon Web Services account

If you do not have an Amazon Web Services account, use the following procedure to create one.

To sign up for Amazon Web Services

1. Open http://www.amazonaws.cn/ and choose **Sign Up**.
2. Follow the on-screen instructions.

Amazon sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to http://www.amazonaws.cn/ and choosing **My Account**.

Secure IAM users

After you sign up for an Amazon Web Services account, safeguard your administrative user by turning on multi-factor authentication (MFA). For instructions, see Enable a virtual MFA device for an IAM user (console) in the *IAM User Guide*.

To give other users access to your Amazon Web Services account resources, create IAM users. To secure your IAM users, turn on MFA and only give the IAM users the permissions needed to perform their tasks.

For more information about creating and securing IAM users, see the following topics in the *IAM User Guide*:

- Creating an IAM user in your Amazon Web Services account
- Access management for Amazon resources
- Example IAM identity-based policies

Sign in to the Amazon CloudWatch console

To sign in to the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. If necessary, use the navigation bar to change the Region to the Region where you have your Amazon resources.
3. Even if this is the first time you are using the CloudWatch console, **Your Metrics** could already report metrics, because you have used an Amazon product that automatically pushes metrics to Amazon CloudWatch for free. Other services require that you enable metrics.

   If you do not have any alarms, the **Your Alarms** section will have a **Create Alarm** button.

Set up the Amazon CLI

You can use the Amazon CLI or the Amazon CloudWatch CLI to perform CloudWatch commands. Note that the Amazon CLI replaces the CloudWatch CLI; we include new CloudWatch features only in the Amazon CLI.

For information about how to install and configure the Amazon CLI, see Getting Set Up with the Amazon Command Line Interface in the *Amazon Command Line Interface User Guide*.

For information about how to install and configure the Amazon CloudWatch CLI, see Set Up the Command Line Interface in the *Amazon CloudWatch CLI Reference*.

Analyzing, optimizing, and reducing CloudWatch costs

This section describes how Amazon CloudWatch features generate costs. It also provides methods that can help you analyze, optimize, and reduce CloudWatch costs. Throughout this section, we sometimes refer to pricing when describing CloudWatch features. For information about pricing, see Amazon CloudWatch pricing.

Topics

Analyze CloudWatch cost and usage data with Cost Explorer

With Amazon Cost Explorer, you can visualize and analyze cost and usage data for Amazon Web Services services over time, including CloudWatch. For more information, see Getting started with Amazon Cost Explorer.

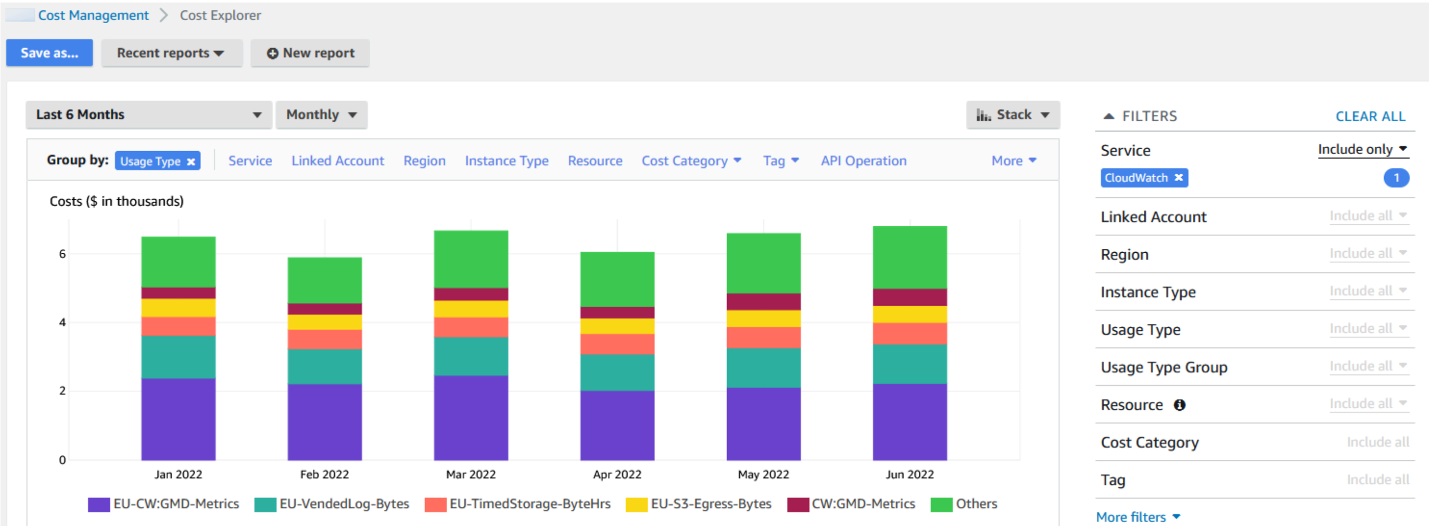
The following procedure describes how to use Cost Explorer to visualize and analyze CloudWatch cost and usage data.

To visualize and analyze CloudWatch cost and usage data

1. Sign in to the Cost Explorer console at https://console.aws.amazon.com/cost-management/home#/custom.
2. Under **FILTERS**, for **Service**, select **CloudWatch**.
3. For **Group by**, choose **Usage Type**. You can also group your results by other categories, such as the following:

   - **API Operation** – See which API operations generated the most costs.
   - **Region** – See which Regions generated the most costs.

The following image shows an example of the costs that CloudWatch features generated over six months.



To see which CloudWatch features generated the most costs, look at the values for `UsageType`. For example, `EU-CW:GMD-Metrics` represents the costs that CloudWatch bulk API requests generated.

> **Note**
>
> The strings for `UsageType` match specific features and Regions. For example, the first part of `EU-CW:GMD-Metrics` (EU) matches the Europe (Ireland) Region, and the second part of `EU-CW:GMD-Metrics` (`GMD-Metrics`) matches CloudWatch bulk API requests.
> The entire string for `UsageType` can be formatted as follows: `<Region>-CW:<Feature>` or `<Region>-<Feature>`.
> Some CloudWatch features such as logs and alarms also uses the `Global` Region to identify the Free Tier usage. For example, `Global-DataScanned-Bytes` represents free CloudWatch Logs data ingestion usage.
> To enhance readability, the strings for `UsageType` in the tables throughout this document have been shortened to their string suffixes. For example, `EU-CW:GMD-Metrics` is shortened to `GMD-Metrics`.

The following table includes the names of each CloudWatch feature, lists the names of each sub-feature, and lists the strings for `UsageType`.

CloudWatch feature	*CloudWatch sub-feature*	`UsageType`
CloudWatch metrics	*Custom metrics*	`MetricMonitorUsage`
	Detailed monitoring	`MetricMonitorUsage`
	Embedded metrics	`MetricMonitorUsage`
CloudWatch API requests	*API requests*	`Requests`
	Bulk (Get)	`GMD-Metrics`
	Contributor Insights	`GIRR-Metrics`
	Bitmap image snapshot	`GMWI-Metrics`
CloudWatch metric streams	*Metric streams*	`MetricStreamUsage`
CloudWatch dashboards	*Dashboard with 50 or fewer metrics*	`DashboardsUsageHour-Basic`
	Dashboard with more than 50 metrics	`DashboardsUsageHour`
CloudWatch alarms	*Standard (metric alarm)*	`AlarmMonitorUsage`
	High resolution (metric alarm)	`HighResAlarmMonitorUsage`
	Metrics Insights query alarm	`MetricInsightAlarmUsage`

CloudWatch feature	***CloudWatch sub-feature***	**UsageType**
	Composite (aggregated alarm)	`CompositeAlarmMonitorUsage`
Container Insights	Enhanced observability for Amazon EKS	`ObservationUsage`
	Enhanced observability for Amazon ECS	`MetricsUsage`
CloudWatch Application Signals	*Application Signals*	`Application-Signals`
CloudWatch custom logs	*Collect (data ingestion for Standard log class)*	`DataProcessing-Bytes`
	Collect (data ingestion for Infrequent Access log class)	`DataProcessingIA-Bytes`
	Analyze (query)	`DataScanned-Bytes`
	Analyze (Live Tail)	`Logs-LiveTail`
	Store (archive)	`TimedStorage-ByteHrs`
	Detect and mask (data protection)	`DataProtection-Bytes`
CloudWatch vended logs	*Delivery (Amazon CloudWatch Logs Standard log class)*	`VendedLog-Bytes`
	Delivery (CloudWatch Logs Infrequent Access log class)	`VendedLogIA-Bytes`

CloudWatch feature	*CloudWatch sub-feature*	UsageType
	Delivery (Amazon S3)	`S3-Egress-Bytes`
	Delivery (Amazon S3) in Parquet format	`S3-Egress-InputBytes`
	Delivery (Amazon Data Firehose)	`FH-Egress-Bytes`
Contributor Insights	*CloudWatch Logs (Rules)*	`ContributorInsight Rules`
	CloudWatch Logs (Events)	`ContributorInsight Events`
	Amazon DynamoDB (Rules)	`ContributorRulesMa naged`
	DynamoDB Events)	`ContributorEventsM anaged`
Canaries (Synthetics)	*Run*	`Canary-runs`
Evidently	*Events*	`Evidently-event`
	Analysis Units	`Evidently-eau`
RUM	*Events*	`RUM-event`

CloudWatch feature	CloudWatch sub-feature	UsageType
Network monitoring	*Network Synthetic Monitor*	`CWNMHybrid-Paid`
	Internet Monitor (monitored resources)	`InternetMonitor-MonitoredResource`
	Internet Monitor (monitored city networks)	`InternetMonitor-CityNetwork`

Analyze CloudWatch cost and usage data with Amazon Cost and Usage Reports and Athena

Another way to analyze CloudWatch cost and usage data is by using Amazon Cost and Usage Reports with Amazon Athena. Amazon Cost and Usage Reports contain a comprehensive set of cost and usage data. You can create reports that track your costs and usage, and you can publish these reports to an S3 bucket of your choice. You also can download and delete your reports from your S3 bucket. For more information, see What are Amazon Cost and Usage Reports? in the *Amazon Cost and Usage Reports User Guide*.

> **Note**
>
> There is no charge for using Amazon Cost and Usage Reports. You only pay for storage when you publish your reports to Amazon Simple Storage Service (Amazon S3). For more information, see Quotas and restrictions in the *Amazon Cost and Usage Reports User Guide*.

Athena is a query service that you can use with Amazon Cost and Usage Reports to analyze cost and usage data. You can query your reports in your S3 bucket without needing to download them first. For more information, see What is Amazon Athena? in the *Amazon Athena User Guide*. For more information, see What is Amazon Athena? in the *Amazon Athena User Guide*. For information about pricing, see Amazon Athena pricing.

The following procedure describes the process for enabling Amazon Cost and Usage Reports and integrating the service with Athena. The procedure contains two example queries that you can use to analyze CloudWatch cost and usage data.

> **Note**
>
> You can use any of the example queries in this document. All of the example queries in this document correspond to a database named ***costandusagereport***, and show results for the month of April and the year 2022. You can change this information. However, before you run a query, make sure that the name of your database matches the name of the database in the query.

To analyze cost and usage data with Amazon Cost and Usage Reports and Athena

1. Enable Amazon Cost and Usage Reports. For more information, see Creating cost and usage reports in the *Amazon Cost and Usage Reports User Guide*.

   > **Tip**
   >
   > When you create your reports, make sure to select **Include resource IDs**. Otherwise, your reports won't include the column `line_item_resource_id`. This line helps you further identify costs when analyzing cost and usage data.

2. Integrate Amazon Cost and Usage Reports with Athena. For more information, see Setting up Athena using Amazon CloudFormation templates in the *Amazon Cost and Usage Reports User Guide*.
3. Query your cost and usage reports.

Example of Athena query to show CloudWatch costs per month

You can use the following query to show which CloudWatch features generated the most costs for a given month.

```
SELECT
CASE
-- Metrics
```

```
WHEN line_item_usage_type LIKE '%%MetricMonitorUsage%%' THEN 'Metrics (Custom, Detailed
 monitoring management portal EMF)'
WHEN line_item_usage_type LIKE '%%Requests%%' THEN 'Metrics (API Requests)'
WHEN line_item_usage_type LIKE '%%GMD-Metrics%%' THEN 'Metrics (Bulk API Requests)'
WHEN line_item_usage_type LIKE '%%MetricStreamUsage%%' THEN 'Metric Streams'
-- Contributor Insights
WHEN line_item_usage_type LIKE '%%Contributor%%' THEN 'Contributor Insights'
-- Dashboard
WHEN line_item_usage_type LIKE '%%DashboardsUsageHour%%' THEN 'Dashboards'
-- Alarms
WHEN line_item_usage_type LIKE '%%AlarmMonitorUsage%%' THEN 'Alarms (Standard)'
WHEN line_item_usage_type LIKE '%%HighResAlarmMonitorUsage%%' THEN 'Alarms (High
 Resolution)'
WHEN line_item_usage_type LIKE '%%MetricInsightAlarmUsage%%' THEN 'Alarms (Metrics
 Insights)'
WHEN line_item_usage_type LIKE '%%CompositeAlarmMonitorUsage%%' THEN 'Alarms
 (Composite)'
-- Container Insights with enhanced observability
WHEN (line_item_usage_type LIKE '%%MetricsUsage%%' OR line_item_usage_type LIKE '%
%ObservationUsage%%') THEN 'Container Insights (Enhanced Observability)'
-- Logs
WHEN line_item_usage_type LIKE '%%DataProcessing-Bytes%%' THEN 'Logs (Collect - Data
 Ingestion)'
WHEN line_item_usage_type LIKE '%%DataProcessingIA-Bytes%%' THEN 'Infrequent Access
 Logs (Collect - Data Ingestion)'
WHEN line_item_usage_type LIKE '%%DataProtection-Bytes%%' THEN 'Logs (Data Protection -
 Detect and Mask)'
WHEN line_item_usage_type LIKE '%%TimedStorage-ByteHrs%%' THEN 'Logs (Storage -
 Archival)'
WHEN line_item_usage_type LIKE '%%DataScanned-Bytes%%' THEN 'Logs (Analyze - Logs
 Insights queries)'
WHEN line_item_usage_type LIKE '%%Logs-LiveTail%%' THEN 'Logs (Analyze - Logs Live
 Tail)'
-- Vended Logs
WHEN line_item_usage_type LIKE '%%VendedLog-Bytes%%' THEN 'Vended Logs (Delivered to
 CW)'
WHEN line_item_usage_type LIKE '%%VendedLogIA-Bytes%%' THEN 'Vended Infrequent Access
 Logs (Delivered to CW)'
WHEN line_item_usage_type LIKE '%%FH-Egress-Bytes%%' THEN 'Vended Logs (Delivered to
 Data Firehose)'
WHEN (line_item_usage_type LIKE '%%S3-Egress%%') THEN 'Vended Logs (Delivered to S3)'
-- Network Monitoring
WHEN line_item_usage_type LIKE '%%CWNMHybrid-Paid%%' THEN 'Network Monitor'
WHEN line_item_usage_type LIKE '%%InternetMonitor%%' THEN 'Internet Monitor'
```

```
-- Other
WHEN line_item_usage_type LIKE '%%Application-Signals%%' THEN 'Application Signals'
WHEN line_item_usage_type LIKE '%%Canary-runs%%' THEN 'Synthetics'
WHEN line_item_usage_type LIKE '%%Evidently%%' THEN 'Evidently'
WHEN line_item_usage_type LIKE '%%RUM-event%%' THEN 'RUM'
ELSE 'Others'
END AS UsageType,
-- REGEXP_EXTRACT(line_item_resource_id,'^(?:.+?:){5}(.+)$',1) as ResourceID,
SUM(CAST(line_item_usage_amount AS double)) AS UsageQuantity,
 SUM(CAST(line_item_unblended_cost AS decimal(16,8))) AS TotalSpend
FROM
costandusagereport
WHERE product_product_name = 'AmazonCloudWatch'
AND year='2022'
AND month='4'
AND line_item_line_item_type NOT IN
 ('Tax','Credit','Refund','EdpDiscount','Fee','RIFee')
-- AND line_item_usage_account_id = '123456789012' – If you want to filter on a
 specific account, you can remove this comment at the beginning of the line and specify
 an AWS account.
GROUP BY
1
ORDER BY TotalSpend DESC,
UsageType;
```

Example of Athena query to show how CloudWatch features generated costs

You can use the following query to show the results for `UsageType` and `Operation`. This shows you how CloudWatch features generated costs. The results also show the values for `UsageQuantity` and `TotalSpend`, so that you can see your total usage costs.

> **Tip**
>
> For more information about `UsageType`, add the following line to this query:
> `line_item_line_item_description`
> This line creates a column called ***Description***.

```
SELECT
bill_payer_account_id as Payer,
line_item_usage_account_id as LinkedAccount,
```

```
line_item_usage_type AS UsageType,
line_item_operation AS Operation,
line_item_resource_id AS ResourceID,
SUM(CAST(line_item_usage_amount AS double)) AS UsageQuantity,
SUM(CAST(line_item_unblended_cost AS decimal(16,8))) AS TotalSpend
FROM
costandusagereport
WHERE
product_product_name = 'AmazonCloudWatch'
AND year='2022'
AND month='4'
AND line_item_line_item_type NOT IN
 ('Tax','Credit','Refund','EdpDiscount','Fee','RIFee')
GROUP BY
bill_payer_account_id,
line_item_usage_account_id,
line_item_usage_type,
line_item_resource_id,
line_item_operation
```

Optimizing and reducing costs of CloudWatch metrics

Many Amazon Web Services services, such as Amazon Elastic Compute Cloud (Amazon EC2) , Amazon S3, and Amazon Data Firehose, automatically send metrics to CloudWatch at no charge. However, metrics that are grouped in the following categories can incur additional costs:

- ***Custom metrics, detailed monitoring, and embedded metrics***
- ***API requests***
- ***Metric streams***

For more information, see Using Amazon CloudWatch metrics.

Custom metrics

You can create custom metrics to organize data points in any order and at any rate.

All custom metrics are prorated by the hour. They're metered only when they're sent to CloudWatch. For information about how metrics are priced, see Amazon CloudWatch Pricing.

The following table lists the names of relevant sub-features for CloudWatch metrics. The table includes the strings for `UsageType` and `Operation`, which can help you analyze and identify metric-related costs.

> **Note**
>
> To get more details about the metrics that are listed in the following table while you're querying cost and usage data with Athena, match the strings for `Operation` with the results that are shown for `line_item_operation`.

CloudWatch sub-feature	**`UsageType`**	**`Operation`**	**Purpose**
Custom metrics	`MetricMonitorUsage`	`MetricStorage`	Custom metrics
Detailed monitoring	`MetricMonitorUsage`	`MetricStorage:AWS/` *`{Service}`*	Detailed monitoring
Embedded metrics	`MetricMonitorUsage`	`MetricStorage:Amazon/Logs-EMF`	Logs embedded metrics
Log filters	`MetricMonitorUsage`	`MetricStorage:Amazon/CloudWatchLogs`	Log group metric filters

Detailed monitoring

CloudWatch has two types of monitoring:

- ***Basic monitoring***

  Basic monitoring is free and automatically enabled for all Amazon Web Services services that support the feature.

- ***Detailed monitoring***

  Detailed monitoring incurs costs and adds different enhancements depending on the Amazon Web Services service. For each Amazon Web Services service that supports detailed monitoring, you can choose whether to enable it for that service. For more information, see Basic and detailed monitoring.

> **Note**
>
> Other Amazon Web Services services support detailed monitoring and might refer to this feature using a different name. For example, detailed monitoring for Amazon S3 is referred to as ***request metrics***.

Similar to custom metrics, detailed monitoring is prorated by the hour and metered only when data is sent to CloudWatch. Detailed monitoring generates costs by the number of metrics that are sent to CloudWatch. To reduce costs, only enable detailed monitoring when necessary. For information about how detailed monitoring is priced, see Amazon CloudWatch Pricing.

Example: Athena query

You can use the following query to show which EC2 instances have detailed monitoring enabled.

```
SELECT
bill_payer_account_id as Payer,
line_item_usage_account_id as LinkedAccount,
line_item_usage_type AS UsageType,
line_item_operation AS Operation,
line_item_resource_id AS ResourceID,
SUM(CAST(line_item_usage_amount AS double)) AS UsageQuantity,
SUM(CAST(line_item_unblended_cost AS decimal(16,8))) AS TotalSpend
FROM
costandusagereport
WHERE
product_product_name = 'AmazonCloudWatch'
AND year='2022'
AND month='4'
AND line_item_operation='MetricStorage:AWS/EC2'
AND line_item_line_item_type NOT IN
 ('Tax','Credit','Refund','EdpDiscount','Fee','RIFee')
```

```
GROUP BY
bill_payer_account_id,
line_item_usage_account_id,
line_item_usage_type,
line_item_resource_id,
line_item_operation,
line_item_line_item_description
ORDER BY line_item_operation
```

Embedded metrics

With the CloudWatch embedded metric format, you can ingest application data as log data, so that you can generate actionable metrics. For more information, see Ingesting high-cardinality logs and generating metrics with the CloudWatch embedded metric format.

Embedded metrics generate costs by the number of logs ingested, number of logs archived, and number of custom metrics generated.

The following table lists the names of relevant sub-features for the CloudWatch embedded metric format. The table includes the strings for `UsageType` and `Operation`, which can help you analyze and identify costs.

CloudWatch subfeature	**`UsageType`**	**`Operation`**	**Purpose**
Custom metrics	`MetricMonitorUsage`	`MetricStorage:AWS/Logs-EMF`	Logs embedded metrics
Logs ingestion	`DataProcessing-Bytes`	`PutLogEvents`	Uploads a batch of log events to the specified log group or log stream
Logs archival	`TimedStorage-ByteHrs`	`HourlyStorageMetering`	Stores logs per hour and logs per byte in CloudWatch Logs

To analyze costs, use Amazon Cost and Usage Reports with Athena so that you can identify which metrics are generating costs and determine how the costs are generated.

To make the most of costs generated by the CloudWatch embedded metric format, avoid creating metrics based on high-cardinality dimensions. This way, CloudWatch doesn't create a custom metric for each unique dimension combination. For more information, see Dimensions.

API requests

CloudWatch has the following types of API requests:

- ***API requests***
- ***Bulk (Get)***
- ***Contributor Insights***
- ***Bitmap image snapshot***

API requests generate costs by the request type and number of metrics requested.

The following table lists the types of API requests and includes the strings for `UsageType` and `Operation`, which can help you analyze and identify API-related costs.

API request type	**`UsageType`**	**`Operation`**	**Purpose**
API requests	`Requests`	`GetMetricStatistics`	Retrieves statistics for the specified metrics
	`Requests`	`ListMetrics`	Lists the specified metrics
	`Requests`	`PutMetricData`	Publishes metric data points to CloudWatch
	`Requests`	`GetDashboard`	Displays details for the specified dashboards

API request type	`UsageType`	`Operation`	Purpose
	`Requests`	`ListDashboards`	Lists the dashboards in your account
	`Requests`	`PutDashboard`	Creates or updates a dashboard
	`Requests`	`DeleteDashboards`	Deletes all specified dashboards
Bulk (Get)	`GMD-Metrics`	`GetMetricData`	Retrieves CloudWatch metric values
Contributor Insights	`GIRR-Metrics`	`GetInsightRuleReport`	Returns time-series data that's collected by a Contributor Insights rule
Bitmap image snapshot	`GMWI-Metrics`	`GetMetricWidgetImage`	Retrieves a snapshot of one or more CloudWatch metrics as a bitmap image

To analyze costs, use Cost Explorer, and group your results by ***API Operation***.

Costs for API requests vary, and you incur costs when you exceed the number of API calls provided to you under the Amazon Free Tier limit.

> **Note**
>
> `GetMetricData` and `GetMetricWidgetImage` aren't included under the Amazon Free Tier limit. For more information, see Using the Amazon Free Tier in the *Amazon Billing User Guide*.

The API requests that typically drive cost are `Put` and `Get` requests.

`PutMetricData`

`PutMetricData` generates costs every time that it's called and can incur significant costs depending on the use case. For more information, see [PutMetricData] in the *Amazon CloudWatch API Reference*.

To make the most of costs that are generated by `PutMetricData`, batch more data into your API calls. Depending on your use case, consider using CloudWatch Logs or the CloudWatch embedded metric format to inject metric data. For more information, see the following resources:

- What is Amazon CloudWatch Logs? in the *Amazon CloudWatch Logs User Guide*
- Ingesting high-cardinality logs and generating metrics with CloudWatch embedded metric format
- Lowering costs and focusing on our customers with Amazon CloudWatch embedded custom metrics

`GetMetricData`

`GetMetricData` can also generate significant costs. Common use cases that drive cost involve third-party monitoring tools that pull data to generate insights. For more information, see GetMetricData in the *Amazon CloudWatch API Reference*.

To reduce costs generated by `GetMetricData`, consider only pulling data that's monitored and used, or consider pulling data less often. Depending on your use case, you might consider using metric streams instead of `GetMetricData`, so that you can push data in near real time to third parties at a lower cost. For more information, see the following resources:

- Using metric streams
- CloudWatch Metric Streams - Send Amazon Metrics to Partners and to Your Apps in Real Time

`GetMetricStatistics`

Depending on your use case, you might consider using `GetMetricStatistics` instead of `GetMetricData`. With `GetMetricData`, you can retrieve data quickly and at scale. However, `GetMetricStatistics` is included under the Amazon Free Tier limit for up to one million API requests, which can help you reduce costs if you don't need to retrieve as many metrics and data points per call. For more information, see the following resources:

- GetMetricStatistics in the *Amazon CloudWatch API Reference*
- Should I use GetMetricData or GetMetricStatistics?

> **Note**
>
> External callers make API calls. For APIs that are supported by CloudTrail data events (such as **GetMetricData** and **GetMetricWidgetImage**), you can use CloudTrail to identify the top CloudWatch API callers and potentially mitigate or identify unexpected calls. For more information, see How to use CloudTrail to analyse your CloudWatch API Usage. For other CloudWatch APIs not supported by CloudTrail, you can open a technical support request to the CloudWatch team and ask for information about them. For information about creating a technical support request, see How do I get technical support from Amazon?.

CloudWatch metric streams

With CloudWatch metric streams, you can send metrics continuously to Amazon destinations and third-party service provider destinations.

Metric streams generate costs by the number of metric updates. Metric updates always include values for the following statistics:

- `Minimum`
- `Maximum`
- `Sample Count`
- `Sum`

For more information, see Statistics that can be streamed.

To analyze costs that are generated by CloudWatch metric streams, use Amazon Cost and Usage Reports with Athena. This way, you can identify which metric streams are generating costs and determine how the costs are generated.

Example: Athena query

You can use the following query to track which metric streams generate costs by Amazon Resource Name (ARN).

```
SELECT
SPLIT_PART(line_item_resource_id,'/',2) AS "Stream Name",
line_item_resource_id as ARN,
```

```
SUM(CAST(line_item_unblended_cost AS decimal(16,2))) AS TotalSpend
FROM
costandusagereport
WHERE
product_product_name = 'AmazonCloudWatch'
AND year='2022'
AND month='4'
AND line_item_line_item_type NOT IN
 ('Tax','Credit','Refund','EdpDiscount','Fee','RIFee')
-- AND line_item_usage_account_id = '123456789012' – If you want to filter on a
 specific account, you can
remove this comment at the beginning of the line and specify an AWS account.
AND line_item_usage_type LIKE '%%MetricStreamUsage%%'
GROUP BY line_item_resource_id
ORDER BY TotalSpend DESC
```

To reduce costs generated by CloudWatch metric streams, stream only the metrics that bring your business value. You also can stop or pause any metric stream that you're not using.

Optimizing and reducing costs of CloudWatch alarms

With CloudWatch alarms, you can create alarms based on a single metric, alarms based on a Metrics Insights query, and composite alarms which watch other alarms.

> **Note**
>
> Costs for metric and composite alarms are prorated by the hour. You incur costs for your alarms only while your alarms exist. To optimize cost, be sure not to leave behind misconfigured or low-value alarms. To help with this, you can automate the cleanup of CloudWatch alarms that you no longer need. For more information, see [Automating Amazon CloudWatch Alarm Cleanup at Scale](https://aws.amazon.com/blogs/mt/automating-amazon-cloudwatch-alarm-cleanup-at-scale/)

Metric alarms

Metric alarms have the following resolution settings:

- **Standard** (evaluated every 60 seconds)
- **High resolution** (evaluated every 10 seconds)

When you create a metric alarm, your costs are based on your alarm’s resolution setting and the number of metrics that your alarm references. For example, a metric alarm that references one metric incurs one alarm-metric cost per hour. For more information, see Using Amazon CloudWatch alarms.

If you create a metric alarm that contains a metric math expression, which references multiple metrics, you incur a cost for each alarm-metric that’s referenced in the metric math expression. For information about how to create a metric alarm that contains a metric math expression, see Creating a CloudWatch alarm based on a metric math expression.

If you create an anomaly detection alarm, where your alarm analyzes past metric data to create a model of expected values, you incur a cost for each alarm-metric that's referenced in your alarm plus two additional metrics, one for the upper and lower band metrics that the anomaly detection model creates. For information about how to create an anomaly detection alarm, see Creating a CloudWatch alarm based on anomaly detection.

Metrics Insights query alarms

Metric Insights query alarms are a specific type of metric alarm, only available with standard resolution (evaluated every 60 seconds).

When you create a Metric Insights query alarm, your costs are based on the number of metrics analyzed by the query that your alarm references. For example, a Metric Insights query alarm that references a query whose filter matches ten metrics incurs ten metrics analyzed cost per hour. For more information, see the pricing example on Amazon CloudWatch Pricing.

If you create an alarm that contains both a Metrics Insights query and a metric math expression, it is reported as a Metrics Insights query alarm. If your alarm contains a metric math expression which references other metrics in addition to the metrics analyzed by the Metrics Insights query, you incur an additional cost for each alarm-metric that’s referenced in the metric math expression. For information about how to create a metric alarm that contains a metric math expression, see Creating a CloudWatch alarm based on a metric math expression.

Composite alarms

Composite alarms contain rule expressions that specify how they should evaluate the states of other alarms to determine their own states. Composite alarms incur a standard cost per hour, regardless of how many other alarms they evaluate. Alarms that composite alarms reference in rule expressions incur separate costs. For more information, see Creating a composite alarm.

Alarm usage types

The following table lists the names of relevant sub-features for CloudWatch alarms. The table includes the strings for `UsageType`, which can help you analyze and identify alarm-related costs.

CloudWatch sub-feature	**`UsageType`**
Standard metric alarm	`AlarmMonitorUsage`
High-resolution metric alarm	`HighResAlarmMonitorUsage`
Metrics Insights query alarm	`MetricInsightAlarmUsage`
Composite alarm	`CompositeAlarmMonitorUsage`

Reducing alarm costs

To optimize costs generated by metric math alarms that aggregate four or more metrics, you can aggregate data before the data is sent to CloudWatch. This way, you can create an alarm for a single metric instead of an alarm that aggregates data for multiple metrics. For more information, see Publishing custom metrics.

To optimize costs generated by Metrics Insights query alarms, you can ensure that the filter used for the query matches only the metrics that you want to monitor.

The best way to reduce costs is to remove all unnecessary or unused alarms. For example, you can delete alarms that evaluate metrics emitted by Amazon resources that no longer exist.

Example of using `DescribeAlarms` to check for alarms in `INSUFFICIENT_DATA` state

If you delete a resource, but not the metric alarms that the resource emits, the alarms still exist and typically will go into the `INSUFFICIENT_DATA` state. To check for alarms that are in the `INSUFFICIENT_DATA` state, use the following Amazon Command Line Interface (Amazon CLI) command.

```
aws cloudwatch describe-alarms –state-value INSUFFICIENT_DATA
```

For more information, see Automating Amazon CloudWatch Alarm Cleanup at Scale.

Other ways to reduce costs include the following:

- Make sure to create alarms for the correct metrics.
- Make sure that you don't have any alarms enabled in Regions where you're not working.
- Remember that, although composite alarms reduce noise, they also generate additional costs.
- When deciding whether to create a standard alarm or high-resolution alarm, consider your use case and the value that each type of alarm brings.

Optimizing and reducing costs of CloudWatch Container Insights

CloudWatch Container Insights offers both standard and enhanced observability features for monitoring containerized applications in Amazon ECS and Amazon EKS. CloudWatch Container Insights leverages the embedded metric format to ingest telemetry from your container environments.

Container Insights with standard observability:

Standard Container Insights collects and visualizes metrics aggregated at the cluster and node levels. You can get started with standard mode of Container Insights using either the CloudWatch agent or the Amazon Distro for Open Telemetry (ADOT). Using ADOT enables you to customize which metrics and dimensions are sent to CloudWatch.

Metrics in Container Insights are treated as "embedded metrics". Costs associated with these metrics are reflected in the usage types `MetricStorage:AWS/Logs-EMF` and `DataProcessing-Bytes`. For detailed pricing information, see the Embedded Metrics section at [Amazon CloudWatch pricing].

Container Insights with enhanced observability:

Detailed visibility comes with Container Insights with enhanced observability, which delivers granular telemetry up to the pod and container levels in your applications. Similar to standard Container Insights, enhanced observability also comes with a standard set of critical metrics where you can get started by using the CloudWatch Observability add-on running on the CloudWatch agent. Container Insights offers enhanced observability with a new observation-based pricing in order to ensure cost effective bills justifying the benefit. See [Amazon CloudWatch pricing] for more information.

Here are the following UsageType and Operation associated with this Container Inisghts with enhanced observability:

CloudWatch sub-feature	UsageType	Operation
Container Insights with enhanced observability for Amazon EKS	`ObservationUsage`	`ObservationCount:CI-EKScode`
Container Insights with enhanced observability for Amazon ECS	`MetricsUsage`	`MetricStorage:CI-ECS`

Optimizing and reducing costs of CloudWatch Logs

Amazon CloudWatch Logs has the following log types:

- ***Custom logs*** *(logs that you create for your applications)*
- ***Vended logs*** *(logs that other Amazon Web Services services, such as Amazon Virtual Private Cloud (Amazon VPC) and Amazon Route 53, create on your behalf)*

For more information about vended logs, see Enabling logging from certain Amazon services in the *Amazon CloudWatch Logs User Guide*.

Custom and vended logs generate costs based on the number of logs that are *collected*, *stored*, and *analyzed*. Separately, vended logs generate costs for delivery to Amazon S3 and Firehose.

The following table lists the names of the CloudWatch Logs features and names of relevant sub-features. The table includes the strings for `UsageType` and `Operation`, which can help you analyze and identify log-related costs.

CloudWatch Logs feature	*CloudWatch Logs sub-feature*	UsageType	Operation	Purpose
Custom logs	*Collect (data ingestion for Standard log class)*	`DataProcessing-Bytes`	`PutLogEvents`	Uploads a batch of logs to a specific log stream in a

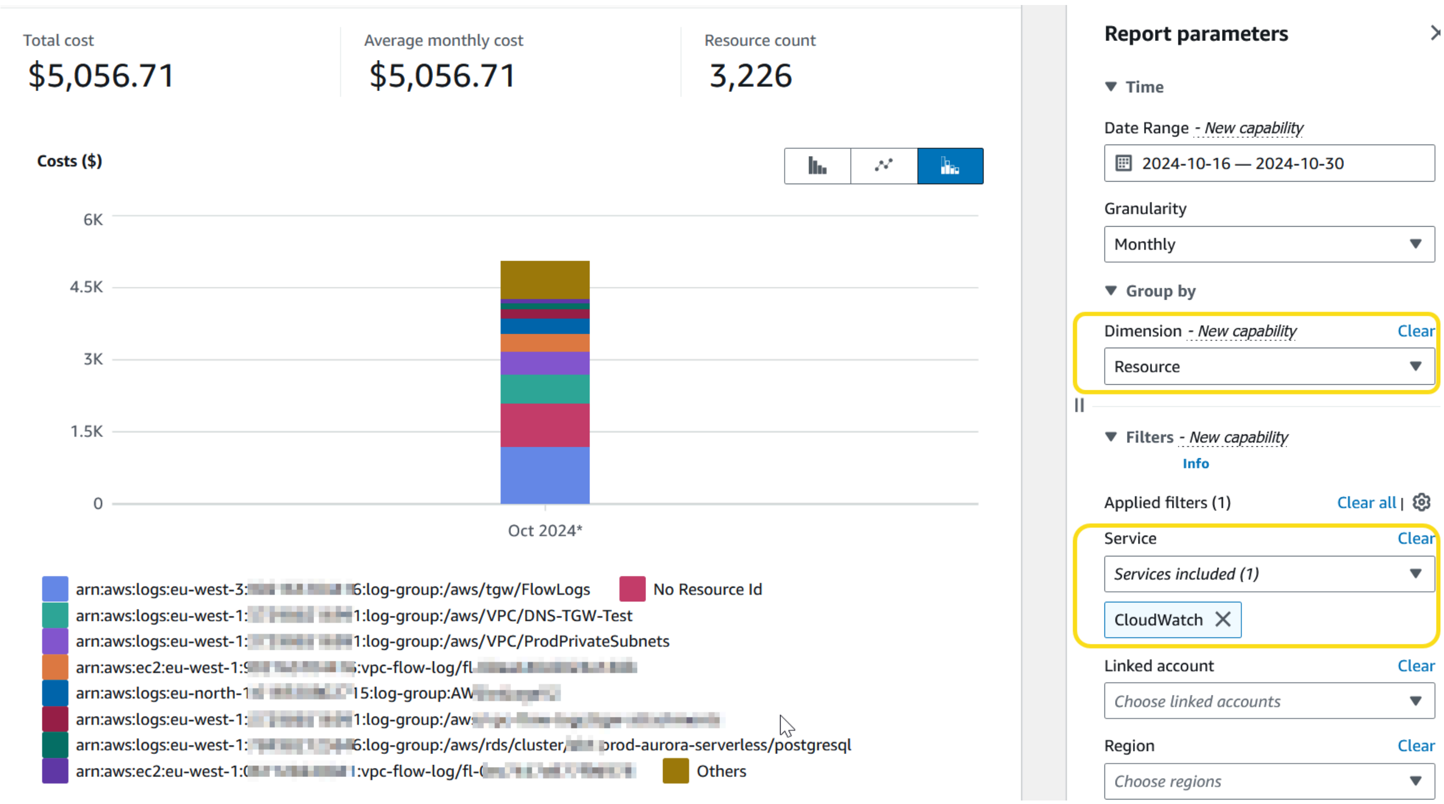
CloudWatch Logs feature	*CloudWatch Logs sub-feature*	UsageType	Operation	Purpose
				Standard class log group.
	Collect (data ingestion for Infrequent Access log class)	`DataProcessingIA-Bytes`	`PutLogEvents`	Uploads a batch of logs to a specific log stream in an Infrequent Access class log group.
	Detect and mask (data protection)	`DataProtection-Bytes`	`PutLogEvents`	Detects and masks protected data in log events.
	Store (archive)	`TimedStorage-ByteHrs`	`HourlyStorageMetering`	Stores logs per hour and logs per byte in CloudWatch Logs.
	Analyze (Logs Insights queries)	`DataScanned-Bytes`	`StartQuery`	Logs data scanned by CloudWatch Logs Insights queries
	Analyze (Logs Live Tail)	`Logs-LiveTail`	`StartLiveTail`	Logs analyzed during a CloudWatch Logs Live Tail session

CloudWatch Logs feature	*CloudWatch Logs sub-feature*	`UsageType`	`Operation`	Purpose
Vended logs	*Delivery (CloudWatch Logs Standard log class)*	`VendedLog-Bytes`	`PutLogEvents`	Uploads a batch of logs to a specific log stream in a log group in the Standard log class.
	Delivery (CloudWatch Logs Infrequent Access log class)	`VendedLogIA-Bytes`	`PutLogEvents`	Uploads a batch of logs to a specific log stream in a log group in the Infrequent Access log class.
	Delivery (Amazon S3)	`S3-Egress-Bytes`	`LogDelivery`	Uploads a batch of vended logs to a specific S3 bucket
	Delivery (Amazon S3) in Parquet format	`S3-Egress-InputBytes`	`ParquetConversion`	Perform Parquet conversion on logs delivered to Amazon S3
	Delivery (Firehose)	`FH-Egress-Bytes`	`LogDelivery`	Uploads a batch of vended logs to Amazon Data Firehose

To analyze costs, use Amazon Cost Explorer Service or Amazon Cost and Usage Reports with Athena. With either method, you can identify which logs are generating costs and determine how the costs are generated.

Using Amazon Cost Explorer Service

Select **CloudWatch** for the **Service** filter and select **Resource** for the **Dimension**. When you select **Resource** as the dimension in Cost Explorer Service you can see only the past 14 days of usage.



Using Amazon Athena query to track logs that generate costs

You can use the following query to track which logs generate costs by resource ID.

```
SELECT
line_item_resource_id AS ResourceID,
line_item_usage_type AS Operation,
SUM(CAST(line_item_unblended_cost AS decimal(16,8))) AS TotalSpend
FROM
costandusagereport
WHERE
product_product_name = 'AmazonCloudWatch'
AND year='2025'
AND month='1'
```

```
AND line_item_operation IN
 ('PutLogEvents','HourlyStorageMetering','StartQuery','LogDelivery','StartLiveTail','ParquetCon
AND line_item_line_item_type NOT IN
 ('Tax','Credit','Refund','EdpDiscount','Fee','RIFee')
GROUP BY
line_item_resource_id,
line_item_usage_type
ORDER BY
TotalSpend DESC
```

To make the most of costs that are generated by CloudWatch Logs, consider the following:

- Identify top log groups by spend per operation by using the previous query.
- Log only the events that bring your business value and choose an efficient log syntax. A verbose log syntax drives volume and thus cost. This helps you generate lower costs for ingestion.
- Change your log retention settings, so that you generate lower costs for storage. For more information, see Change log data retention in CloudWatch Logs in the *Amazon CloudWatch Logs User Guide*.
- Consider using the Infrequent Access log class where appropriate. Infrequent Access logs offers fewer features than Standard class. Determine whether you need the additional features of Standard log class and understand the difference between both classes. For more information, see the blog article New CloudWatch Logs log class for infrequent access logs at a reduced price. While the Infrequent Access class supports fewer features, it is suitable for a majority of use cases.
- Run queries that CloudWatch Logs Insights automatically saves in your history. This way, you generate fewer costs for analysis. For more information, see View running queries or query history in the *Amazon CloudWatch Logs User Guide*.
- Use the CloudWatch agent to collect system and application logs and send them to CloudWatch. This way, you can collect only the log events that meet your criteria. For more information, see Amazon CloudWatch Agent adds Support for Log Filter Expressions.

To reduce costs for vended logs, consider your use case, and then determine whether your logs should be sent to CloudWatch or Amazon S3. For more information, see Logs sent to Amazon S3 in the *Amazon CloudWatch Logs User Guide*.

> **Tip**
>
> If you want to use metric filters, subscription filters, CloudWatch Logs Insights, and Contributor Insights, send vended logs to CloudWatch.
> Alternatively, if you're working with VPC Flow Logs and using them for auditing and compliance purposes, send vended logs to Amazon S3.
> For information about how to track charges that are generated by publishing VPC Flow Logs to S3 buckets, see Using Amazon Cost and Usage Reports and cost allocation tags to understand VPC FLow Logs data ingestion in Amazon S3.

For additional information about how to make the most of costs that are generated by CloudWatch Logs, see Which log group is causing a sudden increase in my CloudWatch Logs bill?.

Using Amazon CloudWatch dashboards

Amazon CloudWatch includes automatic pre-built dashboards and also enables you to create your own dashboards. Dashboards help you to monitor your resources in a single view, even those resources that are spread across different Regions. You can use CloudWatch dashboards to create customized views of the telemetry data for your Amazon resources.

With customizable dashboards, you can create the following:

- A single view for selected metrics and alarms to help you assess the health of your resources and applications across one or more Regions. You can select the color used for each metric on each graph, so that you can easily track the same metric across multiple graphs.
- An operational playbook that provides guidance for team members during operational events about how to respond to specific incidents.
- A common view of critical resource and application measurements that can be shared by team members for faster communication flow during operational events.

If you have multiple Amazon accounts, you can set up *CloudWatch cross-account observability* and then create rich cross-account dashboards in your monitoring accounts. You can seamlessly search, visualize, and analyze your metrics, logs, and traces without account boundaries.

With CloudWatch cross-account observability, you can do the following in a dashboard in a monitoring account:

- Search, view, and create graphs of metrics that reside in source accounts. A single graph can include metrics from multiple accounts.
- Create alarms in the monitoring account that watch metrics in source accounts.
- View the log events from log groups located in source accounts, and run CloudWatch Logs Insights queries of log groups in source accounts. A single CloudWatch Logs Insights query in a monitoring account can query multiple log groups in multiple source accounts at once.
- View nodes from source accounts in a trace map in X-Ray. You can then filter the map to specific source accounts.

When you are signed in to a monitoring account, a blue **Monitoring account** badge appears at the top right of every page that supports CloudWatch cross-account observability functionality.

For more information about setting up CloudWatch cross-account observability, see CloudWatch cross-account observability.

You can create dashboards from the console or using the Amazon CLI or `PutDashboard` API operation. You can add dashboards to a favorites list, where you can access not only your favorite dashboards, but also your recently visited dashboards. For more information, see Add a dashboard to your favorites list.

To access CloudWatch dashboards, you need one of the following:

- The `AdministratorAccess` policy
- The `CloudWatchFullAccess` policy
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  - `cloudwatch:PutDashboard` to be able to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to be able to delete dashboards

Topics

Getting started with CloudWatch automatic dashboards

The CloudWatch home page automatically displays metrics about every Amazon service you use. You can additionally create custom dashboards to display metrics about your custom applications, and display custom collections of metrics that you choose.

Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

The CloudWatch overview home page appears.

The overview displays the following items, refreshed automatically.

- **Alarms by Amazon service** displays a list of Amazon services you use in your account, along with the state of alarms in those services. Next to that, two or four alarms in your account are displayed. The number depends on how many Amazon services you use. The alarms shown are those in the ALARM state or those that most recently changed state.

  These upper areas help you quickly assess the health of your Amazon services, by seeing the alarm states in every service and the alarms that most recently changed state. This helps you monitor and quickly diagnose issues.
- Below these areas is the *default dashboard*, if one exists. The default dashboard is a custom dashboard that you have created and named **CloudWatch-Default**. This is a convenient way for you to add metrics about your own custom services or applications to the overview page, or to bring forward additional key metrics from Amazon services that you most want to monitor.

> **Note**
>
> The automatic dashboards on the CloudWatch home page display only information from the current account, even if the account is a monitoring account set up for CloudWatch cross-account observability. For information about creating custom cross-account dashboards, see Creating a CloudWatch cross-account cross-Region dashboard with the Amazon Web Services Management Console.

From this overview, you can see a cross-service dashboard of metrics from multiple Amazon service, or focus your view to a specific resource group or a specific Amazon service. This enables you to narrow your view to a subset of resources in which you are interested.

Topics

Viewing the cross-service CloudWatch dashboard

You can switch to the Cross-service dashboard screen and interact with dashboards for all of the Amazon services that you're using. The CloudWatch Console displays your dashboards in alphabetical order and displays one or two key metrics from each service.

> **Note**
>
> If you're using five or more Amazon services, the CloudWatch Console won't display the Cross-service dashboard on the Overview screen.

To view the Cross-service dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

   You're directed to the Overview screen.

2. From the Overview screen, select the dropdown that reads **Overview**, and then choose **Cross service dashboard**.

   You're directed to the Cross service dashboard screen.

3. (Optional) If you're using the original interface, scroll to the section **Cross-service dashboard**, and then choose **View Cross-service dashboard**.

   You're directed to the Cross-service dashboard screen.

4. You can focus on a particular service in two ways:

   a. To see more key metrics for a service, choose its name from the list at the top of the screen, where **Cross service dashboard** is currently shown. Or, you can choose **View *Service* dashboard** next to the service name.

An automatic dashboard for that service is displayed, showing more metrics for that service. Additionally, for some services, the bottom of the service dashboard displays resources related to that service. You can choose one of those resources to that service console and focus further on that resource.

b. To see all the alarms related to a service, choose the button on the right of the screen next to that service name. The text on this button indicates how many alarms you have created in this service, and whether any are in the ALARM state.

   When the alarms are displayed, multiple alarms that have similar settings (such as dimensions, threshold, or period) may be shown in a single graph.

   You can then view details about an alarm and see the alarm history. To do so, hover on the alarm graph, and choose the actions icon, **View in alarms**.

   The alarms view appears in a new browser tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the **History** tab.

5. You can focus on resources in a particular resource group. To do so, choose the resource group from the list at the top of the page where **All resources** is displayed.

   For more information, see Viewing a CloudWatch dashboard for a resource group.

6. To change the time range shown in all graphs and alarms currently displayed, select the range you want next to **Time range** at the top of the screen. Choose **custom** to select from more time range options than those displayed by default.

7. Alarms are always refreshed once a minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose the refresh rate you want. You can also choose to turn off automatic refresh.

Removing a service from appearing in the CloudWatch cross-service dashboard

You can prevent a service's metrics from appearing in the cross-service dashboard. This helps you focus your cross-service dashboard on the services you most want to monitor.

If you remove a service from the cross-service dashboard, the alarms for that service still appear in the views of your alarms.

To remove a service's metrics from the cross-service dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

   The home page appears.

2. At the top of the page, under **Overview**, choose the service you want to remove.

   The view changes to show metrics from only that service.

3. Choose **Actions**, then clear the check box next to **Show on cross service dashboard**.

Viewing a CloudWatch dashboard for a single Amazon service

On the CloudWatch home page, you can focus the view to a single Amazon service. You can drill down further by focusing on both a single Amazon service and a resource group at the same time. The following procedure shows only how to focus on an Amazon service.

To focus on a single service

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

   The home page appears.

2. For **Overview**, where **Overview** is currently shown in the drop down menu, choose **Service dashboards**.
3. Choose the service that you want to focus on.

   The view changes to display graphs of key metrics from the selected service.

4. To switch to viewing the alarms for this service, select the check box for **In alarm**, **Insufficient data**, or **OK** near the top of the screen where the service name is currently displayed.
5. When viewing metrics, you can focus on a particular metric in several ways:

   a. To see more details about the metrics in any graph, hover on the graph, and choose the actions icon, **View in metrics**.

      The graph appears in a new tab, with the relevant metrics listed below the graph. You can customize your view of this graph, changing the metrics and resources shown, the statistic, the period, and other factors to get a better understanding of the current situation.

b. You can view log events from the time range shown in the graph. This may help you discover events that happened in your infrastructure that are causing an unexpected change in your metrics.

   To see the log events, hover on the graph, and choose the actions icon, **View in logs**.

   The CloudWatch Logs view appears in a new tab, displaying a list of your log groups. To see the log events in one of these log groups that occurred during the time range shown in the original graph, choose that log group.

6. When viewing alarms, you can focus on a particular alarm in several ways:

   - To see more details about an alarm, hover on the alarm, and choose the actions icon, **View in alarms**.

     The alarms view appears in a new tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the **History** tab.

7. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.

8. To change the time range shown in all graphs and alarms currently displayed, next to **Time range** at the top of the screen, choose the range. To select from more time range options than those displayed by default, choose **custom**.

9. To return to the cross-service dashboard, choose **Overview** in the list at the top of the screen that currently shows the service you are focusing on.

   Alternatively, from any view, you can choose **CloudWatch** at the top of the screen to clear all filters and return to the overview page.

Viewing a CloudWatch dashboard for a resource group

You can focus your view to display metrics and alarms from a single resource group. Using resource groups enables you to use tags to organize projects, focus on a subset of your architecture, or distinguish between your production and development environments. They also enable you to focus on each of these resource groups on the CloudWatch overview. For more information, see What Is Amazon Resource Groups?.

When you focus on a resource group, the display changes to show only the services where you have tagged resources as part of this resource group. The recent alarms area shows only the alarms that are associated with resources that are part of the resource group. Additionally, if you have created a dashboard with the name **CloudWatch-Default-*ResourceGroupName***, it is displayed in the **Default dashboard** area.

You can drill down further by focusing on both a single Amazon service and a resource group at the same time. The following procedure shows just how to focus on a resource group.

To focus on a single resource group

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. At the top of the page, where **All resources** is displayed, choose a resource group.
3. To see more metrics related to this resource group, near the bottom of the screen, choose **View cross service dashboard**.

   The cross-service dashboard appears, showing only the services related to this resource group. For each service, one or two key metrics are displayed.
4. To change the time range shown in all graphs and alarms currently displayed, for **Time range** at the top of the screen, select a range. To select from more time range options than those displayed by default, choose **custom**.
5. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.
6. To return to showing information about all the resources in your account, near the top of the screen where the name of the resource group is currently displayed, choose **All resources**.

Creating a customized CloudWatch dashboard

To get started, create a CloudWatch dashboard. You can create multiple dashboards, and you can add dashboards to a favorites list. You aren't limited to the number of dashboards that you can have in your Amazon Web Services account. All dashboards are global. They are not Region-specific.

The following procedure shows you how to create a dashboard from the CloudWatch console. You can use the `PutDashboard` API operation to create a dashboard from the command line interface. The API operation contains a JSON string that defines your dashboard content. For more information about creating a dashboard with the `PutDashboard` API operation, see PutDashboard in the *Amazon CloudWatch API Reference*.

> **Tip**
>
> If you're creating a new dashboard with the `PutDashboard` API operation, you can use the JSON string from a dashboard that already exists.

To create a dashboard from the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose **Create dashboard**.
3. In the **Create new dashboard** dialog box, enter a name for the dashboard, and then choose **Create dashboard**.

   If you use the name **CloudWatch-Default** or **CloudWatch-Default-*`ResourceGroupName`***, the dashboard appears in the overview of the CloudWatch home page under **Default Dashboard**. For more information, see Getting started with CloudWatch automatic dashboards.
4. In the **Add to this dashboard** dialog box, do one of the following:
   - To add a graph to the dashboard, choose **Line** or **Stacked area**, and then choose **Configure**. In the **Add metric graph** dialog box, select the metric(s) to graph, and then choose **Create widget**. If a metric doesn't appear in the dialog box because it hasn't published data in more than 14 days, you can add it manually. For more information, see Graph metrics manually on a CloudWatch dashboard.
   - To add a number displaying a metric to the dashboard, choose **Number**, and then choose **Configure**. In the **Add metric graph** dialog box, select the metric(s) to graph, and then choose **Create widget**.
   - To add a text block to the dashboard, choose **Text**, and then choose **Configure**. In the **New text widget** dialog box, for **Markdown**, format your text using Markdown, and then choose **Create widget**.
5. (Optional) Choose **Add widget**, and then repeat step 4 to add another widget to the dashboard. You can repeat this step multiple times.

   For each graph on the dashboard, there is an information icon at the upper right. Choose this icon to see the descriptions of the metrics in the graph.

6. Choose **Save dashboard**.

Creating a CloudWatch cross-account cross-Region dashboard with the Amazon Web Services Management Console

You can create *cross-account cross-Region dashboards*, which summarize your CloudWatch data from multiple Amazon accounts and multiple Regions into one dashboard. From this high-level dashboard you can get a view of your entire application, and also drill down into more specific dashboards without having to sign in and out of accounts or switch Regions.

Prerequisite

Before you can create a cross-account cross-Region dashboard, you must enable at least one sharing account and at least one monitoring account. Additionally, to be able to use the CloudWatch console to create a cross-account dashboard, you must enable the console for cross-account functionality. For more information, see Cross-account cross-Region CloudWatch console.

To create a cross-account cross-Region dashboard

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the navigation pane, choose **Dashboards**.
4. Choose a dashboard, or create a new one.
5. At the top of the screen, you can switch between accounts and Regions. As you create your dashboard, you can include widgets from multiple accounts and Regions. Widgets include graphs, alarms, and CloudWatch Logs Insights widgets.

Create a cross-account cross-Region dashboard programmatically

You can use the Amazon APIs and SDKs to create dashboards programmatically. For more information, see PutDashboard.

To enable cross-account cross-Region dashboards, we have added new parameters to the dashboard body structure, as shown in the following table and examples. For more information about overall dashboard body structure, see Dashboard Body Structure and Syntax.

Parameter	Use	Scope	Default
accountId	Specifies the ID of the account where the widget or the metric is located.	Widget or metric	Account that is currently logged in
region	Specifies the Region of the metric.	Widget or metric	Current Region selected in the console

The following examples illustrate the JSON source for widgets in a cross-account cross-Region dashboard.

This example sets the accountId field to the ID of the sharing account at the widget level. This specifies that all metrics in this widget will come from that sharing account and Region.

```
{
  "widgets": [
    {
          ...
          "properties": {
        "metrics": [
                 …
        ],
        "accountId": "111122223333",
        "region": "us-east-1"
      }
    }
  ]
}
```

This example sets the accountId field differently at the level of each metric. In this example, the different metrics in this metric math expression come from different sharing accounts and different Regions.

```
{
```

```
  "widgets": [
    {
          ...
          "properties": {
        "metrics": [
          [
            {
              "expression": "SUM(METRICS())",
              "label": "[avg: ${AVG}] Expression1",
              "id": "e1",
              "stat": "Sum"
            }
          ],
          [
            "AWS/EC2",
            "CPUUtilization",
            {
              "id": "m2",
              "accountId": "5555666677778888",
              "region": "us-east-1",
              "label": "[avg: ${AVG}] ApplicationALabel "
            }
          ],
          [
            ".",
            ".",
            {
              "id": "m1",
              "accountId": "9999000011112222",
              "region": "eu-west-1",
              "label": "[avg: ${AVG}] ApplicationBLabel"
            }
          ]
        ],
        "view": "timeSeries",
        "region": "us-east-1", ---> home region of the metric. Not present in above
 example
              "stacked": false,
        "stat": "Sum",
        "period": 300,
        "title": "Cross account example"
      }
    }
  ]
```

```
}
```

This example shows an alarm widget.

```
{
  "type": "metric",
  "x": 6,
  "y": 0,
  "width": 6,
  "height": 6,
  "properties": {
    "accountID": "111122223333",
    "title": "over50",
    "annotations": {
      "alarms": [
        "arn:aws:cloudwatch:us-east-1:379642911888:alarm:over50"
      ]
    },
    "view": "timeSeries",
    "stacked": false
  }
}
```

This example is for a CloudWatch Logs Insights widget.

```
{
  "type": "log",
  "x": 0,
  "y": 6,
  "width": 24,
  "height": 6,
  "properties": {
    "query": "SOURCE 'route53test' | fields @timestamp, @message\n| sort @timestamp
 desc\n| limit 20",
    "accountId": "111122223333",
    "region": "us-east-1",
    "stacked": false,
```

```
    "view": "table"
  }
}
```

Another way to create dashboards programmatically is to first create one in the Amazon Web Services Management Console, and then copy the JSON source of this dashboard. To do so, load the dashboard and choose **Actions**, **View/edit source**. You can then copy this dashboard JSON to use as a template to create similar dashboards.

Creating a graph with metrics from different accounts and Regions in a CloudWatch dashboard

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the navigation pane, choose **Metrics**, and then choose **All metrics**.
4. Select the account and Region that you want to add metrics from. You can select your account and Region from the account and Region dropdown menus near the top-right of the screen.
5. Add the metrics you want to the graph. For more information, see Graphing metrics.
6. Repeat steps 4-5 to add metrics from other accounts and Regions.
7. (Optional) Choose the **Graphed metrics** tab and add a metric math function that uses the metrics that you have chosen. For more information, see Using math expressions with CloudWatch metrics.

   You can also set up a single graph to include multiple SEARCH functions. Each search can refer to a different account or Region.
8. When you are finished with the graph, choose **Actions**, **Add to dashboard**.

   Select your cross-account dashboard, and choose **Add to dashboard**.

Adding an alarm from a different account to a CloudWatch cross-account dashboard

1. Sign in to the monitoring account.

2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. At the top of the page, choose the account where the alarm is located.
4. In the navigation pane, choose **Alarms**.
5. Select the check box next to the alarm that you want to add, and choose **Add to dashboard**.
6. Select the cross-account dashboard that you want to add it to, and choose **Add to dashboard**.

Creating flexible CloudWatch dashboards with dashboard variables

Use *dashboard variables* to create flexible dashboards that can quickly display different content in multiple widgets, depending on the value of an input field within the dashboard. For example, you can create a dashboard that can quickly switch between different Lambda functions or Amazon EC2 instance IDs, or one that can switch to different Amazon Regions.

After you create a dashboard that uses a variable, you can copy the same variable pattern to other existing dashboards.

Using dashboard variables improves the operational workflow for people who use your dashboards. It can also reduce your costs because you're using dashboard variables in one dashboard instead of creating multiple similar dashboards.

Note

If you share a dashboard that contains dashboard variables, the people that you share it with won't be able to change between the variable values.

Types of dashboard variables

The dashboard variable can be a *property variable* or a *pattern variable*.

- *Property variables* change all instances of a property in all widgets in the dashboard. This property can be any JSON property in the JSON source of a dashboard, such as `region`. Or it can be a dimension name for a metric, such as `InstanceID` or `FunctionName`.

  For a tutorial that uses a property variable, see [Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable](#).

For more information about the JSON source of dashboards, see Dashboard Body Structure and Syntax. In the CloudWatch console, you can see the JSON source for any custom dashboard by choosing **Actions**, **View/edit source**.

- *Pattern variables* use a regular expression pattern to change all of a JSON property or only a certain part of it.

  For a tutorial that uses a pattern variable, see Tutorial: Creating a dashboard that uses a regular expression pattern to switch between Amazon Web Services Regions.

Property variables apply to most use cases and are less complex to set up.

Topics

- Copying a variable to another CloudWatch dashboard
- Tutorial: Creating a dashboard that uses a regular expression pattern to switch between Amazon Web Services Regions
- Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable

Copying a variable to another CloudWatch dashboard

After you create a dashboard with useful variables, you can copy these variables to other existing dashboards. For more information about dashboard variables, see Creating flexible CloudWatch dashboards with dashboard variables.

To copy a dashboard variable to another dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the name of the dashboard that has the variable that you want to copy. Enter a string to find dashboards with matching names, if needed.
3. Choose **Actions**, **Variables**, **Manage variables**.
4. Choose the radio button next to the variable that you want to copy, and choose **Copy to another dashboard**.
5. Choose the selection box and start typing the dashboard name that you want to copy the variable to.
6. Select the dashboard name and choose **Copy variable**.

Tutorial: Creating a dashboard that uses a regular expression pattern to switch between Amazon Web Services Regions

The steps in this procedure illustrate how to create a flexible dashboard that can switch between Regions. This tutorial uses a regular expression *pattern variable* instead of a property variable. For a tutorial that uses a property variable, see Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable.

For many use cases, you can create a dashboard that switches between Regions by using a property variable. But if the widgets rely on Amazon Resource Names (ARNs) that include Region names, you must use a pattern variable to change the Region names within the ARNs.

To use a dashboard pattern variable to create a flexible multi-Region dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, **Create dashboard**.
3. Enter a name for the dashboard, and choose **Create dashboard**.
4. Add widgets to the dashboard. When you add the widgets that you want to display Region-specific data, avoid specifying any dimensions with values that appear in only one Region. For example, for Amazon EC2 metrics, specify metrics that are aggregated instead of metrics that use **InstanceID** as a dimension.

   For more information about adding widgets to a dashboard, see Using widgets on CloudWatch dashboards.
5. After you add the widgets, as you are viewing the dashboard, choose **Actions**, **Variables**, **Create a variable**.
6. Choose **Pattern variable**.
7. For **Property that the variable changes**, enter the name of the current dashboard Region, such as **`us-east-2`**.

   You have the correct Region entered if the label below that box displays the widgets that will be impacted by the variable.
8. For **Input type**, for this use case, select **Radio button**.
9. For **Define how inputs are populated**, choose **Create a list of custom values**.

10. For **Create your custom values**, enter the Regions that you want to switch between, with one Region on each line. After each Region, enter a comma and then the label to display for that radio button. For example:

    `us-east-1, N. Virginia`

    `us-east-2, Ohio`

    `eu-west-3, Paris`

    As you fill in the custom values, the **Preview** pane updates to display what the radio buttons will look like.

11. (Optional) For more settings, choose **Secondary settings** and do one or more of the following:

    - To customize the name of your variable, enter the name in **Custom variable name**.
    - To customize the label for the variable input field, enter the label in **Input label**. For this tutorial, enter **`Region:`**.

      If you enter a value here, the **Preview** pane updates to display what the radio buttons will look like.
    - To set the default value for this variable when the dashboard is first opened, enter the default in **Default value**.

12. Choose **Add variable**.

    The dashboard appears, with a **Region:** label next to the radio buttons for the Regions near the top. When you switch between Regions, all the widgets that use the variable will display information about the selected Region.

Tutorial: Creating a CloudWatch Lambda dashboard with function name as the variable

The steps in this procedure illustrate how to create a flexible dashboard that shows a variety of metric graphs, using a property variable. This includes a dropdown selection box on the dashboard that you can use to switch the metrics in all the graphs between different Lambda functions.

Other use case examples for this type of dashboard include using `InstanceId` as the variable to create a dashboard of metrics with a dropdown for instance IDs. Alternatively, you could create a dashboard that uses `region` as the variable to display the same set of metrics from different Regions.

To use a dashboard property variable to create a flexible Lambda dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, **Create dashboard**.
3. Enter a name for the dashboard, and choose **Create dashboard**.
4. Add widgets to the dashboard that display metrics for a Lambda function. When you create these widgets, specify **Lambda**, **By Function Name** for the widget metrics. For the function, specify one of the Lambda functions that you want to include in this dashboard.

   For more information about adding widgets to a dashboard, see Using widgets on CloudWatch dashboards.
5. After you add the widgets, as you are viewing the dashboard, choose **Actions**, **Variables**, **Create a variable**.
6. Choose **Property variable**.
7. For **Property that the variable changes**, choose **FunctionName**.
8. For **Input type**, for this use case, we recommend choosing **Select menu (dropdown)**. This creates a dropdown menu in the dashboard where you can select the Lambda function name to display metrics for.

   If this was for a dashboard that toggled between only two or three different values for a variable, then **Radio button** would be a good choice.

   If you prefer to enter or paste in values for the variable, you would choose **Text input**. This option doesn't include a dropdown list or radio buttons.
9. When you choose **Select menu (dropdown)**, you must then choose whether to populate the menu by entering values, or using a metric search. For this use case, let's assume that you have a large number of Lambda functions and you don't want to enter all of them manually. Choose **Use the results of a metric search** and then do the following:

   a. Choose **Pre-built queries**, **Lambda**, **Errors**.

      (Choosing **Errors** does not add the **Errors** metric to the dashboard. However, it quickly populates the **FunctionName** variable selection box.)
   b. Choose **By Function Name** and then choose **Search**.

Under the **Search** button, you will then see **FunctionName** selected. You also see a message about how many **FunctionName** dimension values were found to populate the input box.

10. (Optional) For more settings, choose **Secondary settings** and do one or more of the following:
    - To customize the name of your variable, enter the name in **Custom variable name**.
    - To customize the label for the variable input field, enter the label in **Input label**.
    - To set the default value for this variable when the dashboard is first opened, enter the default in **Default value**.
11. Choose **Add variable**.

    A **FunctionName** dropdown selection box appears near the top of the dashboard. You can select a Lambda function in this box and all the widgets that use the variable will display information about the selected function.

    Later, if you add more widgets to the dashboard that watch Lambda metrics with the **FunctionName** dimension, they will automatically use the variable.

Using widgets on CloudWatch dashboards

You can use the following types of widgets on CloudWatch dashboards:

- **Graph widget** – You can add graphs that contain one or more metrics to your CloudWatch dashboard. The types of graphs that you can add to your dashboard include ***Line***, ***Stacked area***, ***Number***, ***Gauge***, ***Bar***, and ***Pie***. You can remove graphs from your dashboard when you don't need them anymore.
- **Manual metrics widget** – If a metric hasn't published data in the past 14 days, you can't find it when searching for metrics to add to a graph on a CloudWatch dashboard. You can add any metric manually to an existing graph.
- **Metrics explorer widget –** Metrics explorer widgets include graphs of multiple resources that have the same tag, or share the same resource property such as an instance type. These widgets stay up to date, as resources that match are created or deleted. Adding metrics explorer widgets to your dashboard helps you to troubleshoot your environment more efficiently.

  For example, you can monitor your fleet of EC2 instances by assigning tags that represent their environments, such as production or test. You can then use these tags to filter and aggregate the operational metrics, such as `CPUUtilization`, to understand the health and performance of the EC2 instances that are associated with each tag.

- **Line widget** – With the line widget, you can compare metrics over periods of time. You also can use the widget's mini-map zoom feature to inspect sections of line graphs without changing between zoomed-in and zoomed-out views. The procedures in this section describe how to add and remove a line widget on a CloudWatch dashboard. For information about using the widget's mini-map zoom feature with line graphs, see Zooming in on a line or stacked area graph.
- **Number widget** – With the number widget, you can look at the latest metric values and trends as soon as they appear. Because the number widget includes the sparkline feature, you can visualize the top and bottom halves of metric trends in a single graph. The procedures in this section describe how to add and remove a number widget from a CloudWatch dashboard.
- **Gauge widget** – With the gauge widget, you can visualize metric values that go between ranges. For example, you can use the gauge widget to graph percentages and CPU utilization, so that you can observe and diagnose any performance issues that occur. The procedures in this section describe how to add and remove a gauge widget from a CloudWatch dashboard.
- **Text widget** – A text widget contains a block of text in Markdown format. You can add, edit, or remove text widgets from your CloudWatch dashboard.
- **Alarm widget** – To add an alarm widget to a dashboard, choose one of the following options:
  - Add a single alarm in a widget, which displays the graph of the alarm's metric and also displays the alarm status.
  - Add an *alarm status widget*, which displays the status of multiple alarms in a grid. Only the alarm names and current status are displayed, Graphs are not displayed. You can include up to 100 alarms in one alarm status widget.
- **Table widget** – With the data table widget, you can see the raw datapoints of your metric and a quick summary of that raw data. Because the data table widget is not a chart to abstract the actual data away from you, it is easier to understand the datapoints being presented. The procedures in this section describe how to add and remove a data table widget from a CloudWatch dashboard. The following image shows an example of a table widget with columns for the Minimum, Maximum, Sum, and Average statistics for a set of CloudWatch metrics.
- **Linked graphs** – You can link the graphs on your dashboard together, so that when you zoom in or zoom out on one graph, the other graphs zoom in or zoom out at the same time. You can unlink graphs to limit zoom to one graph.

Topics

Adding a graph widget to a CloudWatch dashboard

The procedures in this section describe how to add and remove graphs from your dashboard. For information about how to edit a graph on your dashboard, see Edit a graph on a CloudWatch dashboard.

To add a graph to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and then choose the type of graph that you want to add to your dashboard, then choose **Next**.
   - If you select ***Line***, ***Stacked area***, ***Bar***, or ***Pie***, choose **Metrics**.
4. In the **Browse** tab, search or browse for the metrics to graph, and select the ones that you want.
5. (Optional) To change your graph's time range, select one of the predefined time ranges in the upper part of the screen. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.
   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
6. (Optional) To change your graph's widget type, use the dropdown that's next to the predefined time ranges.
7. (Optional) In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

   a. To add a dynamic label, choose **Graphed metrics**, and then choose **Add dynamic labels**. Dynamic labels display a statistic about your metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of your labels. For more information, see Use dynamic labels.

   b. To change the color of a metric, choose the color square that's next to the metric.

   c. To change the statistic, select the dropdown under ***Statistic***, and then choose a new value. For more information, see Statistics.

   d. To change the period, select the dropdown under the ***Period*** column, and then choose a new value.
8. If you are creating a gauge widget, you must choose the **Options** tab and specify the **Min** and **Max** values to use for the two ends of the gauge.

9. (Optional) To customize the Y-axis, choose **Options**. You can add a custom label under ***Left Y-axis*** in the label field. If your graph displays values on the right side of the Y-axis, you can customize that label, too. You also can set minimum and maximum limits on your Y-axis values, so that your graph only displays the value ranges that you specify.

10. (Optional) To add or edit horizontal annotations to line or stacked area graphs, or to add thresholds to gauge widgets, choose **Options**:

    a. To add a horizontal annotation or threshold, choose **Add horizontal annotation** or **Add threshold**.

    b. For ***Label***, enter a label for the annotation then choose the check mark icon.

    c. For ***Value***, choose the pen and paper icon that's next to the current value, and enter your new value. After you enter your value, choose the check mark icon.

    d. For ***Fill***, select the dropdown and specify how your annotation will use shading. You can choose ***None***, ***Above***, ***Between***, or ***Below***. To change the fill color, choose the color square that's next to the annotation.

    e. For ***Axis***, specify whether your annotation appears on the left or right side of the Y-axis.

    f. To hide an annotation, clear the check box that's next to the annotation you want to hide.

    g. To delete an annotation, choose **X** under ***Actions***.

> **Note**
>
> You can repeat these steps to add multiple horizontal annotations or thresholds to the same graph or gauge.

11. (Optional) To add or edit vertical annotations, choose **Options**:

    a. To add a vertical annotation, choose **Add vertical annotation**.

    b. For ***Label***, choose the pen and paper icon that's next to the current annotation, and enter your new annotation. If you want to show only the date and time, leave the label field blank.

    c. For ***Date***, choose the current date and time, and enter the new date and time.

    d. For ***Fill***, select the dropdown, and specify how your annotation will use shading. You can choose ***None***, ***Above***, ***Between***, or ***Below***. To change the fill color, select the color square that's next to the annotation.

    e. To hide an annotation, clear the check box next to the annotation that you want to hide.

f. To delete an annotation, choose **X** under ***Actions***.

> **Note**
>
> You can repeat these steps to add multiple vertical annotations to the same graph.

12. Choose **Create widget**.
13. Choose **Save dashboard**.

Removing a graph widget from a CloudWatch dashboard

To remove a graph from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the graph that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Graph metrics manually on a CloudWatch dashboard

To add a metric that you can't find in search to a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. The dashboard must already contain a graph where you want to add the metric. If it doesn't, create the graph and add any metric to it. For more information, see Adding a graph widget to a CloudWatch dashboard .
4. Choose **Actions**, **View/edit source**.

   A JSON block appears. The block specifies the widgets on the dashboard and their contents. The following is an example of one part of this block, which defines one graph.

```
{
```

```
  "type": "metric",
  "x": 0,
  "y": 0,
  "width": 6,
  "height": 3,
  "properties": {
    "view": "singleValue",
    "metrics": [
      [
        "AWS/EBS",
        "VolumeReadOps",
        "VolumeId",
        "vol-1234567890abcdef0"
      ]
    ],
    "region": "us-west-1"
  }
},
```

In this example, the following section defines the metric shown on this graph.

```
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ]
```

5. Add a comma after the end bracket if there isn't already one and then add a similar bracketed section after the comma. In this new section, specify the namespace, metric name, and any necessary dimensions of the metric that you're adding to the graph. The following is an example.

```
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ],
[ "MyNamespace", "MyMetricName", "DimensionName", "DimensionValue" ]
```

For more information about the formatting of metrics in JSON, see [Properties of a Metric Widget Object](#) in the Amazon CloudWatch API Reference.

6. Choose **Update**.

Editing a graph on a CloudWatch dashboard

You can edit the graphs that you add to your CloudWatch dashboard. You can change a graph's title, statistic, or period. You can add, update, and remove metrics from your graphs. If your graph contains more than one metric, you can reduce clutter by hiding metrics that you aren't using. The procedures in this section describe how to edit a graph on your dashboard. For information about creating a graph, see [Add or remove a graph from a CloudWatch dashboard](#).

New interface

To edit a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the graph that you want to edit, choose **Widget actions**, and then choose **Edit**.
4. To change the graph's title, choose the pen and paper icon that's next to the current title. Enter the new title, and then choose **Apply**.
5. (Optional) To change your graph's time range, select one of the predefined time ranges in the upper are of the graph. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
6. To change your graph's widget type, use dropdown that's next to the predefined time ranges.
7. In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

   a. To add a dynamic label for a metric, choose **Dynamic labels**. Dynamic labels display a statistic about the metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of the labels. For more information, see [Use dynamic labels](#).

b. To change the color of a metric, choose the color square that's next to the metric.

c. To change the statistic, choose the statistic value under the ***Statistic*** column, and then choose a new value. For more information, see Statistics.

d. To change the period, choose the period value under the ***Period*** column, and then choose a new value.

8. To add or edit horizontal annotations, choose **Options**:

   a. To add a horizontal annotation, choose **Add horizontal annotation**.

   b. For **Label**, choose the pen and paper icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

   c. For **Value**, choose the pen and paper icon next to the current metric value. Then enter your new metric value. After you enter your value, select the check mark icon.

   d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, another new label and value field appears.

   > **Tip**
   >
   > You can change the fill color by choosing the colored square next to the annotation.

   e. For **Axis**, specify whether your annotation appears on the left or right side of the Y-axis.

   f. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

   g. To delete an annotation, choose **X** under the **Actions** column.

   > **Note**
   >
   > You can repeat these steps to add multiple horizontal annotations to the same graph.

9. To add or edit vertical annotations, choose **Options**:

   a. To add a vertical annotation, choose **Add vertical annotation**.

b. For **Label**, choose the pen and paper icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

> **Tip**
>
> To show only the date and time, leave the label field blank.

c. For **Date**, choose the current date and time. Then enter the new date and time.

d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

> **Tip**
>
> You can change the fill color by choosing the color square next to the annotation.

> **Note**
>
> You can repeat these steps to add multiple vertical annotations to the same graph.

e. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

f. To delete an annotation, choose **X** under the **Actions** column.

10. To customize the Y-axis, choose **Options**. Under ***Left Y-axis***, you can enter a custom label for **Label**. If the graph displays values on the right Y-axis, you can customize that label, too. You also can set minimums and maximums on the Y-axis values, so that the graph displays only the value range that you specify.
11. When you finish making changes, choose **Update widget**.

To hide or change the position of a graph legend

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.

3. In the upper-right corner of the graph that you want to edit, choose **Widget actions**. Choose **Legend** and select **Hidden**, **Bottom**, or **Right**.

To temporarily hide metrics for a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the color square for the metric that you want to hide in the graph's footer. An ***X*** appears in the color square when you hover over it, and the square turns gray when you choose it.
4. To restore the hidden metric, clear the **X** in the gray square.

Original interface

To edit a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the graph that you want to edit. Choose **Widget actions**, and then choose **Edit**.
4. To change the graph's title, choose the pencil icon that's next to the current title, and then enter the new title.
5. To change the graph's time range, choose one of the predefined time ranges in the upper area of the graph. These span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).
   - To set your own time range, choose **custom**.
6. To change your graph's widget type, select the **Graph options** tab. You can choose ***Line***, ***Stacked area***, ***Number***, ***Bar***, or ***Pie***.

   > **Tip**
   >
   > You can change your graph's widget type by choosing the dropdown that's next to the predefined time ranges.

7. In **Graphed metrics**, you can add a dynamic label to your metric and change your metric's label, label color, statistic, and period. You also can determine the position of labels on the Y-axis from left to right.

    a. To add a dynamic label for a metric, choose **Dynamic labels**. Dynamic labels display a statistic about the metric in the graph legend. Dynamic labels update automatically when your dashboard or graph refreshes. By default, the dynamic values that you add to labels appear at the beginning of the labels. For more information, see Use dynamic labels.

    b. To change the color of a metric, choose the color square that's next to the metric.

    c. To change the statistic, choose the statistic value under the ***Statistic*** column, and then choose a new value. For more information, see Statistics.

    d. To change the period, choose the period value under the ***Period*** column, and then choose a new value.

8. To add or edit horizontal annotations, choose **Graph options**:

    a. To add a horizontal annotation, choose **Add horizontal annotation**.

    b. For **Label**, choose the pencil icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

    c. For **Value**, choose the pencil icon next to the current metric value. Then enter your new metric value. After you enter your value, select the check mark icon.

    d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

    > **Tip**
    >
    > You can change the fill color by choosing the color square next to the annotation.

    e. For **Axis**, specify whether your annotation appears on the left or right side of the Y-axis.

    f. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

    g. To delete an annotation, choose **X** under the **Actions** column.

> **Note**
>
> You can repeat these steps to add multiple horizontal annotations to the same graph.

9. To add or edit vertical annotations, choose **Graph options**:

   a. To add a vertical annotation, choose **Add vertical annotation**.

   b. For **Label**, choose the pencil icon next to the current annotation. Then enter your new annotation. After you enter your annotation, choose the check mark icon.

   > **Tip**
   >
   > To show only the date and time, leave the label field blank.

   c. For **Date**, choose the pencil icon next to the current date and time. Then enter the new date and time.

   d. For **Fill**, choose the dropdown under the column, and then specify how your annotation will use shading. You can choose **None**, **Above**, **Between**, or **Below**. If you choose **Between**, a new label and value field appears.

   > **Tip**
   >
   > You can change the fill color by choosing the color square next to the annotation.

   > **Note**
   >
   > You can repeat these steps to add multiple vertical annotations to the same graph.

   e. To hide an annotation, deselect the check box next to the annotation that you want to hide on the graph.

   f. To delete an annotation, choose **X** under the **Actions** column.

10. To customize the Y-axis, choose **Graph options**. Under ***Left Y-axis***, you can enter a custom label for **Label**. If the graph displays values on the right Y-axis, you can customize that label, too. You also can set minimums and maximums on the Y-axis values, so that the graph displays only the value range that you specify.
11. When you finish making changes, choose **Update widget**.

To hide or change the position of a graph legend

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the graph that you want to edit, and choose **Widget actions**. Choose **Legend**, and select **Hidden**, **Bottom**, or **Right**.

To temporarily hide metrics for a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the color square for the metric that you want to hide in the graph's footer. An ***X*** appears in the color square when you hover over it, and the square turns gray when you choose it.
4. To restore the hidden metric, clear the **X** in the gray square.

Renaming a graph on a CloudWatch dashboard

You can change the default name that CloudWatch assigns to a graph on your dashboard.

To rename a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the title of the graph and choose **Widget actions** and **Edit**.
4. On the **Edit graph** screen, near the top, choose the title of the graph.
5. For **Title**, enter a new name and choose **Ok** (check mark). In the lower-right corner of the **Edit graph** screen, choose **Update widget**.

Moving a graph on a CloudWatch dashboard

To move a graph on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Do one of the following:
   - Hover over the title of the graph until the selection icon appears. Select and drag the graph to a new location on the dashboard.
   - To move the widget to either the top left or bottom left of the dashboard, choose the vertical ellipsis at the upper right of the widget to open the **Widget actions** menu. Then choose **Move**, and choose where to move the widget to.
4. Choose **Save dashboard**.

Changing the size of graphs on CloudWatch dashboards

To change the size of a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. To increase or decrease the size, hover over the graph and drag the lower right corner of the graph. Stop dragging the corner when you have the size that you want.
4. Choose **Save dashboard**.

Changing the size of a graph temporarily on a CloudWatch dashboard

To enlarge a graph temporarily

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select the graph. Alternatively, hover over the title of the graph and choose **Widget actions**, **Enlarge**.

Add a metrics explorer widget to a CloudWatch dashboard

The following steps explain how to add a metrics explorer widget to a dashboard using the console. You can also add it programmatically or by using Amazon CloudFormation. For more information, see Metrics Explorer Widget Object Definition and AWS::CloudWatch::Dashboard.

To add a metrics explorer widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the dashboard where you want to add the metrics explorer widget.
4. Choose the **+** symbol.
5. Choose **Explorer** and then choose **Next**.

   > **Note**
   >
   > You must be opted in to the new dashboard view to be able to add a Metrics Explorer widget. To opt in, choose **Dashboards** in the navigation pane, then choose **try out the new interface** in the banner at the top of the page.

6. Do one of the following:
   - To use a template, choose **Pre-filled Explorer widget** and then select a template to use.
   - To create a custom visualization, choose **Empty Explorer widget**.
7. Choose **Create**.

   If you used a template, the widget appears on your dashboard with the selected metrics. If you're satisfied with the explorer widget and the dashboard, choose **Save dashboard**.

   If you did not use a template, continue to the following steps.
8. In the new widget under **Explorer**, in the **Metrics** box, choose a single metric or all the available metrics from a service.

   After you choose a metric, you can optionally repeat this step to add more metrics.
9. For each metric selected, CloudWatch displays the statistic that it will use immediately after the metric name. To change this, choose the statistic name and then choose the statistic that you want.
10. Under **From**, choose a tag or a resource property to filter your results.

After you do this, you can optionally repeat this step to choose more tags or resource properties.

If you choose multiple values of the same property, such as two EC2 instance types, the explorer displays all the resources that match either chosen property. It's treated as an OR operation.

If you choose different properties or tags, such as the `Production` tag and the M5 instance type, only the resources that match all of these selections are displayed. This is treated as an AND operation.

11. (Optional) For **Aggregate by**, choose a statistic to use to aggregate the metrics. Then, next to **for**, choose how to aggregate the metric from the list. You can aggregate together all the resources that are currently displayed, or aggregate by a single tag or resource property.

    Depending on how you choose to aggregate, the result may be a single time series or multiple time series.
12. Under **Split by**, you can choose to split a single graph with multiple time series into multiple graphs. The split can be made by a variety of criteria, which you choose under **Split by**.
13. Under **Graph options**, you can refine the graph by changing the period, the type of graph, the legend placement, and the layout.
14. If you're satisfied with the explorer widget and the dashboard, choose **Save dashboard**.

Adding a line graph widget to a CloudWatch dashboard

To add a line widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and select **Line**.
4. Choose **Metrics**.
5. Choose **Browse**, and select the metric that you want to graph.
6. Choose **Create widget**, and then choose **Save dashboard**.

Removing a line graph widget from a CloudWatch dashboard

To remove a line graph widget from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the line widget that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Adding a number widget to a CloudWatch dashboard

> **Note**
>
> Only the new interface supports the sparkline feature. When you create a number widget, the sparkline feature is automatically included.

To add a number widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol, and select **Number**.
4. In the **Browse** tab, search or browse for the metric that you want to display.
5. (Optional) To change the color of the sparkline feature, choose **Graphed metrics**, and select the color box next to the metric label. A menu appears where you can choose a different color or enter a six-digit hex color code to specify a color.
6. (Optional) To turn off the sparkline feature, choose **Options**. Under ***Sparkline***, the check box.
7. (Optional) To change your number widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget keep using this time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.

8. (Optional) To have the number widget display an aggregate (***1h***, ***3h***, ***12h***, ***1d***, ***3d***, or ***1w***).

   To set your own time range, choose **Custom**.

   - (Optional) To have this widget display an average of the metric value over the entire time range, instead of the most recent value, choose **Options**, **Time range value shows the value from the entire time range**.

9. Choose **Create widget**, and choose **Save dashboard**.

> **Tip**
>
> You can turn off the sparkline feature from the number widget on the dashboard screen. In the upper-right corner of the number widget that you want to modify, choose **Widget actions**. Select **Sparkline**, and then choose **Hide sparkline**.

Removing a number widget from a CloudWatch dashboard

To remove a number widget from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the dashboard that contains the number widget that you want to delete.
3. In the upper-right corner of the number widget that you want to remove, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**.

Adding a gauge widget to a CloudWatch dashboard

> **Note**
>
> Only the new interface in the CloudWatch console supports creation of the gauge widget. You must set a gauge range when you create this widget.

To add a gauge widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, choose the **+** symbol, and then select **Gauge**.
4. Choose **Browse**, and then select the metric that you want to graph.
5. Choose **Options**. Under ***Gauge range***, set values for **Min** and **Max**. For percentages, such as CPU utilization, we recommend that you set the values for `Min` to `0` and `Max` to `100`.
6. (Optional) To change the color of the gauge widget, choose **Graphed metrics** and select the color box next to the metric label. A menu appears where you can choose a different color or enter a six-digit hex color code to specify a color.
7. Choose **Create widget**, and choose **Save dashboard**.

Removing a gauge widget from a CloudWatch dashboard

To remove a gauge widget from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose the dashboard that contains the gauge widget you want to delete.
3. In the upper-right corner of the gauge widget that you want to delete, choose **Widget actions**, and choose **Delete**.
4. Choose **Save dashboard**.

Using a custom widget on a CloudWatch dashboard

A *custom widget* is a CloudWatch dashboard widget that can call any Amazon Lambda function with custom parameters. It then displays the returned HTML or JSON. Custom widgets are a simple way to build a custom data view on a dashboard. If you can write Lambda code and create HTML, you can create a useful custom widget. Additionally, Amazon provides several prebuilt custom widgets that you can create without any code.

When you create a Lambda function to use as a custom widget, we strongly recommend that you include the prefix **customWidget** in the function name. This helps you know which of your Lambda functions are safe to use when you add custom widgets to your dashboard.

Custom widgets behave like other widgets on your dashboard. They can be refreshed and auto-refreshed, resized, and moved around. They react to the time range of the dashboard.

If you have set up CloudWatch console cross-account functionality, you can add a custom widget created in one account to dashboards in other accounts. For more information, see Cross-account cross-Region CloudWatch console.

You can also use custom widgets on your own website by using the CloudWatch dashboard sharing feature. For more information, see Sharing CloudWatch dashboards.

- Sample custom widgets for a CloudWatch dashboard

Details about custom widgets in CloudWatch

Custom widgets work as follows:

1. The CloudWatch dashboard calls the Lambda function containing the widget code. It passes in any custom parameters that are defined in the widget.
2. The Lambda function returns a string of HTML, JSON, or Markdown. Markdown is returned as JSON in the following format:

   ```
   {"markdown":"markdown content"}
   ```

3. The dashboard displays the returned HTML or JSON.

If the function returns HTML, most HTML tags are supported. You can use Cascading Style Sheets (CSS) styles and Scalable Vector Graphics (SVG) to build sophisticated views.

The default style of HTML elements such as links and tables follow the styling of CloudWatch dashboards. You can customize this style by using inline styles, using the `<style>` tag. You can also deactivate the default styles by including a single HTML element with the class of `cwdb-no-`

`default-styles`. The following example deactivates default styles: `<div class="cwdb-no-default-styles"></div>`.

Every call by a custom widget to Lambda includes a `widgetContext` element with the following contents, to provide the Lambda function developer with useful context information.

```
{
  "widgetContext": {
    "dashboardName": "Name-of-current-dashboard",
    "widgetId": "widget-16",
    "accountId": "012345678901",
    "locale": "en",
    "timezone": {
      "label": "UTC",
      "offsetISO": "+00:00",
      "offsetInMinutes": 0
    },
    "period": 300,
    "isAutoPeriod": true,
    "timeRange": {
      "mode": "relative",
      "start": 1627236199729,
      "end": 1627322599729,
      "relativeStart": 86400012,
      "zoom": {
        "start": 1627276030434,
        "end": 1627282956521
      }
    },
    "theme": "light",
    "linkCharts": true,
    "title": "Tweets for Amazon website problem",
    "forms": {
      "all": {}
    },
    "params": {
      "original": "param-to-widget"
    },
    "width": 588,
    "height": 369
  }
}
```

Default CSS styling

Custom widgets provide the following default CSS styling elements:

- You can use the CSS class **btn** to add a button. It turns an anchor (<a>) into a button as in the following example:

```
<a class="btn" href=https://amazon.com">Open Amazon</a>
```

- You can use the CSS class **btn btn-primary** to add a primary button.
- The following elements are styled by default: **table**, **select**, **headers (h1, h2, and h3)**, **preformatted text (pre)**, **input**, and **text area**.

Using the describe parameter

We strongly recommend that you support the **describe** parameter in your functions, even if it just returns an empty string. If you don't support it, and it is called in the custom widget, it displays widget content as if it was documentation.

If you include the **describe** parameter, the Lambda function returns the documentation in Markdown format and does nothing else.

When you create a custom widget in the console, after you select the Lambda function a **Get documentation** button appears. If you choose this button, the function is invoked with the **describe** parameter and the function's documentation is returned. If the documentation is well-formatted in markdown, CloudWatch parses the first entry in the documentation that is surrounded by three single backtick characters (```) in YAML. Then, it automatically populates the documentation in the parameters. The following is an example of such well-formatted documentation.

````
``` yaml
echo: <h1>Hello world</h1>
```
````

Security and JavaScript for custom CloudWatch widgets

For security reasons, JavaScript is not allowed in the returned HTML. Removing the JavaScript prevents permission escalation issues, where the writer of the Lambda function injects code that could run with higher permissions than the user viewing the widget on the dashboard.

If the returned HTML contains any JavaScript code or other known security vulnerabilities, it is cleaned from the HTML before it is rendered on the dashboard. For example, the **<iframe>** and **<use>** tags are not allowed and are removed.

Custom Widgets won't run by default in a dashboard. Instead, you must explicitly allow a custom widget to run if you trust the Lambda function that it invokes. You can choose to allow it once or allow always, for both individual widgets and entire dashboard. You can also deny permission for individual widgets and the entire dashboard.

Interactivity in the custom widget in CloudWatch

Even though JavaScript is not allowed, there are other ways to allow interactivity with the returned HTML.

- Any element in the returned HTML can be tagged with special configuration in a `<cwdb-action>` tag, which can display information in pop-ups, ask for confirmation on clicks, and call any Lambda function when that element is chosen. For example, you can define buttons that call any Amazon API using a Lambda function. The returned HTML can be set to either replace the existing Lambda widget's content, or display inside a modal.
- The returned HTML can include links that open new consoles, open other customer pages, or load other dashboards.
- The HTML can include the `title` attribute for an element, which gives additional information if the user hovers over that element.
- The element can include CSS selectors, such as `:hover`, which can invoke animations or other CSS effects. You can also show or hide elements in the page.

<cwdb-action> definition and usage

The `<cwdb-action>` element defines a behavior on the immediately previous element. The content of the `<cwdb-action>` is either HTML to display or a JSON block of parameters to pass to a Lambda function.

The following is an example of a `<cwdb-action>` element.

```
<cwdb-action
     action="call|html"
     confirmation="message"
     display="popup|widget"
     endpoint="<lambda ARN>"
     event="click|dblclick|mouseenter">

     html | params in JSON
</cwdb-action>
```

- **action**— Valid values are `call`, which calls a Lambda function, and `html`, which displays any HTML contained within `<cwdb-action>`. The default is `html`.
- **confirmation**— Displays a confirmation message that must be acknowledged before the action is taken, allowing the customer to cancel.
- **display**— Valid values are `popup` and `widget`, which replaces the content of the widget itself. The default is `widget`.
- **endpoint**— The Amazon Resource Name (ARN) of the Lambda function to call. This is required if `action` is `call`.
- **event**— Defines the event on the previous element that invokes the action. Valid values are `click`, `dblclick`, and `mouseenter`. The `mouseenter` event can be used only in combination with the `html` action. The default is `click`.

Examples

The following is an example of how to use the `<cwdb-action>` tag to create a button that reboots an Amazon EC2 instance using a Lambda function call. It displays the success or failure of the call in a pop-up.

```
<a class="btn">Reboot Instance</a>
<cwdb-action action="call" endpoint="arn:aws:lambda:us-
east-1:123456:function:rebootInstance" display="popup">
       { "instanceId": "i-342389adbfef" }
</cwdb-action>
```

The next example displays more information in a pop-up.

```
<a>Click me for more info in popup</a>
<cwdb-action display="popup">
```

```
    <h1>Big title</h1>
    More info about <b>something important</b>.
</cwdb-action>
```

This example is a **Next** button that replaces the content of a widget with a call to a Lambda function.

```
<a class="btn btn-primary">Next</a>
<cwdb-action action="call" endpoint="arn:aws:lambda:us-
east-1:123456:function:nextPage">
    { "pageNum": 2 }
</cwdb-action>
```

Creating a custom widget for a CloudWatch dashboard

To create a custom widget, you can use one of the samples provided by Amazon, or you can create your own. The Amazon samples include samples in both JavaScript and Python, and are created by a Amazon CloudFormation stack. For a list of samples, see Sample custom widgets for a CloudWatch dashboard.

To create a custom widget in a CloudWatch dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol.
4. Choose **Custom widget**.
5. Use one of the following methods:
   - To use a sample custom widget provided by Amazon, do the following:
     a. Select the sample in the dropdown box.

        The Amazon CloudFormation console launches in a new browser. In the Amazon CloudFormation console, do the following:
     b. (Optional) Customize the Amazon CloudFormation stack name.
     c. Make selections for any parameters used by the sample.
     d. Select **I acknowledge that Amazon CloudFormation might create IAM resources**, and choose **Create stack**.
   - To create your own custom widget provided by Amazon, do the following:

a. Choose **Next**.

b. Choose to either select your Lambda function from a list, or enter its Amazon Resource Name (ARN). If you select it from a list, also specify the Region where the function is and the version to use.

c. For **Parameters**, make selections for any parameters used by the function.

d. Enter a title for the widget.

e. For **Update on**, configure when the widget should be updated (when the Lambda function should be called again). This can be one or more of the following: **Refresh** to update it when the dashboard auto-refreshes, **Resize** to update it whenever the widget is resized, or **Time Range** to update it whenever the dashboard's time range is adjusted, including when graphs are zoomed into.

f. If you are satisfied with the preview, choose **Create widget**.

Sample custom widgets for a CloudWatch dashboard

Amazon provides sample custom widgets in both JavaScript and Python. You can create these sample widgets by using the link for each widget in this list. Alternatively, you can create and customize a widget by using the CloudWatch console. The links in this list open an Amazon CloudFormation console and use an Amazon CloudFormation quick-create link to create the custom widget.

You can also access the custom widget samples on GitHub.

Following this list, complete examples of the Echo widget are shown for each language.

JavaScript

Sample custom widgets in JavaScript

- Echo – A basic echoer that you can use to test how HTML appears in a custom widget, without having to write a new widget.
- Hello world – A very basic starter widget.
- Custom widget debugger – A debugger widget that displays useful information about the Lambda runtime environment.
- Query CloudWatch Logs Insights – Run and edit CloudWatch Logs Insights queries.
- Run Amazon Athena queries – Run and edit Athena queries.

- Call Amazon API – Call any read-only Amazon API and display the results in JSON format.
- Fast CloudWatch bitmap graph – Render CloudWatch graphs using on the server side, for fast display.
- Text widget from CloudWatch dashboard – Displays the first text widget from the specified CloudWatch dashboard.
- CloudWatch metric data as a table – Displays raw CloudWatch metric data in a table.
- Amazon EC2 table – Displays the top EC2 instances by CPU utilization. This widget also includes a Reboot button, which is disabled by default.
- Amazon CodeDeploy deployments – Displays CodeDeploy deployments.
- Amazon Cost Explorer report – Displays a report on the cost of each Amazon service for a selected time range.
- Display content of external URL – Displays the content of an externally accessible URL.
- Display an Amazon S3 object – Displays an object in an Amazon S3 bucket in your account.
- Simple SVG pie chart – Example of a graphical SVG-based widget.

Python

Sample custom widgets in Python

- Echo – A basic echoer which you can use to test how HTML appears in a custom widget, without having to write a new widget.
- Hello world – A very basic starter widget.
- Custom widget debugger – A debugger widget that displays useful information about the Lambda runtime environment.
- Call Amazon API – Call any read-only Amazon API and display the results in JSON format.
- Fast CloudWatch bitmap graph – Render CloudWatch graphs using on the server side, for fast display.
- Send dashboard snapshot by email – Take a snapshot of the current dashboard and send it to email recipients.
- Send dashboard snapshot to Amazon S3 – Take a snapshot of the current dashboard and store it in Amazon S3.
- Text widget from CloudWatch dashboard – Displays the first text widget from the specified CloudWatch dashboard.
- Display content of external URL – Displays the content of an externally accessible URL.

- RSS reader – Displays RSS feeds.
- Display an Amazon S3 object – Displays an object in an Amazon S3 bucket in your account.
- Simple SVG pie chart – Example of a graphical SVG-based widget.

Echo widget in JavaScript

The following is the Echo sample widget in JavaScript.

```
const DOCS = `
## Echo
A basic echo script. Anything passed in the \`\`\`echo\`\`\` parameter is returned as
 the content of the custom widget.
### Widget parameters
Param | Description
---|---
**echo** | The content to echo back

### Example parameters
\`\`\` yaml
echo: <h1>Hello world</h1>
\`\`\`
`;

exports.handler = async (event) => {
    if (event.describe) {
        return DOCS;
    }

    let widgetContext = JSON.stringify(event.widgetContext, null, 4);
    widgetContext = widgetContext.replace(/</g, '&lt;');
    widgetContext = widgetContext.replace(/>/g, '&gt;');

    return `${event.echo || ''}<pre>${widgetContext}</pre>`;
};
```

Echo widget in Python

The following is the Echo sample widget in Python.

```
import json

DOCS = """
```

```
## Echo
A basic echo script. Anything passed in the ```echo``` parameter is returned as the
 content of the custom widget.
### Widget parameters
Param | Description
---|---
**echo** | The content to echo back

### Example parameters
``` yaml
echo: <h1>Hello world</h1>
```"""

def lambda_handler(event, context):
    if 'describe' in event:
        return DOCS

    echo = event.get('echo', '')
    widgetContext = event.get('widgetContext')
    widgetContext = json.dumps(widgetContext, indent=4)
    widgetContext = widgetContext.replace('<', '<')
    widgetContext = widgetContext.replace('>', '>')

    return f'{echo}<pre>{widgetContext}</pre>'
```

Echo widget in Java

The following is the Echo sample widget in Java.

```
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

import com.google.gson.Gson;
import com.google.gson.GsonBuilder;

public class Handler implements RequestHandler<Event, String>{

  static String DOCS = ""
    + "## Echo\n"
    + "A basic echo script. Anything passed in the ```echo``` parameter is returned as
 the content of the custom widget.\n"
    + "### Widget parameters\n"
```

```
    + "Param | Description\n"
    + "---|---\n"
    + "**echo** | The content to echo back\n\n"
    + "### Example parameters\n"
    + "```yaml\n"
    + "echo: <h1>Hello world</h1>\n"
    + "```\n";

  Gson gson = new GsonBuilder().setPrettyPrinting().create();

  @Override
  public String handleRequest(Event event, Context context) {

    if (event.describe) {
      return DOCS;
    }

    return (event.echo != null ? event.echo : "") + "<pre>" +
 gson.toJson(event.widgetContext) + "</pre>";
  }
}

class Event {

    public boolean describe;
    public String echo;
    public Object widgetContext;

    public Event() {}

    public Event(String echo, boolean describe, Object widgetContext) {
        this.describe = describe;
        this.echo = echo;
        this.widgetContext = widgetContext;
    }
}
```

Adding a text widget to a CloudWatch dashboard

To add a text widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.

3. Choose the **+** symbol.
4. Choose **Text**.
5. For **Markdown**, add and format your text using Markdown and choose **Create widget**.
6. To make the text widget transparent, choose **Transparent background**.
7. Choose **Save dashboard**.

Editing a text widget on a CloudWatch dashboard

To edit a text widget on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the text block and choose **Widget actions**. Then, choose **Edit**.
4. Update the text as needed and choose **Update widget**.
5. Choose **Save dashboard**.

Removing a text widget from a CloudWatch dashboard

To remove a text widget from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the upper-right corner of the text block and choose **Widget actions**. Then, choose **Delete**.
4. Choose **Save dashboard**.

Adding an alarm to a CloudWatch dashboard

To add a single alarm, including its graph, to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, select the alarm to add, and then choose **Add to Dashboard**.

3. Select a dashboard, choose a widget type (**Line**, **Stacked area**, or **Number**), and then choose **Add to dashboard**.
4. To see your alarm on the dashboard, choose **Dashboards** in the navigation pane and select the dashboard.
5. (Optional) To temporarily make an alarm graph larger, select the graph.
6. (Optional) To change the widget type, hover over the title of the graph, choose **Widget actions**, and then choose **Widget type**.

Adding an alarm status widget to a CloudWatch dashboard

To add an alarm status widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose the **+** symbol.
4. Choose **Alarm status**.
5. Select the check boxes next to the alarms that you want to add to the widget, and then choose **Create widget**.
6. Choose **Add to dashboard**.

Removing an alarm widget from a CloudWatch dashboard

To remove an alarm widget from a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Hover over the widget, choose **Widget actions**, and then choose **Delete**.
4. Choose **Save dashboard**. If you attempt to navigate away from the dashboard before you save your changes, you're prompted to either save or discard your changes.

Using a data table widget in a CloudWatch dashboard

Table properties

A data table has a default set of properties that don't require any changes to be made to the options or source. These properties include a sticky label column, all summary columns enabled, datapoints rounded, and their units converted.

Each data table widget can have the following properties. The information about each property includes how to configure it in the JSON source of the dashboard. For more information about dashboard JSON, see [Dashboard Body Structure and Syntax](#).

Summary

Summary columns are a new property introduced with the data table widget. These columns are a specific subset of summaries of your current table. For example, the **Sum** summary is a sum of all displayed datapoints in its row. The summary columns are not the same as CloudWatch statistics. Represented in source as:

```
"table": {
       "summaryColumns": [
           "MIN",
           "MAX",
           "SUM",
           "AVG"
       ]
   },
```

Thresholds

Use this to apply thresholds to your table. When a data point falls within a threshold, its cell is highlighted with the threshold color. Represented in source as:

```
"annotations": {
    "horizontal": [
        {
            "label": string,
            "value": int,
            "fill": "above" | "below"
        }
    ]
}
```

Unit in label column

To display what unit is associated with the metric, you can enable this option to display the unit in the label column beside the label. Represented in source as:

```
"yAxis": {
    "left": {
        "showUnits": true | false
    }
}
```

Invert rows and columns

This transforms the table so that the datapoints swap from columns to rows, and the metrics become columns. Represented in source as:

```
 "table": {
    "layout": "vertical" | "horizontal"
}
```

Sticky summary columns

This makes the summary columns sticky, so that they remain in view while you scroll. The label is already sticky. Represented in source as:

```
"table": {
    "stickySummary": true | false
}
```

Display only summary columns

This prevents the columns of datapoints from being displayed, so that only the label and summary columns are displayed. Represented in source as:

```
 "table": {
    "showTimeSeriesData": false | true
}
```

Live data

Displays the most recent data point, even if it is not yet fully aggregated. Represented in source as:

```
"liveData": true | false
```

Number widget format

Displays as many digits as can fit in the cell, before rounding and converting. Represented in source as:

```
"singleValueFullPrecision": true | false
```

Adding a data table widget to a CloudWatch dashboard

To add a data table widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards** and then choose a dashboard.
3. Choose the **+** button, select **Data table**, and choose **Next**.
4. In the **Browse** tab, search or browse for the metrics that you want to display in the table widget. Then select the metrics.
5. (Optional) To change the layout of the table, choose the **Options** tab and select **Invert rows and columns**.

   You can also use the **Options** tab to change what columns appear in the table and display the unit being used in the **Label** column.

   > **Tip**
   >
   > To display more accurate thresholds, choose **Show as many digits as can fit before rounding**.

6. (Optional) To change your data table widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week. To set your own time range, choose **Custom**.
7. (Optional) To change your data table widget's time range, select one of the predefined time ranges in the upper area of the widget. The time ranges span from 1 hour to 1 week. To set your own time range, choose **Custom**.

8. (Optional) To have this widget keep using the time range that you select, even if the time range for the rest of the dashboard is later changed, choose **Persist time range**.
9. Choose **Create widget** and then choose **Save dashboard**.

Removing a data table widget from a CloudWatch dashboard

To remove a data table widget to a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the widget that you want to remove, choose **Widget actions**, **Delete**.
4. Choose **Save dashboard**.

Linking graphs on a CloudWatch dashboard

Link graphs on a CloudWatch dashboard so that changes in time are reflected on all graphs.

To link the graphs on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Choose **Actions** and then **Link graphs**.

Unlinking graphs on a CloudWatch dashboard

To unlink the graphs on a dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Clear **Actions** and then **Link graphs**.

Sharing CloudWatch dashboards

You can share your CloudWatch dashboards with people who do not have direct access to your Amazon account. This enables you to share dashboards across teams, with stakeholders, and with people external to your organization. You can even display dashboards on big screens in team areas, or embed them in Wikis and other webpages.

> **Warning**
>
> All people who you share the dashboard with are granted the permissions listed in Permissions that are granted to people who you share the dashboard with for the account. If you share the dashboard publicly, then everyone who has the link to the dashboard has these permissions.
> The `cloudwatch:GetMetricData` and `ec2:DescribeTags` permissions cannot be scoped down to specific metrics or EC2 instances, so the people with access to the dashboard can query all CloudWatch metrics and the names and tags of all EC2 instances in the account.

When you share dashboards, you can designate who can view the dashboard in three ways:

- Share a single dashboard and designate as many as five email addresses of people who can view the dashboard. Each of these users creates their own password that they must enter to view the dashboard.
- Share a single dashboard publicly, so that anyone who has the link can view the dashboard.
- Share all the CloudWatch dashboards in your account and specify a third-party single sign-on (SSO) provider for dashboard access. All users who are members of this SSO provider's list can access all the dashboards in the account. To enable this, you integrate the SSO provider with Amazon Cognito. The SSO provider must support Security Assertion Markup Language (SAML). For more information about Amazon Cognito, see What is Amazon Cognito?

Sharing a dashboard doesn't incur charges, but widgets inside a shared dashboard incur charges at standard CloudWatch rates. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

When you share a dashboard, Amazon Cognito resources are created in the US East (N. Virginia) Region.

Important

Do not modify resource names and identifiers that are created by the dashboard sharing process. This includes Amazon Cognito and IAM resources. Modifying these resources can cause unexpected and incorrect functionality of shared dashboards.

Note

If you share a dashboard that has metric widgets with alarm annotations, the people that you share the dashboard with will not see those widgets. They will instead see a blank widget with text saying that the widget is not available. You will still see metric widgets with alarm annotations when you view the dashboard yourself.

Permissions required to share a dashboard

To be able to share dashboards using any of the following methods and to see which dashboards have already been shared, you must be signed on as a user or with an IAM role that has certain permissions.

To be able to share dashboards, your user or IAM role must include the permissions included in the following policy statement:

```
{
    "Effect": "Allow",
    "Action": [
        "iam:CreateRole",
        "iam:CreatePolicy",
        "iam:AttachRolePolicy",
        "iam:PassRole"
    ],
    "Resource": [
        "arn:aws:iam::*:role/service-role/CWDBSharing*",
        "arn:aws:iam::*:policy/*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
```

```
            "cognito-idp:*",
            "cognito-identity:*",
        ],
        "Resource": [
            "*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "cloudwatch:GetDashboard",
        ],
        "Resource": [
            "*"
            // or the ARNs of dashboards that you want to share
        ]
    }
```

To be able to see which dashboards are shared, but not be able to share dashboards, a user or an IAM role can include a policy statement similar to the following:

```
{
    "Effect": "Allow",
    "Action": [
        "cognito-idp:*",
        "cognito-identity:*"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "cloudwatch:ListDashboards",
    ],
    "Resource": [
        "*"
    ]
}
```

Permissions that are granted to people who you share the dashboard with

When you share a dashboard, CloudWatch creates an IAM role in the account which gives the following permissions to the people who you share the dashboard with:

- `cloudwatch:GetInsightRuleReport`
- `cloudwatch:GetMetricData`
- `cloudwatch:DescribeAlarms`
- `ec2:DescribeTags`

> **Warning**
>
> All people who you share the dashboard with are granted these permissions for the account. If you share the dashboard publicly, then everyone who has the link to the dashboard has these permissions.
> The `cloudwatch:GetMetricData` and `ec2:DescribeTags` permissions cannot be scoped down to specific metrics or EC2 instances, so the people with access to the dashboard can query all CloudWatch metrics and the names and tags of all EC2 instances in the account.

When you share a dashboard, by default the permissions that CloudWatch creates restrict access to only the alarms and Contributor Insights rules that are on the dashboard when it is shared. If you add new alarms or Contributor Insights rules to the dashboard and want them to also be seen by the people who you shared the dashboard with, you must update the policy to allow these resources.

Sharing a CloudWatch dashboard with specific users

Use the steps in this section to share a dashboard with as many as five email addresses that you choose.

> **Note**
>
> By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.
>
> By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share a dashboard with specific users

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Next to **Share your dashboard and require a username and password**, choose **Start sharing**.
6. Under **Add email addresses**, enter the email addresses that you want to share the dashboard with. You can include as many as five email addresses.
7. When you have all the email addresses entered, read the agreement and select the confirmation box. Then choose **Preview policy**.
8. Confirm that the resources that will be shared are what you want, and choose **Confirm and generate shareable link**.
9. On the next page, choose **Copy link to clipboard**. You can then paste this link into email and send it to the invited users. They automatically receive a separate email with their user name and a temporary password to use to connect to the dashboard.

Sharing a CloudWatch dashboard publicly

Follow the steps in this section to share a dashboard publicly. This can be useful to display the dashboard on a big screen in a team room, or embed it in a Wiki page.

> **Important**
>
> Sharing a dashboard publicly makes it accessible to anyone who has the link, with no authentication. Do this only for dashboards that do not contain sensitive information.

> **Note**
>
> By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.
> By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share a dashboard publicly

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Next to **Share your dashboard publicly**, choose **Start sharing**.
6. Enter **`Confirm`** in the text box.
7. Read the agreement and select the confirmation box. Then choose **Preview policy**.
8. Confirm that the resources that will be shared are what you want, and choose **Confirm and generate shareable link**.
9. On the next page, choose **Copy link to clipboard**. You can then share this link. Anyone you share the link with can access the dashboard, without providing credentials.

Sharing all CloudWatch dashboards in the account by using SSO

Use the steps in this section to share all the dashboards in your account with users by using single sign-on (SSO).

Note

By default, any CloudWatch Logs widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see logs table widgets.

By default, any composite alarm widgets on the dashboard are not visible to people who you share the dashboard with. For more information, see Allowing people that you share with to see composite alarms.

To share your CloudWatch dashboards with users who are in an SSO provider's list

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of your dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Choose **Go to CloudWatch Settings**.
6. If the SSO provider that you want isn't listed in **Available SSO providers**, choose **Manage SSO providers** and follow the instructions in Setting up SSO for CloudWatch dashboard sharing.

   Then return to the CloudWatch console and refresh the browser. The SSO provider that you enabled should now appear in the list.
7. Choose the SSO provider that you want in the **Available SSO providers** list.
8. Choose **Save changes**.

Setting up SSO for CloudWatch dashboard sharing

To set up dashboard sharing through a third-party single sign-on provider that supports SAML, follow these steps.

Important

We strongly recommend that you do not share dashboards using a non-SAML SSO provider. Doing so causes a risk of inadvertently allowing third parties to access your account's dashboards.

To set up an SSO provider to enable dashboard sharing

1. Integrate the SSO provider with Amazon Cognito. For more information, see [Integrating Third-Party SAML Identity Providers with Amazon Cognito User Pools](#).
2. Download the metadata XML file from your SSO provider.
3. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
4. In the navigation pane, choose **Settings**.
5. In the **Dashboard sharing** section, choose **Configure**.
6. Choose **Manage SSO providers**.

   This opens the Amazon Cognito console in the US East (N. Virginia) Region (us-east-1). If you don't see any **User Pools**, the Amazon Cognito console might have opened in a different Region. If so, change the Region to **US East (N. Virginia) us-east-1** and proceed with the next steps.
7. Choose the **CloudWatchDashboardSharing** pool.
8. In the navigation pane, choose **Social and external providers**.
9. Choose **Add identity provider**.
10. Choose **SAML**.
11. Enter a name for your SSO provider in **Provider name**.
12. Choose **Select file**, and select the metadata XML file that you downloaded in step 2.
13. Choose **Create provider**.

Seeing how many of your CloudWatch dashboards are shared

You can use the CloudWatch console to see how many of your CloudWatch dashboards are currently being shared with others.

To see how many of your dashboards are being shared

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. The **Dashboard sharing** section displays how many dashboards are shared.
4. To see which dashboards are shared, choose ***number*** **dashboards shared** under **Username and password** and under **Public dashboards.**

Seeing which of your CloudWatch dashboards are shared

You can use the CloudWatch console to see which of your dashboards are currently being shared with others.

To see which of your dashboards are being shared

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. In the list of dashboards, see the **Share** column. Dashboards that have the icon in this column filled in are currently being shared.
4. To see which users a dashboard is being shared with, choose the dashboard name, and then choose **Actions**, **Share dashboard**.

   The **Share dashboard** ***`dashboard name`*** page displays how the dashboard is being shared. If you want, you can stop sharing the dashboard by choosing **Stop sharing**.

Stopping sharing one or more CloudWatch dashboards

You can stop sharing a single shared dashboard, or stop sharing all shared dashboards at once.

To stop sharing a single dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Choose **Stop sharing**.
6. In the confirmation box, choose **Stop sharing**.

To stop sharing all shared dashboards

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. In the **Dashboard sharing** section, choose **Stop sharing all dashboards**.
4. In the confirmation box, choose **Stop sharing all dashboards**.

Reviewing shared CloudWatch dashboard permissions and changing permission scope

Use the steps in this section if you want to review the permissions of the users of your shared dashboards, or change the scope of shared dashboard permissions.

To review shared dashboard permissions

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. (Optional) To limit which alarms that shared dashboard users can see, choose **Edit policy** and move the `cloudwatch:DescribeAlarms` permission from its current position to a new `Allow` statement that lists the ARNs of only the alarms that you want to be seen by shared dashboard users. See the following example.

```
{
   "Effect": "Allow",
    "Action": "cloudwatch:DescribeAlarms",
    "Resource": [
        "AlarmARN1",
        "AlarmARN2"
    ]
}
```

   If you do this, be sure to remove the `cloudwatch:DescribeAlarms` permission from a section of the current policy that looks like this:

```
{
   "Effect": "Allow",
    "Action": [
        "cloudwatch:GetInsightRuleReport",
        "cloudwatch:GetMetricData",
        "cloudwatch:DescribeAlarms",
        "ec2:DescribeTags"
```

```
    ],
    "Resource": "*"
}
```

8. (Optional) To limit the scope of what Contributor Insights rules that shared dashboard users can see, choose **Edit policy** and move the `cloudwatch:GetInsightRuleReport` from its current position to a new `Allow` statement that lists the ARNs of only the Contributor Insights rules that you want to be seen by shared dashboard users. See the following example.

```
{
   "Effect": "Allow",
    "Action": "cloudwatch:GetInsightRuleReport",
    "Resource": [
        "PublicContributorInsightsRuleARN1",
        "PublicContributorInsightsRuleARN2"
    ]
}
```

   If you do this, be sure to remove `cloudwatch:GetInsightRuleReport` from a section of the current policy that looks like this:

```
{
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetInsightRuleReport",
                "cloudwatch:GetMetricData",
                "cloudwatch:DescribeAlarms",
                "ec2:DescribeTags"
            ],
            "Resource": "*"
        }
```

Allowing people that you share with to see composite alarms

When you share a dashboard, by default the composite alarm widgets on the dashboard are not visible to the people who you share the dashboard with. For composite alarm widgets to be visible, you need to add a `DescribeAlarms: *` permission to the dashboard sharing policy. That permission would look like this:

```
{
```

```
    "Effect": "Allow",
    "Action": "cloudwatch:DescribeAlarms",
    "Resource": "*"
}
```

> **Warning**
>
> The preceding policy statement give access to all alarms in the account. To reduce the scope of `cloudwatch:DescribeAlarms`, you must use a `Deny` statement. You can add a `Deny` statement to the policy and specify the ARNs of the alarms that you want to lock down. That deny statement should look similar to the following:
>
> ```
> {
>     "Effect": "Allow",
>     "Action": "cloudwatch:DescribeAlarms",
>     "Resource": "*"
> },
> {
>     "Effect": "Deny",
>     "Action": "cloudwatch:DescribeAlarms",
>     "Resource": [
>         "SensitiveAlarm1ARN",
>         "SensitiveAlarm1ARN"
>     ]
> }
> ```

Allowing people that you share with to see logs table widgets

When you share a dashboard, by default the CloudWatch Logs Insights widgets that are on the dashboard are not visible to the people who you share the dashboard with. This affects both CloudWatch Logs Insights widgets that exist now and any that are added to the dashboard after you share it.

If you want these people to be able to see CloudWatch Logs widgets, you must add permissions to the IAM role for dashboard sharing.

To allow the people that you share a dashboard with to see the CloudWatch Logs widgets

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. Choose **Edit policy** and add the following statement. In the new statement, we recommend that you specify the ARNs of only the log groups that you want shared. See the following example.

```
{
            "Effect": "Allow",
            "Action": [
                "logs:FilterLogEvents",
                "logs:StartQuery",
                "logs:StopQuery",
                "logs:GetLogRecord",
                "logs:DescribeLogGroups"
            ],
            "Resource": [
                "SharedLogGroup1ARN",
                "SharedLogGroup2ARN"
           ]
        },
```

8. Choose **Save Changes**.

If your IAM policy for dashboard sharing already includes those five permissions with * as the resource, we strongly recommend that you change the policy and specify only the ARNs of the log groups that you want shared. For example, if your `Resource` section for these permissions was the following:

```
"Resource": "*"
```

Change the policy to specify only the ARNs of the log groups that you want shared, as in the following example:

```
"Resource": [
  "SharedLogGroup1ARN",
  "SharedLogGroup2ARN"
```

```
]
```

Allowing people that you share with to see custom widgets

When you share a dashboard, by default the custom widgets that are on the dashboard are not visible to the people who you share the dashboard with. This affects both custom widgets that exist now and any that are added to the dashboard after you share it.

If you want these people to be able to see custom widgets, you must add permissions to the IAM role for dashboard sharing.

To allow the people that you share a dashboard with to see the custom widgets

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the shared dashboard.
4. Choose **Actions**, **Share dashboard**.
5. Under **Resources**, choose **IAM Role**.
6. In the IAM console, choose the displayed policy.
7. Choose **Edit policy** and add the following statement. In the new statement, we recommend that you specify the ARNs of only the Lambda functions that you want shared. See the following example.

```
{
  "Sid": "Invoke",
  "Effect": "Allow",
  "Action": [
      "lambda:InvokeFunction"
  ],
  "Resource": [
    "LambdaFunction1ARN",
    "LambdaFunction2ARN"
  ]
 }
```

8. Choose **Save Changes**.

If your IAM policy for dashboard sharing already includes that permission with * as the resource, we strongly recommend that you change the policy and specify only the ARNs of the Lambda functions that you want shared. For example, if your `Resource` section for these permissions was the following:

```
"Resource": "*"
```

Change the policy to specify only the ARNs of the custom widgets that you want shared, as in the following example:

```
"Resource": [
  "LambdaFunction1ARN",
  "LambdaFunction2ARN"
]
```

Using live data in CloudWatch dashboards

You can choose whether your metric widgets display *live data*. Live data is data published within the last minute that has not been fully aggregated.

- If live data is turned **off**, only data points with an aggregation period of at least one minute in the past are shown. For example, when using 5-minute periods, the data point for 12:35 would be aggregated from 12:35 to 12:40, and displayed at 12:41.
- If live data is turned **on**, the most recent data point is shown as soon as any data is published in the corresponding aggregation interval. Each time you refresh the display, the most recent data point may change as new data within that aggregation period is published. If you use a cumulative statistic such as **Sum** or **Sample Count**, using live data may result in a dip at the end of your graph.

You can choose to enable live data for a whole dashboard, or for individual widgets on the dashboard.

Using live data for a CloudWatch dashboard

To choose whether to use live data on your entire dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. To permanently turn live data on or off for all widgets on the dashboard, do the following:

   a. Choose **Actions**, **Settings**, **Bulk update live data.**
   b. Choose **Live Data on** or **Live Data off**, and choose **Set**.

4. To temporarily override the live data settings of each widget, choose **Actions**. Then, under **Overrides**, next to **Live data**, do one of the following:

   - Choose **On** to temporarily turn on live data for all widgets.
   - Choose **Off** to temporarily turn off live data for all widgets.
   - Choose **Do not override** to preserve each widget's live data setting.

Using live data for a CloudWatch dashboard widget

To choose whether to use live data on a single widget

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. Select a widget, and choose **Actions**, **Edit**.
4. Choose the **Graph options** tab.
5. Select or clear the check box under **Live Data**.

Viewing an animated CloudWatch dashboard

You can view an animated dashboard that replays CloudWatch metric data that was captured over time. This can help you see trends, make presentations, or analyze issues after they occur.

Animated widgets in the dashboard include line widgets, stacked area widgets, number widgets, and metrics explorer widgets. Pie graphs, bar charts, text widgets, and logs widgets are displayed in the dashboard but are not animated.

To view an animated dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose the name of the dashboard.
4. Choose **Actions**, **Replay dashboard**.

5. (Optional) By default, when you start the animation, it appears as a sliding window. If you want the animation to appear as a point-by-point animation instead, choose the magnifying glass icon while the animation is paused and reset the zoom.
6. To start the animation, choose the Play button. You can also choose the back and forward buttons to move to other points in time.
7. (Optional) To change the time window for the animation, choose the calendar and select the time period.
8. To change the speed of the animation, choose **Auto speed** and select the new speed.
9. When you are finished, choose **Exit animate**.

Adding a CloudWatch dashboard to your favorites list

In the CloudWatch console, you can add dashboards, alarms, and log groups to a favorites list. You can access the favorites list from the navigation pane. The following procedure describes how to add a dashboard to the favorites list.

To add a dashboard to the favorites list

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. From the list of dashboards, select the star symbol next to the name of the dashboard that you want to favorite.
   - (Optional) You also can favorite a dashboard by selecting a dashboard from the list and choosing the star symbol next to the dashboard name.
4. To access the favorites list, choose **Favorites and recents** in the navigation pane. The menu contains two columns. One contains your favorite dashboards, alarms, and log groups, and the other column contains the dashboards, alarms, and log groups that you recently visited.

> **Tip**
>
> You can favorite dashboards, as well as alarms and log groups, from the ***Favorites and recents*** menu in the CloudWatch console navigation pane. Under the ***Recently visited*** column, hover over the dashboard that you want to favorite, and choose the star symbol next to it.

Changing the period override setting or refresh interval for the CloudWatch dashboard

You can specify how the period setting of graphs added to this dashboard are retained or modified.

When an auto period or persisted time range is applied to a widget, the overall time range of the graph can affect the periods that you have set.

- If the time range is one day or less, period settings are not changed.
- If the time range is between one day and three days, periods set to below five minutes are changed to 5 minutes.
- If the time range is more than three days, periods set to below one hour are changed to one hour.

The following steps explain how to use the console to change the period override options. You can also change them by using the `periodOverride` field in the JSON structure of the dashboard. For more information, see [Dashboard Body Overall Structure](#).

To change the period override options

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Actions**.
3. Under **Period override**, choose one of the following:

   - Choose **Auto** to have the period of the metrics on each graph automatically adapt to the dashboard's time range.
   - Choose **Do not override** to ensure that the period setting of each graph is always obeyed.
   - Choose one of the other options to cause graphs added to the dashboard to always adapt that chosen time as their period setting.

   The **Period override** always reverts to **Auto** when the dashboard is closed or the browser is refreshed. Different settings for **Period override** can't be saved.

You can change how often the data on your CloudWatch dashboard is refreshed.

To change the dashboard refresh interval

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. On the **Refresh options** menu (upper-right corner), choose **10 Seconds**, **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

Changing the time range or time zone format of a CloudWatch dashboard

You can change the time range to display dashboard data over minutes, hours, days, or weeks. You also can change the time zone format to display dashboard data in UTC or local time. Local time is the time zone that's specified in your computer's operating system.

> **Note**
>
> If you create a dashboard with graphs that contain 100 or more high-resolution metrics, we recommend that you don't set the time range to longer than 1 hour. For more information, see [High-resolution metrics](#).

> **Note**
>
> If the time range of a dashboard is shorter than the period used for a widget on the dashboard, the following happens:
>
> - The widget is modified to display the amount of data corresponding one complete period for that widget, even though this is longer than the dashboard time range. This ensures that there is at least one data point on the graph.
> - The start time of the period for this data point is adjusted backwards to ensure that at least one data point can be displayed.

New console

To change the dashboard time range

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, do one of the following:
   - In the upper area of the dashboard, select one of the predefined time ranges. These span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, or **1w**).
   - Alternatively, you can choose one of the following custom time range options:
     - Choose **Custom**, and then choose the **Relative** tab. Choose a time range from 1 minute to 15 months.
     - Choose **Custom**, and then choose the **Absolute** tab. Use the calendar or text fields to specify your time range.

> **Tip**
>
> If the aggregation period is set to **Auto** when you change the time range of a graph, CloudWatch might change the period. To set the period manually, choose the **Actions** dropdown, and then choose **Period override**.

To change the dashboard time zone format

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper area of the dashboard, choose **Custom**.
4. In the upper-right corner of the box that appears, select **UTC** or **Local time** from the dropdown.
5. Choose **Apply**.

Old console

To change the dashboard time range

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. From the dashboard screen, do one of the following:
   - In the upper area of the dashboard, select one of the predefined time ranges. These span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**).
   - Alternatively, you can choose one of the following custom time range options:
     - Choose the **custom** dropdown, and then choose the **Relative** tab. Select one of the predefined ranges, which span from 1 minute to 15 months.
     - Choose the **custom** dropdown, and then choose the **Absolute** tab. Use the calendar or text fields to specify your time range.

> **Tip**
>
> If the aggregation period is set to **Auto** when you change the time range of a graph, CloudWatch might change the period. To set the period manually, choose the **Actions** dropdown, and then choose **Period override**.

To change the dashboard time zone format

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**, and then choose a dashboard.
3. In the upper-right corner of the dashboard screen, choose the **Custom** dropdown.
4. In the upper-right corner of the box that appears, select **UTC** or **Local timezone** from the dropdown.

Metrics in Amazon CloudWatch

Metrics are data about the performance of your systems. By default, many services provide free metrics for resources (such as Amazon EC2 instances, Amazon EBS volumes, and Amazon RDS DB instances). You can also enable detailed monitoring for some resources, such as your Amazon EC2 instances, or publish your own application metrics. Amazon CloudWatch can load all the metrics in your account (both Amazon resource metrics and application metrics that you provide) for search, graphing, and alarms.

Metric data is kept for 15 months, enabling you to view both up-to-the-minute data and historical data.

To graph metrics in the console, you can use CloudWatch Metrics Insights, a high-performance SQL query engine that you can use to identify trends and patterns within all your metrics in real time.

Metrics concepts

The following terminology and concepts are central to your understanding and use of Amazon CloudWatch:

- Namespaces
- Metrics
- Dimensions
- Resolution
- Statistics
- Percentiles
- Alarms

For information about the service quotas for CloudWatch metrics, alarms, API requests, and alarm email notifications, see CloudWatch service quotas.

Namespaces

A *namespace* is a container for CloudWatch metrics. Metrics in different namespaces are isolated from each other, so that metrics from different applications are not mistakenly aggregated into the same statistics.

There is no default namespace. You must specify a namespace for each data point you publish to CloudWatch. You can specify a namespace name when you create a metric. These names must contain valid ASCII characters, and be 255 or fewer characters. Possible characters are: alphanumeric characters (0-9A-Za-z), period (.), hyphen (-), underscore (_), forward slash (/), hash (#), colon (:), and the space character. A namespace must contain at least one non-whitespace character.

The Amazon namespaces typically use the following naming convention: `AWS/service`. For example, Amazon EC2 uses the `AWS/EC2` namespace. For the list of Amazon namespaces, see Amazon services that publish CloudWatch metrics.

Metrics

Metrics are the fundamental concept in CloudWatch. A metric represents a time-ordered set of data points that are published to CloudWatch. Think of a metric as a variable to monitor, and the data points as representing the values of that variable over time. For example, the CPU usage of a particular EC2 instance is one metric provided by Amazon EC2. The data points themselves can come from any application or business activity from which you collect data.

By default, many Amazon services provide metrics at no charge for resources (such as Amazon EC2 instances, Amazon EBS volumes, and Amazon RDS DB instances). For a charge, you can also enable detailed monitoring for some resources, such as your Amazon EC2 instances, or publish your own application metrics. For custom metrics, you can add the data points in any order, and at any rate you choose. You can retrieve statistics about those data points as an ordered set of time-series data.

Metrics exist only in the Region in which they are created. Metrics cannot be deleted, but they automatically expire after 15 months if no new data is published to them. Data points older than 15 months expire on a rolling basis; as new data points come in, data older than 15 months is dropped.

Metrics are uniquely defined by a name, a namespace, and zero or more dimensions. Each data point in a metric has a time stamp, and (optionally) a unit of measure. You can retrieve statistics from CloudWatch for any metric.

For more information, see View available metrics and Publish custom metrics.

Time stamps

Each metric data point must be associated with a time stamp. The time stamp can be up to two weeks in the past and up to two hours into the future. If you do not provide a time stamp, CloudWatch creates a time stamp for you based on the time the data point was received.

Time stamps are `dateTime` objects, with the complete date plus hours, minutes, and seconds (for example, 2016-10-31T23:59:59Z). For more information, see [dateTime](). Although it is not required, we recommend that you use Coordinated Universal Time (UTC). When you retrieve statistics from CloudWatch, all times are in UTC.

CloudWatch alarms check metrics based on the current time in UTC. Custom metrics sent to CloudWatch with time stamps other than the current UTC time can cause alarms to display the **Insufficient Data** state or result in delayed alarms.

Metrics retention

CloudWatch retains metric data as follows:

- Data points with a period of less than 60 seconds are available for 3 hours. These data points are high-resolution custom metrics.
- Data points with a period of 60 seconds (1 minute) are available for 15 days
- Data points with a period of 300 seconds (5 minutes) are available for 63 days
- Data points with a period of 3600 seconds (1 hour) are available for 455 days (15 months)

Data points that are initially published with a shorter period are aggregated together for long-term storage. For example, if you collect data using a period of 1 minute, the data remains available for 15 days with 1-minute resolution. After 15 days this data is still available, but is aggregated and is retrievable only with a resolution of 5 minutes. After 63 days, the data is further aggregated and is available with a resolution of 1 hour.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in the search box in the **All metrics** tab in the console, and they are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the Amazon CLI.

Dimensions

A *dimension* is a name/value pair that is part of the identity of a metric. You can assign up to 30 dimensions to a metric.

Every metric has specific characteristics that describe it, and you can think of dimensions as categories for those characteristics. Dimensions help you design a structure for your statistics plan. Because dimensions are part of the unique identifier for a metric, whenever you add a unique name/value pair to one of your metrics, you are creating a new variation of that metric.

Amazon services that send data to CloudWatch attach dimensions to each metric. You can use dimensions to filter the results that CloudWatch returns. For example, you can get statistics for a specific EC2 instance by specifying the `InstanceId` dimension when you search for metrics.

For metrics produced by certain Amazon services, such as Amazon EC2, CloudWatch can aggregate data across dimensions. For example, if you search for metrics in the `AWS/EC2` namespace but do not specify any dimensions, CloudWatch aggregates all data for the specified metric to create the statistic that you requested. CloudWatch does not aggregate across dimensions for your custom metrics.

Dimension combinations

CloudWatch treats each unique combination of dimensions as a separate metric, even if the metrics have the same metric name. You can only retrieve statistics using combinations of dimensions that you specifically published. When you retrieve statistics, specify the same values for the namespace, metric name, and dimension parameters that were used when the metrics were created. You can also specify the start and end times for CloudWatch to use for aggregation.

For example, suppose that you publish four distinct metrics named ServerStats in the DataCenterMetric namespace with the following properties:

```
Dimensions: Server=Prod, Domain=Frankfurt, Unit: Count, Timestamp:
 2016-10-31T12:30:00Z, Value: 105
Dimensions: Server=Beta, Domain=Frankfurt, Unit: Count, Timestamp:
 2016-10-31T12:31:00Z, Value: 115
Dimensions: Server=Prod, Domain=Rio,       Unit: Count, Timestamp:
 2016-10-31T12:32:00Z, Value: 95
Dimensions: Server=Beta, Domain=Rio,       Unit: Count, Timestamp:
 2016-10-31T12:33:00Z, Value: 97
```

If you publish only those four metrics, you can retrieve statistics for these combinations of dimensions:

- `Server=Prod,Domain=Frankfurt`
- `Server=Prod,Domain=Rio`
- `Server=Beta,Domain=Frankfurt`
- `Server=Beta,Domain=Rio`

You can't retrieve statistics for the following dimensions or if you specify no dimensions. (The exception is by using the metric math **SEARCH** function, which can retrieve statistics for multiple metrics. For more information, see Use search expressions in graphs.)

- `Server=Prod`
- `Server=Beta`
- `Domain=Frankfurt`
- `Domain=Rio`

Resolution

Each metric is one of the following:

- Standard resolution, with data having a one-minute granularity
- High resolution, with data at a granularity of one second

Metrics produced by Amazon services are standard resolution by default. When you publish a custom metric, you can define it as either standard resolution or high resolution. When you publish a high-resolution metric, CloudWatch stores it with a resolution of 1 second, and you can read and retrieve it with a period of 1 second, 5 seconds, 10 seconds, 30 seconds, or any multiple of 60 seconds.

High-resolution metrics can give you more immediate insight into your application's sub-minute activity. Keep in mind that every `PutMetricData` call for a custom metric is charged, so calling `PutMetricData` more often on a high-resolution metric can lead to higher charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms with a period of 10 or 30 seconds.

Statistics

Statistics are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other Amazon services to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify.

For detailed definitions of the statistics supported by CloudWatch, see [CloudWatch statistics definitions](#).

Units

Each statistic has a unit of measure. Example units include `Bytes`, `Seconds`, `Count`, and `Percent`. For the complete list of the units that CloudWatch supports, see the [MetricDatum](#) data type in the *Amazon CloudWatch API Reference*.

You can specify a unit when you create a custom metric. If you do not specify a unit, CloudWatch uses None as the unit. Units help provide conceptual meaning to your data. Though CloudWatch attaches no significance to a unit internally, other applications can derive semantic information based on the unit.

Metric data points that specify a unit of measure are aggregated separately. When you get statistics without specifying a unit, CloudWatch aggregates all data points of the same unit together. If you have two otherwise identical metrics with different units, two separate data streams are returned, one for each unit.

Periods

A *period* is the length of time associated with a specific Amazon CloudWatch statistic. Each statistic represents an aggregation of the metrics data collected for a specified period of time. Periods are defined in numbers of seconds, and valid values for period are 1, 5, 10, 30, or any multiple of 60. For example, to specify a period of six minutes, use 360 as the period value. You can adjust how the data is aggregated by varying the length of the period. The default value of a period is 60 seconds. A period can be as short as one second, and must be a multiple of 60 if it is greater than the default value of 60 seconds.

Only custom metrics that you define with a storage resolution of 1 second support sub-minute periods. Even though the option to set a period below 60 is always available in the console, you should select a period that aligns to how the metric is stored. For more information about metrics that support sub-minute periods, see High-resolution metrics.

When you retrieve statistics, you can specify a period, start time, and end time. These parameters determine the overall length of time associated with the statistics. The default values for the start time and end time get you the last hour's worth of statistics. The values that you specify for the start time and end time determine how many periods CloudWatch returns. For example, retrieving statistics using the default values for the period, start time, and end time returns an aggregated set of statistics for each minute of the previous hour. If you prefer statistics aggregated in ten-minute blocks, specify a period of 600. For statistics aggregated over the entire hour, specify a period of 3600.

When statistics are aggregated over a period of time, they are stamped with the time corresponding to the beginning of the period. For example, data aggregated from 7:00pm to 8:00pm is stamped as 7:00pm. Additionally, data aggregated between 7:00pm and 8:00pm begins to be visible at 7:00pm, then the values of that aggregated data may change as CloudWatch collects more samples during the period.

Periods are also important for CloudWatch alarms. When you create an alarm to monitor a specific metric, you are asking CloudWatch to compare that metric to the threshold value that you specified. You have extensive control over how CloudWatch makes that comparison. Not only can you specify the period over which the comparison is made, but you can also specify how many evaluation periods are used to arrive at a conclusion. For example, if you specify three evaluation periods, CloudWatch compares a window of three data points. CloudWatch only notifies you if the oldest data point is breaching and the others are breaching or missing.

Aggregation

Amazon CloudWatch aggregates statistics according to the period length that you specify when retrieving statistics. You can publish as many data points as you want with the same or similar time stamps. CloudWatch aggregates them according to the specified period length. CloudWatch does not automatically aggregate data across Regions, but you can use metric math to aggregate metrics from different Regions.

You can publish data points for a metric that share not only the same time stamp, but also the same namespace and dimensions. CloudWatch returns aggregated statistics for those data points. You can also publish multiple data points for the same or different metrics, with any time stamp.

For large datasets, you can insert a pre-aggregated dataset called a *statistic set*. With statistic sets, you give CloudWatch the Min, Max, Sum, and SampleCount for a number of data points. This is commonly used when you need to collect data many times in a minute. For example, suppose you have a metric for the request latency of a web page. It doesn't make sense to publish data with every web page hit. We suggest that you collect the latency of all hits to that web page, aggregate them once a minute, and send that statistic set to CloudWatch.

Amazon CloudWatch doesn't differentiate the source of a metric. If you publish a metric with the same namespace and dimensions from different sources, CloudWatch treats this as a single metric. This can be useful for service metrics in a distributed, scaled system. For example, all the hosts in a web server application could publish identical metrics representing the latency of requests they are processing. CloudWatch treats these as a single metric, allowing you to get the statistics for minimum, maximum, average, and sum of all requests across your application.

Percentiles

A *percentile* indicates the relative standing of a value in a dataset. For example, the 95th percentile means that 95 percent of the data is lower than this value and 5 percent of the data is higher than this value. Percentiles help you get a better understanding of the distribution of your metric data.

Percentiles are often used to isolate anomalies. In a normal distribution, 95 percent of the data is within two standard deviations from the mean and 99.7 percent of the data is within three standard deviations from the mean. Any data that falls outside three standard deviations is often considered to be an anomaly because it differs so greatly from the average value. For example, suppose that you are monitoring the CPU utilization of your EC2 instances to ensure that your customers have a good experience. If you monitor the average, this can hide anomalies. If you monitor the maximum, a single anomaly can skew the results. Using percentiles, you can monitor the 95th percentile of CPU utilization to check for instances with an unusually heavy load.

Some CloudWatch metrics support percentiles as a statistic. For these metrics, you can monitor your system and applications using percentiles as you would when using the other CloudWatch statistics (Average, Minimum, Maximum, and Sum). For example, when you create an alarm, you can use percentiles as the statistical function. You can specify the percentile with up to ten decimal places (for example, p95.0123456789).

Percentile statistics are available for custom metrics as long as you publish the raw, unsummarized data points for your custom metric. Percentile statistics are not available for metrics when any of the metric values are negative numbers.

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can only retrieve percentile statistics for this data if one of the following conditions is true:

- The SampleCount value of the statistic set is 1 and Min, Max, and Sum are all equal.
- The Min and Max are equal, and Sum is equal to Min multiplied by SampleCount.

The following Amazon services include metrics that support percentile statistics.

- API Gateway
- Application Load Balancer
- Amazon EC2
- Elastic Load Balancing
- Kinesis
- Lambda
- Amazon RDS

CloudWatch also supports trimmed mean and other performance statistics, which can have a similar use as percentiles. For more information, see CloudWatch statistics definitions.

Alarms

You can use an *alarm* to automatically initiate actions on your behalf. An alarm watches a single metric over a specified time period, and performs one or more specified actions, based on the value of the metric relative to a threshold over time. The action is a notification sent to an Amazon SNS topic or an Auto Scaling policy. You can also add alarms to dashboards.

Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

When creating an alarm, select an alarm monitoring period that is greater than or equal to the metrics resolution. For example, basic monitoring for Amazon EC2 provides metrics for your instances every 5 minutes. When setting an alarm on a basic monitoring metric, select a period of at least 300 seconds (5 minutes). Detailed monitoring for Amazon EC2 provides metrics for your instances with a resolution of 1 minute. When setting an alarm on a detailed monitoring metric, select a period of at least 60 seconds (1 minute).

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publish custom metrics.

For more information, see Using Amazon CloudWatch alarms and Create an alarm from a metric on a graph.

Basic monitoring and detailed monitoring in CloudWatch

CloudWatch provides two categories of monitoring: *basic monitoring* and *detailed monitoring*.

Many Amazon services offer basic monitoring by publishing a default set of metrics to CloudWatch with no charge to customers. By default, when you start using one of these Amazon Web Services services, basic monitoring is automatically enabled. For a list of services that offer basic monitoring, see Amazon services that publish CloudWatch metrics.

Detailed monitoring is offered by only some services. It also incurs charges. To use it for an Amazon service, you must choose to activate it. For more information about pricing, see Amazon CloudWatch pricing.

Detailed monitoring options differ based on the services that offer it. For example, Amazon EC2 detailed monitoring provides more frequent metrics, published at one-minute intervals, instead of the five-minute intervals used in Amazon EC2 basic monitoring. Detailed monitoring for Amazon S3 and Amazon Managed Streaming for Apache Kafka means more fine-grained metrics.

In different Amazon services, detailed monitoring also has different names. For example, in Amazon EC2 it is called detailed monitoring, in Amazon Elastic Beanstalk it is called enhanced monitoring, and in Amazon S3 it is called request metrics.

Using detailed monitoring for Amazon EC2 helps you better manage your Amazon EC2 resources, so that you can find trends and take action faster. For Amazon S3 request metrics are available at one-minute intervals to help you quickly identify and act on operational issues. On Amazon MSK, when you enable the `PER_BROKER`, `PER_TOPIC_PER_BROKER`, or `PER_TOPIC_PER_PARTITION` level monitoring, you get additional metrics that provide more visibility.

The following table lists the services that offer detailed monitoring. It also includes links to the documentation for those services that explain more about the detailed monitoring and provide instructions for how to activate it.

Service	Documentation
Amazon API Gateway	Dimensions for API Gateway metrics
Amazon AppSync	CloudWatch metrics
Amazon CloudFront	Viewing additional CloudFront distribution metrics
Amazon EC2	Manage detailed monitoring for your EC2 instances
Elastic Beanstalk	Enhanced health reporting and monitoring
Amazon Kinesis Data Streams	Enhanced Shard-level Metrics
Amazon Lambda	Event source mapping metrics
Amazon MSK	Amazon MSK Metrics for Monitoring with CloudWatch
Amazon S3	Amazon S3 request metrics in CloudWatch

Service	Documentation
Amazon SES	Collect CloudWatch detailed monitoring metrics using Amazon SES event publishing.

Additionally, CloudWatch offers out-of-the-box monitoring solutions with more detailed metrics and pre-created dashboards for some Amazon services, as shown in the following table.

Service	Feature documentation
Lambda	Lambda Insights
Amazon ECS	Container Insights for Amazon ECS
Amazon EKS	Container Insights for Amazon EKS and Kubernetes
Amazon RDS	CloudWatch Database Insights
Amazon Aurora	CloudWatch Database Insights

Query your CloudWatch metrics with CloudWatch Metrics Insights

CloudWatch Metrics Insights is a powerful high-performance SQL query engine that you can use to query your metrics at scale. You can identify trends and patterns within all of your CloudWatch metrics in real time.

You can also set alarms on any Metrics Insights queries that return a single time series. This can be especially useful to create alarms that watch aggregated metrics across a fleet of your infrastructure or applications. Create the alarm once, and it dynamically adjusts as resources are added to or removed from the fleet.

You can perform a CloudWatch Metrics Insights query in the console with the CloudWatch Metrics Insights query editor. You can also perform a CloudWatch Metrics Insights query with the Amazon CLI or an Amazon SDK by running `GetMetricData` or `PutDashboard`. There's no charge for queries that you run with the CloudWatch Metrics Insights query editor. For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](#).

With the CloudWatch Metrics Insights query editor, you can choose from a variety of prebuilt sample queries and also create your own queries. As you create your queries, you can use a builder view to browse your existing metrics and dimensions. Alternatively, use an editor view to manually write queries.

You can also use natural language to create CloudWatch Metrics Insights queries. To do so, ask questions about or describe the data you're looking for. This AI-assisted capability generates a query based on your prompt and provides a line-by-line explanation of how the query works. For more information, see [Use natural language to generate and update CloudWatch Metrics Insights queries](#).

With Metrics Insights, you can run queries at scale. With the **GROUP BY** clause, you can group your metrics in real time into separate time series per specific dimension value. Because Metrics Insights queries include an **ORDER BY** ability, you can use Metrics Insights to make "Top N" type queries. For example, "Top N" type queries can scan millions of metrics in your account and return the 10 instances that consume the most CPU. This can help you pinpoint and remedy latency issues in your applications.

Building your queries in CloudWatch Metrics Insights

You can run a CloudWatch Metrics Insights query using the CloudWatch console, the Amazon CLI, or the Amazon SDKs. Queries run in the console are free of charge. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

For more information about using the Amazon SDKs to perform a Metrics Insights query, see GetMetricData.

To run a query using the CloudWatch console, follow these steps:

To query your metrics using Metrics Insights

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. (Optional) To run a pre-built sample query, choose **Add query** and select the query to run. If you are satisfied with this query, you can skip the rest of this procedure. Or, you can choose **Editor** to edit the sample query and then choose **Run** to run the modified query.
4. To create your own query, choose **Multi source query**. You can then use the **Builder** view, the **Editor** view, and also use a combination of both. You can switch between the two views anytime and see your work in progress in both views.

   In the **Builder** view, you can browse and select the metric namespace, metric name, filter, group, and order options. For each of these options, the query builder offers you a list of possible selections from your environment to choose from.

In the **Editor** view, you can start writing your query. As you type, the editor offers suggestions based on the characters that you have typed so far.

5. When you are satisfied with your query, choose **Run**.
6. (Optional) Another way to edit a query that you have graphed is to choose the **Graphed metrics** tab and choose the edit icon next to the query formula in the **Details** column.
7. (Optional) To remove a query from the graph, choose **Graphed metrics** and choose the **X** icon at the right side of the row that displays your query.

Query components and syntax in CloudWatch Metrics Insights

CloudWatch Metrics Insights syntax is as follows.

```
SELECT FUNCTION(metricName)
FROM namespace | SCHEMA(...)
[ WHERE labelKey OPERATOR labelValue [AND ... ] ]
[ GROUP BY labelKey [ , ... ] ]
[ ORDER BY FUNCTION() [ DESC | ASC ] ]
[ LIMIT number ]
```

The possible clauses in a Metrics Insights query are as follows. None of the keywords are case sensitive, but the identifiers such as the names of metrics, namespaces, and dimensions are case sensitive.

SELECT

Required. Specifies the function to use to aggregate observations in each time bucket (determined by the provided period). Also specifies the name of the metric to query.

The valid values for **FUNCTION** are `AVG`, `COUNT`, `MAX`, `MIN`, and `SUM`.

- `AVG` calculates the average of the observations matched by the query.
- `COUNT` returns the count of the observations matched by the query.
- `MAX` returns the maximum value of the observations matched by the query.
- `MIN` returns the minimum value of the observations matched by the query.
- `SUM` calculates the sum of the observations matched by the query.

FROM

Required. Specifies the source of the metric. You can specify either the metric namespace that contains the metric that is to be queried, or a **SCHEMA** table function. Examples of metric namespaces include `"AWS/EC2"`, `"AWS/Lambda"`, and metric namespaces that you have created for your custom metrics.

Metric namespaces that include **/** or any other character that is not a letter, number, or underscore must be surrounded by double quotation marks. For more information, see [What needs quotation marks or escape characters?](#).

SCHEMA

An optional table function that can be used within a **FROM** clause. Use **SCHEMA** to scope down the query results to only the metrics that exactly match a list of dimensions, or to metrics that have no dimensions.

If you use a **SCHEMA** clause, it must contain at least one argument, and this first argument must be the metric namespace being queried. If you specify **SCHEMA** with only this namespace argument, the results are scoped down to only metrics that do not have any dimensions.

If you specify **SCHEMA** with additional arguments, the additional arguments after the namespace argument must be *label* keys. Label keys must be dimension names. If you specify one or more of these label keys, the results are scoped down to only those metrics that have that exact set of dimensions. The order of these label keys does not matter.

For example:

- **SELECT AVG(CPUUtilization) FROM "AWS/EC2"** matches all `CPUUtilization` metrics in the `AWS/EC2` namespace, no matter their dimensions, and returns a single aggregated time series.
- **SELECT AVG(CPUUtilization) FROM SCHEMA("AWS/EC2")** matches only the `CPUUtilization` metrics in the `AWS/EC2` namespace that do not have any dimensions defined.
- **SELECT AVG(CPUUtilization) FROM SCHEMA("AWS/EC2", InstanceId)** matches only the `CPUUtilization` metrics that were reported to CloudWatch with exactly one dimension, `InstanceId`.
- **SELECT SUM(RequestCount) FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)** matches only the `RequestCount` metrics that were reported to

CloudWatch from `AWS/ApplicationELB` with exactly two dimensions, `LoadBalancer` and `AvailabilityZone`.

WHERE

Optional. Filters the results to only those metrics that match your specified expression using specific label values for one or more label keys. For example, **WHERE InstanceType = 'c3.4xlarge'** filters the results to only `c3.4xlarge` instance types, and **WHERE InstanceType != 'c3.4xlarge'** filters the results to all instance types except `c3.4xlarge`.

When you run a query in a monitoring account, you can use `WHERE AWS.AccountId` to limit results to only the account that you specify. For example, `WHERE AWS.AccountId=444455556666` queries metrics from only account 444455556666. To limit your query to only metrics in the monitoring account itself, use `WHERE AWS.AccountId=CURRENT_ACCOUNT_ID()`.

Label values must always be enclosed with single quotation marks.

Supported operators

The **WHERE** clause supports the following operators:

- **=** Label value must match the specified string.
- **!=** Label value must not match the specified string.
- **AND** Both conditions that are specified must be true to match. You can use multiple **AND** keywords to specify two or more conditions.

GROUP BY

Optional. Groups the query results into multiple time series, each one corresponding to a different value for the specified label key or keys. For example, using `GROUP BY InstanceId` returns a different time series for each value of `InstanceId`. Using `GROUP BY ServiceName, Operation` creates a different time series for each possible combination of the values of `ServiceName` and `Operation`.

With a **GROUP BY** clause, by default the results are ordered in alphabetical ascending order, using the sequence of labels specified in the **GROUP BY** clause. To change the order of the results, add an **ORDER BY** clause to your query.

When you run a query in a monitoring account, you can use `GROUP BY AWS.AccountId` to group the results based on the accounts they are from.

> **Note**
>
> If some of the matching metrics don't include a specific label key specified in the **GROUP BY** clause, a null group named `Other` is returned. For example, if you specify `GROUP BY ServiceName, Operation` and some of the returned metrics don't include `ServiceName` as a dimension, then those metrics are displayed as having `Other` as the value for `ServiceName`.

ORDER BY

Optional. Specifies the order to use for the returned time series, if the query returns more than one time series. The order is based on the values found by the **FUNCTION** that you specify in the **ORDER BY** clause. The **FUNCTION** is used to calculate a single scalar value from each returned time series, and that value is used to determine the order.

You also specify whether to use ascending **ASC** or descending **DESC** order. If you omit this, the default is ascending **ASC**.

For example, adding an `ORDER BY MAX() DESC` clause orders the results by the maximum data point observed within the time range, in descending order: meaning that the time series that has the highest maximum data point is returned first.

The valid functions to use within an **ORDER BY** clause are `AVG()`, `COUNT()`, `MAX()`, `MIN()`, and `SUM()`.

If you use an **ORDER BY** clause with a **LIMIT** clause, the resulting query is a "Top N" query. **ORDER BY** is also useful for queries that might return a large number of metrics, because each query can return no more than 500 time series. If a query matches more than 500 time series, and you use an **ORDER BY** clause, the time series are sorted and then the 500 time series that come first in the sort order are the ones that are returned.

LIMIT

Optional. Limits the number of time series returned by the query to the value that you specify. The maximum value that you can specify is 500, and a query that does not specify a **LIMIT** can also return no more than 500 time series.

Using a **LIMIT** clause with an **ORDER BY** clause gives you a "Top N" query.

What needs quotation marks or escape characters?

In a query, label values must always be surrounded with single quotation marks. For example, **SELECT MAX(CPUUtilization) FROM "AWS/EC2" WHERE AutoScalingGroupName = 'my-production-fleet'**.

Metric namespaces, metric names, and label keys that contain characters other than letters, numbers, and underscore (_) must be surrounded by double quote marks. For example, **SELECT MAX("My.Metric")**.

If one of these contains a double quotation mark or single quotation mark itself (such as `Bytes"Input"`), you must escape each quotation mark with a backslash, as in **SELECT AVG("Bytes \"Input\"")**.

If a metric namespace, metric name, or label key, contains a word that is a reserved keyword in Metrics Insights, these must also be enclosed in double quotation marks. For example, if you have a metric named `LIMIT`, you would use `SELECT AVG("LIMIT")`. It is also valid to enclose any namespace, metric name, or label in double quotation marks even if it does not include a reserved keyword.

For a complete list of reserved keywords, see Reserved keywords.

Build a rich query step by step

This section illustrates building a full example that uses all possible clauses, step by step.

We start with the following query, which aggregates all of the Application Load Balancer `RequestCount` metrics that are collected with both the dimensions `LoadBalancer` and `AvailabilityZone`.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
```

Now, if we want to see metrics only from a specific load balancer, we can add a **WHERE** clause to limit the metrics returned to only those metrics where the value of the `LoadBalancer` dimension is `app/load-balancer-1`.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
```

The preceding query aggregates the `RequestCount` metrics from all Availability Zones for this load balancer into one time series. If we want to see different time series for each Availability Zone, we can add a **GROUP BY** clause.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
```

Next, we might want to order these results to see the highest values first. The following **ORDER BY** clause orders the time series in descending order, by the maximum value reported by each time series during the query time range:

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
ORDER BY MAX() DESC
```

Finally, if we are primarily interested in a "Top N" type of query, we can use a **LIMIT** clause. This final example limits the results to only the time series with the five highest `MAX` values.

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer, AvailabilityZone)
WHERE LoadBalancer = 'app/load-balancer-1'
GROUP BY AvailabilityZone
ORDER BY MAX() DESC
LIMIT 5
```

Cross-account query examples

These examples are valid when run in an account set up as a monitoring account in CloudWatch cross-account observability.

The following example searches all Amazon EC2 instances in the source account 123456789012 and returns the average.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
WHERE AWS.AccountId ='123456789012'
```

The following example queries the `CPUUtilization` metric in `AWS/EC2` in all the linked source accounts, and groups the results by account ID and instance type.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
GROUP BY AWS.AccountId, InstanceType
```

The following example queries the `CPUUtilization` in the monitoring account itself.

```
SELECT AVG(CpuUtilization)
FROM "AWS/EC2"
WHERE AWS.AccountId = CURRENT_ACCOUNT_ID()
```

Reserved keywords

The following are reserved keywords in CloudWatch Metrics Insights. If any of these words are in a namespace, metric name, or label key in a query, you must enclose them in double quote marks. Reserved keywords are not case sensitive.

```
"ABORT" "ABORTSESSION" "ABS" "ABSOLUTE" "ACCESS" "ACCESSIBLE" "ACCESS_LOCK" "ACCOUNT"

Alarms on CloudWatch Metrics Insights queries in CloudWatch

You can create alarms on Metrics Insights queries. This helps you have alarms that track multiple resources without needing to be updated later. The query catches new resources and resources that change. For example, you can create an alarm that watches the CPU utilization of your fleet, and the alarm automatically evaluates new instances that you launch after creating the alarm.

In a monitoring account that is set up for CloudWatch cross-account observability, your Metrics Insights alarms can watch resources in source accounts and in the monitoring account itself. For more information about how to limit your alarm queries to a specific account or to group the results by account ID, see the `WHERE` and `GROUP BY` sections in Query components and syntax in CloudWatch Metrics Insights.

Contents

Creating a Metrics Insights CloudWatch alarm

To create an alarm on a Metrics Insights query using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. (Optional) To run a pre-built sample query, choose **Add query** and select the query to run. Or, you can choose **Editor** to edit the sample query and then choose **Run** to run the modified query.
4. To create your own query, choose **Multi source query**. You can then use the **Builder** view, the **Editor** view, and also use a combination of both. You can switch between the two views anytime and see your work in progress in both views.

   In the **Builder** view, you can browse and select the metric namespace, metric name, filter, group, and order options. For each of these options, the query builder offers you a list of possible selections from your environment to choose from.

   In the **Editor** view, you can start writing your query. As you type, the editor offers suggestions based on the characters that you have typed so far.

   > **Important**
   >
   > To set an alarm on a Metrics Insights query, the query must return a single time series. If it contains a GROUP BY statement, the GROUP BY statement must be wrapped inside a metric math expression that returns only one time series as the final result of the expression.

5. When you are satisfied with your query, choose **Run**.
6. Choose **Create alarm**.
7. Under **Conditions**, specify the following:

   a. For **Whenever *`metric`* is**, specify whether the metric must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

   b. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an alarm.

c. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

8. Choose **Next**.
9. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   To have the alarm not send notifications, choose **Remove**.
10. To have the alarm perform Auto Scaling, EC2, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    Note

    To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager.
11. When finished, choose **Next**.
12. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
13. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

To create an alarm on a Metrics Insights query using the Amazon CLI

- Use the `put-metric-alarm` command and specify a Metrics Insights query in the `metrics` parameter. For example, the following command sets an alarm that goes into ALARM state if any of your instances go above 50% in CPU utilization.

```
aws cloudwatch put-metric-alarm --alarm-name Metrics-Insights-alarm --
evaluation-periods 1 --comparison-operator GreaterThanThreshold --metrics
 '[{"Id":"m1","Expression":"SELECT MAX(CPUUtilization) FROM SCHEMA(\"AWS/EC2\",
 InstanceId)", "Period":60}]' --threshold 50
```

How partial data from a Metrics Insights query is evaluated

If the Metrics Insights query used for the alarm matches more than 10,000 metrics, the alarm is evaluated based on the first 10,000 metrics that the query finds. This means that the alarm is being evaluated on partial data.

You can use the following methods to find whether a Metrics Insights alarm is currently evaluating its alarm state based on partial data:

- In the console, if you choose an alarm to see the **Details** page, the message **Evaluation warning: Not evaluating all data** appears on that page.
- You see the value `PARTIAL_DATA` in the `EvaluationState` field when you use the describe-alarms Amazon CLI command or the DescribeAlarms API.

Alarms also publish events to Amazon EventBridge when it goes into the partial data state, so you can create an EventBridge rule to watch for these events. In these events, the `evaluationState` field has the value `PARTIAL_DATA`. The following is an example.

```
{
    "version": "0",
    "id": "12345678-3bf9-6a09-dc46-12345EXAMPLE",
    "detail-type": "CloudWatch Alarm State Change",
    "source": "aws.cloudwatch",
    "account": "123456789012",
    "time": "2022-11-08T11:26:05Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:cloudwatch:us-east-1:123456789012:alarm:my-alarm-name"
    ],
    "detail": {
        "alarmName": "my-alarm-name",
        "state": {
            "value": "ALARM",
```

```
            "reason": "Threshold Crossed: 3 out of the last 3 datapoints [20000.0
 (08/11/22 11:25:00), 20000.0 (08/11/22 11:24:00), 20000.0 (08/11/22 11:23:00)] were
 greater than the threshold (0.0) (minimum 1 datapoint for OK -> ALARM transition).",
            "reasonData": "{\"version\":\"1.0\",\"queryDate\":
\"2022-11-08T11:26:05.399+0000\",\"startDate\":\"2022-11-08T11:23:00.000+0000\",
\"period\":60,\"recentDatapoints\":[20000.0,20000.0,20000.0],\"threshold\":0.0,
\"evaluatedDatapoints\":[{\"timestamp\":\"2022-11-08T11:25:00.000+0000\",\"value
\":20000.0}]}",
            "timestamp": "2022-11-08T11:26:05.401+0000",
            "evaluationState": "PARTIAL_DATA"
        },
        "previousState": {
            "value": "INSUFFICIENT_DATA",
            "reason": "Unchecked: Initial alarm creation",
            "timestamp": "2022-11-08T11:25:51.227+0000"
        },
        "configuration": {
            "metrics": [
                {
                    "id": "m2",
                    "expression": "SELECT SUM(PartialDataTestMetric) FROM
 partial_data_test",
                    "returnData": true,
                    "period": 60
                }
            ]
        }
    }
}
```

If the query for the alarm includes a GROUP BY statement that initially returns more than 500 time series, the alarm is evaluated based on the first 500 time series that the query finds. However, if you use an ORDER BY clause, then all the time series that the query finds are sorted, and the 500 that have the highest or lowest values according to your ORDER BY clause are used to evaluate the alarm.

Use Metrics Insights queries with metric math

You can use a Metrics Insights query as an input to a metric math function. For more information about metric math, see Using math expressions with CloudWatch metrics.

A Metrics Insights query that does not include a **GROUP BY** clause returns a single time series. Therefore, its returned results can be used with any metric math function that takes a single time series as input.

A Metrics Insights query that includes a **GROUP BY** clause returns multiple time series. Therefore, its returned results can be used with any metric math function that takes an array of time series as input.

For example, the following query returns the total number of bytes downloaded for each bucket in the Region, as an array of time series:

```
SELECT SUM(BytesDownloaded)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
```

On a graph in the console or in a GetMetricData operation, the results of this query are q1. This query returns the result in bytes, so if you want to see the result as MB instead, you can use the following math function:

```
q1/1024/1024
```

Use natural language to generate and update CloudWatch Metrics Insights queries

CloudWatch supports a natural language query capability to help you generate and update queries for CloudWatch Metrics Insights and CloudWatch Logs Insights.

With this capability, you can ask questions about or describe the CloudWatch data you're looking for in plain English. The natural language capability generates a query based on a prompt that you enter and provides a line-by-line explanation of how the query works. You can also update your query to further investigate your data.

Depending on your environment, you can enter prompts like "Which Amazon Elastic Compute Cloud instance has the highest network out?" and "Show me the top 10 Amazon DynamoDB Tables by consumed reads."

Note

The natural-language query feature is generally available in 10 Regions. For some Regions, the feature makes cross-Region calls to Regions in the United States to process the query prompts. The following table lists the supported Regions, and shows where each Region processes its prompts.

Supported Region	Region where prompt is processed
US East (N. Virginia)	US East (N. Virginia)
US East (Ohio)	US East (N. Virginia)
US West (Oregon)	US West (Oregon)
Asia Pacific (Hong Kong)	US West (Oregon)
Asia Pacific (Singapore)	US West (Oregon)
Asia Pacific (Sydney)	US West (Oregon)
Asia Pacific (Tokyo)	Asia Pacific (Tokyo)
Europe (Frankfurt)	Europe (Frankfurt)
Europe (Ireland)	US East (N. Virginia)
Europe (Stockholm)	US East (N. Virginia)

To generate a CloudWatch Metrics Insights query with this capability, open the CloudWatch Metrics Insights query editor in the *builder* or *editor* view and choose **Generate query**.

Important

To use the natural language query capability, you must use the CloudWatchFullAccess, CloudWatchReadOnlyAccess, CloudWatchFullAccessV2, AdministratorAccess, or ReadOnlyAccess policy.

You can also include the `cloudwatch:GenerateQuery` action in a new or existing customer managed or inline policy.

Example queries

The examples in this section describe how to generate and update queries using the natural language capability.

Note

For more information on the CloudWatch Metrics Insights query editor and syntax, see CloudWatch Metrics Insights query components and syntax.

Example: Generate a natural language query

To generate a query using natural language, enter a prompt and choose **Generate new query**. This example shows a query that performs a basic search.

Prompt

The following is an example of a prompt that directs the capability to search for the top 10 DynamoDB Tables that consume the most read capacity.

```
Show top 10 DynamoDB Tables by consumed reads
```

Query

The following is an example of a query that the natural language capability generates based on the prompt. Notice how the prompt appears in a comment before the query. After the query, you can read an explanation that describes how the query works.

```
# Show top 10 DynamoDB Tables by consumed reads
SELECT SUM("ConsumedReadCapacityUnits")
FROM "AWS/DynamoDB"
GROUP BY TableName
ORDER BY SUM() DESC
LIMIT 10
```

```
# This query selects the sum of consumed read capacity units for each DynamoDB table,
 groups the results by table name, orders the results from highest to lowest read
 capacity consumption, and limits the results to the top 10 tables.
```

> **Note**
>
> To turn off the appearance of your prompt and the explanation of how the query works, use the gear icon in your editor.

Example: Update a natural language query

You can update a query by editing the initial prompt and then choosing **Update query**.

Updated prompt

The following example shows an updated version of the previous prompt. Instead of a prompt that searches for the top 10 DynamoDB Tables that consume the most read capacity, this prompt now directs the capability to sort the results by the number of bytes returned.

```
Sort by bytes returned instead
```

Updated query

The following is an example of the updated query. Notice how the updated prompt appears in a comment before the updated query. After the query, you can read an explanation that describes how the original query has been updated.

```
# Sort by bytes returned instead
SELECT SUM("ReturnedBytes")
FROM "AWS/DynamoDB"
GROUP BY TableName
ORDER BY SUM() DESC
LIMIT 10
# This query modifies the original query to select the sum of returned bytes instead
 of consumed read capacity units, and orders the results from highest to lowest sum of
 returned bytes, limiting the results to the top 10 tables.
```

Opting out of using your data for service improvement

The natural language prompt data you provide to train the AI model and generate relevant queries is used solely to provide and maintain your service. This data might be used to improve the quality of CloudWatch Metrics Insights. Your trust and privacy, as well as the security of your content, is our highest priority. For more information, see Amazon Service Terms and Amazon responsible AI policy.

You can opt out of having your content used to develop or improve the quality of natural language queries by creating an AI service opt-out policy. To opt-out of data collection for all CloudWatch AI features, including the query generation capability, you must create an opt-out policy for CloudWatch. For more information, see AI services opt-out policies in the *Amazon Organizations User Guide*.

SQL inference

CloudWatch Metrics Insights uses several mechanisms to infer the intention of a given SQL query.

Topics

- Time bucketing
- Fields projection
- ORDER BY global aggregation

Time bucketing

Time series data points resulting from a query are rolled up into time buckets based on the requested period. To aggregate values in standard SQL, an explicit GROUP BY clause must be defined to collect all the observations of a given period together. Because this is the standard way to query time series data, CloudWatch Metrics Insights infers time bucketing without the need to express an explicit **GROUP BY** clause.

For example, when a query is performed with a period of one minute, all the observations belonging to that minute until the next (excluded) are rolled up to the start time of the time bucket. This makes Metrics Insights SQL statements more concise and less verbose.

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
```

The previous query returns a single time series (timestamp-value pairs), representing the average CPU utilization of all Amazon EC2 instances. Assuming the requested period is one minute, each data point returned represents the average of all observations measured within a specific one-minute interval (start time inclusive, end time exclusive). The timestamp related to the specific data point is the start time of the bucket

Fields projection

Metrics Insights queries always return the timestamp projection. You don't need to specify a timestamp column in the **SELECT** clause to get the timestamp of each corresponding data point value. For details about how timestamp is calculated, see Time bucketing.

When using **GROUP BY**, each group name is also inferred and projected in the result, so that you can group the returned time series.

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
```

The previous query returns a time series for each Amazon EC2 instance. Each time series is labeled after the value of the instance ID.

ORDER BY global aggregation

When using **ORDER BY**, **FUNCTION()** infers which aggregate function that you want to order by (the data point values of the queried metrics). The aggregate operation is performed across all the matched data points of each individual time series across the queried time window.

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
ORDER BY MAX()
LIMIT 10
```

The previous query returns the CPU utilization for each Amazon EC2 instance, limiting the result set to 10 entries. The results are ordered based on the maximum value of the individual time series within the requested time window. The **ORDER BY** clause is applied before **LIMIT**, so that the ordering is calculated against more than 10 time series.

Metrics Insights sample queries

This section contains examples of useful CloudWatch Metrics Insights queries that you can copy and use directly or copy and modify in query editor. Some of these examples are already available in the console, and you can access them by choosing **Add query** in the **Metrics** view.

Application Load Balancer examples

Total requests across all load balancers

```
SELECT SUM(RequestCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer)
```

Top 10 most active load balancers

```
SELECT MAX(ActiveConnectionCount)
FROM SCHEMA("AWS/ApplicationELB", LoadBalancer)
GROUP BY LoadBalancer
ORDER BY SUM() DESC
LIMIT 10
```

Amazon API usage examples

Top 20 Amazon APIs by the number of calls in your account

```
SELECT COUNT(CallCount)
FROM SCHEMA("AWS/Usage", Class, Resource, Service, Type)
WHERE Type = 'API'
GROUP BY Service, Resource
ORDER BY COUNT() DESC
LIMIT 20
```

CloudWatch APIs sorted by calls

```
SELECT COUNT(CallCount)
FROM SCHEMA("AWS/Usage", Class, Resource, Service, Type)
WHERE Type = 'API' AND Service = 'CloudWatch'
GROUP BY Resource
ORDER BY COUNT() DESC
```

DynamoDB examples

Top 10 tables by consumed reads

```
SELECT SUM(ProvisionedWriteCapacityUnits)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 tables by returned bytes

```
SELECT SUM(ReturnedBytes)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 tables by user errors

```
SELECT SUM(UserErrors)
FROM SCHEMA("AWS/DynamoDB", TableName)
GROUP BY TableName
ORDER BY MAX() DESC LIMIT 10
```

Amazon Elastic Block Store examples

Top 10 Amazon EBS volumes by bytes written

```
SELECT SUM(VolumeWriteBytes)
FROM SCHEMA("AWS/EBS", VolumeId)
GROUP BY VolumeId
ORDER BY SUM() DESC
LIMIT 10
```

Average Amazon EBS volume write time

```
SELECT AVG(VolumeTotalWriteTime)
FROM SCHEMA("AWS/EBS", VolumeId)
```

Amazon EC2 examples

CPU utilization of EC2 instances sorted by highest

```
SELECT AVG(CPUUtilization)
  FROM SCHEMA("AWS/EC2", InstanceId)
  GROUP BY InstanceId
  ORDER BY AVG() DESC
```

Average CPU utilization across the entire fleet

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
```

Top 10 instances by highest CPU utilization

```
SELECT MAX(CPUUtilization)
FROM SCHEMA("AWS/EC2", InstanceId)
GROUP BY InstanceId
ORDER BY MAX() DESC
LIMIT 10
```

In this case, the CloudWatch agent is collecting a `CPUUtilization` metric per application. This query filters the average of this metric for a specific application name.

```
SELECT AVG(CPUUtilization)
FROM "AWS/CWAgent"
WHERE ApplicationName = 'eCommerce'
```

Amazon Elastic Container Service examples

Average CPU utilization across all ECS clusters

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/ECS", ClusterName)
```

Top 10 clusters by memory utilization

```
SELECT AVG(MemoryUtilization)
FROM SCHEMA("AWS/ECS", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 services by CPU utilization

```
SELECT AVG(CPUUtilization)
FROM SCHEMA("AWS/ECS", ClusterName, ServiceName)
GROUP BY ClusterName, ServiceName
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 services by running tasks (Container Insights)

```
SELECT AVG(RunningTaskCount)
FROM SCHEMA("ECS/ContainerInsights", ClusterName, ServiceName)
GROUP BY ClusterName, ServiceName
ORDER BY AVG() DESC
LIMIT 10
```

Amazon Elastic Kubernetes Service Container Insights examples

Average CPU utilization across all EKS clusters

```
SELECT AVG(pod_cpu_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
```

Top 10 clusters by node CPU utilization

```
SELECT AVG(node_cpu_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 clusters by pod memory utilization

```
SELECT AVG(pop_memory_utilization)
FROM SCHEMA("ContainerInsights", ClusterName)
GROUP BY ClusterName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 nodes by CPU utilization

```
SELECT AVG(node_cpu_utilization)
```

```
FROM SCHEMA("ContainerInsights", ClusterName, NodeName)
GROUP BY ClusterName, NodeName
ORDER BY AVG() DESC LIMIT 10
```

Top 10 pods by memory utilization

```
SELECT AVG(pod_memory_utilization)
FROM SCHEMA("ContainerInsights", ClusterName, PodName)
GROUP BY ClusterName, PodName
ORDER BY AVG() DESC LIMIT 10
```

EventBridge examples

Top 10 rules by invocations

```
SELECT SUM(Invocations)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 rules by failed invocations

```
SELECT SUM(FailedInvocations)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Top 10 rules by matched rules

```
SELECT SUM(MatchedEvents)
FROM SCHEMA("AWS/Events", RuleName)
GROUP BY RuleName
ORDER BY MAX() DESC LIMIT 10
```

Kinesis examples

Top 10 streams by bytes written

```
SELECT SUM("PutRecords.Bytes")
```

```
FROM SCHEMA("AWS/Kinesis", StreamName)
GROUP BY StreamName
ORDER BY SUM() DESC LIMIT 10
```

Top 10 streams by earliest items in the stream

```
SELECT MAX("GetRecords.IteratorAgeMilliseconds")
FROM SCHEMA("AWS/Kinesis", StreamName)
GROUP BY StreamName
ORDER BY MAX() DESC LIMIT 10
```

Lambda examples

Lambda functions ordered by number of invocations

```
SELECT SUM(Invocations)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY SUM() DESC
```

Top 10 Lambda functions by longest runtime

```
SELECT AVG(Duration)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY MAX() DESC
LIMIT 10
```

Top 10 Lambda functions by error count

```
SELECT SUM(Errors)
FROM SCHEMA("AWS/Lambda", FunctionName)
GROUP BY FunctionName
ORDER BY SUM() DESC
LIMIT 10
```

CloudWatch Logs examples

Top 10 log groups by incoming events

```
SELECT SUM(IncomingLogEvents)
FROM SCHEMA("AWS/Logs", LogGroupName)
GROUP BY LogGroupName
ORDER BY SUM() DESC LIMIT 10
```

Top 10 log groups by written bytes

```
SELECT SUM(IncomingBytes)
FROM SCHEMA("AWS/Logs", LogGroupName)
GROUP BY LogGroupName
ORDER BY SUM() DESC LIMIT 10
```

Amazon RDS examples

Top 10 Amazon RDS instances by highest CPU utilization

```
SELECT MAX(CPUUtilization)
FROM SCHEMA("AWS/RDS", DBInstanceIdentifier)
GROUP BY DBInstanceIdentifier
ORDER BY MAX() DESC
LIMIT 10
```

Top 10 Amazon RDS clusters by writes

```
SELECT SUM(WriteIOPS)
FROM SCHEMA("AWS/RDS", DBClusterIdentifier)
GROUP BY DBClusterIdentifier
ORDER BY MAX() DESC
LIMIT 10
```

Amazon Simple Storage Service examples

Average latency by bucket

```
SELECT AVG(TotalRequestLatency)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
ORDER BY AVG() DESC
```

Top 10 buckets by bytes downloaded

```
SELECT SUM(BytesDownloaded)
FROM SCHEMA("AWS/S3", BucketName, FilterId)
WHERE FilterId = 'EntireBucket'
GROUP BY BucketName
ORDER BY SUM() DESC
LIMIT 10
```

Amazon Simple Notification Service examples

Total messages published by SNS topics

```
SELECT SUM(NumberOfMessagesPublished)
FROM SCHEMA("AWS/SNS", TopicName)
```

Top 10 topics by messages published

```
SELECT SUM(NumberOfMessagesPublished)
FROM SCHEMA("AWS/SNS", TopicName)
GROUP BY TopicName
ORDER BY SUM() DESC
LIMIT 10
```

Top 10 topics by message delivery failures

```
SELECT SUM(NumberOfNotificationsFailed)
FROM SCHEMA("AWS/SNS", TopicName)
GROUP BY TopicName
ORDER BY SUM() DESC
LIMIT 10
```

Amazon SQS examples

Top 10 queues by number of visible messages

```
SELECT AVG(ApproximateNumberOfMessagesVisible)
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
```

```
ORDER BY AVG() DESC
LIMIT 10
```

Top 10 most active queues

```
SELECT SUM(NumberOfMessagesSent)
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
ORDER BY SUM() DESC
LIMIT 10
```

Top 10 queues by age of earliest message

```
SELECT AVG(ApproximateAgeOfOldestMessage)
FROM SCHEMA("AWS/SQS", QueueName)
GROUP BY QueueName
ORDER BY AVG() DESC
LIMIT 10
```

Metrics Insights limits

CloudWatch Metrics Insights currently has the following limits:

- Currently, you can query only the most recent three hours of data.
- A single query can process no more than 10,000 metrics. This means that if the **SELECT**, **FROM**, and **WHERE** clauses match more than 10,000 metrics, the query only processes the first 10,000 of these metrics that it finds.
- A single query can return no more than 500 time series. This means that if the query would return more than 500 metrics, not all metrics will be returned in the query results. If you use an **ORDER BY** clause, then all the metrics being processed are sorted, and the 500 that have the highest or lowest values according to your **ORDER BY** clause are returned.

  If you do not include an **ORDER BY** clause, you can't control which 500 matching metrics are returned.
- You can have as many as 200 Metrics Insights alarms per Region.
- Metrics Insights does not support high-resolution data, which is metric data reported with a granularity of less than one minute. If you request high-resolution data, the request does not fail, but the output is aggregated at one-minute granularity.

- Each GetMetricData operation can have only one query, but you can have multiple widgets in a dashboard that each include a query.

Metrics Insights glossary

label

In Metrics Insights, a label is a key-value pair that is used to scope a query to return a particular set of data, or to define criteria by which query results are to be separated into separate time series. A label key is similar to a column name in SQL. Currently, labels must be CloudWatch metric dimensions.

observation

An observation is a value recorded for a given metric at a given time.

Troubleshooting Metrics Insights

The results include "Other," but I don't have this as a dimension

This means that the query includes a **GROUP BY** clause that specifies a label key that is not used in some of the metrics that are returned by the query. In this case, a null group named `Other` is returned. The metrics that do not include that label key are probably aggregated metrics that return values aggregated across all values of that label key.

For example, suppose we have the following query:

```
SELECT AVG(Faults)
FROM MyCustomNamespace
GROUP BY Operation, ServiceName
```

If some of the returned metrics don't include `ServiceName` as a dimension, then those metrics are displayed as having `Other` as the value for `ServiceName`.

To prevent seeing "Other" in your results, use **SCHEMA** in your **FROM** clause, as in the following example:

```
SELECT AVG(Faults)
FROM SCHEMA(MyCustomNamespace, Operation)
```

```
GROUP BY Operation, ServiceName
```

This limits the returned results to only the metrics that have both the `Operation` and `ServiceName` dimensions.

The oldest timestamp in my graph has a lower metric value than the others

CloudWatch Metrics Insights currently supports the latest three hours of data only. When you graph with a period larger than one minute, there could be cases where the oldest data point differs from the expected value. This is because the Metrics Insights queries return only the most recent three hours of data. In this case, the oldest data point in the query returns only the observations that have been measured within the last three hours boundary, instead of returning all the observations within the period of that data point.

Use metrics explorer to monitor resources by their tags and properties

Metrics explorer is a tag-based tool that enables you to filter, aggregate, and visualize your metrics by tags and resource properties, to enhance observability for your services. This gives you a flexible and dynamic troubleshooting experience, so that you can create multiple graphs at a time and use these graphs to build your application health dashboards.

Metrics explorer visualizations are dynamic, so if a matching resource is created after you create a metrics explorer widget and add it to a CloudWatch dashboard, the new resource automatically appears in the explorer widget.

For example, if all of your EC2 production instances have the **`production`** tag, you can use metrics explorer to filter and aggregate metrics from all of these instances to understand their health and performance. If a new instance with a matching tag is later created, it's automatically added to the metrics explorer widget.

> **Note**
>
> Metrics explorer provides a point-in-time experience. Resources that have been terminated, or no longer exist with the property or tag that you specified are not displayed in the visualisation. However, you can still find the metrics for these resources in CloudWatch metrics views.

With metrics explorer, you can choose how to aggregate metrics from the resources that match the criteria, and whether to show them all in a single graph or on different graphs within one metrics explorer widget.

Metrics explorer includes templates that you can use to see useful visualization graphs with one click, and you can also extend these templates to create completely customized metrics explorer widgets.

You can use metrics explorer across accounts if you are using the Cross-account cross-Region CloudWatch console. However, metrics explorer is not supported for cross-account use from a monitoring account in CloudWatch cross-account observability.

Metrics explorer supports metrics emitted by Amazon and EC2 metrics that are published by the CloudWatch agent, including memory, disk, and CPU metrics. To use metrics explorer to see the metrics that are published by the CloudWatch agent, you might have to update your CloudWatch agent configuration file. For more information, see CloudWatch agent configuration for metrics explorer

To create a visualization with metrics explorer and optionally add it to a dashboard, follow these steps.

To create a visualization with metrics explorer

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Explorer**.
3. Do one of the following:
   - To use a template, select it in the box that currently shows **Empty Explorer**.

     Depending on the template, the explorer might immediately display graphs of metrics. If it doesn't, choose one or more tags or properties in the **From** box and then data should appear. If it doesn't, use the options at the top of the page to display a longer time range in the graphs.
   - To create a custom visualization, under **Metrics**, choose a single metric or all the available metrics from a service.

     After you choose a metric, you can optionally repeat this step to add more metrics.
4. For each metric selected, CloudWatch displays the statistic that it will use immediately after the metric name. To change this, choose the statistic name, and then choose the statistic that you want.

5. Under **From**, choose a tag or a resource property to filter your results.

   After you do this, you can optionally repeat this step to choose more tags or resource properties.

   If you choose multiple values of the same property, such as two EC2 instance types, the explorer displays all the resources that match either chosen property. It's treated as an OR operation.

   If you choose different properties or tags, such as the **`Production`** tag and the M5 instance type, only the resources that match all of these selections are displayed. It's treated as an AND operation.
6. (Optional) For **Aggregate by**, choose a statistic to use to aggregate the metrics. Then, next to **for**, choose how to aggregate the metric from the list. You can aggregate together all the resources that are currently displayed, or aggregate by a single tag or resource property.

   Depending on how you choose to aggregate, the result may be a single time series or multiple time series.
7. Under **Split by**, you can choose to split a single graph with multiple time series into multiple graphs. The split can be made by a variety of criteria, which you choose under **Split by**.
8. Under **Graph options**, you can refine the graph by changing the period, the type of graph, the legend placement, and the layout.
9. To add this visualization as a widget to a CloudWatch dashboard, choose **Add to dashboard**.

CloudWatch agent configuration for metrics explorer

To enable metrics explorer to discover EC2 metrics published by the CloudWatch agent, make sure that the CloudWatch agent configuration file contains the following values:

- In the `metrics` section, make sure that the `aggregation_dimensions` parameter includes `["InstanceId"]`. It can also contain other dimensions.
- In the `metrics` section, make sure that the `append_dimensions` parameter includes a `{"InstanceId":"${aws:InstanceId}"}` line. It can also contain other lines.
- In the `metrics` section, inside the `metrics_collected` section, check the sections for each resource type that you want metrics explorer to discover, such as the `cpu`, `disk`, and `memory` sections. Make sure that each of these sections has a `"resources": [ "*"] line.`.

- In the `cpu` section of the `metrics_collected` section, make sure there is a `"totalcpu": true` line.
- You must use the default `CWAgent` namespace for the metrics collected by the CloudWatch agent, instead of a custom namespace.

The settings in the previous list cause the CloudWatch agent to publish aggregate metrics for disks, CPUs, and other resources that can be plotted in metrics explorer for all the instances that use it.

These settings will republish the metrics that you had previously set up to be published with multiple dimensions, adding to your metric costs.

For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

Use metric streams

You can use *metric streams* to continually stream CloudWatch metrics to a destination of your choice, with near-real-time delivery and low latency. Supported destinations include Amazon destinations such as Amazon Simple Storage Service and several third-party service provider destinations.

There are three main usage scenarios for CloudWatch metric streams:

- **Custom setup with Firehose**— Create a metric stream and direct it to an Amazon Data Firehose delivery stream that delivers your CloudWatch metrics to where you want them to go. You can stream them to a data lake such as Amazon S3, or to any destination or endpoint supported by Firehose including third-party providers. JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats are supported natively, or you can configure transformations in your Firehose delivery stream to convert the data to a different format such as Parquet. With a metric stream, you can continually update monitoring data, or combine this CloudWatch metric data with billing and performance data to create rich datasets. You can then use tools such as Amazon Athena to get insight into cost optimization, resource performance, and resource utilization.
- **Quick S3 setup**— Stream to Amazon Simple Storage Service with a quick setup process. By default, CloudWatch creates the resources needed for the stream. JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats are supported.
- **Quick Amazon partner setup**— CloudWatch provides a quick setup experience for some third-party partners. You can use third-party service providers to monitor, troubleshoot, and analyze

your applications using the streamed CloudWatch data. When you use the quick partner setup workflow, you need to provide only a destination URL and API key for your destination, and CloudWatch handles the rest of the setup. Quick partner setup is available for the following third-party providers:

- Datadog
- Dynatrace
- Elastic
- New Relic
- Splunk Observability Cloud
- SumoLogic

You can stream all of your CloudWatch metrics, or use filters to stream only specified metrics. Each metric stream can include up to 1000 filters that either include or exclude metric namespaces or specific metrics. A single metric stream can have only include or exclude filters, but not both.

After a metric stream is created, if new metrics are created that match the filters in place, the new metrics are automatically included in the stream.

There is no limit on the number of metric streams per account or per Region, and no limit on the number of metric updates being streamed.

Each stream can use either JSON format, OpenTelemetry 1.0.0, or OpenTelemetry 0.7.0 format. You can edit the output format of a metric stream at any time, such as for upgrading from OpenTelemetry 0.7.0 to OpenTelemetry 1.0.0. For more information about output formats, see CloudWatch metric stream output in JSON format, CloudWatch metric stream output in OpenTelemetry 1.0.0 format, and CloudWatch metric stream output in OpenTelemetry 0.7.0 format.

For metric streams in monitoring accounts, you can choose whether to include metrics from the source accounts linked to that monitoring account. For more information, see CloudWatch cross-account observability.

Metric streams always include the `Minimum`, `Maximum`, `SampleCount`, and `Sum` statistics. You can also choose to include additional statistics at an additional charge. For more information, see Statistics that can be streamed.

Metric streams pricing is based on the number of metric updates. You also incur charges from Firehose for the delivery stream used for the metric stream. For more information, see Amazon CloudWatch Pricing.

Topics

Set up a metric stream

Use the steps in the following sections to set up a CloudWatch metric stream.

After a metric stream is created, the time it takes for metric data to appear at the destination depends on the configured buffering settings on the Firehose delivery stream. The buffering is expressed in maximum payload size or maximum wait time, whichever is reached first. If these are set to the minimum values (60 seconds, 1MB) the expected latency is within 3 minutes if the selected CloudWatch namespaces have active metric updates.

In a CloudWatch metric stream, data is sent every minute. Data might arrive at the final destination out of order. All specified metrics in the specified namespaces are sent in the metric stream, except metrics with a timestamp that is more than two days old.

For each combination of metric name and namespace that you stream, all dimension combinations of that metric name and namespace are streamed.

For metric streams in monitoring accounts, you can choose whether to include metrics from the source accounts linked to that monitoring account. For more information, see CloudWatch cross-account observability.

To create and manage metric streams, you must be logged on to an account that has the **CloudWatchFullAccess** policy and the `iam:PassRole` permission, or an account that has the following list of permissions:

- `iam:PassRole`
- `cloudwatch:PutMetricStream`
- `cloudwatch:DeleteMetricStream`
- `cloudwatch:GetMetricStream`
- `cloudwatch:ListMetricStreams`
- `cloudwatch:StartMetricStreams`
- `cloudwatch:StopMetricStreams`

If you're going to have CloudWatch set up the IAM role needed for metric streams, you must also have the `iam:CreateRole` and `iam:PutRolePolicy` permissions.

> **Important**
>
> A user with the `cloudwatch:PutMetricStream` has access to the CloudWatch metric data that is being streamed, even if they don't have the `cloudwatch:GetMetricData` permission.

Topics

- Custom setup with Firehose
- Use Quick Amazon S3 setup
- Quick partner setup

Custom setup with Firehose

Use this method to create a metric stream and direct it to an Amazon Data Firehose delivery stream that delivers your CloudWatch metrics to where you want them to go. You can stream them to a data lake such as Amazon S3, or to any destination or endpoint supported by Firehose including third-party providers.

JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats are supported natively, or you can configure transformations in your Firehose delivery stream to convert the data to a different format such as Parquet. With a metric stream, you can continually update monitoring data, or combine this CloudWatch metric data with billing and performance data to create rich datasets. You can then use tools such as Amazon Athena to get insight into cost optimization, resource performance, and resource utilization.

You can use the CloudWatch console, the Amazon CLI, Amazon CloudFormation, or the Amazon Cloud Development Kit (Amazon CDK) to set up a metric stream.

The Firehose delivery stream that you use for your metric stream must be in the same account and the same Region where you set up the metric stream. To achieve cross-Region functionality, you can configure the Firehose delivery stream to stream to a final destination that is in a different account or a different Region.

CloudWatch console

This section describes how to use the CloudWatch console to set up a metric stream using Firehose.

To set up a custom metric stream using Firehose

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.
3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Custom setup with Firehose**.
5. For **Select your Kinesis Data Firehose stream**, select the Firehose delivery stream to use. It must be in the same account. The default format for this option is OpenTelemetry 0.7.0, but you can change the format later in this procedure.

   Then select the Firehose delivery stream to use under **Select your Firehose delivery stream**.
6. (Optional)You can choose **Select existing service role** to use an existing IAM role instead of having CloudWatch create a new one for you.
7. (Optional) To change the output format from the default format for your scenario, choose **Change output format**. The supported formats are JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0.
8. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

If you choose **All metrics**, all metrics from this account will be included in the stream.

Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

If you choose **Select metrics**, do one of the following:

- To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
- To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.

9. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add recommended metrics** to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

   To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

   Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

   For definitions of the additional statistics, see CloudWatch statistics definitions.
10. (Optional) Customize the name of the new metric stream under **Metric stream name**.
11. Choose **Create metric stream**.

Amazon CLI or Amazon API

Use the following steps to create a CloudWatch metric stream.

To use the Amazon CLI or Amazon API to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating a Firehose stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.
4. Use the `aws cloudwatch put-metric-stream` CLI command or the `PutMetricStream` API to create the CloudWatch metric stream.

Amazon CloudFormation

You can use Amazon CloudFormation to set up a metric stream. For more information, see AWS::CloudWatch::MetricStream.

To use Amazon CloudFormation to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating a Firehose stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.
4. Create the stream in Amazon CloudFormation. For more information, see AWS::CloudWatch::MetricStream.

Amazon Cloud Development Kit (Amazon CDK)

You can use Amazon Cloud Development Kit (Amazon CDK) to set up a metric stream.

To use the Amazon CDK to create a metric stream

1. If you're streaming to Amazon S3, first create the bucket. For more information, see Creating a bucket.
2. Create the Firehose delivery stream. For more information, see Creating an Amazon Data Firehose Delivery Stream.
3. Create an IAM role that enables CloudWatch to write to the Firehose delivery stream. For more information about the contents of this role, see Trust between CloudWatch and Firehose.

4. Create the metric stream. The metric stream resource is available in Amazon CDK as a Level 1 (L1) Construct named `CfnMetricStream`. For more information, see [Using L1 constructs](#).

Use Quick Amazon S3 setup

The **Quick S3 Setup** method works well if you want to quickly set up a stream to Amazon S3 and you don't need any formatting transformation beyond the supported JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0 formats. CloudWatch will create all necessary resources including the Firehose delivery stream and the necessary IAM roles. The default format for this option is JSON, but you can change the format while you set up the stream.

Alternatively, if you want the final format to be Parquet format or Optimized Row Columnar (ORC), you should instead follow the steps in Custom setup with Firehose.

CloudWatch console

This section describes how to use the CloudWatch console to set up a metric stream Amazon S3 using Quick S3 setup.

To set up a metric stream using Quick S3 setup

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.
3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Quick S3 setup**. CloudWatch will create all necessary resources including the Firehose delivery stream and the necessary IAM roles. The default format for this option is JSON, but you can change the format later in this procedure.
5. (Optional) Choose **Select existing resources** to use an existing S3 bucket or existing IAM roles instead of having CloudWatch create new ones for you.
6. (Optional) To change the output format from the default format for your scenario, choose **Change output format**. The supported formats are JSON, OpenTelemetry 1.0.0, and OpenTelemetry 0.7.0.
7. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

   If you choose **All metrics**, all metrics from this account will be included in the stream.

Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

If you choose **Select metrics**, do one of the following:

- To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
- To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.

8. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add recommended metrics** to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

   To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

   Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

   For definitions of the additional statistics, see CloudWatch statistics definitions.
9. (Optional) Customize the name of the new metric stream under **Metric stream name**.
10. Choose **Create metric stream**.

Quick partner setup

CloudWatch provides a quick setup experience for the following third-party partners. To use this workflow, you need to provide only a destination URL and API key for your destination. CloudWatch handles the rest of setup including creating the Firehose delivery stream and the necessary IAM roles.

> **Important**
>
> Before you use quick partner setup to create a metric stream, we strongly recommend that you read that partner's documentation, linked in the following list.

- Datadog
- Dynatrace
- Elastic
- New Relic
- Splunk Observability Cloud
- SumoLogic

When you set up a metric stream to one of these partners, the stream is created with some default settings, as listed in the following sections.

Topics

- Set up a metric stream using quick partner setup
- Datadog stream defaults
- Dynatrace stream defaults
- Elastic stream defaults
- New Relic stream defaults
- Splunk Observability Cloud stream defaults
- Sumo Logic stream defaults

Set up a metric stream using quick partner setup

CloudWatch provides a quick setup option for some third-party partners. Before you start the steps in this section, you must have certain information for the partner. This information might include a destination URL and/or an API key for your partner destination. You should also read the documentation at the partner's website linked in the previous section, and the defaults for that partner listed in the following sections.

To stream to a third-party destination not supported by quick setup, you can follow the instructions in Follow the instructions in [Custom setup with Firehose](#) to set up a stream using Firehose, and then send those metrics from Firehose to the final destination.

To use quick partner setup to create a metric stream to third-party provider

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**. Then choose **Create metric stream**.
3. (Optional) If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can choose whether to include metrics from linked source accounts in this metric stream. To include metrics from source accounts, choose **Include source account metrics**.
4. Choose **Quick Amazon Web Services partner setup**
5. Select the name of the partner that you want to stream metrics to.
6. For **Endpoint URL**, enter the destination URL.
7. For **Access Key** or **API Key**, enter the access key for the partner. Not all partners require an access key.
8. For **Metrics to be streamed**, choose either **All metrics** or **Select metrics**.

   If you choose **All metrics**, all metrics from this account will be included in the stream.

   Consider carefully whether to stream all metrics, because the more metrics that you stream the higher your metric stream charges will be.

   If you choose **Select metrics**, do one of the following:

   - To stream most metric namespaces, choose **Exclude** and select the namespaces or metrics to exclude. When you specify a namespace in **Exclude**, you can optionally select some specific metrics from that namespace to exclude. If you choose to exclude a namespace but don't then select metrics in that namespace, all metrics from that namespace are excluded.
   - To include only a few metric namespaces or metrics in the metric stream, choose **Include** and then select the namespaces or metrics to include. If you choose to include a namespace but don't then select metrics in that namespace, all metrics from that namespace are included.
9. (Optional) To stream additional statistics for some of these metrics beyond Minimum, Maximum, SampleCount, and Sum, choose **Add additional statistics**. Either choose **Add**

recommended metrics to add some commonly used statistics, or manually select the namespace and metric name to stream additional statistics for. Next, select the additional statistics to stream.

To then choose another group of metrics to stream a different set of additional statistics for, choose **Add additional statistics**. Each metric can include as many as 20 additional statistics, and as many as 100 metrics within a metric stream can include additional statistics.

Streaming additional statistics incurs more charges. For more information, see Statistics that can be streamed.

For definitions of the additional statistics, see CloudWatch statistics definitions.

10. (Optional) Customize the name of the new metric stream under **Metric stream name**.
11. Choose **Create metric stream**.

Datadog stream defaults

Quick partner setup streams to Datadog use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 4 MBs
- **Firehose stream retry option** Duration of 60 seconds

When you use quick partner setup to create a metric stream to Datadog and you stream certain metrics, by default those metrics include some additional statistics. Streaming additional statistics can incur additional charges. For more information about statistics and their charges, see Statistics that can be streamed.

The following list shows the metrics that have additional statistics streamed by default, if you choose to stream those metrics. You can choose to de-select these additional statistics before you start the stream.

- **`Duration` in `AWS/Lambda`:** p50, p80, p95, p99, p99.9
- **`PostRuntimeExtensionDuration` in `AWS/Lambda`:** p50, p99
- **`FirstByteLatency` and `TotalRequestLatency`in `AWS/S3`:** p50, p90, p95, p99, p99.9

- **`ResponseLatency` in `AWS/Polly` and `TargetResponseTime` in `AWS/ApplicationELB`:** p50, p90, p95, p99
- **`Latency` and `IntegrationLatency` in `AWS/ApiGateway`:** p90, p95, p99
- **`Latency` and `TargetResponseTime` in `AWS/ELB`:** p95, p99
- **`RequestLatency` in `AWS/AppRunner`:** p50, p95, p99
- **`ActivityTime`, `ExecutionTime`, `LambdaFunctionRunTime`, `LambdaFunctionScheduleTime`, `LambdaFunctionTime`, `ActivityRunTime`, and `ActivityScheduleTime` in `AWS/States`:** p95, p99
- **`EncoderBitRate`, `ConfiguredBitRate`, and `ConfiguredBitRateAvailable` in `AWS/MediaLive`:** p90
- **`Latency` in `AWS/AppSync`:** p90

Dynatrace stream defaults

Quick partner setup streams to Dynatrace use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 5 MBs
- **Firehose stream retry option** Duration of 600 seconds

Elastic stream defaults

Quick partner setup streams to Elastic use the following defaults:

- **Output format:** OpenTelemetry 1.0.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

New Relic stream defaults

Quick partner setup streams to New Relic use the following defaults:

- **Output format:** OpenTelemetry 0.7.0

- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

Splunk Observability Cloud stream defaults

Quick partner setup streams to Splunk Observability Cloud use the following defaults:

- **Output format:** OpenTelemetry 1.0.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 300 seconds

Sumo Logic stream defaults

Quick partner setup streams to Sumo Logic use the following defaults:

- **Output format:** OpenTelemetry 0.7.0
- **Firehose stream content encoding** GZIP
- **Firehose stream buffering options** Interval of 60 seconds, size of 1 MB
- **Firehose stream retry option** Duration of 60 seconds

Statistics that can be streamed

Metric streams always include the following statistics: `Minimum`, `Maximum`, `SampleCount`, and `Sum`. You can also choose to include the following additional statistics in a metric stream. This choice is on a per-metric basis. For more information about these statistics, see CloudWatch statistics definitions.

- Percentile values such as p95 or p99 (For streams with either JSON or OpenTelemetry format)
- Trimmed mean (Only for streams with the JSON format)
- Winsorized mean (Only for streams with the JSON format)
- Trimmed count (Only for streams with the JSON format)
- Trimmed sum (Only for streams with the JSON format)
- Percentile rank (Only for streams with the JSON format)

- Interquartile mean (Only for streams with the JSON format)

Streaming additional statistics incurs additional charges. Streaming between one and five of these additional statistics for a particular metric is billed as an additional metric update. Thereafter, each additional set of up to five of these statistics is billed as another metric update.

For example, suppose that for one metric you are streaming the following six additional statistics: p95, p99, p99.9, Trimmed mean, Winsorized mean, and Trimmed sum. Each update of this metric is billed as three metric updates: one for the metric update which includes the default statistics, one for the first five additional statistics, and one for the sixth additional statistic. Adding up to four more additional statistics for a total of ten would not increase the billing, but an eleventh additional statistic would do so.

When you specify a metric name and namespace combination to stream additional statistics, all dimension combinations of that metric name and namespace are streamed with the additional statistics.

CloudWatch metric streams publishes a new metric, `TotalMetricUpdate`, which reflects the base number of metric updates plus extra metric updates incurred by streaming additional statistics. For more information, see Monitoring your metric streams with CloudWatch metrics.

For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Some metrics do not support percentiles. Percentile statistics for these metrics are excluded from the stream and do not incur metric stream charges. An example of these statistics that do not support percentiles are some metrics in the `AWS/ECS` namespace.

The additional statistics that you configure are streamed only if they match the filters for the stream. For example, if you create a stream that has only `EC2` and `RDS` in the include filters, and then your statistics configuration lists `EC2` and `Lambda`, then the stream includes `EC2` metrics with additional statistics, `RDS` metrics with only the default statistics, and doesn't include `Lambda` statistics at all.

Metric stream operation and maintenance

Metric streams are always in one of two states, **Running** or **Stopped**.

- **Running**— The metric stream is running correctly. There might not be any metric data streamed to the destination because of the filters on the stream.
- **Stopped**— The metric stream has been explicitly stopped by someone, and not because of an error. It might be useful to stop your stream to temporarily pause the streaming of data without deleting the stream.

If you stop and restart a metric stream, the metric data that was published to CloudWatch while the metric stream was stopped is not backfilled to the metric stream.

If you change the output format of a metric stream, in certain cases you might see a small amount of metric data written to the destination in both the old format and the new format. To avoid this situation, you can create a new Firehose delivery stream with the same configuration as your current one, then change to the new Firehose delivery stream and change the output format at the same time. This way, the Kinesis records with different output format are stored on Amazon S3 in separate objects. Later, you can direct the traffic back to the original Firehose delivery stream and delete the second delivery stream.

To view, edit, stop, and start your metric streams

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **Streams**.

   The list of streams appears, and the **Status** column displays whether each stream is running or stopped.
3. To stop or start a metric stream, select the stream and choose **Stop** or **Start**.
4. To see the details about a metric stream, select the stream and choose **View details**.
5. To change the stream's output format, filters, destination Firehose stream, or roles, choose **Edit** and make the changes that you want.

   If you change the filters, there might be some gaps in the metric data during the transition.

Monitoring your metric streams with CloudWatch metrics

Metric streams emit CloudWatch metrics about their health and operation in the `AWS/CloudWatch/MetricStreams` namespace. The following metrics are emitted. These metrics are emitted with a `MetricStreamName` dimension and with no dimension. You can use the metrics with no dimensions to see aggregated metrics for all of your metric streams. You can use the metrics with the `MetricStreamName` dimension to see the metrics about only that metric stream.

For all of these metrics, values are emitted only for metric streams that are in the **Running** state.

Metric	Description
`MetricUpdate`	The number of metric updates sent to the metric stream. If no metric updates are streamed during a time period, this metric is not emitted during that time period. If you stop the metric stream, this metric stops being emitted until the metric stream is started again. Valid Statistic: `Sum` Units: None
`TotalMetricUpdate`	This is calculated as **MetricUpdate + a number based on additional statistics that are being streamed**. For each unique namespace and metric name combination, streaming 1-5 additional statistics adds 1 to the `TotalMetricUpdate` , streaming 6-10 additional statistics adds 2 to `TotalMetricUpdate` , and so on. Valid Statistic: `Sum` Units: None
`PublishErrorRate`	The number of unrecoverable errors that occur when putting data into the Firehose delivery stream. If no errors occur during a time period, this metric is not emitted during that time period. If you stop the metric stream, this metric stops being emitted until the metric stream is started again. Valid Statistic: `Average` to see the rate of metric updates unable to be written. This value will be between 0.0 and 1.0.

Metric	Description
	Units: None

Trust between CloudWatch and Firehose

The Firehose delivery stream must trust CloudWatch through an IAM role that has write permissions to Firehose. These permissions can be limited to the single Firehose delivery stream that the CloudWatch metric stream uses. The IAM role must trust the `streams.metrics.cloudwatch.amazonaws.com` service principal.

If you use the CloudWatch console to create a metric stream, you can have CloudWatch create the role with the correct permissions. If you use another method to create a metric stream, or you want to create the IAM role itself, it must contain the following permissions policy and trust policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "firehose:PutRecord",
                "firehose:PutRecordBatch"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws:firehose:region:account-id:deliverystream/*"
        }
    ]
}
```

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "streams.metrics.cloudwatch.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
```

```
}
```

Metric data is streamed by CloudWatch to the destination Firehose delivery stream on behalf of the source that owns the metric stream resource.

CloudWatch metric stream output in JSON format

In a CloudWatch metric stream that uses the JSON format, each Firehose record contains multiple JSON objects separated by a newline character (\n). Each object includes a single data point of a single metric.

The JSON format that is used is fully compatible with Amazon Glue and with Amazon Athena. If you have a Firehose delivery stream and an Amazon Glue table formatted correctly, the format can be automatically transformed into Parquet format or Optimized Row Columnar (ORC) format before being stored in S3. For more information about transforming the format, see Converting Your Input Record Format in Firehose. For more information about the correct format for Amazon Glue, see Which Amazon Glue schema should I use for JSON output format?.

In the JSON format, the valid values for `unit` are the same as for the value of `unit` in the `MetricDatum` API structure. For more information, see MetricDatum. The value for the `timestamp` field is in epoch milliseconds, such as `1616004674229`.

The following is an example of the format. In this example, the JSON is formatted for easy reading, but in practice the whole format is on a single line.

```
{
    "metric_stream_name": "MyMetricStream",
    "account_id": "1234567890",
    "region": "us-east-1",
    "namespace": "AWS/EC2",
    "metric_name": "DiskWriteOps",
    "dimensions": {
        "InstanceId": "i-123456789012"
    },
    "timestamp": 1611929698000,
    "value": {
        "count": 3.0,
        "sum": 20.0,
        "max": 18.0,
        "min": 0.0,
```

```
        "p99": 17.56,
        "p99.9": 17.8764,
        "TM(25%:75%)": 16.43
    },
    "unit": "Seconds"
}
```

Which Amazon Glue schema should I use for JSON output format?

The following is an example of a JSON representation of the `StorageDescriptor` for an Amazon Glue table, which would then be used by Firehose. For more information about `StorageDescriptor`, see StorageDescriptor.

```
{
  "Columns": [
    {
      "Name": "metric_stream_name",
      "Type": "string"
    },
    {
      "Name": "account_id",
      "Type": "string"
    },
    {
      "Name": "region",
      "Type": "string"
    },
    {
      "Name": "namespace",
      "Type": "string"
    },
    {
      "Name": "metric_name",
      "Type": "string"
    },
    {
      "Name": "timestamp",
      "Type": "timestamp"
    },
    {
      "Name": "dimensions",
      "Type": "map<string,string>"
    },
```

```
    {
      "Name": "value",
      "Type":
 "struct<min:double,max:double,count:double,sum:double,p99:double,p99.9:double>"
    },
    {
      "Name": "unit",
      "Type": "string"
    }
  ],
  "Location": "s3://amzn-s3-demo-bucket/",
  "InputFormat": "org.apache.hadoop.mapred.TextInputFormat",
  "OutputFormat": "org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat",
  "SerdeInfo": {
    "SerializationLibrary": "org.apache.hive.hcatalog.data.JsonSerDe"
  },
  "Parameters": {
    "classification": "json"
  }
}
```

The preceding example is for data written on Amazon S3 in JSON format. Replace the values in the following fields with the indicated values to store the data in Parquet format or Optimized Row Columnar (ORC) format.

- **Parquet:**
  - inputFormat: org.apache.hadoop.hive.ql.io.parquet.MapredParquetInputFormat
  - outputFormat: org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat
  - SerDeInfo.serializationLib: org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe
  - parameters.classification: parquet
- **ORC:**
  - inputFormat: org.apache.hadoop.hive.ql.io.orc.OrcInputFormat
  - outputFormat: org.apache.hadoop.hive.ql.io.orc.OrcOutputFormat
  - SerDeInfo.serializationLib: org.apache.hadoop.hive.ql.io.orc.OrcSerde
  - parameters.classification: orc

CloudWatch metric stream output in OpenTelemetry 1.0.0 format

Note

With the OpenTelemetry 1.0.0 format, metric attributes are encoded as a list of `KeyValue` objects instead of the `StringKeyValue` type used in the 0.7.0 format. As a consumer, this is the only major change between the 0.7.0 and 1.0.0 formats. A parser generated from the 0.7.0 proto files won't parse metric attributes encoded in the 1.0.0 format. The same is true in reverse, a parser generated from the 1.0.0 proto files will not parse metric attributes encoded in the 0.7.0 format.

OpenTelemetry is a collection of tools, APIs, and SDKs. You can use it to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) for analysis. OpenTelemetry is part of the Cloud Native Computing Foundation. For more information, see OpenTelemetry.

For information about the full OpenTelemetry 1.0.0 specification, see Release version 1.0.0.

A Kinesis record can contain one or more `ExportMetricsServiceRequest` OpenTelemetry data structures. Each data structure starts with a header with an `UnsignedVarInt32` indicating the record length in bytes. Each `ExportMetricsServiceRequest` may contain data from multiple metrics at once.

The following is a string representation of the message of the `ExportMetricsServiceRequest` OpenTelemetry data structure. OpenTelemetry serializes the Google Protocol Buffers binary protocol, and this is not human-readable.

```
resource_metrics {
  resource {
    attributes {
      key: "cloud.provider"
      value {
        string_value: "aws"
      }
    }
    attributes {
      key: "cloud.account.id"
      value {
        string_value: "123456789012"
      }
```

```
    }
    attributes {
      key: "cloud.region"
      value {
        string_value: "us-east-1"
      }
    }
    attributes {
      key: "aws.exporter.arn"
      value {
        string_value: "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/
MyMetricStream"
      }
    }
  }
  scope_metrics {
    metrics {
      name: "amazonaws.com/AWS/DynamoDB/ConsumedReadCapacityUnits"
      unit: "NoneTranslated"
      summary {
        data_points {
          start_time_unix_nano: 60000000000
          time_unix_nano: 120000000000
          count: 1
          sum: 1.0
          quantile_values {
            value: 1.0
          }
          quantile_values {
            quantile: 0.95
            value: 1.0
          }
          quantile_values {
            quantile: 0.99
            value: 1.0
          }
          quantile_values {
            quantile: 1.0
            value: 1.0
          }
          attributes {
            key: "Namespace"
            value {
              string_value: "AWS/DynamoDB"
```

```
          }
        }
        attributes {
          key: "MetricName"
          value {
            string_value: "ConsumedReadCapacityUnits"
          }
        }
        attributes {
          key: "Dimensions"
          value {
            kvlist_value {
              values {
                key: "TableName"
                value {
                  string_value: "MyTable"
                }
              }
            }
          }
        }
      }
      data_points {
        start_time_unix_nano: 70000000000
        time_unix_nano: 130000000000
        count: 2
        sum: 5.0
        quantile_values {
          value: 2.0
        }
        quantile_values {
          quantile: 1.0
          value: 3.0
        }
        attributes {
          key: "Namespace"
          value {
            string_value: "AWS/DynamoDB"
          }
        }
        attributes {
          key: "MetricName"
          value {
            string_value: "ConsumedReadCapacityUnits"
```

```
          }
        }
        attributes {
          key: "Dimensions"
          value {
            kvlist_value {
              values {
                key: "TableName"
                value {
                  string_value: "MyTable"
                }
              }
            }
          }
        }
      }
    }
  }
 }
}
```

Top-level object to serialize OpenTelemetry metric data

`ExportMetricsServiceRequest` is the top-level wrapper to serialize an OpenTelemetry exporter payload. It contains one or more `ResourceMetrics`.

```
message ExportMetricsServiceRequest {
  // An array of ResourceMetrics.
  // For data coming from a single resource this array will typically contain one
  // element. Intermediary nodes (such as OpenTelemetry Collector) that receive
  // data from multiple origins typically batch the data before forwarding further and
  // in that case this array will contain multiple elements.
  repeated opentelemetry.proto.metrics.v1.ResourceMetrics resource_metrics = 1;
}
```

`ResourceMetrics` is the top-level object to represent MetricData objects.

```
// A collection of ScopeMetrics from a Resource.
message ResourceMetrics {
  reserved 1000;

  // The resource for the metrics in this message.
```

```
  // If this field is not set then no resource info is known.
  opentelemetry.proto.resource.v1.Resource resource = 1;

  // A list of metrics that originate from a resource.
  repeated ScopeMetrics scope_metrics = 2;

  // This schema_url applies to the data in the "resource" field. It does not apply
  // to the data in the "scope_metrics" field which have their own schema_url field.
  string schema_url = 3;
}
```

The Resource object

A `Resource` object is a value-pair object that contains some information about the resource that generated the metrics. For metrics created by Amazon, the data structure contains the Amazon Resource Name (ARN) of the resource related to the metric, such as an EC2 instance or an S3 bucket.

The `Resource` object contains an attribute called `attributes`, which store a list of key-value pairs.

- `cloud.account.id` contains the account ID
- `cloud.region` contains the Region
- `aws.exporter.arn` contains the metric stream ARN
- `cloud.provider` is always `aws`.

```
// Resource information.
message Resource {
  // Set of attributes that describe the resource.
  // Attribute keys MUST be unique (it is not allowed to have more than one
  // attribute with the same key).
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 1;

  // dropped_attributes_count is the number of dropped attributes. If the value is 0,
 then
  // no attributes were dropped.
  uint32 dropped_attributes_count = 2;
}
```

The ScopeMetrics object

The scope field will not be filled. We fill only the metrics field that we are exporting.

```
// A collection of Metrics produced by an Scope.
message ScopeMetrics {
  // The instrumentation scope information for the metrics in this message.
  // Semantically when InstrumentationScope isn't set, it is equivalent with
  // an empty instrumentation scope name (unknown).
  opentelemetry.proto.common.v1.InstrumentationScope scope = 1;

  // A list of metrics that originate from an instrumentation library.
  repeated Metric metrics = 2;

  // This schema_url applies to all metrics in the "metrics" field.
  string schema_url = 3;
}
```

The Metric object

The metric object contains some metadata and a `Summary` data field that contains a list of `SummaryDataPoint`.

For metric streams, the metadata is as follows:

- name will be `amazonaws.com/`*`metric_namespace`*`/`*`metric_name`*
- `description` will be blank
- `unit` will be filled by mapping the metric datum's unit to the case-sensitive variant of the Unified code for Units of Measure. For more information, see [Translations with OpenTelemetry 1.0.0 format in CloudWatch] and [The Unified Code For Units of Measure].
- `type` will be SUMMARY

```
message Metric {
  reserved 4, 6, 8;

  // name of the metric, including its DNS name prefix. It must be unique.
  string name = 1;

  // description of the metric, which can be used in documentation.
  string description = 2;

  // unit in which the metric value is reported. Follows the format
```

```
  // described by http://unitsofmeasure.org/ucum.html.
  string unit = 3;

  // Data determines the aggregation type (if any) of the metric, what is the
  // reported value type for the data points, as well as the relatationship to
  // the time interval over which they are reported.
  oneof data {
    Gauge gauge = 5;
    Sum sum = 7;
    Histogram histogram = 9;
    ExponentialHistogram exponential_histogram = 10;
    Summary summary = 11;
  }
}

message Summary {
  repeated SummaryDataPoint data_points = 1;
}
```

The SummaryDataPoint object

The SummaryDataPoint object contains the value of a single data point in a time series in a DoubleSummary metric.

```
// SummaryDataPoint is a single data point in a timeseries that describes the
// time-varying values of a Summary metric.
message SummaryDataPoint {
  reserved 1;

  // The set of key/value pairs that uniquely identify the timeseries from
  // where this point belongs. The list may be empty (may contain 0 elements).
  // Attribute keys MUST be unique (it is not allowed to have more than one
  // attribute with the same key).
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 7;

  // StartTimeUnixNano is optional but strongly encouraged, see the
  // the detailed comments above Metric.
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 start_time_unix_nano = 2;

  // TimeUnixNano is required, see the detailed comments above Metric.
```

```
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 time_unix_nano = 3;

  // count is the number of values in the population. Must be non-negative.
  fixed64 count = 4;

  // sum of the values in the population. If count is zero then this field
  // must be zero.
  //
  // Note: Sum should only be filled out when measuring non-negative discrete
  // events, and is assumed to be monotonic over the values of these events.
  // Negative events *can* be recorded, but sum should not be filled out when
  // doing so.  This is specifically to enforce compatibility w/ OpenMetrics,
  // see: https://github.com/OpenObservability/OpenMetrics/blob/main/specification/
OpenMetrics.md#summary
  double sum = 5;

  // Represents the value at a given quantile of a distribution.
  //
  // To record Min and Max values following conventions are used:
  // - The 1.0 quantile is equivalent to the maximum value observed.
  // - The 0.0 quantile is equivalent to the minimum value observed.
  //
  // See the following issue for more context:
  // https://github.com/open-telemetry/opentelemetry-proto/issues/125
  message ValueAtQuantile {
    // The quantile of a distribution. Must be in the interval
    // [0.0, 1.0].
    double quantile = 1;

    // The value at the given quantile of a distribution.
    //
    // Quantile values must NOT be negative.
    double value = 2;
  }

  // (Optional) list of values at different quantiles of the distribution calculated
  // from the current snapshot. The quantiles must be strictly increasing.
  repeated ValueAtQuantile quantile_values = 6;

  // Flags that apply to this specific data point.  See DataPointFlags
  // for the available flags and their meaning.
```

```
  uint32 flags = 8;
}
```

For more information, see [Translations with OpenTelemetry 1.0.0 format in CloudWatch](#).

Translations with OpenTelemetry 1.0.0 format in CloudWatch

CloudWatch performs some transformations to put CloudWatch data into OpenTelemetry format.

Translating namespace, metric name, and dimensions

These attributes are key-value pairs encoded in the mapping.

- One attribute has the key `Namespace` and its value is the namespace of the metric
- One attribute has the key `MetricName` and its value is the name of the metric
- One pair has the key `Dimensions` and its value is a nested list of key-value pairs. Each pair in this list maps to a CloudWatch metric dimension, where the pair's key is the name of the dimension and its value is the value of the dimension.

Translating Average, Sum, SampleCount, Min and Max

The Summary datapoint enables CloudWatch to export all of these statistics using one datapoint.

- `startTimeUnixNano` contains the CloudWatch `startTime`
- `timeUnixNano` contains the CloudWatch `endTime`
- `sum` contains the Sum statistic.
- `count` contains the SampleCount statistic.
- `quantile_values` contains two `valueAtQuantile.value` objects:
  - `valueAtQuantile.quantile = 0.0` with `valueAtQuantile.value = Min value`
  - `valueAtQuantile.quantile = 0.99` with `valueAtQuantile.value = p99 value`
  - `valueAtQuantile.quantile = 0.999` with `valueAtQuantile.value = p99.9 value`
  - `valueAtQuantile.quantile = 1.0` with `valueAtQuantile.value = Max value`

Resources that consume the metric stream can calculate the Average statistic as **Sum/ SampleCount**.

Translating units

CloudWatch units are mapped to the case-sensitive variant of the Unified code for Units of Measure, as shown in the following table. For more information, see The Unified Code For Units of Measure.

CloudWatch	OpenTelemetry
Second	s
Second or Seconds	s
Microseconds	us
Milliseconds	ms
Bytes	By
Kilobytes	kBy
Megabytes	MBy
Gigabytes	GBy
Terabytes	TBy
Bits	bit
Kilobits	kbit
Megabits	MBit
Gigabits	GBit
Terabits	Tbit
Percent	%
Count	{Count}
None	1

Units that are combined with a slash are mapped by applying the OpenTelemetry conversion of both the units. For example, Bytes/Second is mapped to By/s.

How to parse OpenTelemetry 1.0.0 messages

This section provides information to help you get started with parsing OpenTelemetry 1.0.0.

First, you should get language-specific bindings, which enable you to parse OpenTelemetry 1.0.0 messages in your preferred language.

To get language-specific bindings

- The steps depend on your preferred language.
  - To use Java, add the following Maven dependency to your Java project: OpenTelemetry Java >> 0.14.1.
  - To use any other language, follow these steps:
    a. Make sure that your language is supported by checking the list at Generating Your Classes.
    b. Install the Protobuf compiler by following the steps at Download Protocol Buffers.
    c. Download the OpenTelemetry 1.0.0 ProtoBuf definitions at Release version 1.0.0.
    d. Confirm that you are in the root folder of the downloaded OpenTelemetry 1.0.0 ProtoBuf definitions. Then create a `src` folder and then run the command to generate language-specific bindings. For more information, see Generating Your Classes.

       The following is an example for how to generate Javascript bindings.

```
protoc --proto_path=./ --js_out=import_style=commonjs,binary:src \
opentelemetry/proto/common/v1/common.proto \
opentelemetry/proto/resource/v1/resource.proto \
opentelemetry/proto/metrics/v1/metrics.proto \
opentelemetry/proto/collector/metrics/v1/metrics_service.proto
```

The following section includes examples of using the language-specific bindings that you can build using the previous instructions.

Java

```
package com.example;

import io.opentelemetry.proto.collector.metrics.v1.ExportMetricsServiceRequest;

import java.io.IOException;
import java.io.InputStream;
import java.util.ArrayList;
import java.util.List;

public class MyOpenTelemetryParser {

    public List<ExportMetricsServiceRequest> parse(InputStream inputStream) throws
 IOException {
        List<ExportMetricsServiceRequest> result = new ArrayList<>();

        ExportMetricsServiceRequest request;
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ --------------------------- ------ -----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ --------------------------- ------ -----------------------
         */
        while ((request =
 ExportMetricsServiceRequest.parseDelimitedFrom(inputStream)) != null) {
            // Do whatever we want with the parsed message
            result.add(request);
        }

        return result;
    }
}
```

Javascript

This example assumes that the root folder with the bindings generated is `./`

The data argument of the function `parseRecord` can be one of the following types:

- `Uint8Array` this is optimal
- `Buffer` optimal under node
- `Array.`*`number`* 8-bit integers

```
const pb = require('google-protobuf')
const pbMetrics =
    require('./opentelemetry/proto/collector/metrics/v1/metrics_service_pb')

function parseRecord(data) {
    const result = []

    // Loop until we've read all the data from the buffer
    while (data.length) {
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ -----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ -------------------------- ------ -----------------------
         */
        const reader = new pb.BinaryReader(data)
        const messageLength = reader.decoder_.readUnsignedVarint32()
        const messageFrom = reader.decoder_.cursor_
        const messageTo = messageFrom + messageLength

        // Extract the current `ExportMetricsServiceRequest` message to parse
        const message = data.subarray(messageFrom, messageTo)

        // Parse the current message using the ProtoBuf library
        const parsed =
            pbMetrics.ExportMetricsServiceRequest.deserializeBinary(message)

        // Do whatever we want with the parsed message
        result.push(parsed.toObject())

        // Shrink the remaining buffer, removing the already parsed data
        data = data.subarray(messageTo)
    }

    return result
}
```

Python

You must read the `var-int` delimiters yourself or use the internal methods `_VarintBytes(size)` and `_DecodeVarint32(buffer, position)`. These return the position in the buffer just after the size bytes. The read-side constructs a new buffer that is limited to reading only the bytes of the message.

```
size = my_metric.ByteSize()
f.write(_VarintBytes(size))
f.write(my_metric.SerializeToString())
msg_len, new_pos = _DecodeVarint32(buf, 0)
msg_buf = buf[new_pos:new_pos+msg_len]
request = metrics_service_pb.ExportMetricsServiceRequest()
request.ParseFromString(msg_buf)
```

Go

Use `Buffer.DecodeMessage()`.

C#

Use `CodedInputStream`. This class can read size-delimited messages.

C++

The functions described in `google/protobuf/util/delimited_message_util.h` can read size-delimited messages.

Other languages

For other languages, see [Download Protocol Buffers].

When implementing the parser, consider that a Kinesis record can contain multiple `ExportMetricsServiceRequest` Protocol Buffers messages, each of them starting with a header with an `UnsignedVarInt32` that indicates the record length in bytes.

CloudWatch metric stream output in OpenTelemetry 0.7.0 format

OpenTelemetry is a collection of tools, APIs, and SDKs. You can use it to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) for analysis. OpenTelemetry is part of the Cloud Native Computing Foundation. For more information, see [OpenTelemetry].

For information about the full OpenTelemetry 0.7.0 specification, see [v0.7.0 release].

A Kinesis record can contain one or more `ExportMetricsServiceRequest` OpenTelemetry data structures. Each data structure starts with a header with an `UnsignedVarInt32` indicating the record length in bytes. Each `ExportMetricsServiceRequest` may contain data from multiple metrics at once.

The following is a string representation of the message of the `ExportMetricsServiceRequest` OpenTelemetry data structure. OpenTelemetry serializes the Google Protocol Buffers binary protocol, and this is not human-readable.

```
resource_metrics {
  resource {
    attributes {
      key: "cloud.provider"
      value {
        string_value: "aws"
      }
    }
    attributes {
      key: "cloud.account.id"
      value {
        string_value: "2345678901"
      }
    }
    attributes {
      key: "cloud.region"
      value {
        string_value: "us-east-1"
      }
    }
    attributes {
      key: "aws.exporter.arn"
      value {
        string_value: "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/
MyMetricStream"
      }
    }
  }
  instrumentation_library_metrics {
    metrics {
      name: "amazonaws.com/AWS/DynamoDB/ConsumedReadCapacityUnits"
      unit: "1"
      double_summary {
        data_points {
          labels {
            key: "Namespace"
```

```
        value: "AWS/DynamoDB"
      }
      labels {
        key: "MetricName"
        value: "ConsumedReadCapacityUnits"
      }
      labels {
        key: "TableName"
        value: "MyTable"
      }
      start_time_unix_nano: 1604948400000000000
      time_unix_nano: 1604948460000000000
      count: 1
      sum: 1.0
      quantile_values {
        quantile: 0.0
        value: 1.0
      }
      quantile_values {
        quantile: 0.95
        value: 1.0
      }
      quantile_values {
        quantile: 0.99
        value: 1.0
      }
      quantile_values {
        quantile: 1.0
        value: 1.0
      }
    }
    data_points {
      labels {
        key: "Namespace"
        value: "AWS/DynamoDB"
      }
      labels {
        key: "MetricName"
        value: "ConsumedReadCapacityUnits"
      }
      labels {
        key: "TableName"
        value: "MyTable"
      }
```

```
          start_time_unix_nano: 1604948460000000000
          time_unix_nano: 1604948520000000000
          count: 2
          sum: 5.0
          quantile_values {
            quantile: 0.0
            value: 2.0
          }
          quantile_values {
            quantile: 1.0
            value: 3.0
          }
        }
      }
    }
  }
}
```

Top-level object to serialize OpenTelemetry metric data

`ExportMetricsServiceRequest` is the top-level wrapper to serialize an OpenTelemetry exporter payload. It contains one or more `ResourceMetrics`.

```
message ExportMetricsServiceRequest {
  // An array of ResourceMetrics.
  // For data coming from a single resource this array will typically contain one
  // element. Intermediary nodes (such as OpenTelemetry Collector) that receive
  // data from multiple origins typically batch the data before forwarding further and
  // in that case this array will contain multiple elements.
  repeated opentelemetry.proto.metrics.v1.ResourceMetrics resource_metrics = 1;
}
```

`ResourceMetrics` is the top-level object to represent MetricData objects.

```
// A collection of InstrumentationLibraryMetrics from a Resource.
message ResourceMetrics {
  // The resource for the metrics in this message.
  // If this field is not set then no resource info is known.
  opentelemetry.proto.resource.v1.Resource resource = 1;

  // A list of metrics that originate from a resource.
  repeated InstrumentationLibraryMetrics instrumentation_library_metrics = 2;
```

```
}
```

The Resource object

A `Resource` object is a value-pair object that contains some information about the resource that generated the metrics. For metrics created by Amazon, the data structure contains the Amazon Resource Name (ARN) of the resource related to the metric, such as an EC2 instance or an S3 bucket.

The `Resource` object contains an attribute called `attributes`, which store a list of key-value pairs.

- `cloud.account.id` contains the account ID
- `cloud.region` contains the Region
- `aws.exporter.arn` contains the metric stream ARN
- `cloud.provider` is always `aws`.

```
// Resource information.
message Resource {
  // Set of labels that describe the resource.
  repeated opentelemetry.proto.common.v1.KeyValue attributes = 1;

  // dropped_attributes_count is the number of dropped attributes. If the value is 0,
  // no attributes were dropped.
  uint32 dropped_attributes_count = 2;
}
```

The InstrumentationLibraryMetrics object

The instrumentation_library field will not be filled. We will fill only the metrics field that we are exporting.

```
// A collection of Metrics produced by an InstrumentationLibrary.
message InstrumentationLibraryMetrics {
  // The instrumentation library information for the metrics in this message.
  // If this field is not set then no library info is known.
  opentelemetry.proto.common.v1.InstrumentationLibrary instrumentation_library = 1;
  // A list of metrics that originate from an instrumentation library.
  repeated Metric metrics = 2;
```

```
}
```

The Metric object

The metric object contains a `DoubleSummary` data field that contains a list of `DoubleSummaryDataPoint`.

```
message Metric {
  // name of the metric, including its DNS name prefix. It must be unique.
  string name = 1;

  // description of the metric, which can be used in documentation.
  string description = 2;

  // unit in which the metric value is reported. Follows the format
  // described by http://unitsofmeasure.org/ucum.html.
  string unit = 3;

  oneof data {
    IntGauge int_gauge = 4;
    DoubleGauge double_gauge = 5;
    IntSum int_sum = 6;
    DoubleSum double_sum = 7;
    IntHistogram int_histogram = 8;
    DoubleHistogram double_histogram = 9;
    DoubleSummary double_summary = 11;
  }
}

message DoubleSummary {
  repeated DoubleSummaryDataPoint data_points = 1;
}
```

The MetricDescriptor object

The MetricDescriptor object contains metadata. For more information, see metrics.proto on GitHub.

For metric streams, the MetricDescriptor has the following contents:

- name will be `amazonaws.com/`*`metric_namespace`*`/`*`metric_name`*
- `description` will be blank.

- `unit` will be filled by mapping the metric datum's unit to the case-sensitive variant of the Unified code for Units of Measure. For more information, see [Translations with OpenTelemetry 0.7.0 format in CloudWatch] and [The Unified Code For Units of Measure].
- `type` will be `SUMMARY`.

The DoubleSummaryDataPoint object

The DoubleSummaryDataPoint object contains the value of a single data point in a time series in a DoubleSummary metric.

```
// DoubleSummaryDataPoint is a single data point in a timeseries that describes the
// time-varying values of a Summary metric.
message DoubleSummaryDataPoint {
  // The set of labels that uniquely identify this timeseries.
  repeated opentelemetry.proto.common.v1.StringKeyValue labels = 1;

  // start_time_unix_nano is the last time when the aggregation value was reset
  // to "zero". For some metric types this is ignored, see data types for more
  // details.
  //
  // The aggregation value is over the time interval (start_time_unix_nano,
  // time_unix_nano].
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  //
  // Value of 0 indicates that the timestamp is unspecified. In that case the
  // timestamp may be decided by the backend.
  fixed64 start_time_unix_nano = 2;

  // time_unix_nano is the moment when this aggregation value was reported.
  //
  // Value is UNIX Epoch time in nanoseconds since 00:00:00 UTC on 1 January
  // 1970.
  fixed64 time_unix_nano = 3;

  // count is the number of values in the population. Must be non-negative.
  fixed64 count = 4;

  // sum of the values in the population. If count is zero then this field
  // must be zero.
  double sum = 5;
```

```
  // Represents the value at a given quantile of a distribution.
  //
  // To record Min and Max values following conventions are used:
  // - The 1.0 quantile is equivalent to the maximum value observed.
  // - The 0.0 quantile is equivalent to the minimum value observed.
  message ValueAtQuantile {
    // The quantile of a distribution. Must be in the interval
    // [0.0, 1.0].
    double quantile = 1;

    // The value at the given quantile of a distribution.
    double value = 2;
  }

  // (Optional) list of values at different quantiles of the distribution calculated
  // from the current snapshot. The quantiles must be strictly increasing.
  repeated ValueAtQuantile quantile_values = 6;
}
```

For more information, see Translations with OpenTelemetry 0.7.0 format in CloudWatch.

Translations with OpenTelemetry 0.7.0 format in CloudWatch

CloudWatch performs some transformations to put CloudWatch data into OpenTelemetry format.

Translating namespace, metric name, and dimensions

These attributes are key-value pairs encoded in the mapping.

- One pair contains the namespace of the metric
- One pair contains the name of the metric
- For each dimension, CloudWatch stores the following pair: `metricDatum.Dimensions[i].`*`Name`*`, metricDatum.Dimensions[i].`*`Value`*

Translating Average, Sum, SampleCount, Min and Max

The Summary datapoint enables CloudWatch to export all of these statistics using one datapoint.

- `startTimeUnixNano` contains the CloudWatch `startTime`
- `timeUnixNano` contains the CloudWatch `endTime`

- `sum` contains the Sum statistic.
- `count` contains the SampleCount statistic.
- `quantile_values` contains two `valueAtQuantile.value` objects:
  - `valueAtQuantile.quantile = 0.0` with `valueAtQuantile.value = Min value`
  - `valueAtQuantile.quantile = 0.99` with `valueAtQuantile.value = p99 value`
  - `valueAtQuantile.quantile = 0.999` with `valueAtQuantile.value = p99.9 value`
  - `valueAtQuantile.quantile = 1.0` with `valueAtQuantile.value = Max value`

Resources that consume the metric stream can calculate the Average statistic as **Sum/ SampleCount**.

Translating units

CloudWatch units are mapped to the case-sensitive variant of the Unified code for Units of Measure, as shown in the following table. For more information, see [The Unified Code For Units of Measure](https://ucum.org/ucum).

CloudWatch	OpenTelemetry
Second	s
Second or Seconds	s
Microsecond	us
Milliseconds	ms
Bytes	By
Kilobytes	kBy
Megabytes	MBy
Gigabytes	GBy
Terabytes	TBy
Bits	bit

CloudWatch	OpenTelemetry
Kilobits	kbit
Megabits	MBit
Gigabits	GBit
Terabits	Tbit
Percent	%
Count	{Count}
None	1

Units that are combined with a slash are mapped by applying the OpenTelemetry conversion of both the units. For example, Bytes/Second is mapped to By/s.

How to parse OpenTelemetry 0.7.0 messages

This section provides information to help you get started with parsing OpenTelemetry 0.7.0.

First, you should get language-specific bindings, which enable you to parse OpenTelemetry 0.7.0 messages in your preferred language.

To get language-specific bindings

- The steps depend on your preferred language.
  - To use Java, add the following Maven dependency to your Java project: OpenTelemetry Java >> 0.14.1.
  - To use any other language, follow these steps:

    a. Make sure that your language is supported by checking the list at Generating Your Classes.

    b. Install the Protobuf compiler by following the steps at Download Protocol Buffers.

    c. Download the OpenTelemetry 0.7.0 ProtoBuf definitions at v0.7.0 release.

    d. Confirm that you are in the root folder of the downloaded OpenTelemetry 0.7.0 ProtoBuf definitions. Then create a `src` folder and then run the command to generate language-specific bindings. For more information, see Generating Your Classes.

The following is an example for how to generate Javascript bindings.

```
protoc --proto_path=./ --js_out=import_style=commonjs,binary:src \
opentelemetry/proto/common/v1/common.proto \
opentelemetry/proto/resource/v1/resource.proto \
opentelemetry/proto/metrics/v1/metrics.proto \
opentelemetry/proto/collector/metrics/v1/metrics_service.proto
```

The following section includes examples of using the language-specific bindings that you can build using the previous instructions.

Java

```
package com.example;

import io.opentelemetry.proto.collector.metrics.v1.ExportMetricsServiceRequest;

import java.io.IOException;
import java.io.InputStream;
import java.util.ArrayList;
import java.util.List;

public class MyOpenTelemetryParser {

    public List<ExportMetricsServiceRequest> parse(InputStream inputStream) throws
 IOException {
        List<ExportMetricsServiceRequest> result = new ArrayList<>();

        ExportMetricsServiceRequest request;
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ --------------------------- ------ -----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|pExportMetricsService...
            ------ --------------------------- ------ -----------------------
         */
        while ((request =
 ExportMetricsServiceRequest.parseDelimitedFrom(inputStream)) != null) {
            // Do whatever we want with the parsed message
```

```
            result.add(request);
        }

        return result;
    }
}
```

Javascript

This example assumes that the root folder with the bindings generated is `./`

The data argument of the function `parseRecord` can be one of the following types:

- `Uint8Array` this is optimal
- `Buffer` optimal under node
- `Array.number` 8-bit integers

```
const pb = require('google-protobuf')
const pbMetrics =
    require('./opentelemetry/proto/collector/metrics/v1/metrics_service_pb')

function parseRecord(data) {
    const result = []

    // Loop until we've read all the data from the buffer
    while (data.length) {
        /* A Kinesis record can contain multiple `ExportMetricsServiceRequest`
           records, each of them starting with a header with an
           UnsignedVarInt32 indicating the record length in bytes:
            ------ -------------------------- ------ -----------------------
           |UINT32|ExportMetricsServiceRequest|UINT32|ExportMetricsService...
            ------ -------------------------- ------ -----------------------
         */
        const reader = new pb.BinaryReader(data)
        const messageLength = reader.decoder_.readUnsignedVarint32()
        const messageFrom = reader.decoder_.cursor_
        const messageTo = messageFrom + messageLength

        // Extract the current `ExportMetricsServiceRequest` message to parse
        const message = data.subarray(messageFrom, messageTo)

        // Parse the current message using the ProtoBuf library
```

```
        const parsed =
            pbMetrics.ExportMetricsServiceRequest.deserializeBinary(message)

        // Do whatever we want with the parsed message
        result.push(parsed.toObject())

        // Shrink the remaining buffer, removing the already parsed data
        data = data.subarray(messageTo)
    }

    return result
}
```

Python

You must read the `var-int` delimiters yourself or use the internal methods `_VarintBytes(size)` and `_DecodeVarint32(buffer, position)`. These return the position in the buffer just after the size bytes. The read-side constructs a new buffer that is limited to reading only the bytes of the message.

```
size = my_metric.ByteSize()
f.write(_VarintBytes(size))
f.write(my_metric.SerializeToString())
msg_len, new_pos = _DecodeVarint32(buf, 0)
msg_buf = buf[new_pos:new_pos+msg_len]
request = metrics_service_pb.ExportMetricsServiceRequest()
request.ParseFromString(msg_buf)
```

Go

Use `Buffer.DecodeMessage()`.

C#

Use `CodedInputStream`. This class can read size-delimited messages.

C++

The functions described in `google/protobuf/util/delimited_message_util.h` can read size-delimited messages.

Other languages

For other languages, see Download Protocol Buffers.

When implementing the parser, consider that a Kinesis record can contain multiple `ExportMetricsServiceRequest` Protocol Buffers messages, each of them starting with a header with an `UnsignedVarInt32` that indicates the record length in bytes.

Troubleshooting metric streams in CloudWatch

If you're not seeing metric data at your final destination, check the following:

- Check that the metric stream is in the running state. For steps on how to use the CloudWatch console to do this, see Metric stream operation and maintenance.
- Metrics published more than two days in the past are not streamed. To determine whether a particular metric will be streamed, graph the metric in the CloudWatch console and check how old the last visible datapoint is. If it is more than two days in the past, then it won't be picked up by metric streams.
- Check the metrics emitted by the metric stream. In the CloudWatch console, under **Metrics**, look at the **AWS/CloudWatch/MetricStreams** namespace for the **MetricUpdate**, **TotalMetricUpdate**, and **PublishErrorRate** metrics.
- If the **PublishErrorRate** metric is high, confirm that the destination that is used by the Firehose delivery stream exists and that the IAM role specified in the metric stream's configuration grants the `CloudWatch` service principal permissions to write to it. For more information, see Trust between CloudWatch and Firehose.
- Check that the Firehose delivery stream has permission to write to the final destination.
- In the Firehose console, view the Firehose delivery stream that is used for the metric stream and check the **Monitoring** tab to see whether the Firehose delivery stream is receiving data.
- Confirm that you have configured your Firehose delivery stream with the correct details.
- Check any available logs or metrics for the final destination that the Firehose delivery stream writes to.
- To get more detailed information, enable CloudWatch Logs error logging on the Firehose delivery stream. For more information, see Monitoring Amazon Data Firehose Using CloudWatch Logs.

> **Note**
>
> After a data point for a specific metric and timestamp has been sent, it won't be sent again even if the value of the data point changes later.

View available metrics

Metrics are grouped first by namespace, and then by the various dimension combinations within each namespace. For example, you can view all EC2 metrics, EC2 metrics grouped by instance, or EC2 metrics grouped by Auto Scaling group.

Only the Amazon services that you're using send metrics to Amazon CloudWatch.

For a list of Amazon services that send metrics to CloudWatch, see Amazon services that publish CloudWatch metrics. From this page, you can also see the metrics and dimensions that are published by each of those services.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in the search box in the **All metrics** tab in the console, and they are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the Amazon CLI.
> If the old metric you want to view has a current metric with similar dimensions, you can view that current similar metric and then choose the **Source** tab, and change the metric name and dimension fields to the ones that you want, and also change the time range to a time when the metric was being reported.

The following steps help you browse through the metric namespaces to find and view metrics. You can also search for metrics using targeted search terms. For more information, see Search for available metrics.

If you are browsing in an account set up as a monitoring account in CloudWatch cross-account observability, you can view metrics from the source accounts linked to this monitoring account. When metrics from source accounts are displayed, the ID or label of the account that they are from is also displayed. For more information, see CloudWatch cross-account observability.

To view available metrics by namespace and dimension using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2** or **Lambda**).
4. Select a metric dimension (for example, **Per-Instance Metrics** or **By Function Name**).
5. The **Browse** tab displays all metrics for that dimension in the namespace. By each metric name is an information button you can choose to see a pop-up with the metric definition.

   If this is a monitoring account in CloudWatch cross-account observability, you also see the metrics from the source accounts linked to this monitoring account. The **Account label** and **Account id** columns in the table display which account each metric is from.

   You can do the following:

   a. To sort the table, use the column heading.
   b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
   c. To filter by account, choose the account label or account ID and then choose **Add to search**.
   d. To filter by resource, choose the resource ID and then choose **Add to search**.
   e. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

To view available metrics by account namespace, dimension, or metric using the Amazon CLI

Use the list-metrics command to list CloudWatch metrics. For a list of the namespaces, metrics, and dimensions for all services that publish metrics, see Amazon services that publish CloudWatch metrics.

The following example command lists all the metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

The following is example output.

```
{
```

```
  "Metrics" : [
    ...
    {
        "Namespace": "AWS/EC2",
        "Dimensions": [
            {
                "Name": "InstanceId",
                "Value": "i-1234567890abcdef0"
            }
        ],
        "MetricName": "NetworkOut"
    },
    {
        "Namespace": "AWS/EC2",
        "Dimensions": [
            {
                "Name": "InstanceId",
                "Value": "i-1234567890abcdef0"
            }
        ],
        "MetricName": "CPUUtilization"
    },
    {
        "Namespace": "AWS/EC2",
        "Dimensions": [
            {
                "Name": "InstanceId",
                "Value": "i-1234567890abcdef0"
            }
        ],
        "MetricName": "NetworkIn"
    },
    ...
  ]
}
```

To list all the available metrics for a specified resource

The following example specifies the `AWS/EC2` namespace and the `InstanceId` dimension to view the results for the specified instance only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --dimensions
 Name=InstanceId,Value=i-1234567890abcdef0
```

To list a metric for all resources

The following example specifies the AWS/EC2 namespace and a metric name to view the results for the specified metric only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --metric-name CPUUtilization
```

To retrieve metrics from linked source accounts in CloudWatch cross-account observability

The following example is run in a monitoring account to retrieve metrics from both the monitoring account and all linked source accounts. If you do not add `--include-linked-accounts`, the command returns only the monitoring account's metrics.

```
aws cloudwatch list-metrics --include-linked-accounts
```

To retrieve metrics from a source account in CloudWatch cross-account observability

The following example is run in a monitoring account to retrieve metrics from the source account with the ID 111122223333.

```
aws cloudwatch list-metrics --include-linked-accounts --owning-account "111122223333"
```

Search for available metrics

You can search within all of the metrics in your account using targeted search terms. Metrics are returned that have matching results within their namespace, metric name, or dimensions.

If this is a monitoring account in CloudWatch cross-account observability, you also search for metrics from the source accounts linked to this monitoring account.

> **Note**
>
> Metrics that have not had any new data points in the past two weeks do not appear in the console. They also do not appear when you type their metric name or dimension names in the search box in the **All metrics** tab in the console, and they are not returned in the results of a list-metrics command. The best way to retrieve these metrics is with the get-metric-data or get-metric-statistics commands in the Amazon CLI.

To search for available metrics in CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the search field, enter a search term, such as a metric name, namespace, account ID, account label, dimension name or value, or resource name. This shows you all of the namespaces with metrics with this search term.

   For example, if you search for **`volume`**, this shows the namespaces that contain metrics with this term in their name.

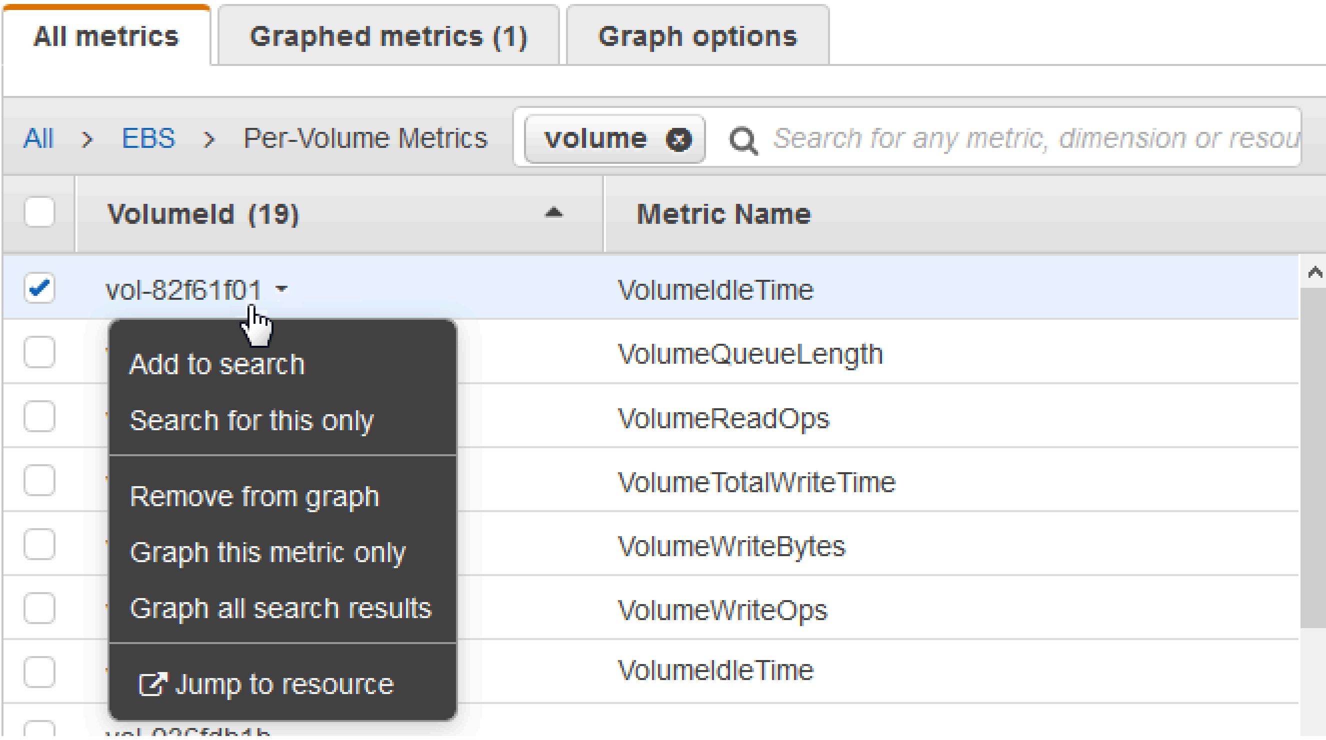
   For more information on search, see Use search expressions in graphs
4. To graph all the search results, choose **Graph search**

   or

   Select a namespace to view the metrics from that namespace. You can then do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
   b. To refine your search, hover over a metric name and choose **Add to search** or **Search for this only**.
   c. To view one of the resources on its console, choose the resource ID and then choose **Jump to resource**.
   d. To view help for a metric, select the metric name and choose **What is this?**.

   The selected metrics appear on the graph.



5. (Optional) Select one of the buttons in the search bar to edit that part of the search term.

Graphing metrics

Use the CloudWatch console to graph metric data generated by other Amazon services. This makes it more efficient to see the metric activity on your services. The following procedures describe how to graph metrics in CloudWatch.

Contents

Graph a metric

You can select metrics and create graphs of the metric data using the CloudWatch console.

CloudWatch supports the following statistics on metrics: `Average`, `Minimum`, `Maximum`, `Sum`, and `SampleCount`. For more information, see Statistics.

You can view your data at different levels of detail. For example, you can choose a one-minute view, which can be useful when troubleshooting. Or, choose a less detailed, one-hour view. That can be useful when viewing a broader time range (for example, 3 days) so that you can see trends over time. For more information, see Periods.

If you are using an account that is set up as a monitoring account in CloudWatch cross-account observability, you can graph metrics from the source accounts linked to this monitoring account. For more information, see CloudWatch cross-account observability.

Creating a graph

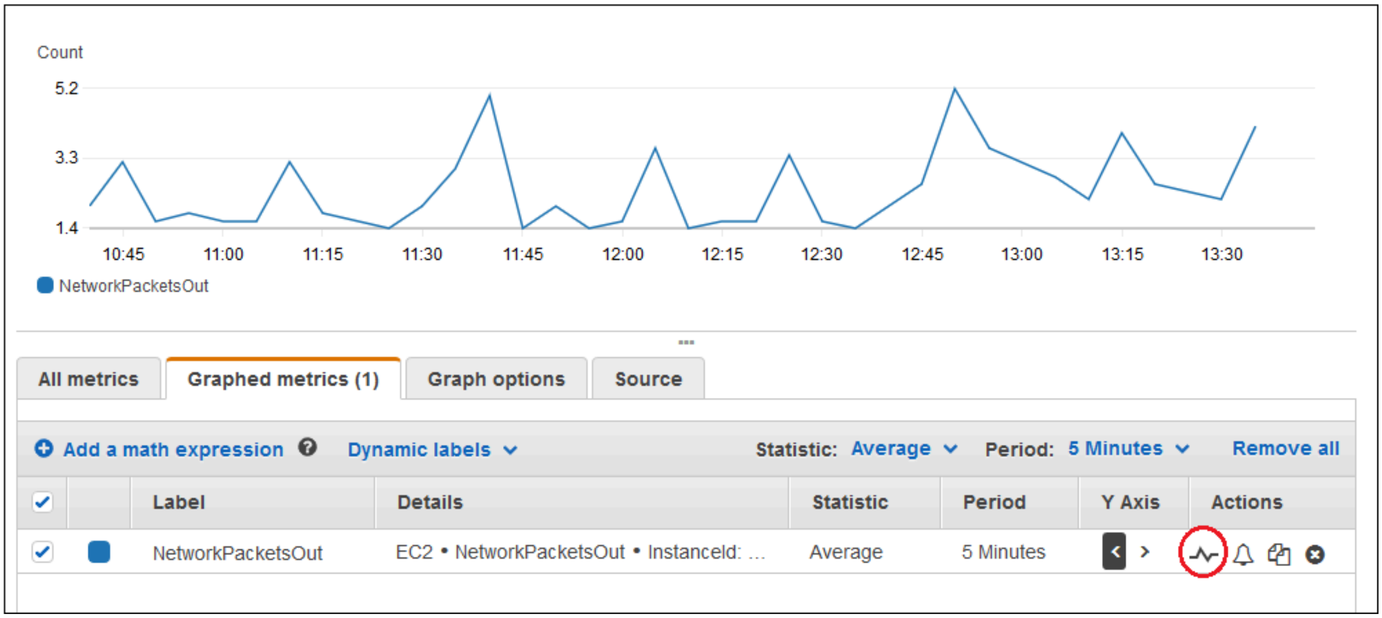
To graph a metric

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the **Browse** tab, enter a search term in the search field, such as a metric name, account ID, or resource name.

   For example, if you search for the `CPUUtilization` metric, you see the namespaces and dimensions with this metric.
4. Select one of the results for your search to view the metrics.
5. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
6. (Optional) To change the type of graph, choose the **Options** tab. You can then choose between a line graph, stacked area chart, number display, gauge, bar chart, or pie chart.
7. Choose the **Graphed metrics** tab.
8. (Optional) To change the statistic used in the graph, choose the new statistic in the **Statistic** column next to the metric name.

   For more information about CloudWatch statistics, see CloudWatch statistics definitions. For more information about the **p*xx* percentile statistics, see Percentiles.**

9. (Optional) To add an anomaly detection band that shows expected values for the metric, choose the anomaly detection icon under **Actions** next to the metric. For more information about anomaly detection, see Using CloudWatch anomaly detection.



CloudWatch uses up to two weeks of the metric's recent historical data to calculate a model for expected values. It then displays this range of expected values as a band on the graph. CloudWatch adds a new row under the metric to display the anomaly detection band math expression, labeled **ANOMALY_DETECTION_BAND**. If recent historical data exists, you immediately see a preview anomaly detection band, which is an approximation of the anomaly detection band generated by the model. It takes up to 15 minutes for the actual anomaly detection band to appear.

By default, CloudWatch creates the upper and lower bounds of the band of expected values with a default value of 2 for the band threshold. To change this number, change the value at the end of the formula under **Details** for the band.

- (Optional) Choose **Edit model** to change how the anomaly detection model is calculated. You can exclude past and future time periods from being used in the training for calculating the model. It is critical to exclude unusual events system as system outage, deployments, and holidays from the training data. You can also specify the time zone to use for the model for daylight saving time changes.

  For more information, see Editing an anomaly detection model .

For more information about anomaly detection, see Using CloudWatch anomaly detection.

To hide the model from the graph, remove the check mark from the line with the `ANOMALY_DETECTION_BAND` function or choose the `X` icon. To delete the model entirely, choose **Edit model**, **Delete model**.

10. (Optional) As you choose metrics to graph, specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric, and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose **Graphed metrics**, **Add dynamic label**.

    By default, the dynamic values that you add to the label appear at the beginning of the label. You can then choose the **Label** value for the metric to edit the label. For more information, see Use dynamic labels.

11. To view more information about the metric being graphed, pause the mouse over the legend.

12. Horizontal annotations can help graph users more efficiently see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose the **Options** tab and then **Add horizontal annotation**:

    a. For **Label**, enter a label for the annotation.

    b. For **Value**, enter the metric value where the horizontal annotation appears.

    c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

    d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis, if the graph includes multiple metrics.

       You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

    Repeat these steps to add multiple horizontal annotations to the same graph.

    To hide an annotation, clear the check box in the left column for that annotation.

    To delete an annotation, choose **x** in the **Actions** column.

13. To get a URL for your graph, choose **Actions**, **Share**. Copy the URL to save or share.

14. To add your graph to a dashboard, choose **Actions**, **Add to dashboard**.

Creating a graph of metrics from another data source

You can create a graph that displays resources from data sources other than CloudWatch. For more information about creating connections to these other data sources, see Query metrics from other data sources.

To graph a metric from another data source

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **Multi source query** tab.
4. For **Data source**, select the data source that you want to use.

   If you haven't already created a connection to the data source that you want, select **Create and manage data sources**, then choose **Create and manage data sources**. For information about the rest of this data source creation process, see Connect to a prebuilt data source with a wizard.
5. The wizard or query editor prompts you for the information necessary for the query. The workflow is different for each data source, and is tailored to the data source. For example, for Amazon Managed Service for Prometheus; and Prometheus data sources, a PromQL query editor box with a query helper appear.
6. When you have finished constructing the query, choose **Graph query**.

   The graph is populated with metrics from the query.
7. (Optional) Horizontal annotations can help graph users more efficiently see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose the **Options** tab and then **Add horizontal annotation**:

   a. For **Label**, enter a label for the annotation.

   b. For **Value**, enter the metric value where the horizontal annotation appears.

   c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

   d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left Y-axis or the right Y-axis, if the graph includes multiple metrics.

      You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

   Repeat these steps to add multiple horizontal annotations to the same graph.

   To hide an annotation, clear the check box in the left column for that annotation.

   To delete an annotation, choose **x** in the **Actions** column.

8. (Optional) To add this graph to a dashboard, choose **Actions**, **Add to dashboard**.

Updating a graph

To update your graph

1. To change the name of the graph, choose the pencil icon.
2. To change the time range, select one of the predefined values or choose **custom**. For more information, see Modify the time range or time zone format for a graph.
3. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **`p95.45`**).
4. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.
5. To add a horizontal annotation, choose **Graph options** and then **Add horizontal annotation**:

   a. For **Label**, enter a label for the annotation.

   b. For **Value**, enter the metric value where the horizontal annotation appears.

   c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

   d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left y-axis or the right y-axis, if the graph includes multiple metrics.

You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

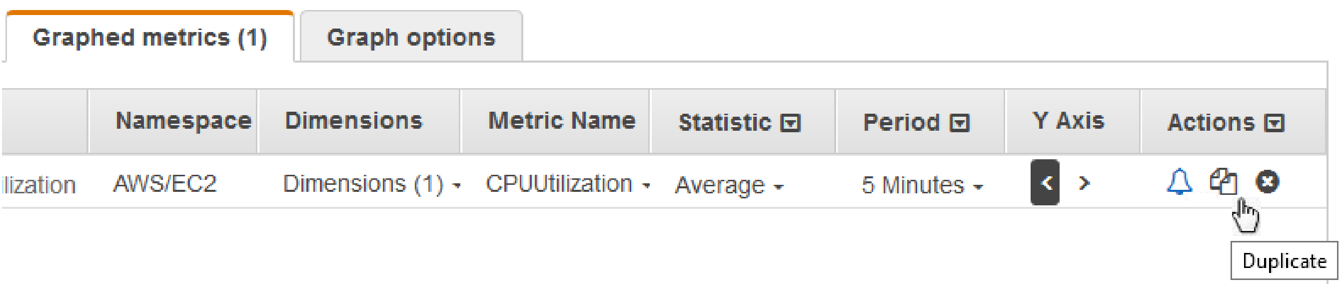
To delete an annotation, choose **x** in the **Actions** column.

6. To change the refresh interval, choose **Refresh options** and then select **Auto refresh** or choose **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

Duplicating a metric

To duplicate a metric

1. Choose the **Graphed metrics** tab.
2. For **Actions**, choose the **Duplicate** icon.



3. Update the duplicate metric as needed.

Merge two graphs into one

You can merge two different graphs into one, and then the resulting graph shows both metrics. This can be useful if you already have different metrics displayed in different graphs and want to combine them, or you want to easily create a single graph with metrics from different Regions.

To merge a graph into another one, you use either the URL or JSON source of the graph that you want to merge in.

To merge two graphs into one

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Open the graph that you want to merge into another graph. To do so, you can choose **Metrics**, **All metrics**, and then choose a metric to graph. Or you can open a dashboard and then open one of the graphs on the dashboard by selecting the graph and choosing **Open in metrics** from the menu at the upper right of the graph.
3. After you have a graph open, do one of the following:.
   - Copy the URL from the browser bar.
   - Choose the **Source** tab and then choose **Copy**.
4. Open the graph that you want to merge the previous graph into.
5. When you have the second graph open in the **Metrics** view, choose **Actions**, **Merge graph**.
6. Enter the URL or JSON that you previously copied, and choose **Merge**.
7. The merged graphs appear. The y-axis on the left is for the original graph, and the y-axis on the right is for the graph that you merged into it.

   > **Note**
   >
   > If the graph that you merged into uses the **METRICS()** function, the metrics in the graph that was merged in are not included in the **METRICS()** calculation in the merged graph.
8. To save the merged graph to a dashboard, choose **Actions**, **Add to dashboard**.

Use dynamic labels

You can use dynamic labels with your graphs. Dynamic labels add a dynamically updated value to the label for the selected metric. You can add a wide range of values to the labels, as shown in the following tables.

The dynamic value shown in the label is derived from the time range currently shown on the graph. The dynamic part of the label automatically updates when either the dashboard or the graph is refreshed.

If you use a dynamic label with a search expression, the dynamic label applies to every metric returned by the search.

You can use the CloudWatch console to add a dynamic value to a label, edit the label, change the position of the dynamic value within the label column, and make other customizations.

Dynamic labels

Within a dynamic label, you can use the following values relating to properties of the metric:

Dynamic label live value	Description
${AVG}	The average of the values in the time range currently shown in the graph.
${DATAPOINT_COUNT}	The number of data points in the time range that is currently shown in the graph.
${FIRST}	The oldest of the metric values in the time range that is currently shown in the graph.
${FIRST_LAST_RANGE}	The difference between the metric values of the oldest and newest data points that are currently shown in the graph.
${FIRST_LAST_TIME_RANGE}	The absolute time range between the oldest and newest data points that are currently shown in the graph.
${FIRST_TIME}	The timestamp of the oldest data point in the time range that is currently shown in the graph.
${FIRST_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the oldest data point in the time range that is currently shown in the graph.
${LABEL}	The representation of the default label for a metric.
${LAST}	The most recent of the metric values in the time range that is currently shown in the graph.
${LAST_TIME}	The timestamp of the newest data point in the time range that is currently shown in the graph.

Dynamic label live value	Description
${LAST_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the newest data point in the time range that is currently shown in the graph.
${MAX}	The maximum of the values in the time range currently shown in the graph.
${MAX_TIME}	The timestamp of the data point that has the highest metric value, of the data points that are currently shown in the graph.
${MAX_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the data point with the highest value, of those data points that are currently shown in the graph.
${MIN}	The minimum of the values in the time range currently shown in the graph.
${MIN_MAX_RANGE}	The difference in metric values between the data points with the highest and lowest metric values, of those data points that are currently shown in the graph.
${MIN_MAX_TIME_RANGE}	The absolute time range between the data points with the highest and lowest metric values, of those data points that are currently shown in the graph.
${MIN_TIME}	The timestamp of the data point that has the lowest metric value, of the data points that are currently shown in the graph.
${MIN_TIME_RELATIVE}	The absolute time difference between now and the timestamp of the data point with the lowest value, of those data points that are currently shown in the graph.
${PROP('AccountId')}	The Amazon account ID of the metric.
${PROP('AccountLabel')}	The label specified for the source account that owns this metric, in CloudWatch cross-account observability.

Dynamic label live value	Description
${PROP('Dim.*dimension_name*')}	The value of the specified dimension. Replace *dimension_name* with the case-sensitive name of your dimension.
${PROP('MetricName')}	The name of the metric.
${PROP('Namespace')}	The namespace of the metric.
${PROP('Period')}	The period of the metric, in seconds.
${PROP('Region')}	The Amazon Region where the metric is published.
${PROP('Stat')}	The metric statistic that is being graphed.
${SUM}	The sum of the values in the time range currently shown in the graph.

For example, suppose you have a search expression **`SEARCH(' {AWS/Lambda, FunctionName} Errors ', 'Sum')`**, which finds the `Errors` for each of your Lambda functions. If you set the label to be `[max: ${MAX} Errors for Function Name ${LABEL}]`, the label for each metric is **[max: *number* Errors for Function Name *Name*]**.

You can add as many as six dynamic values to a label. You can use the `${LABEL}` placeholder only once within each label.

Modify the time range or time zone format for a graph

This section describes how you can modify the date, time, and time zone format on a CloudWatch metrics graph. It also describes how you can zoom in on a graph to apply a specific time range. For information about creating a graph, see Graph a metric.

> **Note**
>
> If the time range of a dashboard is shorter than the period used for a graph on the dashboard, the following happens:

- The graph is modified to display the amount of data corresponding one complete period for that widget, even though this is longer than the dashboard time range. This ensures that there is at least one data point on the graph.
- The start time of the period for this data point is adjusted backwards to ensure that at least one data point can be displayed.

Set a relative time range

New interface

To specify a relative time range for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.
3. Choose **Custom**, and then select the **Relative** tab in the upper left corner of the box. You can specify a time range in **Minutes**, **Hours**, **Days**, **Weeks**, **Months**.
4. After you specify a time range, choose **Apply**.

Original interface

To specify a relative time range for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose **Relative** in the upper left corner of the box. You can specify a time range in **Minutes**, **Hours**, **Days**, **Weeks**, or **Months**.

Set an absolute time range

New interface

To specify an absolute time range for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.
3. Choose **Custom**, and then select the **Absolute** tab in the upper left corner of the box. Use the calendar picker or text field boxes to specify a time range.
4. After you specify a time range, choose **Apply**.

Original interface

To specify an absolute time range for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose **Absolute** in the upper left corner of the box. Use the calendar picker or text field boxes to specify a time range.
4. After you specify a time range, choose **Apply**.

Set the time zone format

New interface

To specify the time zone for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1

hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **Custom** to set your own time range.

3. Choose **Custom**, and then choose the dropdown in the upper right corner of the box. You can change the time zone to **UTC** or **Local time zone**.
4. After you make your changes, choose **Apply**.

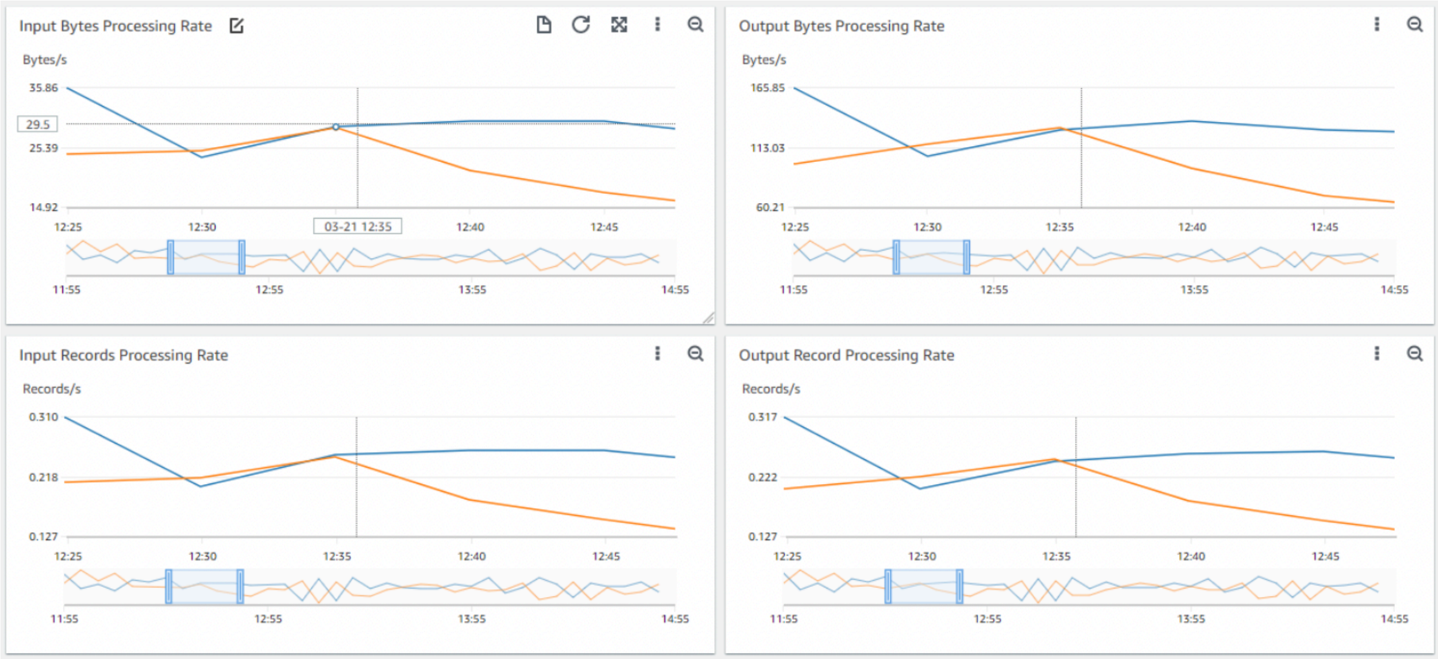
Original interface

To specify the time zone for a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. In the upper right corner of the screen, you can select one of the predefined time ranges, which span from 1 hour to 1 week (**1h**, **3h**, **12h**, **1d**, **3d**, or **1w**). Alternatively, you can choose **custom** to set your own time range.
3. Choose **custom**, and then choose the dropdown in the upper right corner of the box. You can change the time zone to **UTC** or **Local timezone**.

Zoom in on a line graph or stacked area graph

In the CloudWatch console, you can use the mini-map zoom feature to focus on sections of line graphs and stacked area graphs without changing between zoomed-in and zoomed-out views. For example, you can use the mini-map zoom feature to focus on a peak in a line graph, so that you can compare the spike against other metrics in your dashboard from the same timeline. The procedures in this section describe how to use the zoom feature.



In the preceding image, the zoom feature focuses on a spike in a line graph that's related to the input bytes processing rate while also showing other line graphs in the dashboard that focus on sections from the same timeline.

New interface

To zoom in on a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**.
3. Choose **Browse**, and then select a metric or metrics to graph.
4. Choose **Options**, and select **Line** under ***Widget type***.
5. Choose and drag on the area of the graph that you want to focus on, and then release the drag.
6. To reset the zoom, choose the **Reset zoom** icon, which looks like a magnifying glass with a minus (-) symbol inside.

Original interface

To zoom in on a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Metrics**, and then choose **All metrics**. .
3. Choose **All metrics**, and then select a metric to graph.
4. Choose **Graph options**. Under ***Widget type*** select **Line**.
5. Choose and drag on the area of the graph that you want to focus on, and then release the drag.
6. To reset the zoom, choose the **Reset zoom** icon, which looks like a magnifying glass with a minus (-) symbol inside.

> **Tip**
>
> If you already created a dashboard that contains a line graph or stacked area graph, you can go to the dashboard and begin using the zoom feature.

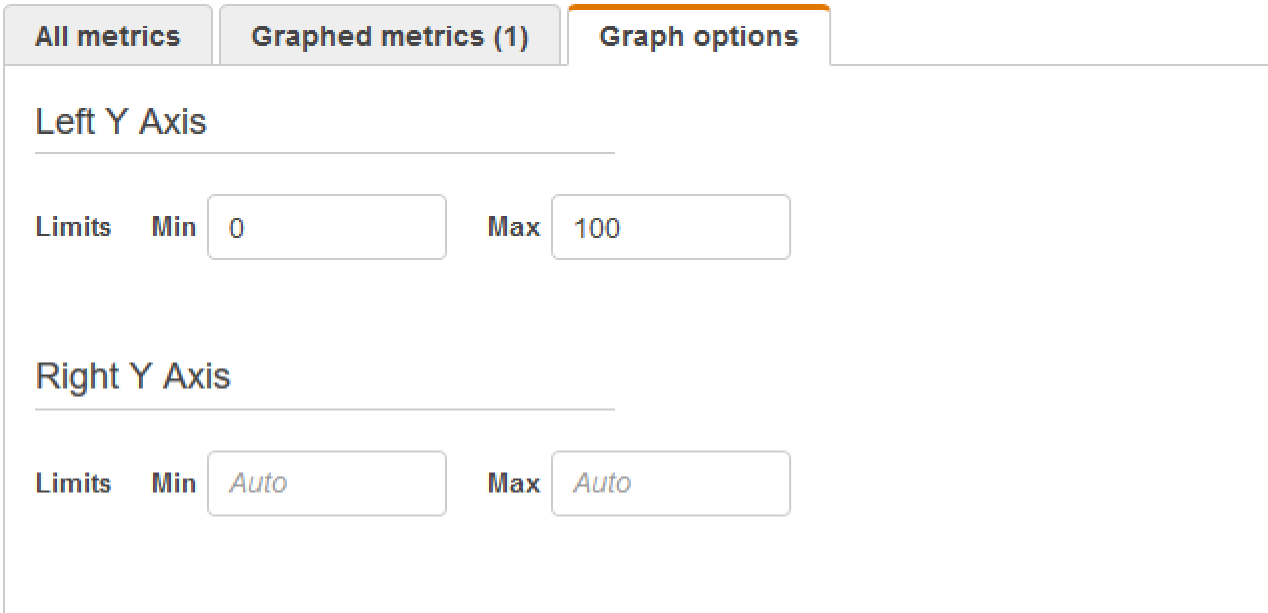
Modify the y-axis for a graph

You can set custom bounds for the y-axis on a graph to help you see the data better. For example, you can change the bounds on a `CPUUtilization` graph to 100 percent so that it's easy to see whether the CPU is low (the plotted line is near the bottom of the graph) or high (the plotted line is near the top of the graph).

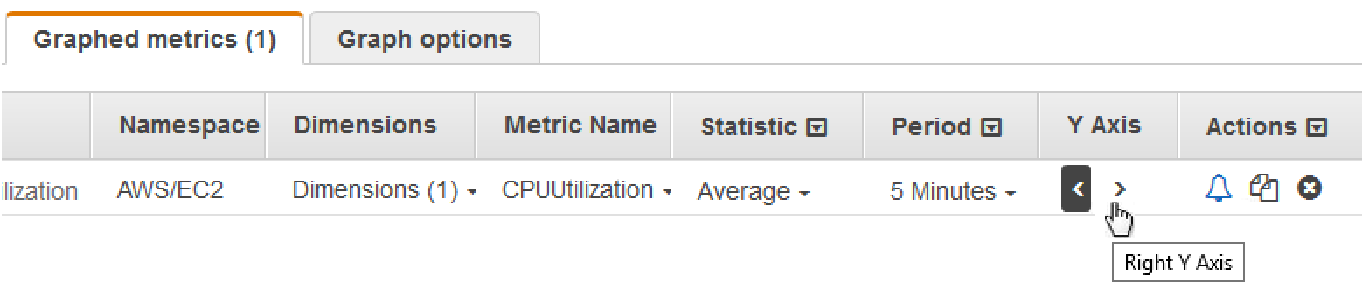
You can switch between two different y-axes for your graph. This is useful if the graph contains metrics that have different units or that differ greatly in their range of values.

To modify the y-axis on a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).
4. The **All metrics** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. On the **Graph options** tab, specify the **Min** and **Max** values for **Left Y Axis**. The value of **Min** can't be greater than the value of **Max**.



6. To create a second y-axis, specify the **Min** and **Max** values for **Right Y Axis**.
7. To switch between the two y-axes, choose the **Graphed metrics** tab. For **Y Axis**, choose **Left Y Axis** or **Right Y Axis**.



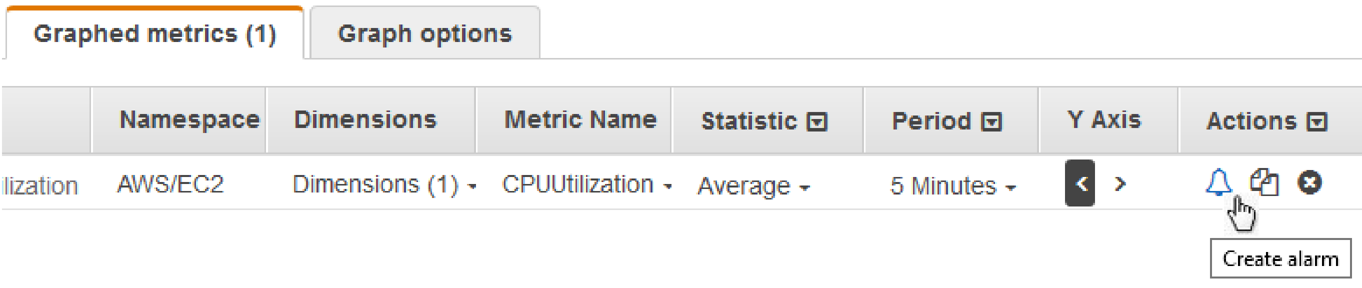
Create an alarm from a metric on a graph

You can graph a metric and then create an alarm from the metric on the graph, which has the benefit of populating many of the alarm fields for you.

To create an alarm from a metric on a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).

4. The **All metrics** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. To create an alarm for the metric, choose the **Graphed metrics** tab. For **Actions**, choose the alarm icon.



6. Under **Conditions**, choose **Static** or **Anomaly detection** to specify whether to use a static threshold or anomaly detection model for the alarm.

   Depending on your choice, enter the rest of the data for the alarm conditions.
7. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an alarm.
8. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
9. Choose **Next**.
10. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.
11. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.
12. When finished, choose **Next**.

13. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
14. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Using CloudWatch anomaly detection

When you enable *anomaly detection* for a metric, CloudWatch applies statistical and machine learning algorithms. These algorithms continuously analyze metrics of systems and applications, determine normal baselines, and surface anomalies with minimal user intervention.

The algorithms generate an anomaly detection model. The model generates a range of expected values that represent normal metric behavior.

You can enable anomaly detection using the Amazon Web Services Management Console, the Amazon CLI, Amazon CloudFormation, or the Amazon SDK. You can enable anomaly detection on metrics vended by Amazon and also on custom metrics. In an account set up as a monitoring account for CloudWatch cross-account observability, you can create anomaly detectors on metrics in source accounts in addition to metrics in the monitoring account.

You can use the model of expected values in two ways:

- Create anomaly detection alarms based on a metric's expected value. These types of alarms don't have a static threshold for determining alarm state. Instead, they compare the metric's value to the expected value based on the anomaly detection model.

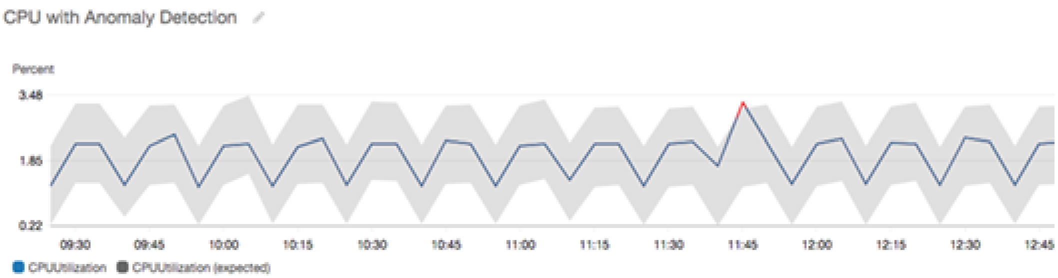
  You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or both.

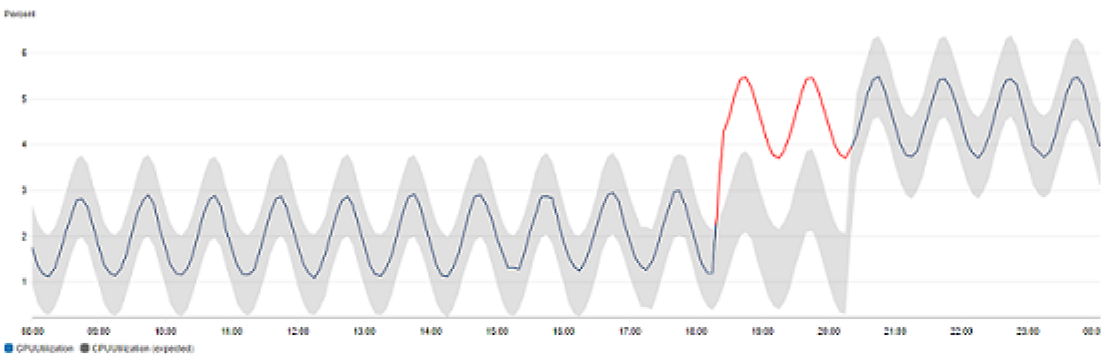
  For more information, see Create a CloudWatch alarm based on anomaly detection.
- When viewing a graph of metric data, overlay the expected values onto the graph as a band. This makes it visually clear which values in the graph are out of the normal range. For more information, see Creating a graph.

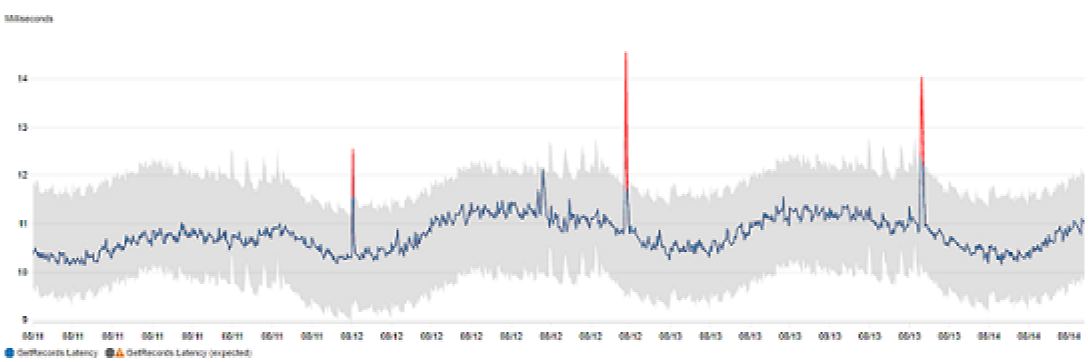
  You can also retrieve the upper and lower values of the model's band by using the `GetMetricData` API request with the `ANOMALY_DETECTION_BAND` metric math function. For more information, see GetMetricData.

In a graph with anomaly detection, the expected range of values is shown as a gray band. If the metric's actual value goes beyond this band, it is shown as red during that time.

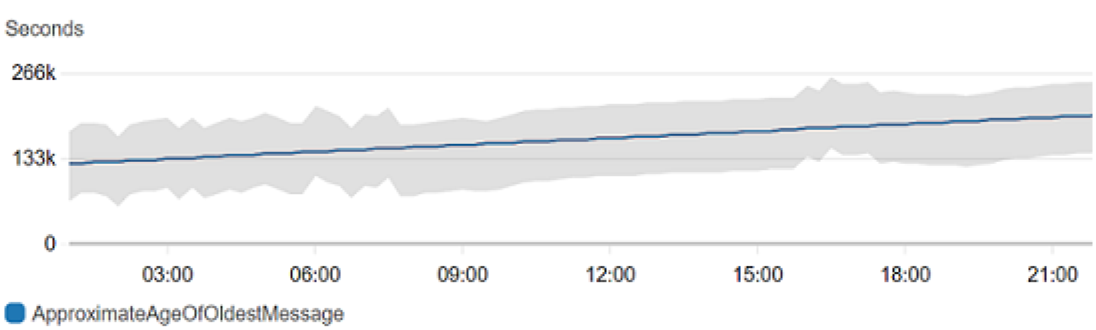
Anomaly detection algorithms account for the seasonality and trend changes of metrics. The seasonality changes could be hourly, daily, or weekly, as shown in the following examples.



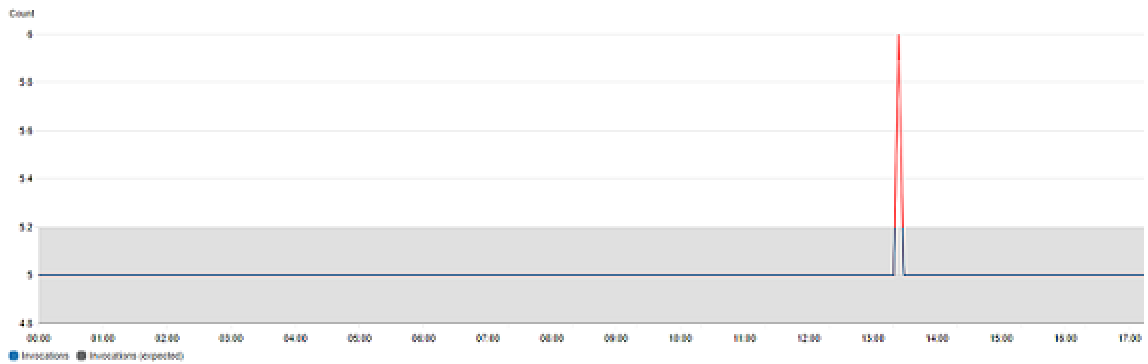




The longer-range trends could be downward or upward.



Anomaly detections also works well with metrics with flat patterns.



How CloudWatch anomaly detection works

When you enable anomaly detection for a metric, CloudWatch applies machine learning algorithms to the metric's past data to create a model of the metric's expected values. The model assesses both trends and hourly, daily, and weekly patterns of the metric. The algorithm trains on up to two weeks of metric data, but you can enable anomaly detection on a metric even if the metric does not have a full two weeks of data.

You specify a value for the anomaly detection threshold that CloudWatch uses along with the model to determine the "normal" range of values for the metric. A higher value for the anomaly detection threshold produces a thicker band of "normal" values.

The machine learning model is specific to a metric and a statistic. For example, if you enable anomaly detection for a metric using the `AVG` statistic, the model is specific to the `AVG` statistic.

When CloudWatch creates a model for many common metrics from Amazon services, it ensures that the band doesn’t extend outside of logical values. For example, the band for `MemoryUtilization` of an EC2 instance will stay between 0 and 100, and the bands tracking CloudFront `Requests`, which can't be negative, will never extend below zero.

After you create a model, CloudWatch anomaly detection continually evaluates the model and makes adjustments to it to ensure that it is as accurate as possible. This includes re-training the model to adjust if the metric values evolve over time or have sudden changes, and also includes predictors to improve the models of metrics that are seasonal, spiky, or sparse.

After you enable anomaly detection on a metric, you can choose to exclude specified time periods of the metric from being used to train the model. This way, you can exclude deployments or other unusual events from being used for model training, ensuring the most accurate model is created.

Using anomaly detection models for alarms incurs charges on your Amazon account. For more information, see [Amazon CloudWatch Pricing](#).

Anomaly detection on metric math

Anomaly detection on metric math is a feature that you can use to create anomaly detection alarms on the output metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands. The feature supports basic arithmetic functions, comparison and logical operators, and most other functions. For information about functions that are not supported, see Using metric math in the *Amazon CloudWatch User Guide*.

You can create anomaly detection models based on metric math expressions similar to how you already create anomaly detection models. From the CloudWatch console, you can apply anomaly detection to metric math expressions and select anomaly detection as a threshold type for these expressions.

> **Note**
>
> Anomaly detection on metric math only can be enabled and edited in the latest version of the metrics user interface. When you create anomaly detectors based on metric math expressions in the new version of the interface, you can view them in the old version, but not edit them.

For information about how to create, edit, and delete alarms and models for anomaly detection and metric math, see the following sections:

- Create a CloudWatch alarm based on anomaly detection
- Editing an anomaly detection model
- Deleting an anomaly detection model
- Creating a CloudWatch alarm based on a metric math expression

You also can create, delete, and discover anomaly detection models based on metric math expressions using the CloudWatch API with `PutAnomalyDetector`, `DeleteAnomalyDetector`, and `DescribeAnomalyDetectors`. For information about these API actions, see the following sections in the *Amazon CloudWatch API Reference*.

- PutAnomalyDetector

- DeleteAnomalyDetector
- DescribeAnomalyDetectors

For information about how anomaly detection alarms are priced, see Amazon CloudWatch pricing.

Using math expressions with CloudWatch metrics

Metric math enables you to query multiple CloudWatch metrics and use math expressions to create new time series based on these metrics. You can visualize the resulting time series on the CloudWatch console and add them to dashboards. Using Amazon Lambda metrics as an example, you could divide the `Errors` metric by the `Invocations` metric to get an error rate. Then add the resulting time series to a graph on your CloudWatch dashboard.

You can also perform metric math programmatically, using the `GetMetricData` API operation. For more information, see GetMetricData.

Add a math expression to a CloudWatch graph

You can add a math expression to a graph on your CloudWatch dashboard. Each graph is limited to using a maximum of 500 metrics and expressions, so you can add a math expression only if the graph has 499 or fewer metrics. This applies even if not all the metrics are displayed on the graph.

To add a math expression to a graph

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Create or edit a graph. There needs to be at least one metric in the graph.
3. Choose **Graphed metrics**.
4. Choose **Math expression**, **Start with empty expression**. A new line appears for the expression.
5. In the new line, under the **Details** column, enter the math expression. The tables in the **Metric Math Syntax and Functions** section list the functions that you can use in the expression.

   To use a metric or the result of another expression as part of the formula for this expression, use the value shown in the **Id** column: for example, **m1+m2** or **e1-MIN(e1)**.

   You can change the value of **Id**. It can include numbers, letters, an underscore, and must start with a lowercase letter. Changing the value of **Id** to a more meaningful name can also make a graph easier to understand;for example, changing **m1** and **m2** to **errors** and **requests**.

> **Tip**
>
> Choose the down arrow next to **Math Expression** to see a list of supported functions, which you can use when creating your expression.

6. For the **Label** column of the expression, enter a name that describes what the expression is calculating.

   If the result of an expression is an array of time series, each of those time series is displayed on the graph with a separate line, with different colors. Immediately under the graph is a legend for each line in the graph. For a single expression that produces multiple time series, the legend captions for those time series are in the format ***`Expression-Label Metric-Label`***. For example, if the graph includes a metric with a label of **Errors** and an expression **FILL(METRICS(), 0)** that has a label of **Filled With 0:**, one line in the legend would be **Filled With 0: Errors**. To have the legend show only the original metric labels, set *`Expression-Label`* to be empty.

   When one expression produces an array of time series on the graph, you can't change the colors used for each of those time series.

7. After you have added the desired expressions, you can simplify the graph by hiding some of the original metrics. To hide a metric or expression, clear the check box to the left of the **Id** field.

Metric math syntax and functions

The following sections explain the functions available for metric math. All functions must be written in uppercase letters (such as **AVG**), and the **Id** field for all metrics and math expressions must start with a lowercase letter.

The final result of any math expression must be a single time series or an array of time series. Some functions produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the **AVG** of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function **m1-AVG(m1)** to display a time series of the difference between each individual data point and the average value in the time series.

Data type abbreviations

Some functions are valid for only certain types of data. The abbreviations in the following list are used in the tables of functions to represent the types of data supported for each function:

- **S** represents a scalar number, such as 2, -5, or 50.25.
- **TS** is a time series (a series of values for a single CloudWatch metric over time): for example, the `CPUUtilization` metric for instance `i-1234567890abcdef0` over the last three days.
- **TS[]** is an array of time series, such as the time series for multiple metrics.
- **String[]** is an array of strings.

The METRICS() function

The **METRICS()** function returns all the metrics in the request. Math expressions aren't included.

You can use **METRICS()** within a larger expression that produces a single time series or an array of time series. For example, the expression **SUM(METRICS())** returns a time series (TS) that is the sum of the values of all the graphed metrics. **METRICS()/100** returns an array of time series, each of which is a time series showing each data point of one of the metrics divided by 100.

You can use the **METRICS()** function with a string to return only the graphed metrics that contain that string in their **Id** field. For example, the expression **SUM(METRICS("errors"))** returns a time series that is the sum of the values of all the graphed metrics that have ‘errors’ in their **Id** field. You can also use **SUM([METRICS(“4xx”), METRICS(“5xx”)])** to match multiple strings.

Basic arithmetic functions

The following table lists the basic arithmetic functions that are supported. Missing values in a time series are treated as 0. If the value of a data point causes a function to attempt to divide by zero, the data point is dropped.

Operation	Arguments	Examples
Arithmetic operators: + - * / ^	S, S	PERIOD(m1)/60
	S, TS	**5 * m1**
	TS, TS	**m1 - m2**

Operation	Arguments	Examples
	S, TS[] TS, TS[]	**SUM(100/[m1, m2])** **AVG(METRICS())** **METRICS()*100**
Unary subtraction -	S TS TS[]	**-5*m1** **-m1** **SUM(-[m1, m2])**

Comparison and logical operators

You can use comparison and logical operators with either a pair of time series or a pair of single scalar values. When you use a comparison operator with a pair of time series, the operators return a time series where each data point is either 0 (false) or 1 (true). If you use a comparison operator on a pair of scalar values, a single scalar value is returned, either 0 or 1.

When comparison operators are used between two time series, and only one of the time series has a value for a particular time stamp, the function treats the missing value in the other time series as **0**.

You can use logical operators in conjunction with comparison operators, to create more complex functions.

The following table lists the operators that are supported.

Type of operator	Supported operators
Comparison operators	== != <= >= <

Type of operator	Supported operators
	>
Logical operators	AND or && OR or ||

To see how these operators are used, suppose we have two time series: **metric1** has values of `[30, 20, 0, 0]` and **metric2** has values of `[20, -, 20, -]` where `-` indicates that there is no value for that timestamp.

Expression	Output
(metric1 < metric2)	**0, 0, 1, 0**
(metric1 >= 30)	**1, 0, 0, 0**
(metric1 > 15 AND metric2 > 15)	**1, 0, 0, 0**

Functions supported for metric math

The following table describes the functions that you can use in math expressions. Enter all functions in uppercase letters.

The final result of any math expression must be a single time series or an array of time series. Some functions in tables in the following sections produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the **AVG** of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function **m1-AVG(m1)** to display a time series of the difference between each individual data point and the average value of that data point.

In the following table, every example in the **Examples** column is an expression that results in a single time series or an array of time series. These examples show how functions that return scalar numbers can be used as part of a valid expression that produces a single time series.

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
ABS	TS TS[]	TS TS[]	Returns the absolute value of each data point.	**ABS(m1-m2)** **MIN(ABS([m1, m2]))** **ABS(METRICS())**	✓
ANOMALY_DETECTION_BAND	TS TS, S	TS[]	Returns an anomaly detection band for the specified metric. The band consists of two time series, one representing the upper limit of the "normal" expected value of the metric, and the other representing the lower limit. The function can take two arguments. The first is the ID of the metric to create the band for. The second argument is the number of standard deviations to use for the band. If you don't specify this argument, the default of 2 is used. For more information, see [Using CloudWatch anomaly detection]().	**ANOMALY_DETECTION_BAND(m1)** **ANOMALY_DETECTION_BAND(m1,4)**	

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
AVG	TS TS[]	S TS	The **AVG** of a single time series returns a scalar representing the average of all the data points in the metric. The **AVG** of an array of time series returns a single time series. Missing values are treated as 0. **Note** We recommend that you do not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `AVG(m2)`. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher	**SUM([m1,m2])/AVG(m2)** **AVG(METRICS())**	✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested. To use this function with alarms, especially alarms that have Auto Scaling actions, we recommend that you set the alarm to use M out of N datapoints, where M < N.		
CEIL	TS TS[]	TS TS[]	Returns the ceiling of each metric. The ceiling is the smallest integer greater than or equal to each value.	**CEIL(m1)** **CEIL(METRICS())** **SUM(CEIL(METRICS()))**	✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
DATAPOINT_COUNT	TS TS[]	S TS	Returns a count of the data points that reported values. This is useful for calculating averages of sparse metrics. **Note** We recommend that you do not use this function in CloudWatch alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when	**SUM(m1) / DATAPOINT_COUNT(m1)** **DATAPOINT_COUNT(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			extra data is requested.		

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
DB_PERF_INSIGHTS	String, String, String String, String, String[]	TS (if given a single string) TS[] (if given an array of strings)	Returns Performance Insights Counter metrics for databases such as Amazon Relational Database Service and Amazon DocumentDB (with MongoDB compatibility). This function returns the same amount of data that you can get by directly querying the Performance Insights APIs. You can use these metrics in CloudWatch for graphing and creating alarms. **Important** When you use this function, you must specify the Unique Database Resource ID of the database. This is different than	**DB_PERF_INSIGHTS('RDS', 'db-ABCDEFGHIJKLMNOPQRSTUVWXY1', 'os.cpuUtilization.user.avg')** **DB_PERF_INSIGHTS('DOCDB, 'db-ABCDEFGHIJKLMNOPQRSTUVWXY1', ['os.cpuUtilization.idle.avg', 'os.cpuUtilization.user.max'])**	

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			the database identifier. To find the database resource ID in the Amazon RDS console, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is displayed in the **Configuration** section. **DB_PERF_INSIGHTS** also brings in the `DBLoad` metric at sub-minute intervals. Performance Insights metrics retrieved with this function are not stored in CloudWatch. Therefore, some CloudWatch features such as cross-acc		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			ount observability, anomaly detection, metric streams, metrics explorer, and Metric Insights don't work with Performance Insights metrics that you retrieve with **DB_PERF_INSIGHTS**. A single request using the **DB_PERF_I NSIGHTS** function can retrieve the following numbers of data points. • 1080 data points for high-resolution periods (1s, 10s, 30s) • 1440 data points for standard-resolution periods (1m, 5m, 1hr, 1d) The **DB_PERF_I NSIGHTS** function supports only the following period lengths: • 1 second		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			• 10 seconds • 30 seconds • 1 minute • 5 minutes • 1 hour • 1 day For more information about Amazon RDS Performance Insights counter metrics, see [Performance Insights counter metrics](#). For more informati on about Amazon DocumentDB Performance Insights counter metrics, see [Performance Insights for counter metrics](#). **Note** High-resolution metrics with sub-minute granularity retrieved by **DB_PERF_I**		

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			NSIGHTS are only applicable to the **DBLoad** metric, or for operating system metrics if you have enabled Enhanced Monitoring at a higher resolution. For more information about Amazon RDS enhanced monitoring, see [Monitoring OS metrics with Enhanced Monitoring](). You can create a high-resolution alarm using the **DB_PERF_INSIGHTS** function for a maximum time range of three hours. You can use the CloudWatc		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			h console to graph metrics retrieved with the **DB_PERF_I NSIGHTS** function for any time range.		
DIFF	TS TS[]	TS TS[]	Returns the difference between each value in the time series and the preceding value from that time series.	**DIFF(m1)**	✓
DIFF_TIME	TS TS[]	TS TS[]	Returns the differenc e in seconds between the timestamp of each value in the time series and the timestamp of the preceding value from that time series.	**DIFF_TIME(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
FILL	TS, [S | REPEAT | LINEAR] TS[], [TS | S | REPEAT | LINEAR]	TS TS[]	Fills the missing values of a time series. There are several options for the values to use as the filler for missing values: • You can specify a value to use as the filler value. • You can specify a metric to use as the filler value. • You can use the **REPEAT** keyword to fill missing values with the most recent actual value of the metric before the missing value. • You can use the **LINEAR** keyword to fill the missing values with values that create a linear interpolation between the values at the beginning and the end of the gap.	**FILL(m1,10)** **FILL(METRICS(), 0)** **FILL(METRICS(), m1)** **FILL(m1, MIN(m1))** **FILL(m1, REPEAT)** **FILL(METRICS(), LINEAR)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			Note When you use this function in an alarm, you can encounter an issue if your metrics are being published with a slight delay, and the most recent minute never has data. In this case, **FILL** replaces that missing data point with the requested value. That causes the latest data point for the metric to always be the FILL value, which can result in the alarm being stuck in either OK state or ALARM state. You can		

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			work around this by using a M out of N alarm. For more information, see [Evaluating an alarm]().		
FIRST **LAST**	TS[]	TS	Returns the first or last time series from an array of time series. This is useful when used with the **SORT** function. It can also be used to get the high and low thresholds from the **ANOMALY_DETECTION_BAND** function.	**IF(FIRST(SORT(METRICS(), AVG, DESC))>100, 1, 0)** Looks at the top metric from an array, which is sorted by AVG. It then returns a 1 or 0 for each data point, depending on whether that data point value is more than 100. **LAST(ANOMALY_DETECTION_BAND(m1))** returns the upper bound of the anomaly prediction band.	✓
FLOOR	TS TS[]	TS TS[]	Returns the floor of each metric. The floor is the largest integer less than or equal to each value.	**FLOOR(m1)** **FLOOR(METRICS())**	✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
IF	**IF** expression	TS	Use **IF** along with a comparison operator to filter out data points from a time series, or create a mixed time-series composed of multiple collated time series. For more information, see Using IF expressions.	For examples, see Using IF expressions.	✓
INSIGHT_RULE_METRIC	**INSIGHT_RULE_METRIC(ruleName, metricName)**	TS	Use **INSIGHT_RULE_METRIC** to extract statistics from a rule in Contributor Insights. For more information, see Graphing metrics generated by rules in CloudWatch.		
LAMBDA	**LAMBDA(LambdaFunctionName [, optional-arg]*)**	TS TS[]	Calls a Lambda function to query metrics from a data source that is not CloudWatch. For more information, see How to pass arguments to your Lambda function.		

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
LOG	TS TS[]	TS TS[]	The **LOG** of a time series returns the natural logarithm value of each value in the time series.	**LOG(METRICS())**	✓
LOG10	TS TS[]	TS TS[]	The **LOG10** of a time series returns the base-10 logarithm value of each value in the time series.	**LOG10(m1)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
MAX	TS TS[]	S TS	The **MAX** of a single time series returns a scalar representing the maximum value of all data points in the metric. If you input an array of time series, the **MAX** function creates and returns a time series that consists of the highest value for each data point, among the time series that were used as the input. **Note** We recommend that you do not use this function in CloudWatc h alarms if you want the function to return a scalar. For example, `MAX(m2)` Whenever an	**MAX(m1)/m1** **MAX(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		
METRIC_CO UNT	TS[]	S	Returns the number of metrics in the time series array.	**m1/METRIC _COUNT(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
METRICS	null string	TS[]	The **METRICS()** function returns all CloudWatch metrics in the request. Math expressions aren't included. You can use **METRICS()** within a larger expression that produces a single time series or an array of time series. You can use the **METRICS()** function with a string to return only the graphed metrics that contain that string in their **Id** field. For example, the expression **SUM(METRICS("errors"))** returns a time series that is the sum of the values of all the graphed metrics that have 'errors' in their **Id** field. You can also use **SUM([METRICS("4xx"), METRICS("5xx")])** to match multiple strings.	**AVG(METRICS())** **SUM(METRICS("errors"))**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
MIN	TS TS[]	S TS	The **MIN** of a single time series returns a scalar representing the minimum value of all data points in the metric. If you input an array of time series, the **MIN** function creates and returns a time series that consists of the lowest value for each data point, among the time series that were used as the input. If you input an array of time series, the **MIN** function creates and returns a time series that consists of the lowest value for each data point, among the time series that were used as the input. **Note** We recommend that you do	**m1-MIN(m1)** **MIN(METRICS())**	✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			not use this function in CloudWatch alarms if you want the function to return a scalar. For example, `MIN(m2)` Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
MINUTE **HOUR** **DAY** **DATE** **MONTH** **YEAR** **EPOCH**	TS	TS	These functions take the period and range of the time series and return a new non-spars e time series where each value is based on its timestamp. • **MINUTE** returns a non-sparse time series of integers between 0 and 59 that represent the UTC minute of each timestamp in the original time series. • **HOUR** returns a non-sparse time series of integers between 0 and 23 that represent the UTC hour of each timestamp in the original time series. • **DAY** returns a non-sparse time series of integers between 1 and 7 that represent the UTC day of the week of each timestamp in the	**MINUTE(m1)** **IF(DAY(m1)<6,m1)** returns metrics only from weekdays, Monday to Friday. **IF(MONTH(m1) == 4,m1)** returns only metrics published in April.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			original time series. 1 represents Monday and 7 represents Sunday. • **DATE** returns a non-sparse time series of integers between 1 and 31 that represent the UTC day of the month of each timestamp in the original time series. • **MONTH** returns a non-sparse time series of integers between 1 and 12 that represent the UTC month of each timestamp in the original time series. 1 represents January and 12 represents December. • **YEAR** returns a non-sparse time series of integers that represent the UTC year of each timestamp in the original time series.		

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			• **EPOCH** returns a non-sparse time series of integers that represent the UTC time in seconds since the Epoch of each timestamp in the original time series. The Epoch is January 1, 1970.		
PERIOD	TS	S	Returns the period of the metric in seconds. Valid input is metrics, not the results of other expressions.	**m1/PERIOD(m1)**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
RATE	TS TS[]	TS TS[]	Returns the rate of change of the metric per second. This is calculated as the difference between the latest data point value and the previous data point value, divided by the time difference in seconds between the two values. **Important** Setting alarms on expressio ns that use the RATE function on metrics with sparse data can behave unpredictably, because the range of data points fetched when evaluatin g the alarm can vary based on when the data	**RATE(m1)** **RATE(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			points were last published.		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
REMOVE_EMPTY	TS[]	TS[]	Removes any time series that have no data points from an array of time series. The result is an array of time series where each time series contains at least one data point. **Note** We recommend that you do not use this function in CloudWatch alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts	**REMOVE_EMPTY(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
RUNNING_S UM	TS TS[]	TS TS[]	Returns a time series with the running sum of the values in the original time series. **Note** We recommend that you do not use this function in CloudWatc h alarms. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.	**RUNNING_S UM([m1,m2])**	✓

Function	Argument	Return type*	Description	Examples	Supported for cross-account?
SEARCH	Search expression	One or more TS	Returns one or more time series that match a search criteria that you specify. The **SEARCH** function enables you to add multiple related time series to a graph with one expression. The graph is dynamically updated to include new metrics that are added later and match the search criteria. For more information, see [Use search expressions in graphs](). You can't create an alarm based on a **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series. If you are signed in to a monitoring account in CloudWatch cross-		✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			account observability, the **SEARCH** function finds metrics in the source accounts and the monitoring account.		
SERVICE_QUOTA	TS that is a usage metric	TS	Returns the service quota for the given usage metric. You can use this to visualize how your current usage compares to the quota, and to set alarms that warn you when you approach the quota. For more information, see [Amazon usage metrics]().		✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
SLICE	(TS[], S, S) or (TS[], S)	TS[] TS	Retrieves part of an array of time series. This is especially useful when combined with **SORT**. For example, you can exclude the top result from an array of time series. You can use two scalar arguments to define the set of time series that you want returned. The two scalars define the start (inclusive) and end (exclusive) of the array to return. The array is zero-indexed, so the first time series in the array is time series 0. Alternatively, you can specify just one value, and CloudWatch returns all time series starting with that value.	**SLICE(SORT(METRICS (), SUM, DESC), 0, 10)** returns the 10 metrics from the array of metrics in the request that have the highest SUM value. **SLICE(SORT(METRICS (), AVG, ASC), 5)** sorts the array of metrics by the AVG statistic, then returns all the time series except for the 5 with the lowest AVG.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
SORT	(TS[], FUNCTI SORT_C R) (TS[], FUNCTI SORT_C R, S)	TS[]	Sorts an array of time series according to the function you specify. The function you use can be **AVG**, **MIN**, **MAX**, or **SUM**. The sort order can be either **ASC** for ascending (lowest values first) or **DESC** to sort the higher values first. You can optionall y specify a number after the sort order which acts as a limit. For example, specifying a limit of 5 returns only the top 5 time series from the sort. When this math function is displayed on a graph, the labels for each metric in the graph are also sorted and numbered.	**SORT(METRICS(), AVG, DESC, 10)** calculates the average value of each time series, sorts the time series with the highest values at the beginning of the sort, and returns only the 10 time series with the highest averages. **SORT(METRICS(), MAX, ASC)** sorts the array of metrics by the MAX statistic, then returns all of them in ascending order.	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
STDDEV	TS TS[]	S TS	The **STDDEV** of a single time series returns a scalar representing the standard deviation of all data points in the metric. The **STDDEV** of an array of time series returns a single time series. **Note** We recommend that you do not use this function in CloudWatc h alarms if you want the function to return a scalar. For example, `STDDEV(m2)` Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data	**m1/STDDEV(m1)** **STDDEV(METRICS())**	✓

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
			points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		

Function	Argume	Return type*	Description	Examples	Supported for cross-acc ount?
SUM	TS TS[]	S TS	The **SUM** of a single time series returns a scalar representing the sum of the values of all data points in the metric. The **SUM** of an array of time series returns a single time series. **Note** We recommend that you do not use this function in CloudWatc h alarms if you want the function to return a scalar. For example, `SUM(m1)`. Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data	**SUM(METRICS())/SUM (m1)** **SUM([m1,m2])** **SUM(METRICS("error s"))/SUM(METRICS(" requests"))*100**	✓

Function	Arguments	Return type*	Description	Examples	Supported for cross-account?
			points than the number specified as Evaluation Periods. This function acts differently when extra data is requested.		
TIME_SERIES	S	TS	Returns a non-sparse time series where every value is set to a scalar argument.	**TIME_SERIES(MAX(m1))** **TIME_SERIES(5*AVG(m1))** **TIME_SERIES(10)**	✓

*Using a function that returns only a scalar number is not valid, as all final results of expressions must be a single time series or an array of time series. Instead, use these functions as part of a larger expression that returns a time series.

Using IF expressions

Use **IF** along with a comparison operator to filter out data points from a time series, or create a mixed time-series composed of multiple collated time series.

IF uses the following arguments:

```
IF(condition, trueValue, falseValue)
```

The condition evaluates to FALSE if the value of the condition data point is 0, and to TRUE if the value of the condition is any other value, whether that value is positive or negative. If the condition is a time series, it is evaluated separately for every timestamp.

The following lists the valid syntax's. For each of these syntax's, the output is a single time series.

- **IF(TS *`Comparison Operator`* S, S | TS, *S* / *TS*)**

> **Note**
>
> If the `TS comparison operator S` is TRUE but `metric2` doesn't have a corresponding data point, the output will be 0.

- **IF(TS, TS, *TS*)**
- **IF(TS, S, *TS*)**
- **IF(TS, TS, S)**
- **IF(TS, S, S)**
- **IF(S, TS, *TS*)**

The following sections provide more details and examples for these syntax's.

IF(TS *`Comparison Operator`* S, scalar2 | metric2, scalar3 | metric3)

The corresponding output time series value:

- has the value of **scalar2** or **metric2**, if **TS** *`Comparison Operator`* **S** is TRUE
- has the value of **scalar3** or **metric3**, if **TS** *`Comparison Operator`* **S** is FALSE
- has the value of **0** if the **TS** *`Comparison Operator`* is TRUE and the corresponding data point in **metric2** doesn't exist.
- has the value of **0** if the **TS** *`Comparison Operator`* is FALSE and the corresponding data point in **metric3** doesn't exist.
- is an empty time series, if the corresponding data point of does not exist in **metric3**, or if **scalar3/metric3** is omitted from the expression

IF(metric1, metric2, *metric3*)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **metric2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **metric3**, if the corresponding data point of **metric1** is FALSE.
- has the value of **0**, if the corresponding data point of **metric1** is TRUE and the corresponding data point does not exist in **metric2**.
- is dropped, if the corresponding data point of **metric1** is FALSE and the corresponding data point does not exist in **metric3**
- is dropped, if the corresponding data point of **metric1** is FALSE and **metric3** is omitted from the expression.
- is dropped, if the corresponding data point of **metric1** is missing.

The following table shows an example for this syntax.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**
(metric2)	**[30, -, 0, 0, 30]**
(metric3)	**[0, 0, 20, -, 20]**
IF(metric1, metric2, metric3)	**[30, 0, 20, 0, -]**

IF(metric1, scalar2, metric3)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **scalar2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **metric3**, if the corresponding data point of **metric1** is FALSE.
- is dropped, if the corresponding data point of **metric1** is FALSE and the corresponding data point does not exist on **metric3**, or if **metric3** is omitted from the expression.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**

Metric or function	Values
scalar2	**5**
(metric3)	**[0, 0, 20, -, 20]**
IF(metric1, scalar2, metric3)	**[5, 5, 20, -, -]**

IF(metric1, metric2, scalar3)

For each data point of **metric1**, the corresponding output time series value:

- has the value of **metric2**, if the corresponding data point of **metric1** is TRUE.
- has the value of **scalar3**, if the corresponding data point of **metric1** is FALSE.
- has the value of **0**, if the corresponding data point of **metric1** is TRUE and the corresponding data point does not exist in **metric2**.
- is dropped if the corresponding data point in **metric1** does not exist.

Metric or function	Values
(metric1)	**[1, 1, 0, 0, -]**
(metric2)	**[30, -, 0, 0, 30]**
scalar3	**5**
IF(metric1, metric2, scalar3)	**[30, 0, 5, 5, -]**

IF(scalar1, metric2, *metric3*)

The corresponding output time series value:

- has the value of **metric2**, if **scalar1** is TRUE.
- has the value of **metric3**, if **scalar1** is FALSE.
- is an empty time series, if **metric3** is omitted from the expression.

Use case examples for IF expressions

The following examples illustrate the possible uses of the **IF** function.

- To display only the low values of a metric:

  IF(metric1<400, metric1)

- To change each data point in a metric to one of two values, to show relative highs and lows of the original metric:

  IF(metric1<400, 10, 2)

- To display a 1 for each timestamp where latency is over the threshold, and display a 0 for all other data points:

  IF(latency>threshold, 1, 0)

Use metric math with the GetMetricData API operation

You can use `GetMetricData` to perform calculations using math expressions, and also retrieve large batches of metric data in one API call. For more information, see GetMetricData.

Anomaly detection on metric math

Anomaly detection on metric math is a feature that you can use to create anomaly detection alarms on single metrics and the outputs of metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands. The feature supports basic arithmetic functions, comparison and logical operators, and most other functions.

Anomaly detection on metric math doesn't support the following functions:

- Expressions that contain more than one **ANOMALY_DETECTION_BAND** in the same line.
- Expressions that contain more than 10 metrics or math expressions.
- Expressions that contain the **METRICS** expression.
- Expressions that contain the **SEARCH** function.
- Expressions that use the **DP_PERF_INSIGHTS** function.
- Expressions that use metrics with different periods.
- Expressions that use periods longer than one hour as input.

- Expressions that use high-resolution metrics as input.

For more information about this feature, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

Use search expressions in graphs

Search expressions are a type of math expression that you can add to CloudWatch graphs. Search expressions enable you to quickly add multiple related metrics to a graph. They also enable you to create dynamic graphs that automatically add appropriate metrics to their display, even if those metrics don't exist when you first create the graph.

For example, you can create a search expression that displays the `AWS/EC2 CPUUtilization` metric for all instances in the Region. If you later launch a new instance, the `CPUUtilization` of the new instance is automatically added to the graph.

When you use a search expression in a graph, the search finds the search expression in metric names, namespaces, dimension names, and dimension values. You can use Boolean operators for more complex and powerful searches. A search expression can find only metrics that have reported data within the past two weeks.

You can't create an alarm based on the **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series.

If you are using a monitoring account in CloudWatch cross-account observability, your search expressions can find metrics in the source accounts linked to that monitoring account.

Topics

CloudWatch search expression syntax

A valid search expression has the following format.

```
SEARCH(' {Namespace, DimensionName1, DimensionName2, ...} SearchTerm', 'Statistic')
```

For example:

```
SEARCH('{AWS/EC2,InstanceId} MetricName="CPUUtilization"', 'Average')
```

- The first part of the query after the word `SEARCH`, enclosed in curly braces, is the *metric schema* to be searched. The metric schema contains a metric namespace and one or more dimension names. Including a metric schema in a search query is optional. If specified, the metric schema must contain a namespace and can optionally contain one or more dimension names that are valid in that namespace.

  You don't need to use quote marks inside the metric schema unless a namespace or dimension name includes spaces or non-alphanumeric characters. In that case, you must enclose the name that contains those characters with double quotes.
- The `SearchTerm` is also optional, but a valid search must contain either the metric schema, the `SearchTerm`, or both. The `SearchTerm` usually contains one or more account IDs, metric names or dimension values. The `SearchTerm` can include multiple terms to search for, by both partial match and exact match. It can also contain Boolean operators.

  Using an account ID in a `SearchTerm` works only in accounts that are set up as monitoring accounts for CloudWatch cross-account observability. The syntax for an account ID in `SearchTerm` is `:aws.AccountId = `*444455556666*. You can also use `'LOCAL'` to specify the monitoring account itself: `:aws.AccountId = 'LOCAL'`

  For more information, see CloudWatch cross-account observability.

  The `SearchTerm` can include one or more designators, such as `MetricName=` as in this example, but using designators isn't required.

  The metric schema and `SearchTerm` must be enclosed together in a pair of single quote marks.
- The `Statistic` is the name of any valid CloudWatch statistic. It must be enclosed by single quotes. For more information, see Statistics.

The preceding example searches the `AWS/EC2` namespace for any metrics that have `InstanceId` as a dimension name. It returns all `CPUUtilization` metrics that it finds, with the graph showing the `Average` statistic.

A search expression can find only metrics that have reported data within the past two weeks.

Search expression limits

The maximum search expression query size is 1024 characters. You can have as many as 100 search expressions on one graph. A graph can display as many as 500 time series.

CloudWatch search expressions: Tokenization

When you specify a `SearchTerm`, the search function searches for *tokens*, which are substrings that CloudWatch automatically generates from full metric names, dimension names, dimension values, and namespaces. CloudWatch generates tokens distinguished by the camel-case capitalization in the original string. Numeric characters also serve as the start of new tokens, and non-alphanumeric characters serve as delimiters, creating tokens before and after the non-alphanumeric characters.

A continuous string of the same type of token delimiter character results in one token.

All generated tokens are in lowercase. The following table shows some examples of tokens generated.

Original string	Tokens generated
CustomCount1	`customcount1` , `custom`, `count`, `1`
SDBFailure	`sdbfailure` , `sdb`, `failure`
Project2-trial333	`project2trial333` , `project`, `2`, `trial`, `333`

CloudWatch search expressions: Partial matches

When you specify a `SearchTerm`, the search term is also tokenized. CloudWatch finds metrics based on partial matches, which are matches of a single token generated from the search term to a single token generated from a metric name, namespace, dimension name, or dimension value.

Partial match searches to match a single token are case insensitive. For example, using any of the following search terms can return the `CustomCount1` metric:

- `count`

- `Count`
- `COUNT`

However, using `couNT` as a search term doesn't find `CustomCount1` because the capitalization in the search term `couNT` is tokenized into `cou` and `NT`.

Searches can also match composite tokens, which are multiple tokens that appear consecutively in the original name. To match a composite token, the search is case sensitive. For example, if the original term is `CustomCount1`, searches for `CustomCount` or `Count1` are successful, but searches for `customcount` or `count1` aren't.

CloudWatch search expressions: Exact matches

You can define a search to find only exact matches of your search term by using double quotes around the part of the search term that requires an exact match. These double-quotes are enclosed in the single-quotes used around the entire search term. For example, **`SEARCH(' {MyNamespace}, "CustomCount1" ', 'Maximum')`** finds the exact string `CustomCount1` if it exists as a metric name, dimension name, or dimension value in the namespace named `MyNamespace`. However, the searches **`SEARCH(' {MyNamespace}, "customcount1" ', 'Maximum')`** or **`SEARCH(' {MyNamespace}, "Custom" ', 'Maximum')`** do not find this string.

You can combine partial match terms and exact match terms in a single search expression. For example, **`SEARCH(' {AWS/NetworkELB, LoadBalancer} "ConsumedLCUs" OR flow ', 'Maximum')`** returns the Elastic Load Balancing metric named `ConsumedLCUs` as well as all Elastic Load Balancing metrics or dimensions that contain the token `flow`.

Using exact match is also a good way to find names with special characters, such as non-alphanumeric characters or spaces, as in the following example.

```
SEARCH(' {"My Namespace", "Dimension@Name"}, "Custom:Name[Special_Characters" ',
 'Maximum')
```

CloudWatch search expressions: Excluding a metric schema

All examples shown so far include a metric schema, in curly braces. Searches that omit a metric schema are also valid.

For example, **SEARCH(' "CPUUtilization" ', 'Average')** returns all metric names, dimension names, dimension values, and namespaces that are an exact match for the string `CPUUtilization`. In the Amazon metric namespaces, this can include metrics from several services including Amazon EC2, Amazon ECS, SageMaker AI, and others.

To narrow this search to only one Amazon service, the best practice is to specify the namespace and any necessary dimensions in the metric schema, as in the following example. Although this narrows the search to the `AWS/EC2` namespace, it would still return results of other metrics if you have defined `CPUUtilization` as a dimension value for those metrics.

```
SEARCH(' {AWS/EC2, InstanceType} "CPUUtilization" ', 'Average')
```

Alternatively you could add the namespace in the `SearchTerm` as in the following example. But in this example, the search would match any `AWS/EC2` string, even if it was a custom dimension name or value.

```
SEARCH(' "AWS/EC2" MetricName="CPUUtilization" ', 'Average')
```

CloudWatch search expressions: Specifying property names in the search

The following exact match search for `"CustomCount1"` returns all metrics with exactly that name.

```
SEARCH(' "CustomCount1" ', 'Maximum')
```

But it also returns metrics with dimension names, dimension values, or namespaces of `CustomCount1`. To structure your search further, you can specify the property name of the type of object that you want to find in your searches. The following example searches all namespaces and returns metrics named `CustomCount1`.

```
SEARCH(' MetricName="CustomCount1" ', 'Maximum')
```

You can also use namespaces and dimension name/value pairs as property names, as in the following examples. The first of these examples also illustrates that you can use property names with partial match searches as well.

```
SEARCH(' InstanceType=micro ', 'Average')
```

```
SEARCH(' InstanceType="t2.micro" Namespace="AWS/EC2" ', 'Average')
```

CloudWatch search expressions: Non-alphanumeric characters

Non-alphanumeric characters serve as delimiters, and mark where the names of metrics, dimensions, namespaces, and search terms are to be separated into tokens. When terms are tokenized, non-alphanumeric characters are stripped out and don't appear in the tokens. For example, `Network-Errors_2` generates the tokens `network`, `errors`, and `2`.

Your search term can include any non-alphanumeric characters. If these characters appear in your search term, they can specify composite tokens in a partial match. For example, all of the following searches would find metrics named either `Network-Errors-2` or `NetworkErrors2`.

```
network/errors
network+errors
network-errors
Network_Errors
```

When you're doing an exact value search, any non-alphanumeric characters used in the exact search must be the correct characters that appear in the string being searched for. For example, if you want to find `Network-Errors-2`, searching for `"Network-Errors-2"` is successful, but a search for `"Network_Errors_2"` isn't.

When you perform an exact match search, the following characters must be escaped with a backslash.

```
" \ ( )
```

For example, to find the metric name `Europe\France Traffic(Network)` by exact match, use the search term **`"Europe\\France Traffic\(Network\)"`**

CloudWatch search expressions: Boolean operators

Search supports the use of the Boolean operators `AND`, `OR`, and `NOT` within the `SearchTerm`. Boolean operators are enclosed in the single quote marks that you use to enclose the entire search term. Boolean operators are case sensitive, so `and`, `or`, and `not` aren't valid as Boolean operators.

You can use `AND` explicitly in your search, such as **`SEARCH('{AWS/EC2,InstanceId} network AND packets', 'Average')`**. Not using any Boolean operator between search terms implicitly searches them as if there were an `AND` operator, so **`SEARCH(' {AWS/EC2,InstanceId} network packets ', 'Average')`** yields the same search results.

Use NOT to exclude subsets of data from the results. For example, **SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" NOT i-1234567890123456 ', 'Average')** returns the CPUUtilization for all your instances, except for the instance i-1234567890123456. You can also use a NOT clause as the only search term. For example, **SEARCH('NOT Namespace=AWS ', 'Maximum')** yields all your custom metrics (metrics with namespaces that don't include AWS).

You can use multiple NOT phrases in a query. For example, **SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" NOT "ProjectA" NOT "ProjectB" ', 'Average')** returns the CPUUtilization of all instances in the Region, except for those with dimension values of ProjectA or ProjectB.

You can combine Boolean operators for more powerful and detailed searches, as in the following examples. Use parentheses to group the operators.

Both of the next two examples return all metric names containing ReadOps from both the EC2 and EBS namespaces.

```
SEARCH(' (EC2 OR EBS) AND MetricName=ReadOps ', 'Maximum')
```

```
SEARCH(' (EC2 OR EBS) MetricName=ReadOps ', 'Maximum')
```

The following example narrows the previous search to only results that include ProjectA, which could be the value of a dimension.

```
SEARCH(' (EC2 OR EBS) AND ReadOps AND ProjectA ', 'Maximum')
```

The following example uses nested grouping. It returns Lambda metrics for Errors from all functions, and Invocations of functions with names that include the strings ProjectA or ProjectB.

```
SEARCH(' {AWS/Lambda,FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND
 (ProjectA OR ProjectB)) ', 'Average')
```

CloudWatch search expressions: Using math expressions

You can use a search expression within a math expressions in a graph.

For example, **`SUM(SEARCH(' {AWS/Lambda, FunctionName} MetricName="Errors" ', 'Sum'))`** returns the sum of the `Errors` metric of all your Lambda functions.

Using separate lines for your search expression and math expression might yield more useful results. For example, suppose that you use the following two expressions in a graph. The first line displays separate `Errors` lines for each of your Lambda functions. The ID of this expression is `e1`. The second line adds another line showing the sum of the errors from all of the functions.

```
SEARCH(' {AWS/Lambda, FunctionName}, MetricName="Errors" ', 'Sum')
SUM(e1)
```

CloudWatch search expression examples

The following examples illustrate more search expression uses and syntax. Let's start with a search for `CPUUtilization` across all instances in the Region and then look at variations.

This example displays one line for each instance in the Region, showing the `CPUUtilization` metric from the `AWS/EC2` namespace.

```
SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" ', 'Average')
```

Changing `InstanceId` to `InstanceType` changes the graph to show one line for each instance type used in the Region. Data from all instances of each type is aggregated into one line for that instance type.

```
SEARCH(' {AWS/EC2,InstanceType} MetricName="CPUUtilization" ', 'Average')
```

The following example aggregates the `CPUUtilization` by instance type and displays one line for each instance type that includes the string `micro`.

```
SEARCH('{AWS/EC2,InstanceType} InstanceType=micro MetricName="CPUUtilization" ',
 'Average')
```

This example narrows the previous example, changing the `InstanceType` to an exact search for t2.micro instances.

```
SEARCH('{AWS/EC2,InstanceType} InstanceType="t2.micro" MetricName="CPUUtilization" ',
 'Average')
```

The following search removes the `{metric schema}` part of the query, so the `CPUUtilization` metric from all namespaces appears in the graph. This can return quite a few results because the graph includes multiple lines for the `CPUUtilization` metric from each Amazon service, aggregated along different dimensions.

```
SEARCH('MetricName="CPUUtilization" ', 'Average')
```

To narrow these results a bit, you can specify two specific metric namespaces.

```
SEARCH('MetricName="CPUUtilization" AND ("AWS/ECS" OR "AWS/ES") ', 'Average')
```

The preceding example is the only way to do a search of specific multiple namespaces with one search query, as you can specify only one metric schema in each query. However, to add more structure, you could use two queries in the graph, as in the following example. This example also adds more structure by specifying a dimension to use to aggregate the data for Amazon ECS.

```
SEARCH('{AWS/ECS ClusterName}, MetricName="CPUUtilization" ', 'Average')
SEARCH(' {AWS/EBS} MetricName="CPUUtilization" ', 'Average')
```

The following example returns the Elastic Load Balancing metric named `ConsumedLCUs` as well as all Elastic Load Balancing metrics or dimensions that contain the token `flow`.

```
SEARCH('{AWS/NetworkELB, LoadBalancer} "ConsumedLCUs" OR flow ', 'Maximum')
```

The following example uses nested grouping. It returns Lambda metrics for `Errors` from all functions and `Invocations` of functions with names that include the strings `ProjectA` or `ProjectB`.

```
SEARCH('{AWS/Lambda,FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND
 (ProjectA OR ProjectB)) ', 'Average')
```

The following example displays all of your custom metrics, excluding metrics generated by Amazon services.

```
SEARCH('NOT Namespace=AWS ', 'Average')
```

The following example displays metrics with metric names, namespaces, dimension names, and dimension values that contain the string `Errors` as part of their name.

```
SEARCH('Errors', 'Average')
```

The following example narrows that search to exact matches. For example, this search finds the metric name `Errors` but not metrics named `ConnectionErrors` or `errors`.

```
SEARCH(' "Errors" ', 'Average')
```

The following example shows how to specify names that contain spaces or special characters in the metric schema part of the search term.

```
SEARCH('{"Custom-Namespace", "Dimension Name With Spaces"}, ErrorCount ', 'Maximum')
```

CloudWatch cross-account observability search expression examples

CloudWatch cross-account observability examples

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can use the **SEARCH** function to return metrics from specified source accounts. For more information, see CloudWatch cross-account observability.

The following example retrieves all Lambda metrics from the account with the account ID 111122223333.

```
SEARCH(' AWS/Lambda :aws.AccountId = 111122223333 ', 'Average')
```

The following example retrieves all `AWS/EC2` metrics from two accounts: 111122223333 and 777788889999.

```
SEARCH(' AWS/EC2 :aws.AccountId = (111122223333 OR 777788889999) ', 'Average')
```

The following example retrieves all `AWS/EC2` metrics from the source account 111122223333 and from the monitoring account itself.

```
SEARCH(' AWS/EC2 :aws.AccountId = (111122223333 OR 'LOCAL') ', 'Average')
```

The following example retrieves the `SUM` of the `MetaDataToken` metric from the account `444455556666` with the `InstanceId` dimension.

```
SEARCH('{AWS/EC2,InstanceId} :aws.AccountId=444455556666 MetricName=\"MetadataNoToken
\"','Sum')
```

Create a CloudWatch graph with a search expression

On the CloudWatch console, you can access search capability when you add a graph to a dashboard, or by using the **Metrics** view.

You can't create an alarm based on a **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series.

To add a graph with a search expression to an existing dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Choose **Add widget**.
4. Choose either **Line** or **Stacked area** and choose **Configure**.
5. On the **Graphed metrics** tab, choose **Add a math expression**.
6. For **Details**, enter the search expression that you want. For example, **`SEARCH('{AWS/EC2,InstanceId} MetricName="CPUUtilization"', 'Average')`**
7. (Optional) To add another search expression or math expression to the graph, choose **Add a math expression**
8. (Optional) After you add a search expression, you can specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose **Graphed metrics** and then **Dynamic labels**.

   By default, the dynamic values you add to the label appear at the beginning of the label. You can then click the **Label** value for the metric to edit the label. For more information, see Use dynamic labels.
9. (Optional) To add a single metric to the graph, choose the **All metrics** tab and drill down to the metric you want.
10. (Optional) To change the time range shown on the graph, choose either **custom** at the top of the graph or one of the time periods to the left of **custom**.

11. (Optional) Horizontal annotations help dashboard users quickly see when a metric has spiked to a certain level or whether the metric is within a predefined range. To add a horizontal annotation, choose **Graph options** and then **Add horizontal annotation**:

    a. For **Label**, enter a label for the annotation.

    b. For **Value**, enter the metric value where the horizontal annotation appears.

    c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose `Above` or `Below` for the corresponding area to be filled. If you specify `Between`, another `Value` field appears, and the area of the graph between the two values is filled.

    d. For **Axis**, specify whether the numbers in `Value` refer to the metric associated with the left y-axis or the right y-axis if the graph includes multiple metrics.

       You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

    Repeat these steps to add multiple horizontal annotations to the same graph.

    To hide an annotation, clear the check box in the left column for that annotation.

    To delete an annotation, choose **x** in the **Actions** column.

12. (Optional) Vertical annotations help you mark milestones in a graph, such as operational events or the beginning and end of a deployment. To add a vertical annotation, choose **Graph options** and then **Add vertical annotation**:

    a. For **Label**, enter a label for the annotation. To show only the date and time on the annotation, keep the **Label** field blank.

    b. For **Date**, specify the date and time where the vertical annotation appears.

    c. For **Fill**, specify whether to use fill shading before or after a vertical annotation or between two vertical annotations. For example, choose `Before` or `After` for the corresponding area to be filled. If you specify `Between`, another `Date` field appears, and the area of the graph between the two values is filled.

    Repeat these steps to add multiple vertical annotations to the same graph.

    To hide an annotation, clear the check box in the left column for that annotation.

    To delete an annotation, choose **x** in the **Actions** column.

13. Choose **Create widget**.
14. Choose **Save dashboard**.

To use the Metrics view to graph searched metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. In the search field, enter the tokens to search for: for example, **`cpuutilization t2.small`**.

   Results that match your search appear.
4. To graph all of the metrics that match your search, choose **Graph search**.

   or

   To refine your search, choose one of the namespaces that appeared in your search results.
5. If you selected a namespace to narrow your results, you can do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
   b. To refine your search, hover over a metric name and choose **Add to search** or **Search for this only**.
   c. To view help for a metric, select the metric name and choose **What is this?**.

   The selected metrics appear on the graph.
6. (Optional) Select one of the buttons in the search bar to edit that part of the search term.
7. (Optional) To add the graph to a dashboard, choose **Actions** and then **Add to dashboard**.

Get statistics for a metric

CloudWatch statistics definitions

Statistics are metric data aggregations over specified periods of time. When you graph or retrieve the statistics for a metric, you specify the *Period* of time, such as five minutes, to use to calculate each statistical value. For example, if the **Period** is five minutes, the **Sum** is the sum of all sample values collected during the five-minute period, while the **Minimum** is the lowest value collected during the five-minute period.

CloudWatch supports the following statistics for metrics.

- **SampleCount** is the number of data points during the period.
- **Sum** is the sum of the values of the all data points collected during the period.
- **Average** is the value of `Sum/SampleCount` during the specified period.
- **Minimum** is the lowest value observed during the specified period.
- **Maximum** is the highest value observed during the specified period.
- **Percentile (p)** indicates the relative standing of a value in a dataset. For example, **p95** is the 95th percentile and means that 95 percent of the data within the period is lower than this value and 5 percent of the data is higher than this value. Percentiles help you get a better understanding of the distribution of your metric data.
- **Trimmed mean (TM)** is the mean of all values that are between two specified boundaries. Values outside of the boundaries are ignored when the mean is calculated. You define the boundaries as one or two numbers between 0 and 100, up to 10 decimal places. The numbers can be absolute values or percentages. For example, **tm90** calculates the average after removing the 10% of data points with the highest values. **TM(2%:98%)** calculates the average after removing the 2% lowest data points and the 2% highest data points. **TM(150:1000)** calculates the average after removing all data points that are lower than or equal to 150, or higher than 1000.
- **Interquartile mean (IQM)** is the trimmed mean of the *interquartile range*, or the middle 50% of values. It is equivalent to **TM(25%:75%)**.
- **Winsorized mean (WM)** is similar to trimmed mean. However, with winsorized mean, the values that are outside the boundary are not ignored, but instead are considered to be equal to the value at the edge of the appropriate boundary. After this normalization, the average is calculated. You define the boundaries as one or two numbers between 0 and 100, up to 10 decimal places. For example, **wm98** calculates the average while treating the 2% of the highest values to be equal to the value at the 98th percentile. **WM(10%:90%)** calculates the average while treating the highest 10% of data points to be the value of the 90% boundary, and treating the lowest 10% of data points to be the value of the 10% boundary.
- **Percentile rank (PR)** is the percentage of values that meet a fixed threshold. For example, **PR(:300)** returns the percentage of data points that have a value of 300 or less. **PR(100:2000)** returns the percentage of data points that have a value between 100 and 2000.

  Percentile rank is exclusive on the lower bound and inclusive on the upper bound.

- **Trimmed count (TC)** is the number of data points in the chosen range for a trimmed mean statistic. For example, **tc90** returns the number of data points not including any data points that fall in the highest 10% of the values. **TC(0.005:0.030)** returns the number of data points with values between 0.005 (exclusive) and 0.030 (inclusive).

  Trimmed count can return a decimal value instead of an integer. This is because it is an interpolated, approximate value and can give fractional results.
- **Trimmed sum (TS)** is the sum of the values of data points in a chosen range for a trimmed mean statistic. It is equivalent to (Trimmed Mean) * (Trimmed count). For example, **ts90** returns the sum of the data points not including any data points that fall in the highest 10% of the values. **TS(80%:)** returns the sum of the data point values, not including any data points with values in the lowest 80% of the range of values.

> **Note**
>
> For Trimmed Mean, Trimmed Count, Trimmed Sum, and Winsorized Mean, if you define two boundaries as fixed values instead of percentages, the calculation includes values equal to the higher boundary, but does not include values equal to the lower boundary.

Syntax

For Trimmed Mean, Trimmed Count, Trimmed Sum, and Winsorized Mean, the following syntax rules apply:

- Using parentheses with one or two numbers with percent signs defines the boundaries to use as the values in the data set that fall in between the two percentiles that you specify. For example, **TM(10%:90%)** uses only the values between the 10th and 90th percentiles. **TM(:95%)** uses the values from the lowest end of the data set up to the 95th percentile, ignoring the 5% of data points with the highest values.
- Using parenthesis with one or two numbers without percent signs defines the boundaries to use as the values in the data set that fall in between the explicit values that you specify. For example, **TC(80:500)** uses only the values that are between 80 (exclusive) and 500 (inclusive). **TC(:0.5)** uses only the values that equal 0.5 or are lower.
- Using one number without parentheses calculates using percentages, ignoring data points that are higher than the specified percentile. For example, **tm99** calculates the mean while ignoring the 1% of the data points with the highest value. It is the same as **TM(:99%)**.

- Trimmed mean, Trimmed Count, Trimmed Sum, and Winsorized Mean can all be abbreviated using uppercase letters when specifying a range, such as **TM(5%:95%)**, **TM(100:200)**, or **TM(:95%)**. They can only be abbreviated using lowercase letters when you specifying only one number, such as **tm99**.

Statistics use cases

- **Trimmed mean** is most useful for metrics with a large sample size, such as webpage latency. For example, **tm99** disregards extreme high outliers that could result from network problems or human errors, to give a more accurate number for the average latency of typical requests. Similarly, **TM(10%:)** disregards the lowest 10% of latency values, such as those resulting from cache hits. And **TM(10%:99%)** excludes both of these types of outliers. We recommend that you use trimmed mean for monitoring latency.
- It is a good idea to keep watch on trimmed count whenever you are using trimmed mean, to make sure that the number of values being used in your trimmed mean calculations are enough to be statistically significant.
- Percentile rank enables you to put values into "bins" of ranges, and you can use this to manually create a histogram. To do this, break your values down into various bins, such as **PR(:1)**, **PR(1:5)**, **PR(5:10)**, and **PR(10:)**. Put each of these bins into a visualization as bar charts, and you have a histogram.

  Percentile rank is exclusive on the lower bound and inclusive on the upper bound.

Percentiles versus trimmed mean

A percentile such as **p99** and a trimmed mean such as **tm99** measure similar, but not identical values. Both **p99** and **tm99** ignore the 1% of the data points with the highest values, which are considered outliers. After that, **p99** is the maximum value of the remaining 99%, while **tm99** is the *average* of the remaining 99%. If you are looking at the latency of web requests, **p99** tells you the worst customer experience, ignoring outliers, while **tm99** tells you the average customer experience, ignoring outliers.

Trimmed mean is a good latency statistic to watch if you are looking to optimize your customer experience.

Requirements to use percentiles, trimmed mean, and some other statistics

CloudWatch needs raw data points to calculate the following statistics:

- Percentiles
- Trimmed mean
- Interquartile mean
- Winsorized mean
- Trimmed sum
- Trimmed count
- Percentile rank

If you publish data for a custom statistics using a statistic set instead of raw data, you can retrieve these types of statistics for this data only if one of the following conditions is true:

- The SampleCount value of the statistic set is 1 and Min, Max, and Sum are all equal.
- The Min and Max are equal, and Sum is equal to Min multiplied by SampleCount.

The following Amazon services include metrics that support these types of statistics.

- API Gateway
- Application Load Balancer
- Amazon EC2
- Elastic Load Balancing
- Kinesis
- Amazon RDS

Additionally, these type of statistics are not available for metrics when any of the metric values are negative numbers.

The following examples show you how to get statistics for the CloudWatch metrics for your resources, such as your EC2 instances.

Examples

- Get statistics for a specific resource

- Aggregate statistics across resources
- Aggregate statistics by Auto Scaling group
- Aggregate statistics by Amazon Machine Image (AMI)

Get statistics for a specific resource

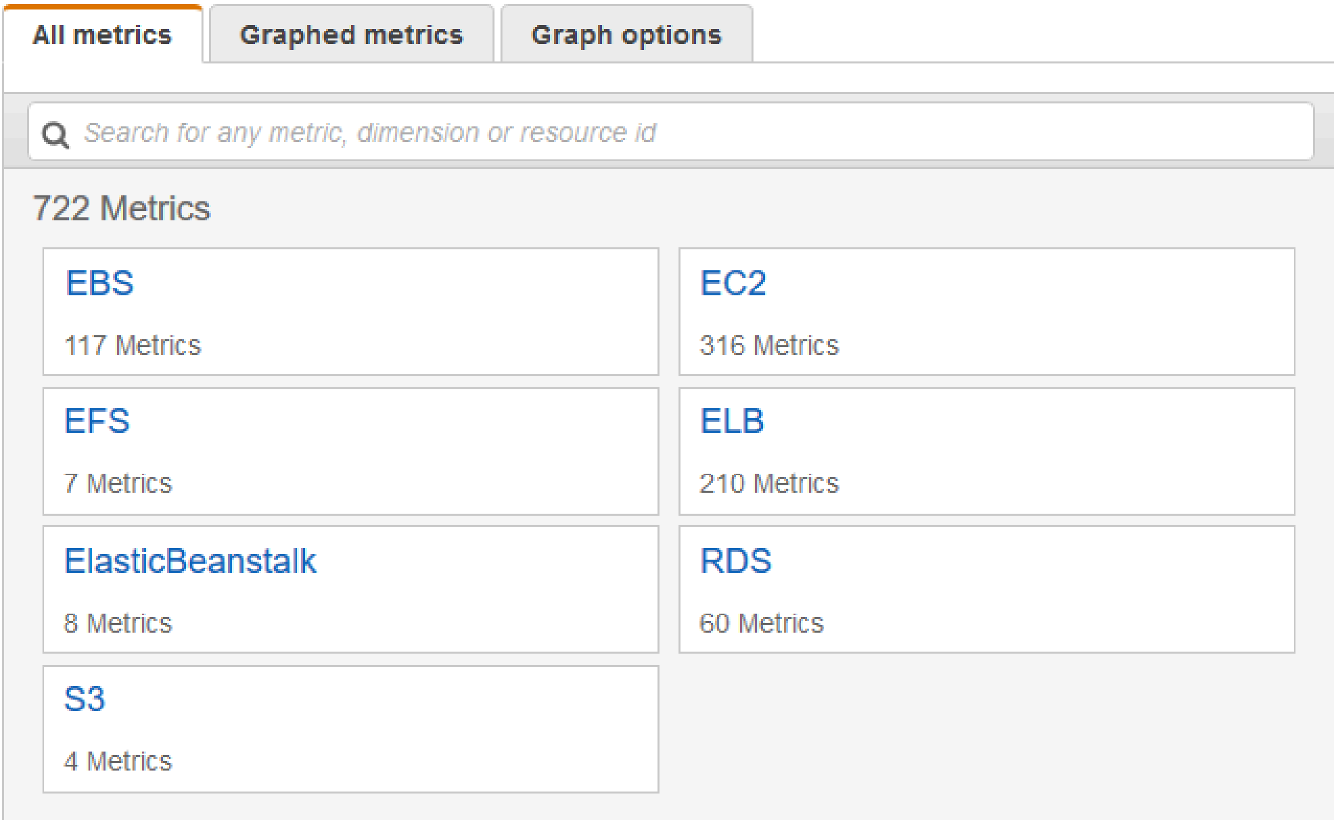
The following example shows you how to determine the maximum CPU utilization of a specific EC2 instance.

Requirements

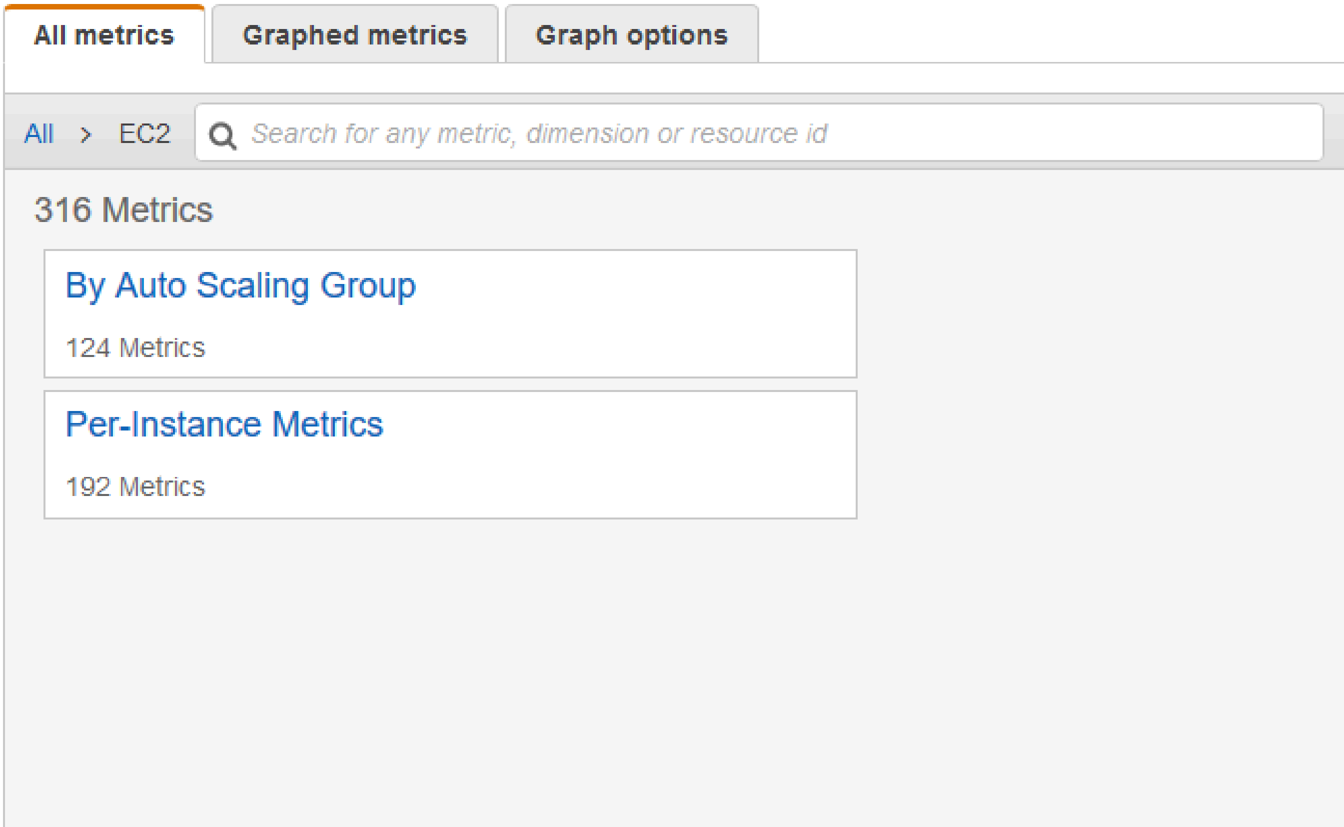
- You must have the ID of the instance. You can get the instance ID using the Amazon EC2 console or the describe-instances command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the *Amazon EC2 User Guide*.

To display the average CPU utilization for a specific instance using the console

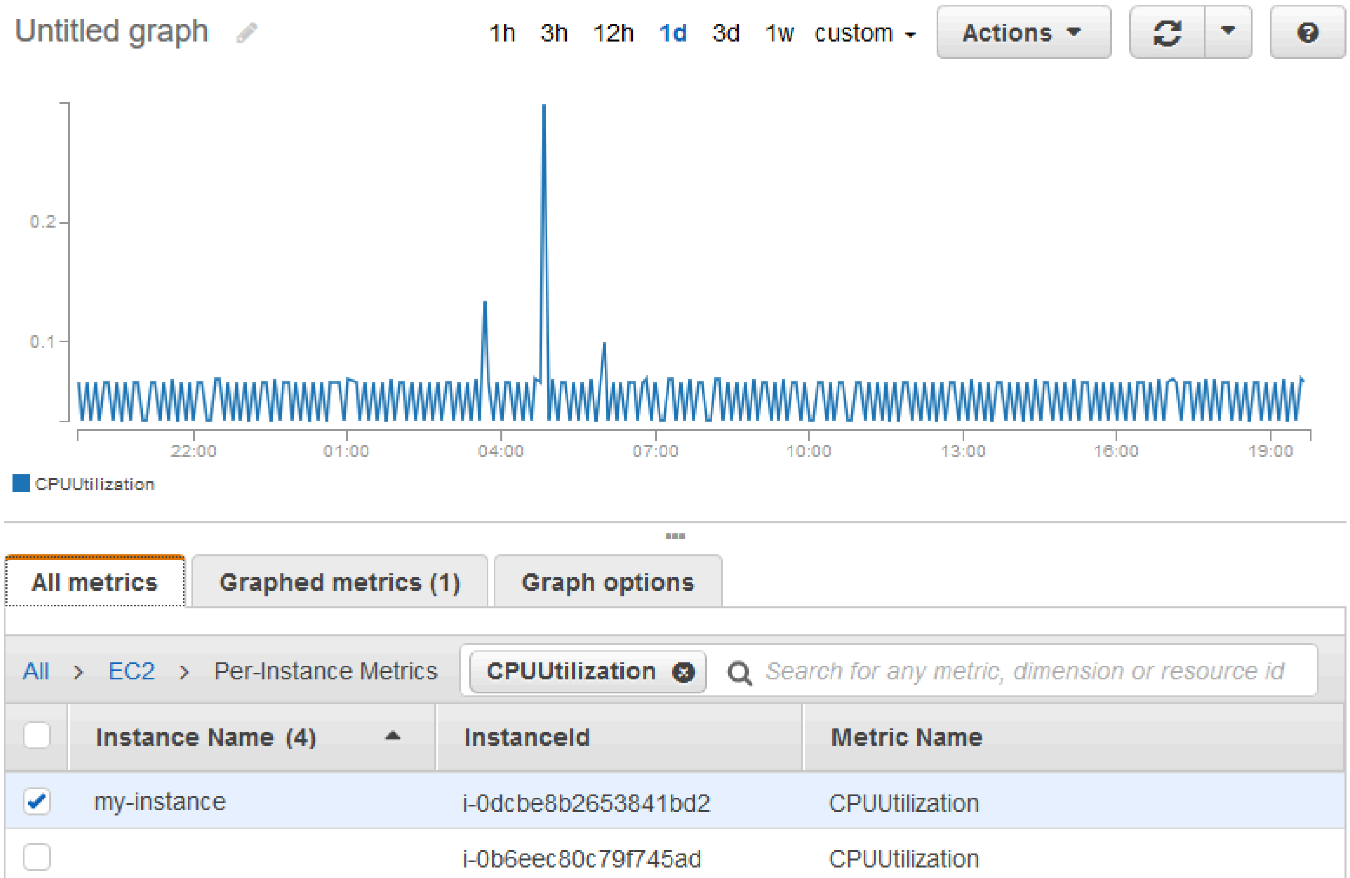
1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Select the **EC2** metric namespace.



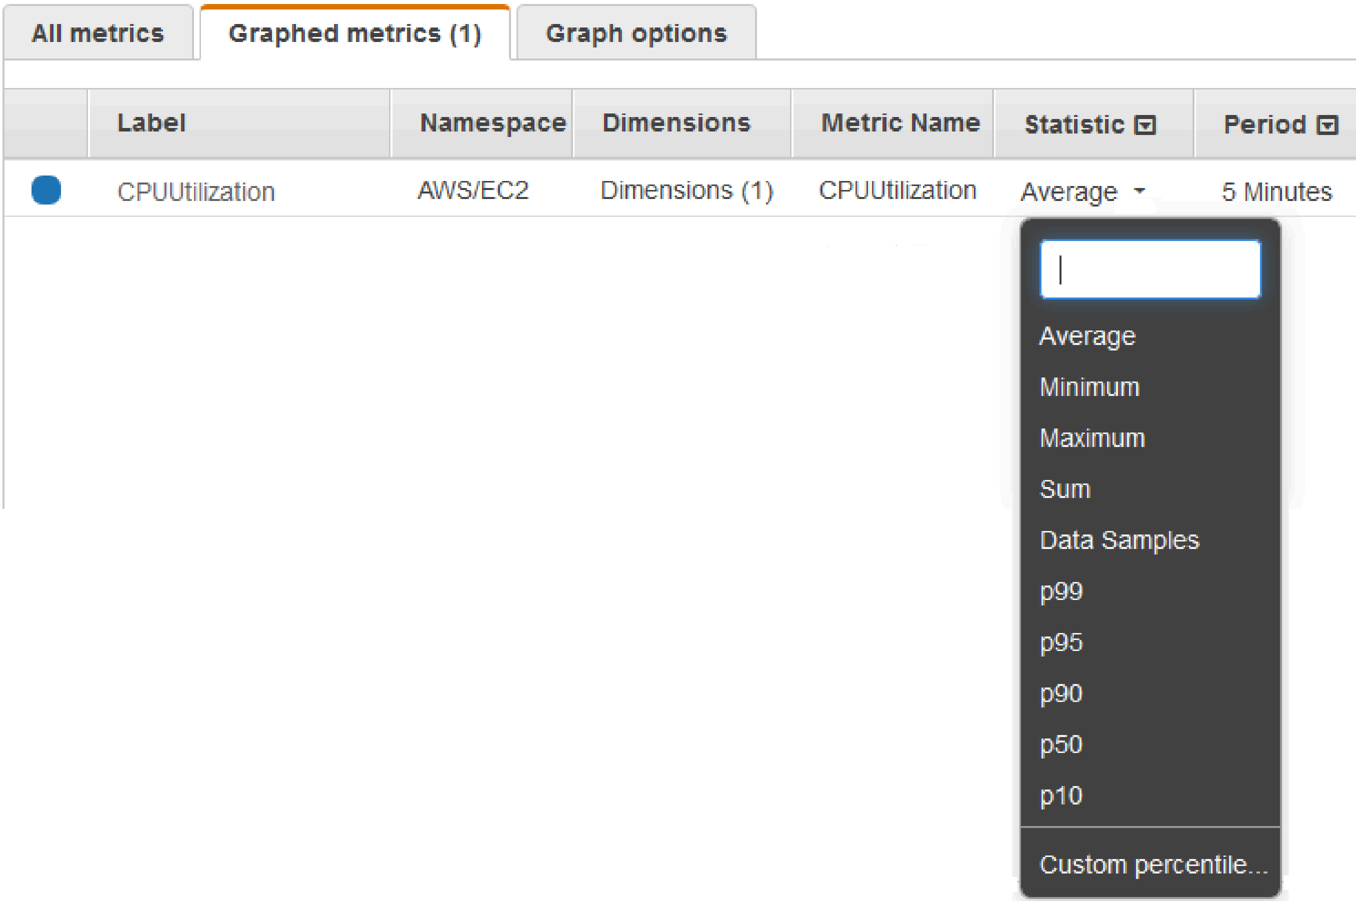
4. Select the **Per-Instance Metrics** dimension.



5. In the search field, enter **`CPUUtilization`** and press Enter. Select the row for the specific instance, which displays a graph for the `CPUUtilization` metric for the instance. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



6. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **`p99.999`**).



7. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

To get the CPU utilization per EC2 instance using the Amazon CLI

Use the get-metric-statistics command as follows to get the `CPUUtilization` metric for the specified instance.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization \
--dimensions Name=InstanceId,Value=i-1234567890abcdef0 --statistics Maximum \
--start-time 2016-10-18T23:18:00 --end-time 2016-10-19T23:18:00 --period 360
```

The returned statistics are 6-minute values for the requested 24-hour time interval. Each value represents the maximum CPU utilization percentage for the specified instance for a particular 6-minute time period. The data points aren't returned in chronological order. The following shows the beginning of the example output (the full output includes data points for every 6 minutes of the 24-hour period).

```
{
    "Datapoints": [
        {
            "Timestamp": "2016-10-19T00:18:00Z",
            "Maximum": 0.33000000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2016-10-19T03:18:00Z",
            "Maximum": 99.670000000000002,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2016-10-19T07:18:00Z",
            "Maximum": 0.34000000000000002,
            "Unit": "Percent"
        },
        ...
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics across resources

You can aggregate the metrics for Amazon resources across multiple resources. Metrics are completely separate between Regions, but you can use metric math to aggregate similar metrics across Regions. For more information, see Using math expressions with CloudWatch metrics.

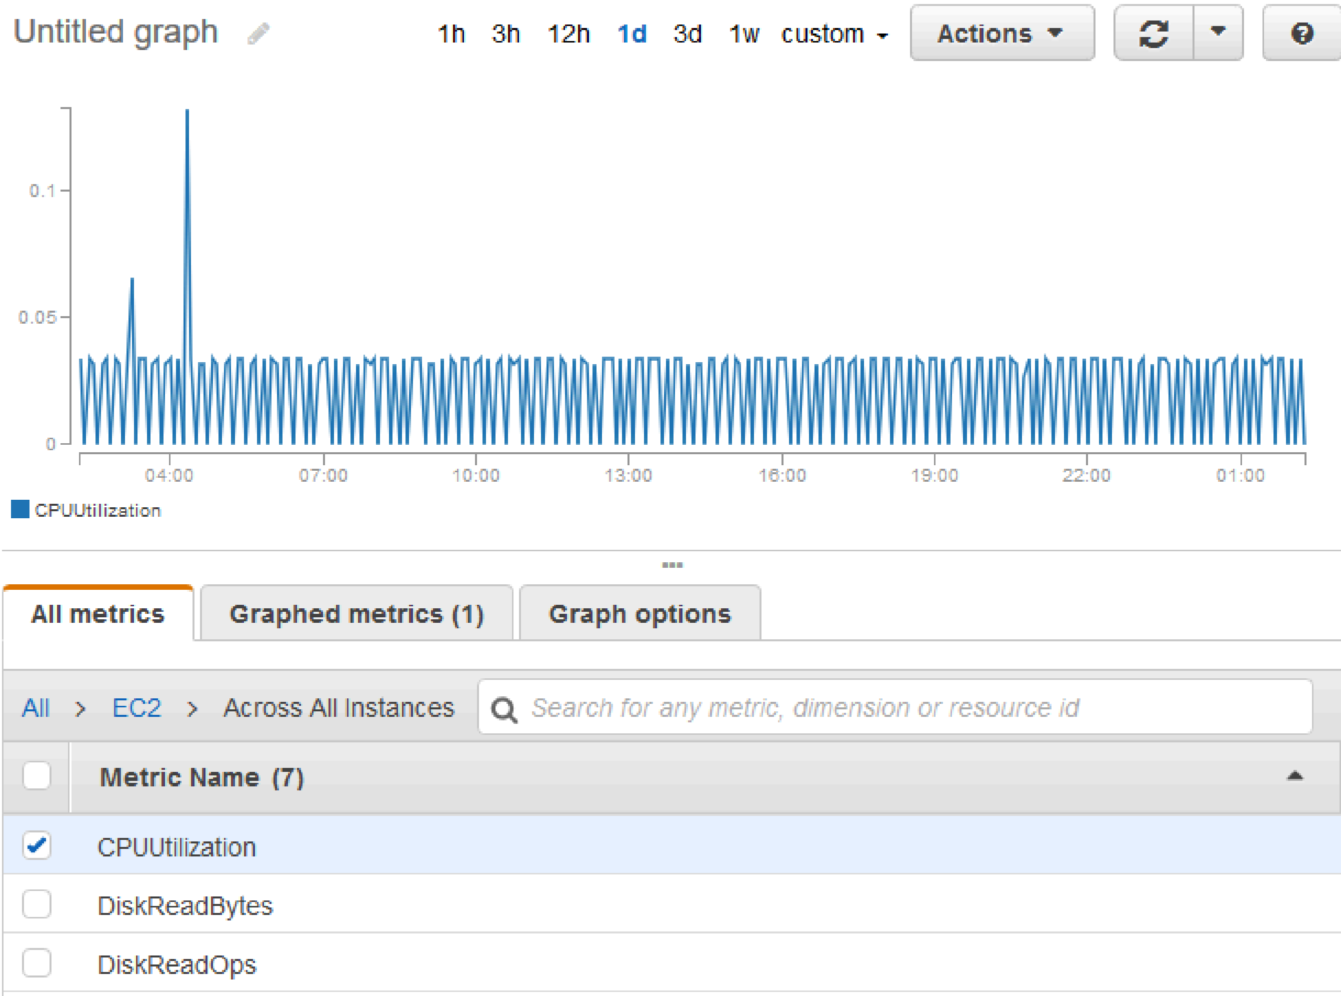
For example, you can aggregate statistics for your EC2 instances that have detailed monitoring enabled. Instances that use basic monitoring aren't included. Therefore, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the *Amazon EC2 User Guide*.

This example shows you how to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the `AWS/EC2` namespace. To get statistics for other metrics, see Amazon services that publish CloudWatch metrics.

> **Important**
>
> This technique for retrieving all dimensions across an Amazon namespace doesn't work for custom namespaces that you publish to CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

To display average CPU utilization for your EC2 instances

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **EC2** namespace and choose **Across All Instances**.
4. Select the row that contains `CPUUtilization`, which displays a graph for the metric for all your EC2 instances. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



5. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **p95.45**).

6. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.

To get average CPU utilization across your EC2 instances using the Amazon CLI

Use the get-metric-statistics command as follows:

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization
 --statistics "Average" "SampleCount" \
--start-time 2016-10-11T23:18:00 --end-time 2016-10-12T23:18:00 --period 3600
```

The following is example output:

```
{
    "Datapoints": [
        {
            "SampleCount": 238.0,
            "Timestamp": "2016-10-12T07:18:00Z",
            "Average": 0.038235294117647062,
            "Unit": "Percent"
        },
        {
            "SampleCount": 240.0,
            "Timestamp": "2016-10-12T09:18:00Z",
            "Average": 0.16670833333333332,
            "Unit": "Percent"
        },
        {
            "SampleCount": 238.0,
            "Timestamp": "2016-10-11T23:18:00Z",
            "Average": 0.041596638655462197,
            "Unit": "Percent"
        },
        ...
    ],
    "Label": "CPUUtilization"
}
```

Aggregate statistics by Auto Scaling group

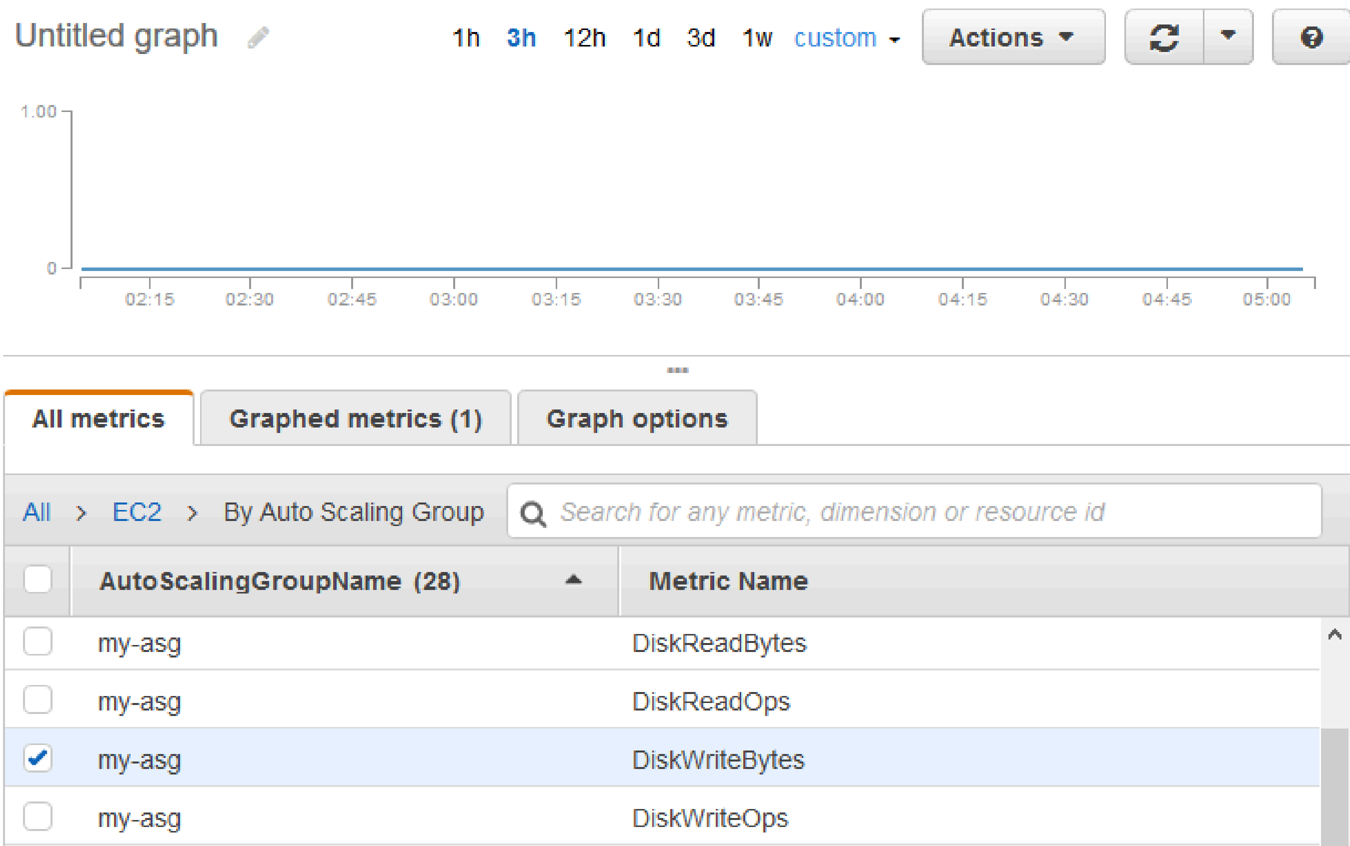
You can aggregate statistics for the EC2 instances in an Auto Scaling group. Metrics are completely separate between Regions, but you can use CloudWatch metric math to aggregate and transform metrics from multiple Regions. You can also use the cross-account dashboard to perform metric math on metrics from different accounts.

This example shows you how to get the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **EC2** namespace and then choose **By Auto Scaling Group**.

4. Select the row for the **DiskWriteBytes** metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



5. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **p95.45**).
6. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.

To get DiskWriteBytes for the instances in an Auto Scaling group using the Amazon CLI

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes
--dimensions Name=AutoScalingGroupName,Value=my-asg --statistics "Sum" "SampleCount" \
--start-time 2016-10-16T23:18:00 --end-time 2016-10-18T23:18:00 --period 360
```

The following is example output.

```
{
    "Datapoints": [
        {
            "SampleCount": 18.0,
            "Timestamp": "2016-10-19T21:36:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        },
        {
            "SampleCount": 5.0,
            "Timestamp": "2016-10-19T21:42:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "DiskWriteBytes"
}
```

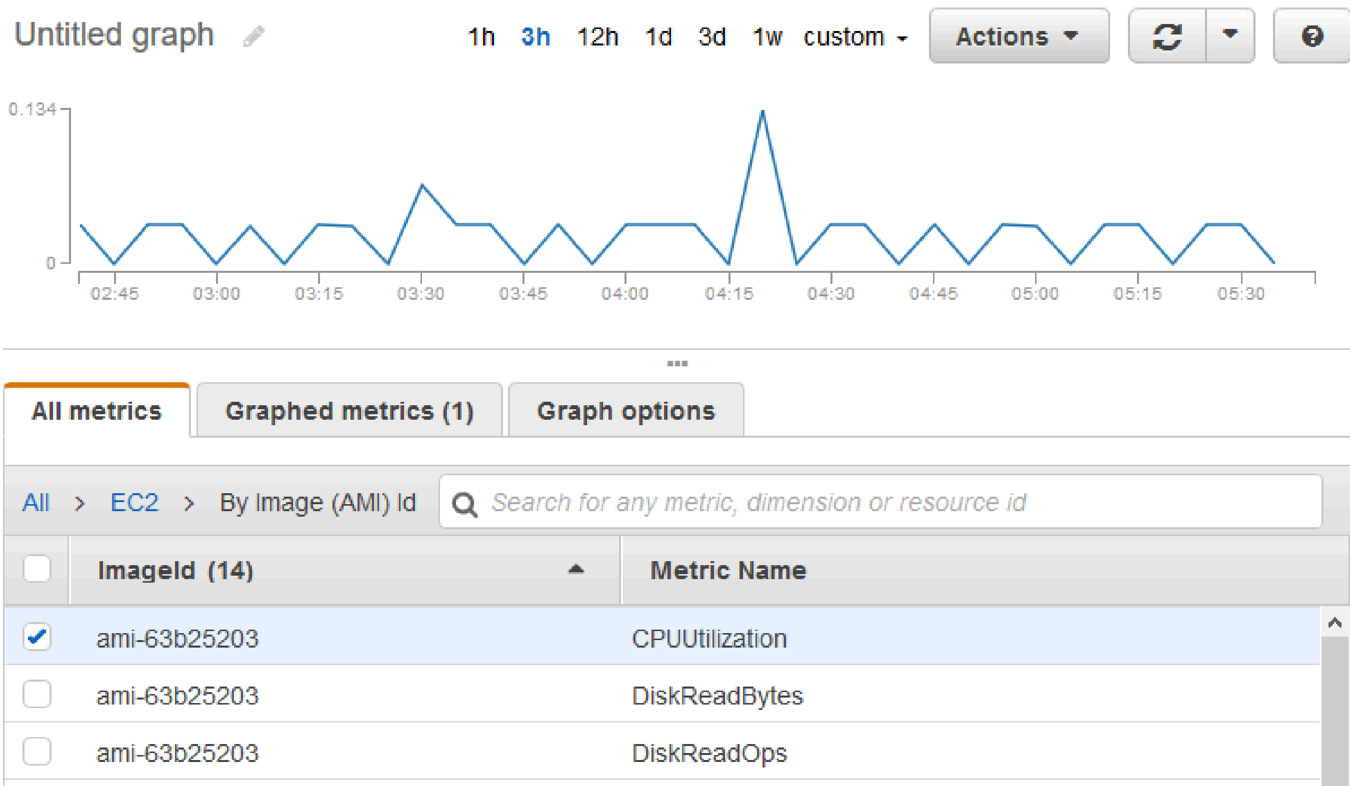
Aggregate statistics by Amazon Machine Image (AMI)

You can aggregate statistics for the EC2 instances that have detailed monitoring enabled. Instances that use basic monitoring aren't included. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the *Amazon EC2 User Guide*.

This example shows you how to determine average CPU utilization for all instances that use the specified AMI. The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **EC2** namespace and then choose **By Image (AMI) Id**.
4. Select the row for the `CPUUtilization` metric and the specific AMI, which displays a graph for the metric for the specified AMI. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.



5. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **`p95.45`**).
6. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.

To get the average CPU utilization by AMI using the Amazon CLI

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization \
--dimensions Name=ImageId,Value=ami-3c47a355 --statistics Average \
--start-time 2016-10-10T00:00:00 --end-time 2016-10-11T00:00:00 --period 3600
```

The operation returns statistics that are one-hour values for the one-day interval. Each value represents an average CPU utilization percentage for EC2 instances running the specified AMI. The following is example output.

```
{
    "Datapoints": [
```

```
        {
            "Timestamp": "2016-10-10T07:00:00Z",
            "Average": 0.04100000000000009,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2016-10-10T14:00:00Z",
            "Average": 0.079579831932773085,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2016-10-10T06:00:00Z",
            "Average": 0.036000000000000011,
            "Unit": "Percent"
        },
        ...
    ],
    "Label": "CPUUtilization"
}
```

Publish custom metrics

You can publish your own metrics to CloudWatch using the Amazon CLI or an API. You can view statistical graphs of your published metrics with the Amazon Web Services Management Console.

CloudWatch stores data about a metric as a series of data points. Each data point has an associated time stamp. You can even publish an aggregated set of data points called a *statistic set*.

Topics

- High-resolution metrics
- Use dimensions
- Publish single data points
- Publish statistic sets
- Publish the value zero
- Stop publishing metrics

High-resolution metrics

Each metric is one of the following:

- Standard resolution, with data having a one-minute granularity
- High resolution, with data at a granularity of one second

Metrics produced by Amazon services are standard resolution by default. When you publish a custom metric, you can define it as either standard resolution or high resolution. When you publish a high-resolution metric, CloudWatch stores it with a resolution of 1 second, and you can read and retrieve it with a period of 1 second, 5 seconds, 10 seconds, 30 seconds, or any multiple of 60 seconds.

High-resolution metrics can give you more immediate insight into your application's sub-minute activity. Keep in mind that every `PutMetricData` call for a custom metric is charged, so calling `PutMetricData` more often on a high-resolution metric can lead to higher charges. For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](#).

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms with a period of 10 or 30 seconds.

Use dimensions

In custom metrics, the `--dimensions` parameter is common. A dimension further clarifies what the metric is and what data it stores. You can have up to 30 dimensions assigned to one metric, and each dimension is defined by a name and value pair.

How you specify a dimension is different when you use different commands. With put-metric-data, you specify each dimension as *MyName*=*MyValue*, and with get-metric-statistics or put-metric-alarm you use the format `Name=`*MyName*, `Value=`*MyValue*. For example, the following command publishes a `Buffers` metric with two dimensions named `InstanceId` and `InstanceType`.

```
aws cloudwatch put-metric-data --metric-name Buffers --namespace MyNameSpace --unit
 Bytes --value 231434333 --dimensions InstanceId=1-23456789,InstanceType=m1.small
```

This command retrieves statistics for that same metric. Separate the Name and Value parts of a single dimension with commas, but if you have multiple dimensions, use a space between one dimension and the next.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --namespace MyNameSpace --
dimensions Name=InstanceId,Value=1-23456789 Name=InstanceType,Value=m1.small --start-
```

```
time 2016-10-15T04:00:00Z --end-time 2016-10-19T07:00:00Z --statistics Average --period
 60
```

If a single metric includes multiple dimensions, you must specify a value for every defined dimension when you use [get-metric-statistics](). For example, the Amazon S3 metric `BucketSizeBytes` includes the dimensions `BucketName` and `StorageType`, so you must specify both dimensions with [get-metric-statistics]().

```
aws cloudwatch get-metric-statistics --metric-name BucketSizeBytes --start-time
 2017-01-23T14:23:00Z --end-time 2017-01-26T19:30:00Z --period 3600 --namespace
 AWS/S3 --statistics Maximum --dimensions Name=BucketName,Value=amzn-s3-demo-bucket
 Name=StorageType,Value=StandardStorage --output table
```

To see what dimensions are defined for a metric, use the [list-metrics]() command.

Publish single data points

To publish a single data point for a new or existing metric, use the [put-metric-data]() command with one value and time stamp. For example, the following actions each publish one data point.

```
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 2 --timestamp 2016-10-20T12:00:00.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 4 --timestamp 2016-10-20T12:00:01.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --
value 5 --timestamp 2016-10-20T12:00:02.000Z
```

If you call this command with a new metric name, CloudWatch creates a metric for you. Otherwise, CloudWatch associates your data with the existing metric that you specified.

> **Note**
>
> When you create a metric, it can take up to 2 minutes before you can retrieve statistics for the new metric using the [get-metric-statistics]() command. However, it can take up to 15 minutes before the new metric appears in the list of metrics retrieved using the [list-metrics]() command.

Although you can publish data points with time stamps as granular as one-thousandth of a second, CloudWatch aggregates the data to a minimum granularity of 1 second. CloudWatch records the average (sum of all items divided by number of items) of the values received for each period, as well as the number of samples, maximum value, and minimum value for the same time period. For example, the PageViewCount metric from the previous examples contains three data points with time stamps just seconds apart. If you have your period set to 1 minute, CloudWatch aggregates the three data points because they all have time stamps within a 1-minute period.

You can use the **get-metric-statistics** command to retrieve statistics based on the data points that you published.

```
aws cloudwatch get-metric-statistics --namespace MyService --metric-name PageViewCount
 \
--statistics "Sum" "Maximum" "Minimum" "Average" "SampleCount" \
--start-time 2016-10-20T12:00:00.000Z --end-time 2016-10-20T12:05:00.000Z --period 60
```

The following is example output.

```
{
    "Datapoints": [
        {
            "SampleCount": 3.0,
            "Timestamp": "2016-10-20T12:00:00Z",
            "Average": 3.6666666666666665,
            "Maximum": 5.0,
            "Minimum": 2.0,
            "Sum": 11.0,
            "Unit": "None"
        }
    ],
    "Label": "PageViewCount"
}
```

Publish statistic sets

You can aggregate your data before you publish to CloudWatch. When you have multiple data points per minute, aggregating data minimizes the number of calls to **put-metric-data**. For example, instead of calling **put-metric-data** multiple times for three data points that are within 3 seconds of each other, you can aggregate the data into a statistic set that you publish with one call, using the `--statistic-values` parameter.

```
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService
 --statistic-values Sum=11,Minimum=2,Maximum=5,SampleCount=3 --
timestamp 2016-10-14T12:00:00.000Z
```

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can't retrieve percentile statistics for this data unless one of the following conditions is true:

- The `SampleCount` of the statistic set is 1
- The `Minimum` and the `Maximum` of the statistic set are equal

Publish the value zero

When your data is more sporadic and you have periods that have no associated data, you can choose to publish the value zero (`0`) for that period or no value at all. If you use periodic calls to `PutMetricData` to monitor the health of your application, you might want to publish zero instead of no value. For example, you can set a CloudWatch alarm to notify you if your application fails to publish metrics every five minutes. You want such an application to publish zeros for periods with no associated data.

You might also publish zeros if you want to track the total number of data points or if you want statistics such as minimum and average to include data points with the value 0.

Stop publishing metrics

To stop publishing custom metrics to CloudWatch, change your application's or service's code to stop using **PutMetricData**. CloudWatch doesn't pull metrics from applications, it only receives what is pushed to it, so to stop publishing your metrics you must stop them at the source.

Using Amazon CloudWatch alarms

You can create alarms that watch metrics and send notifications or automatically make changes to the resources you are monitoring when a threshold is breached. For example, you can monitor the CPU usage and disk reads and writes of your Amazon EC2 instances and then use that data to determine whether you should launch additional instances to handle increased load. You can also use this data to stop under-used instances to save money.

You can create both *metric* and *composite* alarms in Amazon CloudWatch.

- A *metric alarm* watches a single CloudWatch metric or the result of a math expression based on CloudWatch metrics. The alarm performs one or more actions based on the value of the metric or expression relative to a threshold over a number of time periods. The action can be sending a notification to an Amazon SNS topic, performing an Amazon EC2 action or an Amazon EC2 Auto Scaling action, starting an investigation in Amazon Q Developer operational investigations, or creating an OpsItem or incident in Systems Manager.
- A *composite alarm* includes a rule expression that takes into account the alarm states of other alarms that you have created. The composite alarm goes into ALARM state only if all conditions of the rule are met. The alarms specified in a composite alarm's rule expression can include metric alarms and other composite alarms.

  Using composite alarms can reduce alarm noise. You can create multiple metric alarms, and also create a composite alarm and set up alerts only for the composite alarm. For example, a composite might go into ALARM state only when all of the underlying metric alarms are in ALARM state.

  Composite alarms can send Amazon SNS notifications when they change state, and can create investigations, Systems Manager OpsItems, or incidents when they go into ALARM state, but can't perform EC2 actions or Auto Scaling actions.

> **Note**
>
> You can create as many alarms as you want in your Amazon account.

You can add alarms to dashboards, so you can monitor and receive alerts about your Amazon resources and applications across multiple regions. After you add an alarm to a dashboard, the alarm turns gray when it's in the `INSUFFICIENT_DATA` state and red when it's in the `ALARM` state. The alarm is shown with no color when it's in the `OK` state.

You also can favorite recently visited alarms from the *Favorites and recents* option in the CloudWatch console navigation pane. The *Favorites and recents* option has columns for your favorited alarms and recently visited alarms.

An alarm invokes actions only when the alarm changes state. The exception is for alarms with Auto Scaling actions. For Auto Scaling actions, the alarm continues to invoke the action once per minute that the alarm remains in the new state.

An alarm can watch a metric in the same account. If you have enabled cross-account functionality in your CloudWatch console, you can also create alarms that watch metrics in other Amazon accounts. Creating cross-account composite alarms is not supported. Creating cross-account alarms that use math expressions is supported, except that the `ANOMALY_DETECTION_BAND`, `INSIGHT_RULE`, and `SERVICE_QUOTA` functions are not supported for cross-account alarms.

Note

CloudWatch doesn't test or validate the actions that you specify, nor does it detect any Amazon EC2 Auto Scaling or Amazon SNS errors resulting from an attempt to invoke nonexistent actions. Make sure that your alarm actions exist.

Metric alarm states

A metric alarm has the following possible states:

- `OK` – The metric or expression is within the defined threshold.
- `ALARM` – The metric or expression is outside of the defined threshold.
- `INSUFFICIENT_DATA` – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.

Evaluating an alarm

When you create an alarm, you specify three settings to enable CloudWatch to evaluate when to change the alarm state:

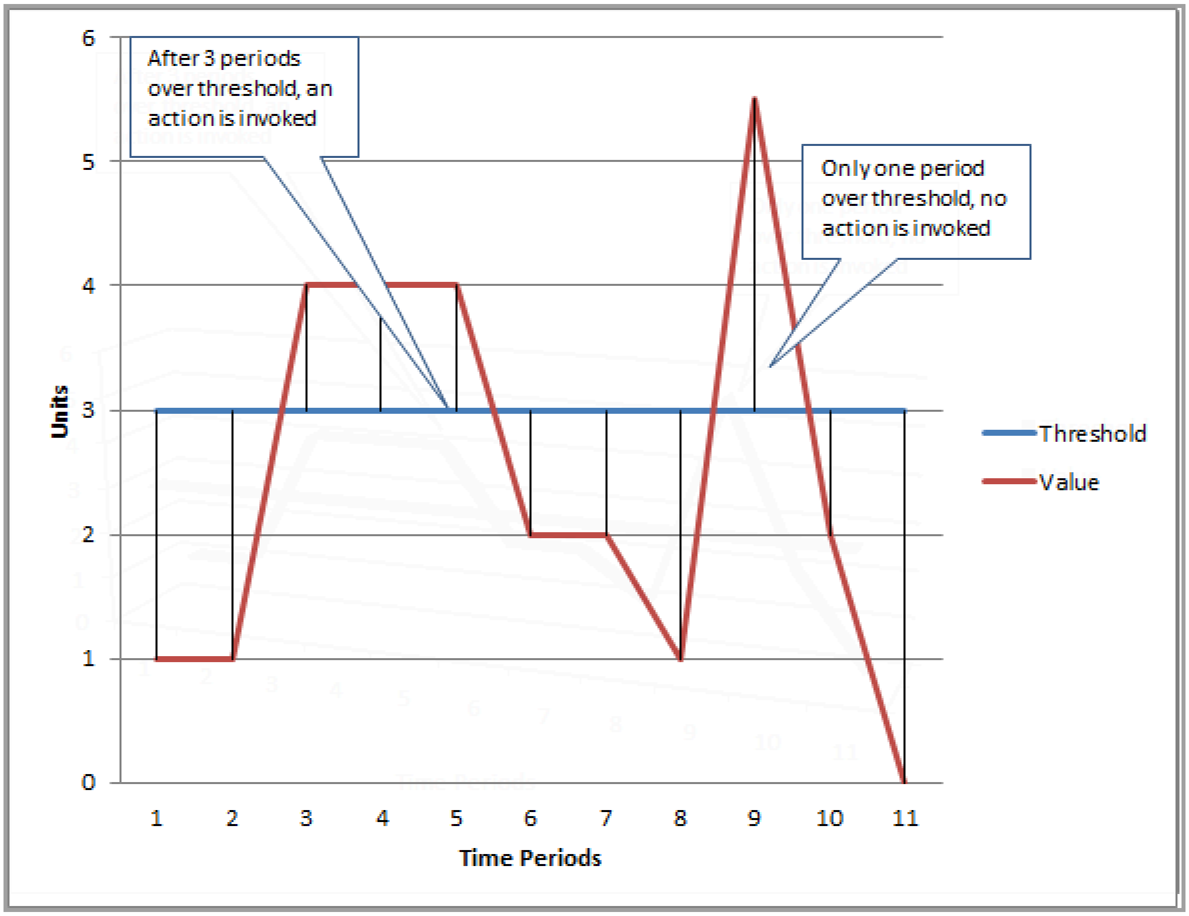
- **Period** is the length of time to use to evaluate the metric or expression to create each individual data point for an alarm. It is expressed in seconds.
- **Evaluation Periods** is the number of the most recent periods, or data points, to evaluate when determining alarm state.
- **Datapoints to Alarm** is the number of data points within the Evaluation Periods that must be breaching to cause the alarm to go to the `ALARM` state. The breaching data points don't have to be consecutive, but they must all be within the last number of data points equal to **Evaluation Period**.

For any period of one minute or longer, an alarm is evaluated every minute and the evaluation is based on the window of time defined by the **Period** and **Evaluation Periods**. For example, if the **Period** is 5 minutes (300 seconds) and **Evaluation Periods** is 1, then at the end of minute 5 the alarm evaluates based on data from minutes 1 to 5. Then at the end of minute 6, the alarm is evaluated based on the data from minutes 2 to 6.

If the alarm period is 10 seconds, 20 seconds, or 30 seconds, the alarm is evaluated every 10 seconds.

If the number of evaluation periods multiplied by the length of each evaluation period exceeds one day, the alarm is evaluated once per hour. For more details about how these multi-day alarms are evaluated, see the example at the end of this section.

In the following figure, the alarm threshold for a metric alarm is set to three units. Both **Evaluation Period** and **Datapoints to Alarm** are 3. That is, when all existing data points in the most recent three consecutive periods are above the threshold, the alarm goes to `ALARM` state. In the figure, this happens in the third through fifth time periods. At period six, the value dips below the threshold, so one of the periods being evaluated is not breaching, and the alarm state changes back to `OK`. During the ninth time period, the threshold is breached again, but for only one period. Consequently, the alarm state remains `OK`.



When you configure **Evaluation Periods** and **Datapoints to Alarm** as different values, you're setting an "M out of N" alarm. **Datapoints to Alarm** is ("M") and **Evaluation Periods** is ("N"). The evaluation interval is the number of evaluation periods multiplied by the period length. For example, if you configure 4 out of 5 data points with a period of 1 minute, the evaluation interval is 5 minutes. If you configure 3 out of 3 data points with a period of 10 minutes, the evaluation interval is 30 minutes.

Note

If data points are missing soon after you create an alarm, and the metric was being reported to CloudWatch before you created the alarm, CloudWatch retrieves the most recent data points from before the alarm was created when evaluating the alarm.

Example of evaluating a multi-day alarm

An alarm is a multi-day alarm if the number of evaluation periods multiplied by the length of each evaluation period exceeds one day. Multi-day alarms are evaluated once per hour. When multi-day alarms are evaluated, CloudWatch takes into account only the metrics up to the current hour at the :00 minute when evaluating.

For example, consider an alarm that monitors a job that runs every 3 days at 10:00.

1. At 10:02, the job fails
2. At 10:03, the alarm evaluates and stays in `OK` state, because the evaluation considers data only up to 10:00.
3. At 11:03, the alarm considers data up to 11:00 and goes into `ALARM` state.
4. At 11:43, you correct the error and the job now runs successfully.
5. At 12:03, the alarm evaluates again, sees the successful job, and returns to `OK` state.

Alarm actions

You can specify what actions an alarm takes when it changes state between the OK, ALARM, and INSUFFICIENT_DATA states.

Most actions can be set for the transition into each of the three states. Except for Auto Scaling actions, the actions happen only on state transitions, and are not performed again if the condition persists for hours or days. You can use the fact that multiple actions are allowed for an alarm to send an email when a threshold is breached, and then another when the breaching condition ends. This helps you verify that your scaling or recovery actions are triggered when expected and are working as desired.

The following are supported as alarm actions.

- Notify one or more subscribers by **using an Amazon Simple Notification Service topic**. Subscribers can be applications as well as persons. For more information about Amazon SNS, see [What is Amazon SNS?](#).
- **Invoke a Lambda function.** This is the easiest way for you to automate custom actions on alarm state changes.

- Alarms based on EC2 metrics can also **perform EC2 actions**, such as stopping, terminating, rebooting, or recovering an EC2 instance. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.
- Alarms can perform actions to **scale an Auto Scaling group**. For more information, see Step and simple scaling policies for Amazon EC2 Auto Scaling.
- Alarms can **create OpsItems in Systems Manager Ops Center or create incidents in Amazon Systems Manager Incident Manager**. These actions are performed only when the alarm goes into ALARM state. For more information, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.
- An alarm can start an investigation when it goes into ALARM state. For more information about Amazon Q Developer operational investigations, see Amazon Q Developer operational investigations (Preview).

Alarms also emit events to Amazon EventBridge when they change state, and you can set up Amazon EventBridge to trigger other actions for these state changes. For more information, see What is Amazon EventBridge?.

Lambda alarm actions

CloudWatch alarms guarantees an asynchronous invocation of the Lambda function for a given state change, except in the following cases:

- When the function doesn't exist.
- When CloudWatch is not authorized to invoke the Lambda function.

If CloudWatch can't reach the Lambda service or the message is rejected for another reason, CloudWatch retries until the invocation is successful. Lambda queues the message and handles execution retries. For more information about this execution model, including information about how Lambda handles errors, see Asynchronous invocation in the Amazon Lambda Developer Guide.

You can invoke a Lambda function in the same account, or in other Amazon accounts.

When you specify an alarm to invoke a Lambda function as an alarm action, you can choose to specify the function name, function alias, or a specific version of a function.

When you specify a Lambda function as an alarm action, you must create a resource policy for the function to allow the CloudWatch service principal to invoke the function.

One way to do this is by using the Amazon CLI, as in the following example:

```
aws lambda add-permission \
--function-name my-function-name \
--statement-id AlarmAction \
--action 'lambda:InvokeFunction' \
--principal lambda.alarms.cloudwatch.amazonaws.com \
--source-account 111122223333 \
--source-arn arn:aws:cloudwatch:us-east-1:111122223333:alarm:alarm-name
```

Alternatively, you can create a policy similar to one of the following examples and then assign it to the function.

The following example specifies the account where the alarm is located, so that only alarms in that account (111122223333) can invoke the function.

```
{
    "Version": "2012-10-17",
    "Id": "default",
    "Statement": [{
        "Sid": "AlarmAction",
        "Effect": "Allow",
        "Principal": {
            "Service": "lambda.alarms.cloudwatch.amazonaws.com"
        },
        "Action": "lambda:InvokeFunction",
        "Resource": "arn:aws:lambda:us-east-1:444455556666:function:function-name",
        "Condition": {
            "StringEquals": {
                "AWS:SourceAccount": "111122223333"
            }
        }
    }]
}
```

The following example has a narrower scope, allowing only the specified alarm in the specified account to invoke the function.

```
{
```

```
  "Version": "2012-10-17",
  "Id": "default",
  "Statement": [
    {
      "Sid": "AlarmAction",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.alarms.cloudwatch.amazonaws.com"
      },
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:us-east-1:444455556666:function:function-name",
      "Condition": {
        "StringEquals": {
          "AWS:SourceAccount": "111122223333",
          "AWS:SourceArn": "arn:aws:cloudwatch:us-east-1:111122223333:alarm:alarm-name"
        }
      }
    }]
}
```

We don't recommend creating a policy that doesn't specify a source account, because such policies are vulnerable to confused deputy issues.

Event object sent from CloudWatch to Lambda

When you configure a Lambda function as an alarm action, CloudWatch delivers a JSON payload to the Lambda function when it invokes the function. This JSON payload serves as the event object for the function. You can extract data from this JSON object and use it in your function. The following is an example of an event object from a metric alarm.

```
{
  'source': 'aws.cloudwatch',
  'alarmArn': 'arn:aws:cloudwatch:us-east-1:444455556666:alarm:lambda-demo-metric-
alarm',
  'accountId': '444455556666',
  'time': '2023-08-04T12:36:15.490+0000',
  'region': 'us-east-1',
  'alarmData': {
    'alarmName': 'lambda-demo-metric-alarm',
    'state': {
      'value': 'ALARM',
      'reason': 'test',
      'timestamp': '2023-08-04T12:36:15.490+0000'
```

```
    },
    'previousState': {
      'value': 'INSUFFICIENT_DATA',
      'reason': 'Insufficient Data: 5 datapoints were unknown.',
      'reasonData':
 '{"version":"1.0","queryDate":"2023-08-04T12:31:29.591+0000","statistic":"Average","period":60
[],"threshold":5.0,"evaluatedDatapoints":[{"timestamp":"2023-08-04T12:30:00.000+0000"},
{"timestamp":"2023-08-04T12:29:00.000+0000"},
{"timestamp":"2023-08-04T12:28:00.000+0000"},
{"timestamp":"2023-08-04T12:27:00.000+0000"},
{"timestamp":"2023-08-04T12:26:00.000+0000"}]}',
      'timestamp': '2023-08-04T12:31:29.595+0000'
    },
    'configuration': {
      'description': 'Metric Alarm to test Lambda actions',
      'metrics': [
        {
          'id': '1234e046-06f0-a3da-9534-EXAMPLEe4c',
          'metricStat': {
            'metric': {
              'namespace': 'AWS/Logs',
              'name': 'CallCount',
              'dimensions': {
                'InstanceId': 'i-12345678'
              }
            },
            'period': 60,
            'stat': 'Average',
            'unit': 'Percent'
          },
          'returnData': True
        }
      ]
    }
  }
}
```

The following is an example of an event object from a composite alarm.

```
{
  'source': 'aws.cloudwatch',
  'alarmArn': 'arn:aws:cloudwatch:us-east-1:111122223333:alarm:SuppressionDemo.Main',
  'accountId': '111122223333',
```

```
  'time': '2023-08-04T12:56:46.138+0000',
  'region': 'us-east-1',
  'alarmData': {
    'alarmName': 'CompositeDemo.Main',
    'state': {
      'value': 'ALARM',
      'reason': 'arn:aws:cloudwatch:us-
east-1:111122223333:alarm:CompositeDemo.FirstChild transitioned to ALARM at Friday 04
 August, 2023 12:54:46 UTC',
      'reasonData': '{"triggeringAlarms":[{"arn":"arn:aws:cloudwatch:us-
east-1:111122223333:alarm:CompositeDemo.FirstChild","state":

      'actionsSuppressorWaitPeriod': 120,
      'actionsSuppressorExtensionPeriod': 180
    }
  }
}
```

Configuring how CloudWatch alarms treat missing data

Sometimes, not every expected data point for a metric gets reported to CloudWatch. For example, this can happen when a connection is lost, a server goes down, or when a metric reports data only intermittently by design.

CloudWatch enables you to specify how to treat missing data points when evaluating an alarm. This helps you to configure your alarm so that it goes to `ALARM` state only when appropriate for the type of data being monitored. You can avoid false positives when missing data doesn't indicate a problem.

Similar to how each alarm is always in one of three states, each specific data point reported to CloudWatch falls under one of three categories:

- Not breaching (within the threshold)
- Breaching (violating the threshold)
- Missing

For each alarm, you can specify CloudWatch to treat missing data points as any of the following:

- `notBreaching` – Missing data points are treated as "good" and within the threshold
- `breaching` – Missing data points are treated as "bad" and breaching the threshold
- `ignore` – The current alarm state is maintained
- `missing` – If all data points in the alarm evaluation range are missing, the alarm transitions to INSUFFICIENT_DATA.

The best choice depends on the type of metric and the purpose of the alarm. For example, if you are creating an application rollback alarm using a metric that continually reports data, you might want to treat missing data points as breaching, because it might indicate that something is wrong. But for a metric that generates data points only when an error occurs, such as `ThrottledRequests` in Amazon DynamoDB, you would want to treat missing data as `notBreaching`. The default behavior is `missing`.

> **Important**
>
> Alarms configured on Amazon EC2 metrics can temporarily enter the INSUFFICIENT_DATA state if there are missing metric data points. This is rare, but can happen when the metric reporting is interrupted, even when the Amazon EC2 instance is healthy. For alarms on Amazon EC2 metrics that are configured to take stop, terminate, reboot, or recover actions, we recommend that you configure those alarms to treat missing data as `missing`, and to have these alarms trigger only when in the ALARM state.

Choosing the best option for your alarm prevents unnecessary and misleading alarm condition changes, and also more accurately indicates the health of your system.

> **Important**
>
> Alarms that evaluate metrics in the `AWS/DynamoDB` namespace always ignore missing data even if you choose a different option for how the alarm should treat missing data. When an `AWS/DynamoDB` metric has missing data, alarms that evaluate that metric remain in their current state.

How alarm state is evaluated when data is missing

Whenever an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than the number specified as **Evaluation Periods**. The exact number of data points it attempts to retrieve depends on the length of the alarm period and whether it is based on a metric with standard resolution or high resolution. The time frame of the data points that it attempts to retrieve is the *evaluation range*.

Once CloudWatch retrieves these data points, the following happens:

- If no data points in the evaluation range are missing, CloudWatch evaluates the alarm based on the most recent data points collected. The number of data points evaluated is equal to the **Evaluation Periods** for the alarm. The extra data points from farther back in the evaluation range are not needed and are ignored.
- If some data points in the evaluation range are missing, but the total number of existing data points that were successfully retrieved from the evaluation range is equal to or more than the alarm's **Evaluation Periods**, CloudWatch evaluates the alarm state based on the most recent real data points that were successfully retrieved, including the necessary extra data points from farther back in the evaluation range. In this case, the value you set for how to treat missing data is not needed and is ignored.
- If some data points in the evaluation range are missing, and the number of actual data points that were retrieved is lower than the alarm's number of **Evaluation Periods**, CloudWatch fills in the missing data points with the result you specified for how to treat missing data, and then evaluates the alarm. However, all real data points in the evaluation range are included in the evaluation. CloudWatch uses missing data points only as few times as possible.

> **Note**
>
> A particular case of this behavior is that CloudWatch alarms might repeatedly re-evaluate the last set of data points for a period of time after the metric has stopped flowing. This re-evaluation might cause the alarm to change state and re-execute actions, if it had changed state immediately prior to the metric stream stopping. To mitigate this behavior, use shorter periods.

The following tables illustrate examples of the alarm evaluation behavior. In the first table, **Datapoints to Alarm** and **Evaluation Periods** are both 3. CloudWatch retrieves the 5 most recent data points when evaluating the alarm, in case some of the most recent 3 data points are missing. 5 is the evaluation range for the alarm.

Column 1 shows the 5 most recent data points, because the evaluation range is 5. These data points are shown with the most recent data point on the right. 0 is a non-breaching data point, X is a breaching data point, and - is a missing data point.

Column 2 shows how many of the 3 necessary data points are missing. Even though the most recent 5 data points are evaluated, only 3 (the setting for **Evaluation Periods**) are necessary to evaluate the alarm state. The number of data points in Column 2 is the number of data points that must be "filled in", using the setting for how missing data is being treated.

In columns 3-6, the column headers are the possible values for how to treat missing data. The rows in these columns show the alarm state that is set for each of these possible ways to treat missing data.

Data points	# of data points that must be filled	MISSING	IGNORE	BREACHING	NOT BREACHING
0 - X - X	0	`OK`	`OK`	`OK`	`OK`
0 - - - -	2	`OK`	`OK`	`OK`	`OK`
- - - - -	3	`INSUFFICIENT_DATA`	Retain current state	`ALARM`	`OK`

Data points	# of data points that must be filled	MISSING	IGNORE	BREACHING	NOT BREACHING
0 X X - X	0	`ALARM`	`ALARM`	`ALARM`	`ALARM`
- - X - -	2	`ALARM`	Retain current state	`ALARM`	`OK`

In the second row of the preceding table, the alarm stays `OK` even if missing data is treated as breaching, because the one existing data point is not breaching, and this is evaluated along with two missing data points which are treated as breaching. The next time this alarm is evaluated, if the data is still missing it will go to `ALARM`, as that non-breaching data point will no longer be in the evaluation range.

The third row, where all five of the most recent data points are missing, illustrates how the various settings for how to treat missing data affect the alarm state. If missing data points are considered breaching, the alarm goes into ALARM state, while if they are considered not breaching, then the alarm goes into OK state. If missing data points are ignored, the alarm retains the current state it had before the missing data points. And if missing data points are just considered as missing, then the alarm does not have enough recent real data to make an evaluation, and goes into INSUFFICIENT_DATA.

In the fourth row, the alarm goes to `ALARM` state in all cases because the three most recent data points are breaching, and the alarm's **Evaluation Periods** and **Datapoints to Alarm** are both set to 3. In this case, the missing data point is ignored and the setting for how to evaluate missing data is not needed, because there are 3 real data points to evaluate.

Row 5 represents a special case of alarm evaluation called *premature alarm state*. For more information, see [Avoiding premature transitions to alarm state](#).

In the next table, the **Period** is again set to 5 minutes, and **Datapoints to Alarm** is only 2 while **Evaluation Periods** is 3. This is a 2 out of 3, M out of N alarm.

The evaluation range is 5. This is the maximum number of recent data points that are retrieved and can be used in case some data points are missing.

Data points	# of missing data points	MISSING	IGNORE	BREACHING	NOT BREACHING
0 - X - X	0	ALARM	ALARM	ALARM	ALARM
0 0 X 0 X	0	ALARM	ALARM	ALARM	ALARM
0 - X - -	1	OK	OK	ALARM	OK
- - - - 0	2	OK	OK	ALARM	OK
- - - X -	2	ALARM	Retain current state	ALARM	OK

In rows 1 and 2, the alarm always goes to ALARM state because 2 of the 3 most recent data points are breaching. In row 2, the two oldest data points in the evaluation range are not needed because none of the 3 most recent data points are missing, so these two older data points are ignored.

In rows 3 and 4, the alarm goes to ALARM state only if missing data is treated as breaching, in which case the two most recent missing data points are both treated as breaching. In row 4, these two missing data points that are treated as breaching provide the two necessary breaching data points to trigger the ALARM state.

Row 5 represents a special case of alarm evaluation called *premature alarm state*. For more information, see the following section.

Avoiding premature transitions to alarm state

CloudWatch alarm evaluation includes logic to try to avoid false alarms, where the alarm goes into ALARM state prematurely when data is intermittent. The example shown in row 5 in the tables in the previous section illustrate this logic. In those rows, and in the following examples, the **Evaluation Periods** is 3 and the evaluation range is 5 data points. **Datapoints to Alarm** is 3, except for the M out of N example, where **Datapoints to Alarm** is 2.

Suppose an alarm's most recent data is `- - - - X`, with four missing data points and then a breaching data point as the most recent data point. Because the next data point may be non-breaching, the alarm does not go immediately into ALARM state when the data is either `- - - - X` or `- - - X -` and **Datapoints to Alarm** is 3. This way, false positives are avoided when the next data point is non-breaching and causes the data to be `- - - X 0` or `- - X - 0`.

However, if the last few data points are `- - X - -`, the alarm goes into ALARM state even if missing data points are treated as missing. This is because alarms are designed to always go into ALARM state when the oldest available breaching datapoint during the **Evaluation Periods** number of data points is at least as old as the value of **Datapoints to Alarm**, and all other more recent data points are breaching or missing. In this case, the alarm goes into ALARM state even if the total number of datapoints available is lower than M (**Datapoints to Alarm**).

This alarm logic applies to M out of N alarms as well. If the oldest breaching data point during the evaluation range is at least as old as the value of **Datapoints to Alarm**, and all of the more recent data points are either breaching or missing, the alarm goes into ALARM state no matter the value of M (**Datapoints to Alarm**).

High-resolution alarms

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds, 20 seconds, or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publish custom metrics.

Alarms on math expressions

You can set an alarm on the result of a math expression that is based on one or more CloudWatch metrics. A math expression used for an alarm can include as many as 10 metrics. Each metric must be using the same period.

For an alarm based on a math expression, you can specify how you want CloudWatch to treat missing data points. In this case, the data point is considered missing if the math expression doesn't return a value for that data point.

Alarms based on math expressions can't perform Amazon EC2 actions.

For more information about metric math expressions and syntax, see Using math expressions with CloudWatch metrics.

Percentile-based CloudWatch alarms and low data samples

When you set a percentile as the statistic for an alarm, you can specify what to do when there is not enough data for a good statistical assessment. You can choose to have the alarm evaluate the statistic anyway and possibly change the alarm state. Or, you can have the alarm ignore the metric while the sample size is low, and wait to evaluate it until there is enough data to be statistically significant.

For percentiles between 0.5 (inclusive) and 1.00 (exclusive), this setting is used when there are fewer than 10/(1-percentile) data points during the evaluation period. For example, this setting would be used if there were fewer than 1000 samples for an alarm on a p99 percentile. For percentiles between 0 and 0.5 (exclusive), the setting is used when there are fewer than 10/percentile data points.

Common features of CloudWatch alarms

The following features apply to all CloudWatch alarms:

- There is no limit to the number of alarms that you can create. To create or update an alarm, you use the CloudWatch console, the PutMetricAlarm API action, or the put-metric-alarm command in the Amazon CLI.
- Alarm names must contain only UTF-8 characters, and can't contain ASCII control characters
- You can list any or all of the currently configured alarms, and list any alarms in a particular state by using the CloudWatch console, the DescribeAlarms API action, or the describe-alarms command in the Amazon CLI.
- You can disable and enable alarm actions by using the DisableAlarmActions and EnableAlarmActions API actions, or the disable-alarm-actions and enable-alarm-actions commands in the Amazon CLI.
- You can test an alarm by setting it to any state using the SetAlarmState API action or the set-alarm-state command in the Amazon CLI. This temporary state change lasts only until the next alarm comparison occurs.
- You can create an alarm for a custom metric before you've created that custom metric. For the alarm to be valid, you must include all of the dimensions for the custom metric in addition to the metric namespace and metric name in the alarm definition. To do this, you can use the PutMetricAlarm API action, or the put-metric-alarm command in the Amazon CLI.
- You can view an alarm's history using the CloudWatch console, the DescribeAlarmHistory API action, or the describe-alarm-history command in the Amazon CLI. CloudWatch preserves alarm history for 30 days. Each state transition is marked with a unique timestamp. In rare cases, your history might show more than one notification for a state change. The timestamp enables you to confirm unique state changes.

- You can favorite alarms from the *Favorites and recents* option in the CloudWatch console navigation pane by hovering over the alarm that you want to favorite and choosing the star symbol next to it.
- Alarms have an evaluation period quota. The evaluation period is calculated by multiplying the alarm period by the number of evaluation periods used.
  - The maximum evaluation period is seven days for alarms with a period of at least one hour (3600 seconds).
  - The maximum evaluation period is one day for alarms with a shorter period.
  - The maximum evaluation period is one day for alarms that use the custom Lambda data source.

> **Note**
>
> Some Amazon resources don't send metric data to CloudWatch under certain conditions. For example, Amazon EBS might not send metric data for an available volume that is not attached to an Amazon EC2 instance, because there is no metric activity to be monitored for that volume. If you have an alarm set for such a metric, you might notice its state change to `INSUFFICIENT_DATA`. This might indicate that your resource is inactive, and might not necessarily mean that there is a problem. You can specify how each alarm treats missing data. For more information, see Configuring how CloudWatch alarms treat missing data.

Best practice alarm recommendations for Amazon services

CloudWatch provides out-of-the box alarm recommendations. These are CloudWatch alarms that we recommend that you create for metrics that are published by other Amazon services. These recommendations can help you identify the metrics that you should set alarms for to follow best practices for monitoring. The recommendations also suggest the alarm thresholds to set. Following these recommendations can help you not miss important monitoring of your Amazon infrastructure.

To find the alarm recommendations, you use the metrics section of the CloudWatch console, and select the alarm recommendations filter toggle. If you navigate to the recommended alarms in the console and then create a recommended alarm, CloudWatch can pre-fill some of the alarm settings. For some recommended alarms, the alarm threshold value is also pre-filled. You can also use the console to download infrastructure-as-code alarm definitions for recommended alarms, and then use this code to create the alarm in Amazon CloudFormation, the Amazon CLI, or Terraform.

You can also see the list of recommended alarms in Recommended alarms.

You are charged for the alarms that you create, at the same rate as any other alarms that you create in CloudWatch. Using the recommendations incurs no extra charges. For more information, see Amazon CloudWatch Pricing.

Find and create recommended alarms

Follow these steps to find the metrics that CloudWatch recommends that you set alarms for, and optionally to create one of these alarms. The first procedure explains how to find the metrics that have recommended alarms, and how to create one of these alarms.

You can also get a bulk download of infrastructure-as-code alarm definitions for all recommended alarms in an Amazon namespace, such as `AWS/Lambda` or `AWS/S3`. Those instructions are later in this topic.

To find the metrics with recommended alarms, and create a single recommended alarm

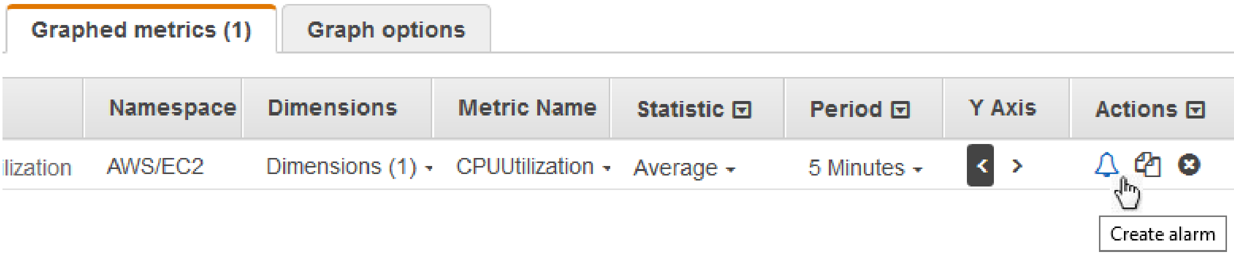
1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Above the **Metrics** table, Choose **Alarm recommendations**.

   The list of metric namespaces is filtered to include only the metrics that have alarm recommendations and that services in your account are publishing.
4. Choose the namespace for a service.

   The list of metrics under this namespace is filtered to include only those that have alarm recommendations.
5. To see the alarm intent and recommended threshold for a metric, choose **View details**.
6. To create an alarm for one of the metrics, do one of the following:
   - To use the console to create the alarm, do the following:

     a. Select the checkbox for the metric and choose the **Graphed metrics** tab.

     b. Choose the alarm icon.



The alarm creation wizard appears, with the metric name, statistic, and period filled in based on the alarm recommendation. If the recommendation includes a specific threshold value, that value is also pre-filled.

c. Choose **Next**.

d. Under **Notification**, select an SNS topic to notify when the alarm transitions to `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   To have the alarm not send notifications, choose **Remove**.

e. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.

f. When finished, choose **Next**.

g. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.

h. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

- To download an infrastructure-as-code alarm definition to use in either Amazon CloudFormation, Amazon CLI, or Terraform, choose **Download alarm code** and select the format that you want. The downloaded code will have the recommended settings for the metric name, statistic, and threshold.

To download infrastructure-as-code alarm definitions for all recommended alarms for an Amazon service

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.

3. Above the **Metrics** table, Choose **Alarm recommendations**.

   The list of metric namespaces is filtered to include only the metrics that have alarm recommendations and that services in your account are publishing.

4. Choose the namespace for a service.

   The list of metrics under this namespace is filtered to include only those that have alarm recommendations.

5. The **Download alarm code** displays how many alarms are recommended for the metrics in this namespace. To download infrastructure-as-code alarm definitions for all recommended alarms, choose **Download alarm code** and then choose the code format that you want.

Recommended alarms

The following sections list the metrics that we recommend that you set best practice alarms for. For each metric, the dimensions, alarm intent, recommended threshold, threshold justification, and the period length and number of datapoints is also displayed.

Some metrics might appear twice in the list. This happens when different alarms are recommended for different combinations of dimensions of that metric.

Datapoints to alarm is the number of data points that must be breaching to send the alarm into ALARM state. **Evaluation periods** is the number of periods that are taken into account when the alarm is evaluated. If these numbers are the same, the alarm goes into ALARM state only when that number of consecutive periods have values that breach the threshold. If **Datapoints to alarm** is lower than **Evaluation periods**, then it is an "M out of N" alarm and the alarm goes into ALARM state if at least **Datapoints to alarm** data points are breaching within any **Evaluation periods** set of data points. For more information, see Evaluating an alarm.

Amazon API Gateway

4XXError

Dimensions: ApiName, Stage

Alarm description: This alarm detects a high rate of client-side errors. This can indicate an issue in the authorization or client request parameters. It could also mean that a resource was removed or a client is requesting one that doesn't exist. Consider enabling CloudWatch Logs and checking for any errors that may be causing the 4XX errors. Moreover, consider enabling detailed CloudWatch metrics to view this metric per resource and method and narrow down the source of the errors. Errors could also be caused by exceeding the configured throttling limit. If the responses and logs are reporting high and unexpected rates of 429 errors, follow this guide to troubleshoot this issue.

Intent: This alarm can detect high rates of client-side errors for the API Gateway requests.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting 4XX errors. However, you can tune the threshold to suit the traffic of the requests as well as acceptable error rates. You can also analyze historical data to determine the acceptable error rate for the application workload and then tune the threshold accordingly. Frequently occurring 4XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

5XXError

Dimensions: ApiName, Stage

Alarm description: This alarm helps to detect a high rate of server-side errors. This can indicate that there is something wrong on the API backend, the network, or the integration between the API gateway and the backend API. This documentation can help you troubleshoot the cause of 5xx errors.

Intent: This alarm can detect high rates of server-side errors for the API Gateway requests.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting 5XX errors. However, you can tune the threshold to suit the traffic of the requests as well as acceptable error rates. you can also analyze historical data to determine the acceptable error rate for the application workload and then tune the threshold accordingly. Frequently occurring 5XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

Count

Dimensions: ApiName, Stage

Alarm description: This alarm helps to detect low traffic volume for the REST API stage. This can be an indicator of an issue with the application calling the API such as using incorrect endpoints. It could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the REST API stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. If you have detailed CloudWatch metrics enabled and you can predict the normal traffic volume per method and resource, we recommend that you create alternative alarms to have more fine-grained monitoring of traffic volume drops for each resource and method. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiName, Stage, Resource, Method

Alarm description: This alarm helps to detect low traffic volume for the REST API resource and method in the stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the REST API resource and method in the stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiId, Stage

Alarm description: This alarm helps to detect low traffic volume for the HTTP API stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It could also be an indicator of an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the HTTP API stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. If you have detailed CloudWatch metrics enabled and you can predict the normal traffic volume per route, we recommend that you create alternative alarms to this in order to have more fine-grained monitoring of traffic volume drops for each route. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold value based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Count

Dimensions: ApiId, Stage, Resource, Method

Alarm description: This alarm helps to detect low traffic volume for the HTTP API route in the stage. This can indicate an issue with the application calling the API such as using incorrect endpoints. It could also indicate an issue with the configuration or permissions of the API making it unreachable for clients.

Intent: This alarm can detect unexpectedly low traffic volume for the HTTP API route in the stage. We recommend that you create this alarm if your API receives a predictable and consistent number of requests under normal conditions. This alarm is not recommended for APIs that don't expect constant and consistent traffic.

Statistic: SampleCount

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold value based on historical data analysis to determine what the expected baseline request count for your API is. Setting the threshold at a very high value might cause the alarm to be too sensitive at periods of normal and expected low traffic. Conversely, setting it at a very low value might cause the alarm to miss anomalous smaller drops in traffic volume.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

IntegrationLatency

Dimensions: ApiId, Stage

Alarm description: This alarm helps to detect if there is high integration latency for the API requests in a stage. You can correlate the `IntegrationLatency` metric value with the corresponding latency metric of your backend such as the `Duration` metric for Lambda integrations. This helps you determine whether the API backend is taking more time to process requests from clients due to performance issues, or if there is some other overhead from initialization or cold start. Additionally, consider enabling CloudWatch Logs for your API and checking the logs for any errors that may be causing the high latency issues. Moreover, consider enabling detailed CloudWatch metrics to get a view of this metric per route, to help you narrow down the source of the integration latency.

Intent: This alarm can detect when the API Gateway requests in a stage have a high integration latency. We recommend this alarm for WebSocket APIs, and we consider it optional for HTTP APIs because they already have separate alarm recommendations for the Latency metric. If you have detailed CloudWatch metrics enabled and you have different integration latency performance requirements per route, we recommend that you create alternative alarms in order to have more fine-grained monitoring of the integration latency for each route.

Statistic: p90

Recommended threshold: 2000.0

Threshold justification: The suggested threshold value does not work for all the API workloads. However, you can use it as a starting point for the threshold. You can then choose different threshold values based on the workload and acceptable latency, performance, and SLA requirements for the API. If is acceptable for the API to have a higher latency in general, set a higher threshold value to make the alarm less sensitive. However, if the API is expected to provide near real-time responses, set a lower threshold value. You can also analyze historical data to determine the expected baseline latency for the application workload, and then used to tune the threshold value accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

IntegrationLatency

Dimensions: ApiId, Stage, Route

Alarm description: This alarm helps to detect if there is high integration latency for the WebSocket API requests for a route in a stage. You can correlate the `IntegrationLatency` metric value with the corresponding latency metric of your backend such as the `Duration` metric for Lambda integrations. This helps you determine whether the API backend is taking more time to process requests from clients due to performance issues or if there is some other overhead from initialization or cold start. Additionally, consider enabling CloudWatch Logs for your API and checking the logs for any errors that may be causing the high latency issues.

Intent: This alarm can detect when the API Gateway requests for a route in a stage have high integration latency.

Statistic: p90

Recommended threshold: 2000.0

Threshold justification: The suggested threshold value does not work for all the API workloads. However, you can use it as a starting point for the threshold. You can then choose different threshold values based on the workload and acceptable latency, performance, and SLA requirements for the API. If it is acceptable for the API to have a higher latency in general, you can set a higher threshold value to make the alarm less sensitive. However, if the API is expected to provide near real-time responses, set a lower threshold value. You can also analyze historical data to determine the expected baseline latency for the application workload, and then used to tune the threshold value accordingly.

Intent: This alarm can detect high rates of client errors for the WebSocket API Gateway messages.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting 4xx errors. You can tune the threshold to suit the traffic of the requests as well as to suit your acceptable error rates. You can also analyze historical data to determine the acceptable error rate for the application workload, and then tune the threshold accordingly. Frequently occurring 4xx errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ExecutionError

Dimensions: ApiId, Stage

Alarm description: This alarm helps to detect a high rate of execution errors. This can be caused by 5xx errors from your integration, permission issues, or other factors preventing successful invocation of the integration, such as the integration being throttled or deleted. Consider enabling CloudWatch Logs for your API and checking the logs for the type and cause of the errors. Moreover, consider enabling detailed CloudWatch metrics to get a view of this metric per route, to help you narrow down the source of the errors. This documentation can also help you troubleshoot the cause of any connection errors.

Intent: This alarm can detect high rates of execution errors for the WebSocket API Gateway messages.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The suggested threshold detects when more than 5% of total requests are getting execution errors. You can tune the threshold to suit the traffic of the requests, as well as to suit your acceptable error rates. You can analyze historical data to determine the acceptable error rate for the application workload, and then tune the threshold accordingly. Frequently occurring execution errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EC2 Auto Scaling

GroupInServiceCapacity

Dimensions: AutoScalingGroupName

Alarm description: This alarm helps to detect when the capacity in the group is below the desired capacity required for your workload. To troubleshoot, check your scaling activities for launch failures and confirm that your desired capacity configuration is correct.

Intent: This alarm can detect a low availability in your auto scaling group because of launch failures or suspended launches.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The threshold value should be the minimum capacity required to run your workload. In most cases, you can set this to match the GroupDesiredCapacity metric.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

Amazon Certificate Manager (ACM)

DaysToExpiry

Dimensions: CertificateArn

Alarm description: This alarm helps you detect when a certificate managed by or imported into ACM is approaching its expiration date. It helps to prevent unexpected certificate expirations that could lead to service disruptions. When the alarm transitions into ALARM state, you should take immediate action to renew or re-import the certificate. For ACM-managed certificates, see the instructions at certificate renewal process. For imported certificates, see the instructions at re-import process.

Intent: This alarm can proactively alert you about upcoming certificate expirations. It provides sufficient advance notice to allow for manual intervention, enabling you to renew or replace certificates before they expire. This helps you maintain the security and availability of TLS-enabled services. When this goes into ALARM, immediately investigate the certificate status and initiate the renewal process if necessary.

Statistic: Minimum

Recommended threshold: 44.0

Threshold justification: The 44-day threshold provides a balance between early warning and avoiding false alarms. It allows sufficient time for manual intervention if automatic renewal fails. Adjust this value based on your certificate renewal process and operational response times.

Period: 86400

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Amazon CloudFront

5xxErrorRate

Dimensions: DistributionId, Region=Global

Alarm description: This alarm monitors the percentage of 5xx error responses from your origin server, to help you detect if the CloudFront service is having issues. See Troubleshooting error responses from your origin for information to help you understand the problems with your server. Also, turn on additional metrics to get detailed error metrics.

Intent: This alarm is used to detect problems with serving requests from the origin server, or problems with communication between CloudFront and your origin server.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the tolerance for 5xx responses. You can analyze historical data and trends, and then set the threshold accordingly. Because 5xx errors can be caused by transient issues, we recommend that you set the threshold to a value greater than 0 so that the alarm is not too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

OriginLatency

Dimensions: DistributionId, Region=Global

Alarm description: The alarm helps to monitor if the origin server is taking too long to respond. If the server takes too long to respond, it might lead to a timeout. Refer to find and fix delayed responses from applications on your origin server if you experience consistently high `OriginLatency` values.

Intent: This alarm is used to detect problems with the origin server taking too long to respond.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of about 80% of the origin response timeout, and use the result as the threshold value. If this metric is consistently close to the origin response timeout value, you might start experiencing 504 errors.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionValidationErrors

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you monitor validation errors from CloudFront functions so that you can take steps to resolve them. Analyze the CloudWatch function logs and look at the function code to find and resolve the root cause of the problem. See Restrictions on edge functions to understand the common misconfigurations for CloudFront Functions.

Intent: This alarm is used to detect validation errors from CloudFront functions.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: A value greater than 0 indicates a validation error. We recommend setting the threshold to 0 because validation errors imply a problem when CloudFront functions hand off back to CloudFront. For example, CloudFront needs the HTTP Host header in order to process a request. There is nothing stopping a user from deleting the Host header in their CloudFront functions code. But when CloudFront gets the response back and the Host header is missing, CloudFront throws a validation error.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionExecutionErrors

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you monitor execution errors from CloudFront functions so that you can take steps to resolve them. Analyze the CloudWatch function logs and look at the function code to find and resolve the root cause of the problem.

Intent: This alarm is used to detect execution errors from CloudFront functions.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: We recommend to set the threshold to 0 because an execution error indicates a problem with the code that occurs at runtime.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FunctionThrottles

Dimensions: DistributionId, FunctionName, Region=Global

Alarm description: This alarm helps you to monitor if your CloudFront function is throttled. If your function is throttled, it means that it is taking too long to execute. To avoid function throttles, consider optimizing the function code.

Intent: This alarm can detect when your CloudFront function is throttled so that you can react and resolve the issue for a smooth customer experience.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: We recommend setting the threshold to 0, to allow quicker resolution of the function throttles.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Cognito

SignUpThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: This alarm monitors the count of throttled requests. If users are consistently getting throttled, you should increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase. To take actions proactively, consider tracking the usage quota.

Intent: This alarm helps to monitor the occurrence of throttled sign-up requests. This can help you know when to take actions to mitigate any degradation in sign-up experience. Sustained throttling of requests is a negative user sign-up experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: A well-provisioned user pool should not encounter any throttling which spans across multiple data points. So, a typical threshold for an expected workload should be zero. For an irregular workload with frequent bursts, you can analyze historical data to determine the acceptable throttling for the application workload, and then you can tune the threshold accordingly. A throttled request should be retried to minimize the impact on the application.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SignInThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: This alarm monitors the count of throttled user authentication requests. If users are consistently getting throttled, you might need to increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase. To take actions proactively, consider tracking the usage quota.

Intent: This alarm helps to monitor the occurrence of throttled sign-in requests. This can help you know when to take actions to mitigate any degradation in sign-in experience. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: A well-provisioned user pool should not encounter any throttling which spans across multiple data points. So, a typical threshold for an expected workload should be zero. For an irregular workload with frequent bursts, you can analyze historical data to determine the acceptable throttling for the application workload, and then you can tune the threshold accordingly. A throttled request should be retried to minimize the impact on the application.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TokenRefreshThrottles

Dimensions: UserPool, UserPoolClient

Alarm description: You can set the threshold value can to suit the traffic of the request as well as to match acceptable throttling for token refresh requests. Throttling is used to protect your system from too many requests. However, it is important to monitor if you are under provisioned for your normal traffic as well. You can analyze historical data to find the acceptable throttling for the application workload, and then you can tune your alarm threshold to be higher than your acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Intent: This alarm helps to monitor the occurrence of throttled token refresh requests. This can help you know when to take actions to mitigate any potential problems, to ensure a smooth user experience and the health and reliability of your authentication system. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Threshold value can also be set/tuned to suit the traffic of the request as well as acceptable throttling for token refresh requests. Throttling are there for protecting your system from too many requests, however it is important to monitor if you are under provisioned for your normal traffic as well and see if it is causing the impact. Historical data can also be analyzed to see what is the acceptable throttling for the application workload and threshold can be tuned higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

FederationThrottles

Dimensions: UserPool, UserPoolClient, IdentityProvider

Alarm description: This alarm monitors the count of throttled identity federation requests. If you consistently see throttling, it might indicate that you need to increase the limit by requesting a service quota increase. Refer to Quotas in Amazon Cognito to learn how to request a quota increase.

Intent: This alarm helps to monitor the occurrence of throttled identity federation requests. This can help you take proactive responses to performance bottlenecks or misconfigurations, and ensure a smooth authentication experience for your users. Sustained throttling of requests is a bad user authentication experience.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: You can set the threshold to suit the traffic of the request as well as to match the acceptable throttling for identity federation requests. Throttling is used for protecting your system from too many requests. However, it is important to monitor if you are under provisioned for your normal traffic as well. You can analyze historical data to find the acceptable throttling for the application workload, and then set the threshold to a value above your acceptable throttling level. Throttled requests should be retried by the application/ service as they are transient. Therefore, a very low value for the threshold can cause alarm to be sensitive.

Amazon DynamoDB

AccountProvisionedReadCapacityUtilization

Dimensions: None

Alarm description: This alarm detects if the account's read capacity is reaching its provisioned limit. You can raise the account quota for read capacity utilization if this occurs. You can view your current quotas for read capacity units and request increases using Service Quotas.

Intent: The alarm can detect if the account's read capacity utilization is approaching its provisioned read capacity utilization. If the utilization reaches its maximum limit, DynamoDB starts to throttle read requests.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: Set the threshold to 80%, so that action (such as raising the account limits) can be taken before it reaches full capacity to avoid throttling.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

AccountProvisionedWriteCapacityUtilization

Dimensions: None

Alarm description: This alarm detects if the account's write capacity is reaching its provisioned limit. You can raise the account quota for write capacity utilization if this occurs. You can view your current quotas for write capacity units and request increases using Service Quotas.

Intent: This alarm can detect if the account's write capacity utilization is approaching its provisioned write capacity utilization. If the utilization reaches its maximum limit, DynamoDB starts to throttle write requests.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: Set the threshold to 80%, so that the action (such as raising the account limits) can be taken before it reaches full capacity to avoid throttling.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_THRESHOLD

AgeOfOldestUnreplicatedRecord

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the delay in replication to a Kinesis data stream. Under normal operation, `AgeOfOldestUnreplicatedRecord` should be only milliseconds. This number grows based on unsuccessful replication attempts caused by customer-controlled configuration choices. Customer-controlled configuration examples that lead to unsuccessful replication attempts are an under-provisioned Kinesis data stream capacity that leads to excessive throttling. or a manual update to the Kinesis data stream's access policies that prevents DynamoDB from adding data to the data stream. To keep this metric as low as possible, you need to ensure the right provisioning of Kinesis data stream capacity and make sure that DynamoDB's permissions are unchanged.

Intent: This alarm can monitor unsuccessful replication attempts and the resulting delay in replication to the Kinesis data stream.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the desired replication delay measured in milliseconds. This value depends on your workload's requirements and expected performance.

Period: 300

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

FailedToReplicateRecordCount

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the number of records that DynamoDB failed to replicate to your Kinesis data stream. Certain items larger than 34 KB might expand in size to change data records that are larger than the 1 MB item size limit of Kinesis Data Streams. This size expansion occurs when these larger than 34 KB items include a large number of Boolean or empty attribute values. Boolean and empty attribute values are stored as 1 byte in DynamoDB, but expand up to 5 bytes when they're serialized using standard JSON for Kinesis Data Streams replication. DynamoDB can't replicate such change records to your Kinesis data stream. DynamoDB skips these change data records, and automatically continues replicating subsequent records.

Intent: This alarm can monitor the number of records that DynamoDB failed to replicate to your Kinesis data stream because of the item size limit of Kinesis Data Streams.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect any records that DynamoDB failed to replicate.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

ReadThrottleEvents

Dimensions: TableName

Alarm description: This alarm detects if there are high number of read requests getting throttled for the DynamoDB table. To troubleshoot the issue, see Troubleshooting throttling issues in Amazon DynamoDB.

Intent: This alarm can detect sustained throttling for read requests to the DynamoDB table. Sustained throttling of read requests can negatively impact your workload read operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected read traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor whether you are under provisioned and not causing consistent throttling. You can also analyze historical data to find the acceptable throttling level for the application workload, and then tune the threshold to be higher than your usual throttling level. Throttled requests should be retried by the application or service as they are transient. Therefore, a very low threshold may cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReadThrottleEvents

Dimensions: TableName, GlobalSecondaryIndexName

Alarm description: This alarm detects if there are a high number of read requests getting throttled for the Global Secondary Index of the DynamoDB table. To troubleshoot the issue, see Troubleshooting throttling issues in Amazon DynamoDB.

Intent: The alarm can detect sustained throttling for read requests for the Global Secondary Index of the DynamoDB Table. Sustained throttling of read requests can negatively impact your workload read operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected read traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze historical data to find an acceptable throttling level for the application workload, and then tune the threshold to be higher than your usual acceptable throttling level. Throttled requests should be retried by the application or service as they are transient. Therefore, a very low threshold may cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicationLatency

Dimensions: TableName, ReceivingRegion

Alarm description: The alarm detects if the replica in a Region for the global table is lagging behind the source Region. The latency can increase if an Amazon Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different Amazon Region. If you are using 2017.11.29 (Legacy) of global tables, you should verify that write capacity units (WCUs) are identical for each of the replica tables. You can also make sure to follow recommendations in Best practices and requirements for managing capacity.

Intent: The alarm can detect if the replica table in a Region is falling behind replicating the changes from another Region. This could cause your replica to diverge from the other replicas. It's useful to know the replication latency of each Amazon Region and alert if that replication latency increases continually. The replication of the table applies to global tables only.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Replication latencies longer than 3 minutes are generally a cause for investigation. Review the criticality and requirements of replication delay and analyze historical trends, and then select the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

SuccessfulRequestLatency

Dimensions: TableName, Operation

Alarm description: This alarm detects a high latency for the DynamoDB table operation (indicated by the dimension value of the `Operation` in the alarm). See this troubleshooting document for troubleshooting latency issues in Amazon DynamoDB.

Intent: This alarm can detect a high latency for the DynamoDB table operation. Higher latency for the operations can negatively impact the overall efficiency of the system.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: DynamoDB provides single-digit millisecond latency on average for singleton operations such as GetItem, PutItem, and so on. However, you can set the threshold based on acceptable tolerance for the latency for the type of operation and table involved in the workload. You can analyze historical data of this metric to find the usual latency for the table operation, and then set the threshold to a number which represents critical delay for the operation.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

SystemErrors

Dimensions: TableName

Alarm description: This alarm detects a sustained high number of system errors for the DynamoDB table requests. If you continue to get 5xx errors, open the Amazon Service Health Dashboard to check for operational issues with the service. You can use this alarm to get notified in case there is a prolonged internal service issue from DynamoDB and it helps you correlate with the issue your client application is facing. Refer Error handling for DynamoDB for more information.

Intent: This alarm can detect sustained system errors for the DynamoDB table requests. System errors indicate internal service errors from DynamoDB and helps correlate to the issue that the client is having.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected traffic, accounting for an acceptable level of system errors. You can also analyze historical data to find the acceptable error count for the application workload, and then tune the threshold accordingly. System errors should be retried by the application/service as they are transient. Therefore, a very low threshold might cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

ThrottledPutRecordCount

Dimensions: TableName, DelegatedOperation

Alarm description: This alarm detects the records getting throttled by your Kinesis data stream during the replication of change data capture to Kinesis. This throttling happens because of insufficient Kinesis data stream capacity. If you experience excessive and regular throttling, you might need to increase the number of Kinesis stream shards proportionally to the observed write throughput of your table. To learn more about determining the size of a Kinesis data stream, see Determining the Initial Size of a Kinesis Data Stream.

Intent: This alarm can monitor the number of records that that were throttled by your Kinesis data stream because of insufficient Kinesis data stream capacity.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: You might experience some throttling during exceptional usage peaks, but throttled records should remain as low as possible to avoid higher replication latency (DynamoDB retries sending throttled records to the Kinesis data stream). Set the threshold to a number which can help you catch regular excessive throttling. You can also analyze historical data of this metric to find the acceptable throttling rates for the application workload. Tune the threshold to a value that the application can tolerate based on your use case.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

UserErrors

Dimensions: None

Alarm description: This alarm detects a sustained high number of user errors for the DynamoDB table requests. You can check client application logs during the issue time frame to see why the requests are invalid. You can check HTTP status code 400 to see the type of error you are getting and take action accordingly. You might have to fix the application logic to create valid requests.

Intent: This alarm can detect sustained user errors for the DynamoDB table requests. User errors for requested operations mean that the client is producing invalid requests and it is failing.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to zero to detect any client side errors. Or you can set it to a higher value if you want to avoid the alarm triggering for a very lower number of errors. Decide based on your use case and traffic for the requests.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

WriteThrottleEvents

Dimensions: TableName

Alarm description: This alarm detects if there are a high number of write requests getting throttled for the DynamoDB table. See [Troubleshooting throttling issues in Amazon DynamoDB] to troubleshoot the issue.

Intent: This alarm can detect sustained throttling for write requests to the DynamoDB table. Sustained throttling of write requests can negatively impact your workload write operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected write traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze historical data to find the acceptable level of throttling for the application workload, and then tune the threshold to a value higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low threshold might cause the alarm to be too sensitive, causing unwanted state transitions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

WriteThrottleEvents

Dimensions: TableName, GlobalSecondaryIndexName

Alarm description: This alarm detects if there are a high number of write requests getting throttled for Global Secondary Index of the DynamoDB table. See [Troubleshooting throttling issues in Amazon DynamoDB]() to troubleshoot the issue.

Intent: This alarm can detect sustained throttling for write requests for the Global Secondary Index of DynamoDB Table. Sustained throttling of write requests can negatively impact your workload write operations and reduce the overall efficiency of the system.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the expected Write traffic for the DynamoDB table, accounting for an acceptable level of throttling. It is important to monitor if you are under provisioned and not causing consistent throttling. You can also analyze historical data to find the acceptable throttling level for the application workload, and then tune the threshold to a value higher than your usual acceptable throttling level. Throttled requests should be retried by the application/service as they are transient. Therefore, a very low value might cause the alarm to be too sensitive, causing unwanted state transitions.

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EBS

VolumeStalledIOCheck

Dimensions: VolumeId, InstanceId

Alarm description: This alarm helps you monitor the IO performance of your Amazon EBS volumes. This check detects underlying issues with the Amazon EBS infrastructure, such as hardware or software issues on the storage subsystems underlying the Amazon EBS volumes, hardware issues on the physical host that impact the reachability of the Amazon EBS volumes from your Amazon EC2 instance, and can detect connectivity issues between the instance and the Amazon EBS volumes. If the Stalled IO Check fails, you can either wait for Amazon to resolve the issue, or you can take action such as replacing the affected volume or stopping and restarting the instance to which the volume is attached. In most cases, when this metric fails, Amazon EBS will automatically diagnose and recover your volume within a few minutes.

Intent: This alarm can detect the status of your Amazon EBS volumes to determine when these volumes are impaired and can not complete I/O operations.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Amazon EC2

CPUUtilization

Dimensions: InstanceId

Alarm description: This alarm helps to monitor the CPU utilization of an EC2 instance. Depending on the application, consistently high utilization levels might be normal. But if performance is degraded, and the application is not constrained by disk I/O, memory, or network resources, then a maxed-out CPU might indicate a resource bottleneck or application performance problems. High CPU utilization might indicate that an upgrade to a more CPU intensive instance is required. If detailed monitoring is enabled, you can change the period to 60 seconds instead of 300 seconds. For more information, see Enable or turn off detailed monitoring for your instances.

Intent: This alarm is used to detect high CPU utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for CPU utilization to 70-80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some systems, consistently high CPU utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical CPU utilization data to identify the usage, find what CPU utilization is acceptable for your system, and set the threshold accordingly.

Period: 300

Datapoints to alarm: 3

StatusCheckFailed

Dimensions: InstanceId

Alarm description: This alarm helps to monitor both system status checks and instance status checks. If either type of status check fails, then this alarm should be in ALARM state.

Intent: This alarm is used to detect the underlying problems with instances, including both system status check failures and instance status check failures.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 300

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

StatusCheckFailed_AttachedEBS

Dimensions: InstanceId

Alarm description: This alarm helps you monitor whether the Amazon EBS volumes attached to an instance are reachable and able to complete I/O operations. This status check detects underlying issues with the compute or Amazon EBS infrastructure such as the following:

- Hardware or software issues on the storage subsystems underlying the Amazon EBS volumes
- Hardware issues on the physical host that impact reachability of the Amazon EBS volumes
- Connectivity issues between the instance and Amazon EBS volumes

When the attached EBS status check fails, you can either wait for Amazon to resolve the issue, or you can take an action such as replacing the affected volumes or stopping and restarting the instance.

Intent: This alarm is used to detect unreachable Amazon EBS volumes attached to an instance. These can cause failures in I/O operations.

Statistic: Maximum

Recommended threshold: 1.0

Threshold justification: When a status check fails, the value of this metric is 1. The threshold is set so that whenever the status check fails, the alarm is in ALARM state.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Amazon ElastiCache

CPUUtilization

Dimensions: CacheClusterId, CacheNodeId

Alarm description: This alarm helps to monitor the CPU utilization for the entire ElastiCache instance, including the database engine processes and other processes running on the instance. Amazon Elasticache supports two engine types: Memcached and Redis OSS. When you reach high CPU utilization on a Memcached node, you should consider scaling up your instance type or adding new cache nodes. For Redis OSS, if your main workload is from read requests, you should consider adding more read replicas to your cache cluster. If your main workload is from write requests, you should consider adding more shards to distribute the workload across more primary nodes if you're running in clustered mode, or scaling up your instance type if you're running Redis OSS in non-clustered mode.

Intent: This alarm is used to detect high CPU utilization of ElastiCache hosts. It is useful to get a broad view of the CPU usage across the entire instance, including non-engine processes.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to the percentage that reflects a critical CPU utilization level for your application. For Memcached, the engine can use up to num_threads cores. For Redis OSS, the engine is largely single-threaded, but might use additional cores if available to accelerate I/O. In most cases, you can set the threshold to about 90% of your available CPU. Because Redis OSS is single-threaded, the actual threshold value should be calculated as a fraction of the node's total capacity.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

CurrConnections

Dimensions: CacheClusterId, CacheNodeId

Alarm description: This alarm detects high connection count, which might indicate heavy load or performance issues. A constant increase of `CurrConnections` might lead to exhaustion of the 65,000 available connections. It may indicate that connections improperly closed on the application side and were left established on the server side. You should consider using connection pooling or idle connection timeouts to limit the number of connections made to the cluster, or for Redis OSS, consider tuning tcp-keepalive on your cluster to detect and terminate potential dead peers.

Intent: The alarm helps you identify high connection counts that could impact the performance and stability of your ElastiCache cluster.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the acceptable range of connections for your cluster. Review the capacity and the expected workload of your ElastiCache cluster and analyze the historical connection counts during regular usage to establish a baseline, and then select a threshold accordingly. Remember that each node can support up to 65,000 concurrent connections.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

DatabaseMemoryUsagePercentage

Dimensions: CacheClusterId

Alarm description: This alarm helps you monitor the memory utilization of your cluster. When your `DatabaseMemoryUsagePercentage` reaches 100%, the Redis OSS maxmemory policy is triggered and evictions might occur based on the policy selected. If no object in the cache matches the eviction policy, write operations fail. Some workloads expect or rely on evictions, but if not, you will need to increase the memory capacity of your cluster. You can scale your cluster out by adding more primary nodes, or scale it up by using a larger node type. Refer to Scaling ElastiCache for Redis OSS clusters for details.

Intent: This alarm is used to detect high memory utilization of your cluster so that you can avoid failures when writing to your cluster. It is useful to know when you'll need to scale up your cluster if your application does not expect to experience evictions.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on your application's memory requirements and the memory capacity of your ElastiCache cluster, you should set the threshold to the percentage that reflects the critical level of memory usage of the cluster. You can use historical memory usage data as reference for acceptable memory usage threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EngineCPUUtilization

Dimensions: CacheClusterId

Alarm description: This alarm helps to monitor the CPU utilization of a Redis OSS engine thread within the ElastiCache instance. Common reasons for high engine CPU are long-running commands that consume high CPU, a high number of requests, an increase of new client connection requests in a short time period, and high evictions when the cache doesn't have enough memory to hold new data. You should consider Scaling ElastiCache for Redis OSS clusters by adding more nodes or scaling up your instance type.

Intent: This alarm is used to detect high CPU utilization of the Redis OSS engine thread. It is useful if you want to monitor the CPU usage of the database engine itself.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: Set the threshold to a percentage that reflects the critical engine CPU utilization level for your application. You can benchmark your cluster using your application and expected workload to correlate EngineCPUUtilization and performance as a reference, and then set the threshold accordingly. In most cases, you can set the threshold to about 90% of your available CPU.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicationLag

Dimensions: CacheClusterId

Alarm description: This alarm helps to monitor the replication health of your ElastiCache cluster. A high replication lag means that the primary node or the replica can't keep up the pace of the replication. If your write activity is too high, consider scaling your cluster out by adding more primary nodes, or scaling it up by using a larger node type. Refer to Scaling ElastiCache for Redis OSS clusters for details. If your read replicas are overloaded by the amount of read requests, consider adding more read replicas.

Intent: This alarm is used to detect a delay between data updates on the primary node and their synchronization to replica node. It helps to ensure data consistency of a read replica cluster node.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to your application's requirements and the potential impact of replication lag. You should consider your application's expected write rates and network conditions for the acceptable replication lag.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon ECS

The following are the recommended alarms for Amazon ECS.

CPUReservation

Dimensions: ClusterName

Alarm description: This alarm helps you detect a high CPU reservation of the ECS cluster. High CPU reservation might indicate that the cluster is running out of registered CPUs for the task. To troubleshoot, you can add more capacity, you can scale the cluster, or you can set up auto scaling.

Intent: The alarm is used to detect whether the total number of CPU units reserved by tasks on the cluster is reaching the total CPU units registered for the cluster. This helps you know when to scale up the cluster. Reaching the total CPU units for the cluster can result in running out of CPU for tasks. If you have EC2 capacity providers managed scaling turned on, or you have associated Fargate to capacity providers, then this alarm is not recommended.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold for CPU reservation to 80%. Alternatively, you can choose a lower value based on cluster characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

CPUUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high CPU utilization of the ECS service. If there is no ongoing ECS deployment, a maxed-out CPU utilization might indicate a resource bottleneck or application performance problems. To troubleshoot, you can increase the CPU limit.

Intent: This alarm is used to detect high CPU utilization for the Amazon ECS service. Consistent high CPU utilization can indicate a resource bottleneck or application performance problems.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: The service metrics for CPU utilization might exceed 100% utilization. However, we recommend that you monitor the metric for high CPU utilization to avoid impacting other services. Set the threshold to about 80-85%. We recommend that you update your task definitions to reflect actual usage to prevent future issues with other services.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EBSFilesystemUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high storage utilization of the Amazon EBS volume attached to Amazon ECS tasks. If the utilization of the Amazon EBS volume is consistently high, you can check the usage and increase the volume size for new tasks.

Intent: This alarm is used to detect high storage utilization of the Amazon EBS volumes attached to Amazon ECS tasks. Consistently high storage utilization can indicate that the Amazon EBS volume is full and it might lead to failure of the container.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: You can set the threshold for Amazon EBS file system utilization to about 80%. You can adjust this value based on the acceptable storage utilization. For a read-only snapshot volume, a high utilization might indicate that the volume is right sized. For an active data volume, high storage utilization might indicate that the application is writing a large amount of data which may cause the container to fail if there is not enough capacity.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

MemoryReservation

Dimensions: ClusterName

Alarm description: This alarm helps you detect a high memory reservation of the Amazon ECS cluster. High memory reservation might indicate a resource bottleneck for the cluster. To troubleshoot, analyze the service task for performance to see if memory utilization of the task can be optimized. Also, you can register more memory or set up auto scaling.

Intent: The alarm is used to detect whether the total memory units reserved by tasks on the cluster is reaching the total memory units registered for the cluster. This can help you know when to scale up the cluster. Reaching the total memory units for the cluster can cause the cluster to be unable to launch new tasks. If you have EC2 capacity providers managed scaling turned on or you have associated Fargate to capacity providers, this alarm is not recommended.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold for memory reservation to 80%. You can adjust this to a lower value based on cluster characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

MemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high memory utilization of the Amazon ECS service. If there is no ongoing Amazon ECS deployment, a maxed-out memory utilization might indicate a resource bottleneck or application performance problems. To troubleshoot, you can increase the memory limit.

Intent: This alarm is used to detect high memory utilization for the Amazon ECS service. Consistent high memory utilization can indicate a resource bottleneck or application performance problems.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: The service metrics for memory utilization might exceed 100% utilization. However, we recommend that you monitor the metric for high memory utilization to avoid impacting other services. Set the threshold to about 80%. We recommend that you update your task definitions to reflect actual usage to prevent future issues with other services.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

HTTPCode_Target_5XX_Count

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high server-side error count for the ECS service. This can indicate that there are errors that cause the server to be unable to serve requests. To troubleshoot, check your application logs.

Intent: This alarm is used to detect a high server-side error count for the ECS service.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Calculate the value of about 5% of the your average traffic and use this value as a starting point for the threshold. You can find the average traffic by using the `RequestCount` metric. You can also analyze historical data to determine the acceptable error rate for the application workload, and then tune the threshold accordingly. Frequently occurring 5XX errors need to be alarmed on. However, setting a very low value for the threshold can cause the alarm to be too sensitive.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TargetResponseTime

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a high target response time for ECS service requests. This can indicate that there are problems that cause the service to be unable to serve requests in time. To troubleshoot, check the CPUUtilization metric to see if the service is running out of CPU, or check the CPU utilization of other downstream services that your service depends on.

Intent: This alarm is used to detect a high target response time for ECS service requests.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Review the criticality and requirements of the target response time of the service and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon ECS with Container Insights

The following are the recommended alarms for Amazon ECS with Container Insights.

EphemeralStorageUtilized

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high ephemeral storage utilized of the Fargate cluster. If ephemeral storage is consistently high, you can check ephemeral storage usage and increase the ephemeral storage.

Intent: This alarm is used to detect high ephemeral storage usage for the Fargate cluster. Consistent high ephemeral storage utilized can indicate that the disk is full and it might lead to failure of the container.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to about 90% of the ephemeral storage size. You can adjust this value based on your acceptable ephemeral storage utilization of the Fargate cluster. For some systems, a consistently high ephemeral storage utilized might be normal, while for others, it might lead to failure of the container.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

RunningTaskCount

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect a low running task count of the Amazon ECS service. If the running task count is too low, it can can indicate that the application can't handle the service load and it might lead to performance issues. If there is no running task, the Amazon ECS service might be unavailable or there might be deployment issues.

Intent: This alarm is used to detect whether the number of running tasks are too low. A consistent low running task count can indicate Amazon ECS service deployment or performance issues.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: You can adjust the threshold based on the minimum running task count of the Amazon ECS service. If the running task count is 0, the Amazon ECS service will be unavailable.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

TaskCpuUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high CPU utilization of tasks in your Amazon ECS cluster. If task CPU utilization is consistently high, you might need to optimize your tasks or increase their CPU reservation.

Intent: This alarm is used to detect high CPU utilization for tasks in the Amazon ECS cluster. Consistent high CPU utilization can indicate that the tasks are under stress and might need more CPU resources or optimization to maintain performance.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's CPU reservation. You can adjust this value based on your acceptable CPU utilization for the tasks. For some workloads, consistently high CPU utilization might be normal, while for others, it might indicate performance issues or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskCpuUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high CPU utilization of tasks belonging to the Amazon ECS service. If task CPU utilization is consistently high, you might need to optimize your tasks or increase their CPU reservation.

Intent: This alarm is used to detect high CPU utilization for tasks belonging to the Amazon ECS service. Consistent high CPU utilization can indicate that the tasks are under stress and might need more CPU resources or optimization to maintain performance.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's CPU reservation. You can adjust this value based on your acceptable CPU utilization for the tasks. For some workloads, consistently high CPU utilization might be normal, while for others, it might indicate performance issues or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ContainerCpuUtilization

Dimensions: ClusterName

Alarm description: This alarm monitors the percentage of CPU units used by containers in your Amazon ECS cluster relative to their reserved CPU. It helps detect when containers are approaching their CPU limits based on the ContainerCpuUtilized/ContainerCpuReserved ratio.

Intent: This alarm detects when containers in the Amazon ECS cluster are using a high percentage of their reserved CPU capacity, calculated as `ContainerCpuUtilized/ContainerCpuReserved`. Sustained high values indicate containers are operating near their CPU limits and might need capacity adjustments.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the container's CPU utilization ratio. This provides an early warning when containers are approaching their CPU capacity limits while allowing for normal fluctuations in CPU usage. The threshold can be adjusted based on your workload characteristics and performance requirements.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ContainerCpuUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm monitors the percentage of CPU units used by containers belonging to the Amazon ECS service relative to their reserved CPU. It helps detect when containers are approaching their CPU limits based on the ContainerCpuUtilized/ContainerCpuReserved ratio.

Intent: This alarm detects when containers belonging to the Amazon ECS service are using a high percentage of their reserved CPU capacity, calculated as ContainerCpuUtilized/ContainerCpuReserved. Sustained high values indicate containers are operating near their CPU limits and might need capacity adjustments.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the container's CPU utilization ratio. This provides an early warning when containers are approaching their CPU capacity limits while allowing for normal fluctuations in CPU usage. The threshold can be adjusted based on your workload characteristics and performance requirements.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEphemeralStorageUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high ephemeral storage utilization of tasks in your Amazon ECS cluster. If storage utilization is consistently high, you might need to optimize your storage usage or increase the storage reservation.

Intent: This alarm is used to detect high ephemeral storage utilization for tasks in the Amazon ECS cluster. Consistent high storage utilization can indicate that the task is running out of disk space and might need more storage resources or optimization to maintain proper operation.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's ephemeral storage reservation. You can adjust this value based on your acceptable storage utilization for the tasks. For some workloads, consistently high storage utilization might be normal, while for others, it might indicate potential disk space issues or the need for more storage.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEphemeralStorageUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high ephemeral storage utilization of tasks belonging to the Amazon ECS service. If storage utilization is consistently high, you might need to optimize your storage usage or increase the storage reservation.

Intent: This alarm is used to detect high ephemeral storage utilization for tasks belonging to the Amazon ECS service. Consistent high storage utilization can indicate that the task is running out of disk space and might need more storage resources or optimization to maintain proper operation.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's ephemeral storage reservation. You can adjust this value based on your acceptable storage utilization for the tasks. For some workloads, consistently high storage utilization might be normal, while for others, it might indicate potential disk space issues or the need for more storage.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskMemoryUtilization

Dimensions: ClusterName

Alarm description: This alarm helps you detect high memory utilization of tasks in your Amazon ECS cluster. If memory utilization is consistently high, you might need to optimize your tasks or increase the memory reservation.

Intent: This alarm is used to detect high memory utilization for tasks in the Amazon ECS cluster. Consistent high memory utilization can indicate that the task is under memory pressure and might need more memory resources or optimization to maintain stability.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's memory reservation. You can adjust this value based on your acceptable memory utilization for the tasks. For some workloads, consistently high memory utilization might be normal, while for others, it might indicate memory pressure or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskMemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high memory utilization of tasks belonging to the Amazon ECS service. If memory utilization is consistently high, you might need to optimize your tasks or increase the memory reservation.

Intent: This alarm is used to detect high memory utilization for tasks belonging to the Amazon ECS service. Consistent high memory utilization can indicate that the task is under memory pressure and might need more memory resources or optimization to maintain stability.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the task's memory reservation. You can adjust this value based on your acceptable memory utilization for the tasks. For some workloads, consistently high memory utilization might be normal, while for others, it might indicate memory pressure or the need for more resources.

Period: 60

Comparison Operator: GREATER_THAN_THRESHOLD

ContainerMemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect high memory utilization of containers belonging to the Amazon ECS service. If memory utilization is consistently high, you might need to optimize your containers or increase the memory reservation.

Intent: This alarm is used to detect high memory utilization for containers belonging to the Amazon ECS service. Consistent high memory utilization can indicate that the container is under memory pressure and might need more memory resources or optimization to maintain stability.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the container's memory reservation. You can adjust this value based on your acceptable memory utilization for the containers. For some workloads, consistently high memory utilization might be normal, while for others, it might indicate memory pressure or the need for more resources.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

instance_filesystem_utilization

Dimensions: InstanceId, ContainerInstanceId, ClusterName

Alarm description: This alarm helps you detect a high file system utilization of the Amazon ECS cluster. If the file system utilization is consistently high, check the disk usage.

Intent: This alarm is used to detect high file system utilization for the Amazon ECS cluster. A consistent high file system utilization can indicate a resource bottleneck or application performance problems, and it might prevent running new tasks.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: You can set the threshold for file system utilization to about 90-95%. You can adjust this value based on the acceptable file system capacity level of the Amazon ECS cluster. For some systems, a consistently high file system utilization might be normal and not indicate a problem, while for others, it might be a cause of concern and might lead to performance issues and prevent running new tasks.

Amazon ECS with Container Insights with enhanced observability

The following are the recommended alarms for Amazon ECS with Container Insights with enhanced observability.

TaskCpuUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of CPU units being used by a task.

Intent: This alarm is used to detect high task CPU utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for CPU utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some tasks, consistently high CPU utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical CPU utilization data to identify the usage, find what CPU utilization is acceptable for your tasks, and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskMemoryUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of memory being used by a task.

Intent: This alarm is used to detect high memory utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for memory utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some tasks, consistently high memory utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical memory utilization data to identify the usage, find what memory utilization is acceptable for your tasks, and set the threshold accordingly.

Comparison Operator: GREATER_THAN_THRESHOLD

ContainerMemoryUtilization

Dimensions: ContainerName, ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of memory units being used by a container.

Intent: This alarm is used to detect high task memory utilization.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Typically, you can set the threshold for memory utilization to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics. For some containers, consistently high memory utilization may be normal and not indicate a problem, while for others, it may be cause of concern. Analyze historical memory utilization data to identify the usage, find what memory utilization is acceptable for your tasks, and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

TaskEBSfilesystemUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of ephemeral storage being used by a task. .

Intent: This alarm is used to detect high Amazon EBS file system usage for a task.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the Amazon EBS file system size.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

TaskEphemeralStorageUtilization

Dimensions: ClusterName, ServiceName

Alarm description: This alarm helps you detect the total percentage of ephemeral storage being used by a task.

Intent: This alarm is used to detect high ephemeral storage usage for a task. Consistent high ephemeral storage utilized can indicate that the disk is full and it might lead to failure of the task.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: Set the threshold to about 80% of the ephemeral storage size.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EFS

PercentIOLimit

Dimensions: FileSystemId

Alarm description: This alarm helps in ensuring that the workload stays within the I/O limit available to the file system. If the metric reaches its I/O limit consistently, consider moving the application to a file system that uses Max I/O performance as mode. For troubleshooting, check clients that are connected to the file system and applications of the clients that throttles the file system.

Intent: This alarm is used to detect how close the file system is to reach the I/O limit of the General Purpose performance mode. Consistent high I/O percentage can be an indicator of the file system cannot scale with respect to I/O requests enough and the file system can be a resource bottleneck for the applications that use the file system.

Statistic: Average

Recommended threshold: 100.0

Threshold justification: When the file system reaches its I/O limit, it may respond to read and write requests slower. Therefore, it is recommended that the metric is monitored to avoid impacting applications that use the file system. The threshold can be set around 100%. However, this value can be adjusted to a lower value based on file system characteristics.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

BurstCreditBalance

Dimensions: FileSystemId

Alarm description: This alarm helps in ensuring that there is available burst credit balance for the file system usage. When there is no available burst credit, applications access to the the file system will be limited due to low throughput. If the metric drops to 0 consistently, consider changing the throughput mode to Elastic or Provisioned throughput mode.

Intent: This alarm is used to detect low burst credit balance of the file system. Consistent low burst credit balance can be an indicator of the slowing down in throughput and increase in I/O latency.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: When the file system run out of burst credits and even if the baseline throughput rate is lower, EFS continues to provide a metered throughput of 1 MiBps to all file systems. However, it is recommended that the metric is monitored for low burst credit balance to avoid the file system acting as resource bottleneck for the applications. The threshold can be set around 0 bytes.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Amazon EKS with Container Insights

node_cpu_utilization

Dimensions: ClusterName

Alarm description: This alarm helps to detect high CPU utilization in worker nodes of the EKS cluster. If the utilization is consistently high, it might indicate a need for replacing your worker nodes with instances that have greater CPU or a need to scale the system horizontally.

Intent: This alarm helps to monitor the CPU utilization of the worker nodes in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

node_filesystem_utilization

Dimensions: ClusterName

Alarm description: This alarm helps to detect high file system utilization in the worker nodes of the EKS cluster. If the utilization is consistently high, you might need to update your worker nodes to have larger disk volume, or you might need to scale horizontally.

Intent: This alarm helps to monitor the filesystem utilization of the worker nodes in the EKS cluster. If the utilization reaches 100%, it can lead to application failure, disk I/O bottlenecks, pod eviction, or the node to become unresponsive entirely.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: If there's sufficient disk pressure (meaning that the disk is getting full), nodes are marked as not healthy, and the pods are evicted from the node. Pods on a node with disk pressure are evicted when the available file system is lower than the eviction thresholds set on the kubelet. Set the alarm threshold so that you have enough time to react before the node is evicted from the cluster.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

node_memory_utilization

Dimensions: ClusterName

Alarm description: This alarm helps in detecting high memory utilization in worker nodes of the EKS cluster. If the utilization is consistently high, it might indicate a need to scale the number of pod replicas, or optimize your application.

Intent: This alarm helps to monitor the memory utilization of the worker nodes in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

pod_cpu_utilization_over_pod_limit

Dimensions: ClusterName, Namespace, Service

Alarm description: This alarm helps in detecting high CPU utilization in pods of the EKS cluster. If the utilization is consistently high, it might indicate a need to increase the CPU limit for the affected pod.

Intent: This alarm helps to monitor the CPU utilization of the pods belonging to a Kubernetes Service in the EKS cluster, so that you can quickly identify if a service's pod is consuming higher CPU than expected.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

pod_memory_utilization_over_pod_limit

Dimensions: ClusterName, Namespace, Service

Alarm description: This alarm helps in detecting high memory utilization in pods of the EKS cluster. If the utilization is consistently high, it might indicate a need to increase the memory limit for the affected pod.

Intent: This alarm helps to monitor the memory utilization of the pods in the EKS cluster so that the system performance doesn't degrade.

Statistic: Maximum

Recommended threshold: 80.0

Threshold justification: It is recommended to set the threshold at less than or equal to 80% to allow having enough time to debug the issue before the system starts seeing impact.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon EventBridge Scheduler

TargetErrorThrottledCount

Dimensions: None

Alarm description: This alarm helps you identify target throttling. To avoid target throttling error, consider configuring flexible time windows to spread your invocation load or increasing limits with the target service.

Intent: This alarm is used to detect target throttling errors, which can cause schedule delays.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the target throttling error is consistently greater than 0, schedule delivery is delayed. For some systems, target throttling errors for a brief period of time might be normal, while for others, it might be a cause of concern. Set this alarm's threshold, `datapointsToAlarm`, and `evaluationPeriods` accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationThrottleCount

Dimensions: None

Alarm description: This alarm helps you identify invocation throttling by Amazon EventBridge Scheduler. To avoid invocation throttling errors, consider configuring flexible time windows to spread your invocation load or increasing invocations throttle limit.

Intent: This alarm is used to detect Amazon EventBridge Scheduler invocation throttling errors, which can cause schedule delays.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the invocation throttling is consistently greater than 0, schedule delivery is delayed. For some systems, invocation throttling errors for a brief period of time might be normal, while for others, it might be a cause of concern. Set this alarm's threshold, `datapointsToAlarm`, and `evaluationPeriods` accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationDroppedCount

Dimensions: None

Alarm description: This alarm helps you identify invocations dropped by Amazon EventBridge Scheduler. Consider investigating by configuring a DLQ for the schedule.

Intent: This alarm is used to detect dropped invocations by Amazon EventBridge Scheduler. If you have configured a DLQ correctly on all of your schedules, dropped invocations will appear in the DLQ and you can skip setting up this alarm.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect dropped invocations.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

InvocationsFailedToBeSentToDeadLetterCount

Dimensions: None

Alarm description: This alarm helps you identify invocations that were failed to be sent to the configured DLQ by Amazon EventBridge Scheduler. If the metric is consistently greater than 0, modify your DLQ configuration to resolve the issue. Use `InvocationsFailedToBeSentToDeadLetterCount`_metrics to determine the issue.

Intent: This alarm is used to detect invocations failed to be sent to the configured DLQ by Amazon EventBridge Scheduler.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Set the threshold to 0 to detect any invocations that were failed to be sent to the configured DLQ. Retryable errors also show up in this metric, so `datapointsToAlarm` for this alarm has been set to 15.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Kinesis Data Streams

GetRecords.IteratorAgeMilliseconds

Dimensions: StreamName

Alarm description: This alarm can detect if iterator maximum age is too high. For real-time data processing applications, configure data retention according to tolerance of the delay. This is usually within minutes. For applications that process historic data, use this metric to monitor catchup speed. A quick solution to stop data loss is to increase the retention period while you troubleshoot the issue. You can also increase the number of workers processing records in your consumer application. The most common causes for gradual iterator age increase are insufficient physical resources or record processing logic that has not scaled with an increase in stream throughput. See link for more details.

Intent: This alarm is used to detect if data in your stream is going to expire because of being preserved too long or because record processing is too slow. It helps you avoid data loss after reaching 100% of the stream retention time.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the stream retention period and tolerance of processing delay for the records. Review your requirements and analyze historical trends, and then set the threshold to the number of milliseconds that represents a critical processing delay. If an iterator's age passes 50% of the retention period (by default, 24 hours, configurable up to 365 days), there is a risk for data loss because of record expiration. You can monitor the metric to make sure that none of your shards ever approach this limit.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

GetRecords.Success

Dimensions: StreamName

Alarm description: This metric increments whenever your consumers successfully read data from your stream. `GetRecords` doesn't return any data when it throws an exception. The most common exception is `ProvisionedThroughputExceededException` because request rate for the stream is too high, or because available throughput is already served for the given second. Reduce the frequency or size of your requests. For more information, see Streams [Limits](#) in the Amazon Kinesis Data Streams Developer Guide, and [Error Retries and Exponential Backoff in Amazon](#).

Intent: This alarm can detect if the retrieval of records from the stream by consumers is failing. By setting an alarm on this metric, you can proactively detect any issues with data consumption, such as increased error rates or a decline in successful retrievals. This allows you to take timely actions to resolve potential problems and maintain a smooth data processing pipeline.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the importance of retrieving records from the stream, set the threshold based on your application’s tolerance for failed records. The threshold should be the corresponding percentage of successful operations. You can use historical GetRecords metric data as reference for the acceptable failure rate. You should also consider retries when setting the threshold because failed records can be retried. This helps to prevent transient spikes from triggering unnecessary alerts.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

PutRecord.Success

Dimensions: StreamName

Alarm description: This alarm detects when the number of failed `PutRecord` operations breaches the threshold. Investigate the data producer logs to find the root causes of the failures. The most common reason is insufficient provisioned throughput on the shard that caused the `ProvisionedThroughputExceededException`. It happens because the request rate for the stream is too high, or the throughput attempted to be ingested into the shard is too high. Reduce the frequency or size of your requests. For more information, see Streams Limits and Error Retries and Exponential Backoff in Amazon.

Intent: This alarm can detect if ingestion of records into the stream is failing. It helps you identify issues in writing data to the stream. By setting an alarm on this metric, you can proactively detect any issues of producers in publishing data to the stream, such as increased error rates or a decrease in successful records being published. This enables you to take timely actions to address potential problems and maintain a reliable data ingestion process.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the importance of data ingestion and processing to your service, set the threshold based on your application’s tolerance for failed records. The threshold should be the corresponding percentage of successful operations. You can use historical PutRecord metric data as reference for the acceptable failure rate. You should also consider retries when setting the threshold because failed records can be retried.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

PutRecords.FailedRecords

Dimensions: StreamName

Alarm description: This alarm detects when the number of failed `PutRecords` exceeds the threshold. Kinesis Data Streams attempts to process all records in each `PutRecords` request, but a single record failure does not stop the processing of subsequent records. The main reason for these failures is exceeding the throughput of a stream or an individual shard. Common causes are traffic spikes and network latencies that cause records to arrive to the stream unevenly. You should detect unsuccessfully processed records and retry them in a subsequent call. Refer to [Handling Failures When Using PutRecords] for more details.

Intent: This alarm can detect consistent failures when using batch operation to put records to your stream. By setting an alarm on this metric, you can proactively detect an increase in failed records, enabling you to take timely actions to address the underlying problems and ensure a smooth and reliable data ingestion process.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to the number of failed records reflecting the tolerance of the the application for failed records. You can use historical data as reference for the acceptable failure value. You should also consider retries when setting the threshold because failed records can be retried in subsequent PutRecords calls.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReadProvisionedThroughputExceeded

Dimensions: StreamName

Alarm description: The alarm tracks the number of records that result in read throughput capacity throttling. If you find that you are being consistently throttled, you should consider adding more shards to your stream to increase your provisioned read throughput. If there is more than one consumer application running on the stream, and they share the `GetRecords` limit, we recommend that you register new consumer applications via Enhanced Fan-Out. If adding more shards does not lower the number of throttles, you may have a “hot” shard that is being read from more than other shards are. Enable enhanced monitoring, find the “hot” shard, and split it.

Intent: This alarm can detect if consumers are throttled when they exceed your provisioned read throughput (determined by the number of shards you have). In that case, you won’t be able to read from the stream, and the stream can start backing up.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Usually throttled requests can be retried and hence setting the threshold to zero makes the alarm too sensitive. However, consistent throttling can impact reading from the stream and should trigger the alarm. Set the threshold to a percentage according to the throttled requests for the application and retry configurations.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SubscribeToShardEvent.MillisBehindLatest

Dimensions: StreamName, ConsumerName

Alarm description: This alarm detects when the delay of record processing in the application breaches the threshold. Transient problems such as API operation failures to a downstream application can cause a sudden increase in the metric. You should investigate if they consistently happen. A common cause is the consumer is not processing records fast enough because of insufficient physical resources or record processing logic that has not scaled with an increase in stream throughput. Blocking calls in critical path is often the cause of slowdowns in record processing. You can increase your parallelism by increasing the number of shards. You should also confirm underlying processing nodes have sufficient physical resources during peak demand.

Intent: This alarm can detect delay in the subscription to shard event of the stream. This indicates a processing lag and can help identify potential issues with the consumer application's performance or the overall stream's health. When the processing lag becomes significant, you should investigate and address any bottlenecks or consumer application inefficiencies to ensure real-time data processing and minimize data backlog.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the delay that your application can tolerate. Review your application's requirements and analyze historical trends, and then select a threshold accordingly. When the SubscribeToShard call succeeds, your consumer starts receiving SubscribeToShardEvent events over the persistent connection for up to 5 minutes, after which time you need to call SubscribeToShard again to renew the subscription if you want to continue to receive records.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

WriteProvisionedThroughputExceeded

Dimensions: StreamName

Alarm description: This alarm detects when the number of records resulting in write throughput capacity throttling reached the threshold. When your producers exceed your provisioned write throughput (determined by the number of shards you have), they are throttled and you won’t be able to put records to the stream. To address consistent throttling, you should consider adding shards to your stream. This raises your provisioned write throughput and prevents future throttling. You should also consider partition key choice when ingesting records. Random partition key is preferred because it spreads records evenly across the shards of the stream, whenever possible.

Intent: This alarm can detect if your producers are being rejected for writing records because of throttling of the stream or shard. If your stream is in Provisioned mode, then setting this alarm helps you proactively take actions when the data stream reaches its limits, allowing you to optimize the provisioned capacity or take appropriate scaling actions to avoid data loss and maintain smooth data processing.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Usually throttled requests can be retried, so setting the threshold to zero makes the alarm too sensitive. However, consistent throttling can impact writing to the stream, and you should set the alarm threshold to detect this. Set the threshold to a percentage according to the throttled requests for the application and retry configurations.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Lambda

ClaimedAccountConcurrency

Dimensions: None

Alarm description: This alarm helps to monitor if the concurrency of your Lambda functions is approaching the Region-level concurrency limit of your account. A function starts to be throttled if it reaches the concurrency limit. You can take the following actions to avoid throttling.

1. Request a concurrency increase in this Region.
2. Identify and reduce any unused reserved concurrency or provisioned concurrency.

3. Identify performance issues in the functions to improve the speed of processing and therefore improve throughput.
4. Increase the batch size of the functions, so that more messages are processed by each function invocation.

Intent: This alarm can proactively detect if the concurrency of your Lambda functions is approaching the Region-level concurrency quota of your account, so that you can act on it. Functions are throttled if `ClaimedAccountConcurrency` reaches the Region-level concurrency quota of the account. If you are using Reserved Concurrency (RC) or Provisioned Concurrency (PC), this alarm gives you more visibility on concurrency utilization than an alarm on `ConcurrentExecutions` would.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of about 90% of the concurrency quota set for the account in the Region, and use the result as the threshold value. By default, your account has a concurrency quota of 1,000 across all functions in a Region. However, you should check the quota of your account from the Service Quotas dashboard.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

Errors

Dimensions: FunctionName

Alarm description: This alarm detects high error counts. Errors includes the exceptions thrown by the code as well as exceptions thrown by the Lambda runtime. You can check the logs related to the function to diagnose the issue.

Intent: The alarm helps detect high error counts in function invocations.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to a number greater than zero. The exact value can depend on the tolerance for errors in your application. Understand the criticality of the invocations that the function is handling. For some applications, any error might be unacceptable, while other applications might allow for a certain margin of error.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: GREATER_THAN_THRESHOLD

Throttles

Dimensions: FunctionName

Alarm description: This alarm detects a high number of throttled invocation requests. Throttling occurs when there is no concurrency is available for scale up. There are several approaches to resolve this issue. 1) Request a concurrency increase from Amazon Support in this Region. 2) Identify performance issues in the function to improve the speed of processing and therefore improve throughput. 3) Increase the batch size of the function, so that more messages are processed by each function invocation.

Intent: The alarm helps detect a high number of throttled invocation requests for a Lambda function. It is important to know if requests are constantly getting rejected due to throttling and if you need to improve Lambda function performance or increase concurrency capacity to avoid constant throttling.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to a number greater than zero. The exact value of the threshold can depend on the tolerance of the application. Set the threshold according to its usage and scaling requirements of the function.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

Duration

Dimensions: FunctionName

Alarm description: This alarm detects long duration times for processing an event by a Lambda function. Long durations might be because of changes in function code making the function take longer to execute, or the function's dependencies taking longer.

Intent: This alarm can detect a long running duration of a Lambda function. High runtime duration indicates that a function is taking a longer time for invocation, and can also impact the concurrency capacity of invocation if Lambda is handling a higher number of events. It is critical to know if the Lambda function is constantly taking longer execution time than expected.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The threshold for the duration depends on your application and workloads and your performance requirements. For high-performance requirements, set the threshold to a shorter time to see if the function is meeting expectations. You can also analyze historical data for duration metrics to see the if the time taken matches the performance expectation of the function, and then set the threshold to a longer time than the historical average. Make sure to set the threshold lower than the configured function timeout.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

ConcurrentExecutions

Dimensions: FunctionName

Alarm description: This alarm helps to monitor if the concurrency of the function is approaching the Region-level concurrency limit of your account. A function starts to be throttled if it reaches the concurrency limit. You can take the following actions to avoid throttling.

1. Request a concurrency increase in this Region.

2. Identify performance issues in the functions to improve the speed of processing and therefore improve throughput.
3. Increase the batch size of the functions, so that more messages are processed by each function invocation.

To get better visibility on reserved concurrency and provisioned concurrency utilization, set an alarm on the new metric `ClaimedAccountConcurrency` instead.

Intent: This alarm can proactively detect if the concurrency of the function is approaching the Region-level concurrency quota of your account, so that you can act on it. A function is throttled if it reaches the Region-level concurrency quota of the account.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold to about 90% of the concurrency quota set for the account in the Region. By default, your account has a concurrency quota of 1,000 across all functions in a Region. However, you can check the quota of your account, as it can be increased by contacting Amazon support.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

Lambda Insights

We recommend setting best-practice alarms for the following Lambda Insights metrics.

memory_utilization

Dimensions: function_name

Alarm description: This alarm is used to detect if the memory utilization of a lambda function is approaching the configured limit. For troubleshooting, you can try to 1) Optimize your code. 2) Rightly size your memory allocation by accurately estimating the memory requirements. You can refer to Lambda Power Tuning for the same. 3) Use connection pooling. Refer to Using

Amazon RDS Proxy with Lambda for the connection pooling for RDS database. 4) You can also consider designing your functions to avoid storing large amounts of data in memory between invocations.

Intent: This alarm is used to detect if the memory utilization for the Lambda function is approaching the configured limit.

Statistic: Average

Threshold Suggestion: 90.0

Threshold Justification: Set the threshold to 90% to get an alert when memory utilization exceeds 90% of the allocated memory. You can adjust this to a lower value if you have a concern for the workload for memory utilization. You can also check the historical data for this metric and set the threshold accordingly.

Period: 60

Datapoints to alarm: 10

Evaluation Periods: 10

ComparisonOperator: GREATER_THAN_THRESHOLD

Amazon VPC (`AWS/NATGateway`)

ErrorPortAllocation

Dimensions: NatGatewayId

Alarm description: This alarm helps to detect when the NAT Gateway is unable to allocate ports to new connections. To resolve this issue, see Resolve port allocation errors on NAT Gateway.

Intent: This alarm is used to detect if the NAT gateway could not allocate a source port.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the value of ErrorPortAllocation is greater than zero, that means too many concurrent connections to a single popular destination are open through NATGateway.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

PacketsDropCount

Dimensions: NatGatewayId

Alarm description: This alarm helps to detect when packets are dropped by NAT Gateway. This might happen because of an issue with NAT Gateway, so check [Amazon service health dashboard](#) for the status of Amazon NAT Gateway in your Region. This can help you correlate the network issue related to traffic using NAT gateway.

Intent: This alarm is used to detect if packets are being dropped by NAT Gateway.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: You should calculate the value of 0.01 percent of the total traffic on the NAT Gateway and use that result as the threshold value. Use historical data of the traffic on NAT Gateway to determine the threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Private Link (`AWS/PrivateLinkEndpoints`)

PacketsDropped

Dimensions: VPC Id, VPC Endpoint Id, Endpoint Type, Subnet Id, Service Name

Alarm description: This alarm helps to detect if the endpoint or endpoint service is unhealthy by monitoring the number of packets dropped by the endpoint. Note that packets larger than

8500 bytes that arrive at the VPC endpoint are dropped. For troubleshooting, see connectivity problems between an interface VPC endpoint and an endpoint service.

Intent: This alarm is used to detect if the endpoint or endpoint service is unhealthy.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold according to the use case. If you want to be aware of the unhealthy status of the endpoint or endpoint service, you should set the threshold low so that you get a chance to fix the issue before a huge data loss. You can use historical data to understand the tolerance for dropped packets and set the threshold accordingly.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Private Link (`AWS/PrivateLinkServices`)

RstPacketsSent

Dimensions: Service Id, Load Balancer Arn, Az

Alarm description: This alarm helps you detect unhealthy targets of an endpoint service based on the number of reset packets that are sent to endpoints. When you debug connection errors with a consumer of your service, you can validate whether the service is resetting connections with the RstPacketsSent metric, or if something else is failing on the network path.

Intent: This alarm is used to detect unhealthy targets of an endpoint service.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The threshold depends on the use case. If your use case can tolerate targets being unhealthy, you can set the threshold high. If the use case can’t tolerate unhealthy targets you can set the threshold very low.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon RDS

CPUUtilization

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor consistent high CPU utilization. CPU utilization measures non-idle time. Consider using Enhanced Monitoring or Performance Insights to review which wait time is consuming the most of the CPU time (`guest`, `irq`, `wait`, `nice`, and so on) for MariaDB, MySQL, Oracle, and PostgreSQL. Then evaluate which queries consume the highest amount of CPU. If you can't tune your workload, consider moving to a larger DB instance class.

Intent: This alarm is used to detect consistent high CPU utilization in order to prevent very high response time and time-outs. If you want to check micro-bursting of CPU utilization you can set a lower alarm evaluation time.

Statistic: Average

Recommended threshold: 90.0

Threshold justification: Random spikes in CPU consumption might not hamper database performance, but sustained high CPU can hinder upcoming database requests. Depending on the overall database workload, high CPU at your RDS/Aurora instance can degrade the overall performance.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

DatabaseConnections

Dimensions: DBInstanceIdentifier

Alarm description: This alarm detects a high number of connections. Review existing connections and terminate any that are in `sleep` state or that are improperly closed. Consider using connection pooling to limit the number of new connections. Alternatively, increase the DB instance size to use a class with more memory and hence a higher default value for `max_connections` or increase the `max_connections` value in RDS and Aurora MySQL and PostgreSQL for the current class if it can support your workload.

Intent: This alarm is used to help prevent rejected connections when the maximum number of DB connections is reached. This alarm is not recommended if you frequently change DB instance class, because doing so changes the memory and default maximum number of connections.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The number of connections allowed depends on the size of your DB instance class and database engine-specific parameters related to processes/connections. You should calculate a value between 90-95% of the maximum number of connections for your database and use that result as the threshold value.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

EBSByteBalance%

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a low percentage of throughput credits remaining. For troubleshooting, check latency problems in RDS.

Intent: This alarm is used to detect a low percentage of throughput credits remaining in the burst bucket. Low byte balance percentage can cause throughput bottleneck issues. This alarm is not recommended for Aurora PostgreSQL instances.

Statistic: Average

Recommended threshold: 10.0

Threshold justification: A throughput credit balance below 10% is considered to be poor and you should set the threshold accordingly. You can also set a lower threshold if your application can tolerate a lower throughput for the workload.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

EBSIOBalance%

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low percentage of IOPS credits remaining. For troubleshooting, see latency problems in RDS.

Intent: This alarm is used to detect a low percentage of I/O credits remaining in the burst bucket. Low IOPS balance percentage can cause IOPS bottleneck issues. This alarm is not recommended for Aurora instances.

Statistic: Average

Recommended threshold: 10.0

Threshold justification: An IOPS credits balance below 10% is considered to be poor and you can set the threshold accordingly. You can also set a lower threshold, if your application can tolerate a lower IOPS for the workload.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

FreeableMemory

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low freeable memory which can mean that there is a spike in database connections or that your instance may be under high memory pressure. Check for memory pressure by monitoring the CloudWatch metrics for `SwapUsage`\`in addition to `FreeableMemory`. If the instance memory consumption is frequently too high, this indicates that you should check your workload or upgrade your instance class. For Aurora reader DB instance, consider adding additional reader DB instances to the cluster. For information about troubleshooting Aurora, see freeable memory issues.

Intent: This alarm is used to help prevent running out of memory which can result in rejected connections.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Depending on the workload and instance class, different values for the threshold can be appropriate. Ideally, available memory should not go below 25% of total memory for prolonged periods. For Aurora, you can set the threshold close to 5%, because the metric approaching 0 means that the DB instance has scaled up as much as it can. You can analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_THRESHOLD

FreeLocalStorage

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor low free local storage. Aurora PostgreSQL-Compatible Edition uses local storage for storing error logs and temporary files. Aurora MySQL uses local storage for storing error logs, general logs, slow query logs, audit logs, and non-InnoDB temporary tables. These local storage volumes are backed by Amazon EBS Store and can be extended by using a larger DB instance class. For troubleshooting, check Aurora PostgreSQL-Compatible and MySQL-Compatible.

Intent: This alarm is used to detect how close the Aurora DB instance is to reaching the local storage limit, if you do not use Aurora Serverless v2 or higher. Local storage can reach capacity when you store non-persistent data, such as temporary table and log files, in the local storage. This alarm can prevent an out-of-space error that occurs when your DB instance runs out of local storage.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate about 10%-20% of the amount of storage available based on velocity and trend of volume usage, and then use that result as the threshold value to proactively take action before the volume reaches its limit.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

FreeStorageSpace

Dimensions: DBInstanceIdentifier

Alarm description: This alarm watches for a low amount of available storage space. Consider scaling up your database storage if you frequently approach storage capacity limits. Include some buffer to accommodate unforeseen increases in demand from your applications. Alternatively, consider enabling RDS storage auto scaling. Additionally, consider freeing up more space by deleting unused or outdated data and logs. For further information, check RDS run out of storage document and PostgreSQL storage issues document.

Intent: This alarm helps prevent storage full issues. This can prevent downtime that occurs when your database instance runs out of storage. We do not recommend using this alarm if you have storage auto scaling enabled, or if you frequently change the storage capacity of the database instance.

Statistic: Minimum

Recommended threshold: Depends on your situation

Threshold justification: The threshold value will depend on the currently allocated storage space. Typically, you should calculate the value of 10 percent of the allocated storage space and use that result as the threshold value.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

MaximumUsedTransactionIDs

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps prevent transaction ID wraparound for PostgreSQL. Refer to the troubleshooting steps in this blog to investigate and resolve the issue. You can also refer to this blog to familiarize yourself further with autovacuum concepts, common issues and best practices.

Intent: This alarm is used to help prevent transaction ID wraparound for PostgreSQL.

Statistic: Average

Recommended threshold: 1.0E9

Threshold justification: Setting this threshold to 1 billion should give you time to investigate the problem. The default autovacuum_freeze_max_age value is 200 million. If the age of the oldest transaction is 1 billion, autovacuum is having a problem keeping this threshold below the target of 200 million transaction IDs.

Period: 60

Datapoints to alarm: 1

Evaluation periods: 1

Comparison Operator: GREATER_THAN_THRESHOLD

ReadLatency

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high read latency. If storage latency is high, it's because the workload is exceeding resource limits. You can review I/O utilization relative to instance and allocated storage configuration. Refer to troubleshoot the latency of Amazon EBS volumes caused by an IOPS bottleneck. For Aurora, you can switch to an instance class that has I/O-Optimized storage configuration. See Planning I/O in Aurora for guidance.

Intent: This alarm is used to detect high read latency. Database disks normally have a low read/write latency, but they can have issues that can cause high latency operations.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Read latencies higher than 20 milliseconds are likely a cause for investigation. You can also set a higher threshold if your application can have higher latency for read operations. Review the criticality and requirements of read latency and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

ReplicaLag

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps you understand the number of seconds a replica is behind the primary instance. A PostgreSQL Read Replica reports a replication lag of up to five minutes if there are no user transactions occurring on the source database instance. When the ReplicaLag metric reaches 0, the replica has caught up to the primary DB instance. If the ReplicaLag metric returns -1, then replication is currently not active. For guidance related to RDS PostgreSQL, see replication best practices and for troubleshooting `ReplicaLag` and related errors, see troubleshooting ReplicaLag.

Intent: This alarm can detect the replica lag which reflects the data loss that could happen in case of a failure of the primary instance. If the replica gets too far behind the primary and the primary fails, the replica will be missing data that was in the primary instance.

Statistic: Maximum

Recommended threshold: 60.0

Threshold justification: Typically, the acceptable lag depends on the application. We recommend no more than 60 seconds.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: GREATER_THAN_THRESHOLD

WriteLatency

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high write latency. If storage latency is high, it's because the workload is exceeding resource limits. You can review I/O utilization relative to instance and allocated storage configuration. Refer to troubleshoot the latency of Amazon EBS volumes caused by an IOPS bottleneck. For Aurora, you can switch to an instance class that has I/O-Optimized storage configuration. See Planning I/O in Aurora for guidance.

Intent: This alarm is used to detect high write latency. Although database disks typically have low read/write latency, they may experience problems that cause high latency operations. Monitoring this will assure you the disk latency is as low as expected.

Statistic: p90

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on your use case. Write latencies higher than 20 milliseconds are likely a cause for investigation. You can also set a higher threshold if your application can have a higher latency for write operations. Review the criticality and requirements of write latency and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

DBLoad

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor high DB load. If the number of processes exceed the number of vCPUs, the processes start queuing. When the queuing increases, the performance is impacted. If the DB load is often above the maximum vCPU, and the primary wait state is CPU, the CPU is overloaded. In this case, you can monitor `CPUUtilization`, `DBLoadCPU` and queued tasks in Performance Insights/Enhanced Monitoring. You might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve.

Intent: This alarm is used to detect a high DB load. High DB load can cause performance issues in the DB instance. This alarm is not applicable to serverless DB instances.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The maximum vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance. Depending on the maximum vCPU, different values for the threshold can be appropriate. Ideally, DB load should not go above vCPU line.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

AuroraVolumeBytesLeftTotal

Dimensions: DBClusterIdentifier

Alarm description: This alarm helps to monitor low remaining total volume. When the total volume left reaches the size limit, the cluster reports an out-of-space error. Aurora storage automatically scales with the data in the cluster volume and expands up to 128 TiB or 64 TiB depending on the DB engine version. Consider reducing storage by dropping tables and databases that you no longer need. For more information, check storage scaling.

Intent: This alarm is used to detect how close the Aurora cluster is to the volume size limit. This alarm can prevent an out-of-space error that occurs when your cluster runs out of space. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate 10%-20% of the actual size limit based on velocity and trend of volume usage increase, and then use that result as the threshold value to proactively take action before the volume reaches its limit.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

AuroraBinlogReplicaLag

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor the error state of Aurora writer instance replication. For more information, see [Replicating Aurora MySQL DB clusters across Amazon Regions]. For troubleshooting, see [Aurora MySQL replication issues].

Intent: This alarm is used to detect whether the writer instance is in an error state and can't replicate the source. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: -1.0

Threshold justification: We recommend that you use -1 as the threshold value because Aurora MySQL publishes this value if the replica is in an error state.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

BlockedTransactions

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a high blocked transaction count in an Aurora DB instance. Blocked transactions can end in either a rollback or a commit. High concurrency, idles in transaction, or long running transactions can lead to blocked transactions. For troubleshooting, see Aurora MySQL documentation.

Intent: This alarm is used to detect a high count of blocked transactions in an Aurora DB instance in order to prevent transaction rollbacks and performance degradation.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate 5% of all transactions of your instance using the `ActiveTransactions` metric and use that result as the threshold value. You can also review the criticality and requirements of blocked transactions and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

BufferCacheHitRatio

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps you monitor a consistent low cache hit ratio of the Aurora cluster. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. For troubleshooting, investigate your workload to see which queries are causing this behavior, and see the DB instance RAM recommendations document.

Intent: This alarm is used to detect consistent low cache hit ratio in order to prevent a sustained performance decrease in the Aurora instance.

Statistic: Average

Recommended threshold: 80.0

Threshold justification: You can set the threshold for buffer cache hit ratio to 80%. However, you can adjust this value based on your acceptable performance level and workload characteristics.

Period: 60

Datapoints to alarm: 10

Evaluation periods: 10

Comparison Operator: LESS_THAN_THRESHOLD

EngineUptime

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor low downtime of the writer DB instance. The writer DB instance can go down due to a reboot, maintenance, upgrade, or failover. When the uptime reaches 0 because of a failover in the cluster, and the cluster has one or more Aurora Replicas, then an Aurora Replica is promoted to the primary writer instance during a failure event. To increase the availability of your DB cluster, consider creating one or more Aurora Replicas in two or more different Availability Zones. For more information check factors that influence Aurora downtime.

Intent: This alarm is used to detect whether the Aurora writer DB instance is in downtime. This can prevent long-running failure in the writer instance that occurs because of a crash or failover.

Statistic: Average

Recommended threshold: 0.0

Threshold justification: A failure event results in a brief interruption, during which read and write operations fail with an exception. However, service is typically restored in less than 60 seconds, and often less than 30 seconds.

Period: 60

Datapoints to alarm: 2

Evaluation periods: 2

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

RollbackSegmentHistoryListLength

Dimensions: DBInstanceIdentifier

Alarm description: This alarm helps to monitor a consistent high rollback segment history length of an Aurora instance. A high InnoDB history list length indicates that a large number of old row versions, queries and database shutdowns have become slower. For more information and troubleshooting, see the InnoDB history list length increased significantly documentation.

Intent: This alarm is used to detect consistent high rollback segment history length. This can help you prevent sustained performance degradation and high CPU usage in the Aurora instance. This alarm is recommended only for Aurora MySQL.

Statistic: Average

Recommended threshold: 1000000.0

Threshold justification: Setting this threshold to 1 million should give you time to investigate the problem. However, you can adjust this value based on your acceptable performance level and workload characteristics.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

StorageNetworkThroughput

Dimensions: DBClusterIdentifier, Role=WRITER

Alarm description: This alarm helps to monitor high storage network throughput. If storage network throughput passes the total network bandwidth of the EC2 instance, it can lead to high read and write latency, which can cause degraded performance. You can check your EC2 instance type from Amazon Console. For troubleshooting, check any changes on write/read latencies and evaluate if you've also hit an alarm on this metric. If that is the case, evaluate your workload pattern during the times that the alarm was triggered. This can help you identify if you can optimize y our workload to reduce the total amount of network traffic. If this is not possible, you might need to consider scaling your instance.

Intent: This alarm is used to detect high storage network throughput. Detecting high throughput can prevent network packet drops and degraded performance.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: You should calculate about 80%-90% of the total network bandwidth of the EC2 instance type, and then use that result as the threshold value to proactively take action before the network packets are affected. You can also review the criticality and requirements of storage network throughput and analyze the historical behavior of this metric to determine sensible threshold levels.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon Route 53 Public Data Plane

HealthCheckStatus

Dimensions: HealthCheckId

Alarm description: This alarm helps to detect unhealthy endpoints as per health checkers. To understand the reason for a failure that results in unhealthy status, use the Health Checkers tab in the Route 53 Health Check Console to view the status from each Region as well as the last failure of the health check. The status tab also displays the reason that the endpoint is reported as unhealthy. Refer to troubleshooting steps.

Intent: This alarm uses Route53 health checkers to detect unhealthy endpoints.

Statistic: Average

Recommended threshold: 1.0

Threshold justification: The status of the endpoint is reported as 1 when it's healthy. Everything less than 1 is unhealthy.

Period: 60

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

Amazon S3

4xxErrors

Dimensions: BucketName, FilterId

Alarm description: This alarm helps us report the total number of 4xx error status codes that are made in response to client requests. 403 error codes might indicate an incorrect IAM policy, and 404 error codes might indicate mis-behaving client application, for example. Enabling S3 server access logging on a temporary basis will help you to pinpoint the issue's origin using the fields HTTP status and Error Code. To understand more about the error code, see Error Responses.

Intent: This alarm is used to create a baseline for typical 4xx error rates so that you can look into any abnormalities that might indicate a setup issue.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: The recommended threshold is to detect if more than 5% of total requests are getting 4XX errors. Frequently occurring 4XX errors should be alarmed. However, setting a very low value for the threshold can cause alarm to be too sensitive. You can also tune the threshold to suit to the load of the requests, accounting for an acceptable level of 4XX errors. You can also analyze historical data to find the acceptable error rate for the application workload, and then tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

5xxErrors

Dimensions: BucketName, FilterId

Alarm description: This alarm helps you detect a high number of server-side errors. These errors indicate that a client made a request that the server couldn't complete. This can help you correlate the issue your application is facing because of S3. For more information to help you efficiently handle or reduce errors, see Optimizing performance design patterns. Errors might also be caused by an the issue with S3, check Amazon service health dashboard for the status of Amazon S3 in your Region.

Intent: This alarm can help to detect if the application is experiencing issues due to 5xx errors.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: We recommend setting the threshold to detect if more than 5% of total requests are getting 5XXError. However, you can tune the threshold to suit the traffic of the requests, as well as acceptable error rates. You can also analyze historical data to see what is the acceptable error rate for the application workload, and tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

OperationsFailedReplication

Dimensions: SourceBucket, DestinationBucket, RuleId

Alarm description: This alarm helps in understanding a replication failure. This metric tracks the status of new objects replicated using S3 CRR or S3 SRR, and also tracks existing objects replicated using S3 batch replication. See Replication troubleshooting for more details.

Intent: This alarm is used to detect if there is a failed replication operation.

Statistic: Maximum

Recommended threshold: 0.0

Threshold justification: This metric emits a value of 0 for successful operations, and nothing when there are no replication operations carried out for the minute. When the metric emits a value greater than 0, the replication operation is unsuccessful.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

`S3ObjectLambda`

4xxErrors

Dimensions: AccessPointName, DataSourceARN

Alarm description: This alarm helps us report the total number of 4xx error status code that are made in response to client requests. Enabling S3 server access logging on a temporary basis will help you to pinpoint the issue's origin using the fields HTTP status and Error Code.

Intent: This alarm is used to create a baseline for typical 4xx error rates so that you can look into any abnormalities that might indicate a setup issue.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: We recommend setting the threshold to detect if more than 5% of total requests are getting 4XXError. Frequently occurring 4XX errors should be alarmed. However, setting a very low value for the threshold can cause alarm to be too sensitive. You can also tune the threshold to suit to the load of the requests, accounting for an acceptable level of 4XX errors. You can also analyze historical data to find the acceptable error rate for the application workload, and then tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

5xxErrors

Dimensions: AccessPointName, DataSourceARN

Alarm description: This alarm helps to detect high number of server-side errors. These errors indicate that a client made a request that the server couldn’t complete. These errors might be caused by an issue with S3, check Amazon service health dashboard for the status of Amazon S3 in your Region. This can help you correlate the issue your application is facing because of S3. For information to help you efficiently handle or reduce these errors, see Optimizing performance design patterns.

Intent: This alarm can help to detect if the application is experiencing issues due to 5xx errors.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: We recommend setting the threshold to detect if more than 5% of total requests are getting 5XX errors. However, you can tune the threshold to suit the traffic of the requests, as well as acceptable error rates. You can also analyze historical data to see what is the acceptable error rate for the application workload, and tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

LambdaResponse4xx

Dimensions: AccessPointName, DataSourceARN

Alarm description: This alarm helps you detect and diagnose failures (500s) in calls to S3 Object Lambda. These errors can be caused by errors or misconfigurations in the Lambda function responsible for responding to your requests. Investigating the CloudWatch Log Streams of the Lambda function associated with the Object Lambda Access Point can help you pinpoint the issue's origin based on the response from S3 Object Lambda.

Intent: This alarm is used to detect 4xx client errors for WriteGetObjectResponse calls.

Statistic: Average

Recommended threshold: 0.05

Threshold justification: We recommend setting the threshold to detect if more than 5% of total requests are getting 4XXError. Frequently occurring 4XX errors should be alarmed. However, setting a very low value for the threshold can cause alarm to be too sensitive. You can also tune the threshold to suit to the load of the requests, accounting for an acceptable level of 4XX errors. You can also analyze historical data to find the acceptable error rate for the application workload, and then tune the threshold accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon SNS

NumberOfMessagesPublished

Dimensions: TopicName

Alarm description: This alarm can detect when the number of SNS messages published is too low. For troubleshooting, check why the publishers are sending less traffic.

Intent: This alarm helps you proactively monitor and detect significant drops in notification publishing. This helps you identify potential issues with your application or business processes, so that you can take appropriate actions to maintain the expected flow of notifications. You should create this alarm if you expect your system to have a minimum traffic that it is serving.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The number of messages published should be in line with the expected number of published messages for your application. You can also analyze the historical data, trends and traffic to find the right threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

NumberOfNotificationsDelivered

Dimensions: TopicName

Alarm description: This alarm can detect when the number of SNS messages delivered is too low. This could be because of unintentional unsubscribing of an endpoint, or because of an SNS event that causes messages to experience delay.

Intent: This alarm helps you detect a drop in the volume of messages delivered. You should create this alarm if you expect your system to have a minimum traffic that it is serving.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The number of messages delivered should be in line with the expected number of messages produced and the number of consumers. You can also analyze the historical data, trends and traffic to find the right threshold.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: LESS_THAN_THRESHOLD

NumberOfNotificationsFailed

Dimensions: TopicName

Alarm description: This alarm can detect when the number of failed SNS messages is too high. To troubleshoot failed notifications, enable logging to CloudWatch Logs. Checking the logs can help you find which subscribers are failing, as well as the status codes they are returning.

Intent: This alarm helps you proactively find issues with the delivery of notifications and take appropriate actions to address them.

Statistic: Sum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the impact of failed notifications. Review the SLAs provided to your end users, fault tolerance and criticality of notifications and analyze historical data, and then select a threshold accordingly. The number of notifications failed should be 0 for topics that have only SQS, Lambda or Firehose subscriptions.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFilteredOut-InvalidAttributes

Dimensions: TopicName

Alarm description: This alarm helps to monitor and resolve potential problems with the publisher or subscribers. Check if a publisher is publishing messages with invalid attributes or if an inappropriate filter is applied to a subscriber. You can also analyze CloudWatch Logs to help find the root cause of the issue.

Intent: The alarm is used to detect if the published messages are not valid or if inappropriate filters have been applied to a subscriber.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Invalid attributes are almost always a mistake by the publisher. We recommend to set the threshold to 0 because invalid attributes are not expected in a healthy system.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFilteredOut-InvalidMessageBody

Dimensions: TopicName

Alarm description: This alarm helps to monitor and resolve potential problems with the publisher or subscribers. Check if a publisher is publishing messages with invalid message bodies, or if an inappropriate filter is applied to a subscriber. You can also analyze CloudWatch Logs to help find the root cause of the issue.

Intent: The alarm is used to detect if the published messages are not valid or if inappropriate filters have been applied to a subscriber.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: Invalid message bodies are almost always a mistake by the publisher. We recommend to set the threshold to 0 because invalid message bodies are not expected in a healthy system.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsRedrivenToDlq

Dimensions: TopicName

Alarm description: This alarm helps to monitor the number of messages that are moved to a dead-letter queue.

Intent: The alarm is used to detect messages that moved to a dead-letter queue. We recommend that you create this alarm when SNS is coupled with SQS, Lambda or Firehose.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: In a healthy system of any subscriber type, messages should not be moved to the dead-letter queue. We recommend that you be notified if any messages land in the queue, so that you can identify and address the root cause, and potentially redrive the messages in the dead-letter queue to prevent data loss.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

NumberOfNotificationsFailedToRedriveToDlq

Dimensions: TopicName

Alarm description: This alarm helps to monitor messages that couldn't be moved to a dead-letter queue. Check whether your dead-letter queue exists and that it's configured correctly. Also, verify that SNS has permissions to access the dead-letter queue. Refer to the dead-letter queue documentation to learn more.

Intent: The alarm is used to detect messages that couldn't be moved to a dead-letter queue.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: It's almost always a mistake if messages can't be moved to the dead-letter queue. The recommendation for the threshold is 0, meaning all messages that fail processing must be able to reach the dead-letter queue when the queue has been configured.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SMSMonthToDateSpentUSD

Dimensions: TopicName

Alarm description: The alarm helps to monitor if you have a sufficient quota in your account for SNS to be able to deliver messages. If you reach your quota, SNS won't be able to deliver SMS messages. For information about setting your monthly SMS spend quota, or for information about requesting a spend quota increase with Amazon, see Setting SMS messaging preferences.

Intent: This alarm is used to detect if you have a sufficient quota in your account for your SMS messages to be delivered successfully.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold in accordance with the quota (Account spend limit) for the account. Choose a threshold which informs you early enough that you are reaching your quota limit so that you have time to request an increase.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

SMSSuccessRate

Dimensions: TopicName

Alarm description: This alarm helps to monitor the rate of failing SMS message deliveries. You can set up Cloudwatch Logs to understand the nature of the failure and take action based on that.

Intent: This alarm is used to detect failing SMS message deliveries.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: Set the threshold for the alarm in line with your tolerance for failing SMS message deliveries.

Period: 60

Datapoints to alarm: 5

Evaluation periods: 5

Comparison Operator: GREATER_THAN_THRESHOLD

Amazon SQS

ApproximateAgeOfOldestMessage

Dimensions: QueueName

Alarm description: This alarm watches the age of the oldest message in the queue. You can use this alarm to monitor if your consumers are processing SQS messages at the desired speed. Consider increasing the consumer count or consumer throughput to reduce message age. This metric can be used in combination with `ApproximateNumberOfMessagesVisible` to determine how big the queue backlog is and how quickly messages are being processed. To prevent messages from being deleted before processed, consider configuring the dead-letter queue to sideline potential poison pill messages.

Intent: This alarm is used to detect whether the age of the oldest message in the QueueName queue is too high. High age can be an indication that messages are not processed quickly enough or that there are some poison-pill messages that are stuck in the queue and can't be processed.

Statistic: Maximum

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the expected message processing time. You can use historical data to calculate the average message processing time, and then set the threshold to 50% higher than the maximum expected SQS message processing time by queue consumers.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

ApproximateNumberOfMessagesNotVisible

Dimensions: QueueName

Alarm description: This alarm helps to detect a high number of in-flight messages with respect to `QueueName`. For troubleshooting, check [message backlog decreasing](#).

Intent: This alarm is used to detect a high number of in-flight messages in the queue. If consumers do not delete messages within the visibility timeout period, when the queue is polled, messages reappear in the queue. For FIFO queues, there can be a maximum of 20,000 in-flight messages. If you reach this quota, SQS returns no error messages. A FIFO queue looks through the first 20k messages to determine available message groups. This means that if you have a backlog of messages in a single message group, you cannot consume messages from other message groups that were sent to the queue at a later time until you successfully consume the messages from the backlog.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: The recommended threshold value for this alarm is highly dependent on the expected number of messages in flight. You can use historical data to calculate the maximum expected number of messages in flight and set the threshold to 50% over this value. If consumers of the queue are processing but not deleting messages from the queue, this number will suddenly increase.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

ApproximateNumberOfMessagesVisible

Dimensions: QueueName

Alarm description: This alarm watches for the message queue backlog to be bigger than expected, indicating that consumers are too slow or there are not enough consumers. Consider increasing the consumer count or speeding up consumers, if this alarm goes into ALARM state.

Intent: This alarm is used to detect whether the message count of the active queue is too high and consumers are slow to process the messages or there are not enough consumers to process them.

Statistic: Average

Recommended threshold: Depends on your situation

Threshold justification: An unexpectedly high number of messages visible indicates that messages are not being processed by a consumer at the expected rate. You should consider historical data when you set this threshold.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: GREATER_THAN_OR_EQUAL_TO_THRESHOLD

NumberOfMessagesSent

Dimensions: QueueName

Alarm description: This alarm helps to detect if there are no messages being sent from a producer with respect to `QueueName`. For troubleshooting, check the reason that the producer is not sending messages.

Intent: This alarm is used to detect when a producer stops sending messages.

Statistic: Sum

Recommended threshold: 0.0

Threshold justification: If the number of messages sent is 0, the producer is not sending any messages. If this queue has a low TPS, increase the number of EvaluationPeriods accordingly.

Period: 60

Datapoints to alarm: 15

Evaluation periods: 15

Comparison Operator: LESS_THAN_OR_EQUAL_TO_THRESHOLD

Amazon VPN

TunnelState

Dimensions: VpnId

Alarm description: This alarm helps you understand if the state of one or more tunnels is DOWN. For troubleshooting, see [VPN tunnel troubleshooting].

Intent: This alarm is used to detect if at least one tunnel is in the DOWN state for this VPN, so that you can troubleshoot the impacted VPN. This alarm will always be in the ALARM state for networks that only have a single tunnel configured.

Statistic: Minimum

Recommended threshold: 1.0

Threshold justification: A value less than 1 indicates that at least one tunnel is in DOWN state.

Period: 300

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

TunnelState

Dimensions: TunnelIpAddress

Alarm description: This alarm helps you understand if the state of this tunnel is DOWN. For troubleshooting, see [VPN tunnel troubleshooting].

Intent: This alarm is used to detect if the tunnel is in the DOWN state, so that you can troubleshoot the impacted VPN. This alarm will always be in the ALARM state for networks that only have a single tunnel configured.

Statistic: Minimum

Recommended threshold: 1.0

Threshold justification: A value less than 1 indicates that the tunnel is in DOWN state.

Period: 300

Datapoints to alarm: 3

Evaluation periods: 3

Comparison Operator: LESS_THAN_THRESHOLD

Alarming on metrics

The steps in the following sections explain how to create CloudWatch alarms on metrics.

Create a CloudWatch alarm based on a static threshold

You choose a CloudWatch metric for the alarm to watch, and the threshold for that metric. The alarm goes to `ALARM` state when the metric breaches the threshold for a specified number of evaluation periods.

If you are creating an alarm in an account set up as a monitoring account in CloudWatch cross-account observability, you can set up the alarm to watch a metric in a source account linked to this monitoring account. For more information, see [CloudWatch cross-account observability](#).

To create an alarm based on a single metric

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Do one of the following:
   - Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, account ID, account label, dimension, or resource ID. Then, choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.
6. Choose the **Graphed metrics** tab.

   a. Under **Statistic** , choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, **`p95.45`**).

   b. Under **Period**, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.

      You can also choose whether the y-axis legend appears on the left or right while you're creating the alarm. This preference is used only while you're creating the alarm.

   c. Choose **Select metric**.

The **Specify metric and conditions** page appears, showing a graph and other information about the metric and statistic that you selected.

7. Under **Conditions**, specify the following:

   a. For **Whenever *`metric`* is**, specify whether the metric must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

   b. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

      To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see [Evaluating an alarm](#).

   c. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see [Configuring how CloudWatch alarms treat missing data](#).

   d. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see [Percentile-based CloudWatch alarms and low data samples](#).

8. Choose **Next**.

9. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   In CloudWatch cross-account observability, you can choose to have notifications sent to multiple Amazon accounts. For example, to both the monitoring account and the source account.

   To have the alarm not send notifications, choose **Remove**.

10. To have the alarm perform Auto Scaling, EC2, Lambda, investigation, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. Alarms can perform Systems Manager actions and investigation actions only when they go

into ALARM state. For more information about Systems Manager actions, see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

To have the alarm start an investigation, choose **Add investigation action** and then select your investigation group. For more information about Amazon Q Developer operational investigations, see Amazon Q Developer operational investigations (Preview).

> **Note**
>
> To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager.

11. When finished, choose **Next**.
12. Enter a name and description for the alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources. Then choose **Next**.
13. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

You can also add alarms to a dashboard. For more information, see Adding an alarm to a CloudWatch dashboard.

Create a CloudWatch alarm based on a metric math expression

To create an alarm based on a metric math expression, choose one or more CloudWatch metrics to use in the expression. Then, specify the expression, threshold, and evaluation periods.

You can't create an alarm based on the **SEARCH** expression. This is because search expressions return multiple time series, and an alarm based on a math expression can watch only one time series.

To create an alarm that's based on a metric math expression

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.

4. Choose **Select Metric**, and then perform one of the following actions:
   - Select a namespace from the **Amazon namespaces** dropdown or **Custom namespaces** dropdown. After you select a namespace, you continue choosing options until a list of metrics appears, where you select the checkbox next to the correct metric.
   - Use the search box to find a metric, account ID, dimension, or resource ID. After you enter the metric, dimension, or resource ID, you continue choosing options until a list of metrics appears, where you select the check box next to the correct metric.
5. (Optional) If you want to add another metric to a metric math expression, you can use the search box to find a specific metric. You can add as many as 10 metrics to a metric math expression.
6. Select the **Graphed metrics** tab. For each of the metrics that you previously added, perform the following actions:

   a. Under the **Statistic** column, select the dropdown menu. In the dropdown menu, choose one of the predefined statistics or percentiles. Use the search box in the dropdown menu to specify a custom percentile.

   b. Under the **Period** column, select the dropdown menu. In the dropdown menu, choose one of the predefined evaluation periods.

      While you're creating your alarm, you can specify whether the Y-axis legend appears on the left or right side of your graph.

   > **Note**
   >
   > When CloudWatch evaluates alarms, periods are aggregated into single data points.

7. Choose the **Add math** dropdown, and then select **Start with an empty expression** from the list of predefined metric math expressions.

   After you choose **Start with an empty expression**, a math expression box appears where you apply or edit math expressions.
8. In the math expression box, enter your math expression, and then choose **Apply**.

   After you choose **Apply**, an **ID** column appears next to the **Label** column.

   To use a metric or the result of another metric math expression as part of your current math expression's formula, you use the value that's shown under the **ID** column. To change the value of **ID**, you select the pen-and-paper icon next to the current value. The new value must begin with a lowercase letter and can include numbers, letters, and the underscore symbol. Changing the value of **ID** to a more significant name can make your alarm graph easier to understand.

For information about the functions that are available for metric math, see [Metric math syntax and functions](#).

9. (Optional) Add more math expressions, using both metrics and the results of other math expressions in the formulas of the new math expressions.

10. When you have the expression to use for the alarm, clear the check boxes to the left of every other expression and every metric on the page. Only the check box next to the expression to use for the alarm should be selected. The expression that you choose for the alarm must produce a single time series and show only one line on the graph. Then choose **Select metric**.

    The **Specify metric and conditions** page appears, showing a graph and other information about the math expression that you have selected.

11. For **Whenever *`expression`* is**, specify whether the expression must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

12. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

    To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see [Evaluating an alarm](#).

13. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see [Configuring how CloudWatch alarms treat missing data](#).

14. Choose **Next**.

15. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.

16. To have the alarm perform Auto Scaling, EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a

Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

> **Note**
>
> To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager.

17. When finished, choose **Next**.
18. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
19. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

You can also add alarms to a dashboard. For more information, see Adding an alarm to a CloudWatch dashboard.

Create a CloudWatch alarm based on a Metrics Insights query

You can create an alarm on any Metrics Insights query that returns a single time series. This can be especially useful to create dynamic alarms that watch aggregated metrics across a fleet of your infrastructure or applications. Create the alarm once, and it adjusts as resources are added to or removed from the fleet. For example, you can create an alarm that watches the CPU ulitization of all your instances, and the alarm dynamically adjusts as you add or remove instances.

For complete instructions, see Alarms on CloudWatch Metrics Insights queries in CloudWatch.

Create an alarm based on a connected data source

You can create alarms that watch metrics from data sources that aren't in CloudWatch. For more information about creating connections to these other data sources, see Query metrics from other data sources.

To create an alarm on metrics from a data source that you have connected to

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, **All metrics**.
3. Choose the **Multi source query** tab.
4. For **Data source**, select the data source that you want to use.
5. The query builder prompts you for the information necessary for the query to retrieve the metrics to use for the alarm. The workflow is different for each data source, and is tailored to the data source. For example, for Amazon Managed Service for Prometheus and Prometheus data sources, a PromQL query editor box with a query helper appears.
6. When you have finished constructing the query, choose **Graph query**.
7. If the sample graph looks the way that you expect, choose **Create alarm**.
8. The **Specify metric and conditions** page appears. If the query you are using produces more than one time series, you see a warning banner at the top of the page. If you do, select a function to use to aggregate the time series in **Aggregation function**.
9. (Optional) Add a **Label** for the alarm.
10. For **Whenever *`your-metric-name`* is . . .**, choose **Greater**, **Greater/Equal**, **Lower/Equal**, or **Lower**. Then for **than . . .**, specify a number for your threshold value.
11. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

    To create an M out of N alarm, specify a number for the first value that is lower than the number for the second value. For more information, see Evaluating an alarm.
12. For **Missing data treatment**, choose how the alarm behaves when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.
13. Choose **Next**.

14. For **Notification**, specify an Amazon SNS topic to notify when your alarm transitions to the `ALARM`, `OK`, or `INSUFFICIENT_DATA` state.

    a. (Optional) To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    > **Note**
    >
    > We recommend that you set the alarm to take actions when it goes into **Insufficient data** state in addition to when it goes into **Alarm** state. This is because many issues with the Lambda function that connects to the data source can cause the alarm to transition to **Insufficient data**.

    b. (Optional) To not send Amazon SNS notifications, choose **Remove**.

15. To have the alarm perform Auto Scaling, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager.

16. Choose **Next**.

17. Under **Name and description**, enter a name and description for your alarm, and choose **Next**. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

> **Tip**
>
> The alarm name must contain only UTF-8 characters. It can't contain ASCII control characters.

18. Under **Preview and create**, confirm that your alarm's information and conditions are correct, and choose **Create alarm**.

Details about alarms for connected data sources

- When CloudWatch evaluates an alarm, it does so every minute, even if the period for the alarm is longer than one minute. For the alarm to work, the Lambda function must be able to return a list of timestamps starting on any minute, not only on multiples of the period length. These timestamps must be spaced one period length apart.

  Therefore, if the data source queried by the Lambda can only return timestamps that are multiples of the period length, the function should "re-sample" the fetched data to match the timestamps expected by the `GetMetricData` request.

  For example, an alarm with a five-minute period is evaluated every minute using five-minute windows that shift by one minute each time. In this case:

  - For the alarm evaluation at 12:15:00, CloudWatch expects data points with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`.
  - Then for the alarm evaluation at 12:16:00, CloudWatch expects data points with timestamps of `12:01:00`, `12:06:00`, and `12:11:00`.
- When CloudWatch evaluates an alarm, any data points returned by the Lambda function that don't align with the expected timestamps are dropped, and the alarm is evaluated using the remaining expected data points. For example, when the alarm is evaluated at `12:15:00` it expects data with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`. If it receives data with timestamps of `12:00:00`, `12:05:00`, `12:06:00`, and `12:10:00`, the data from `12:06:00` is dropped and CloudWatch evaluates the alarm using the other timestamps.

  Then for the next evaluation at `12:16:00`, it expects data with timestamps of `12:01:00`, `12:06:00`, and `12:11:00`. If it only has the data with timestamps of `12:00:00`, `12:05:00`, and `12:10:00`, all of these data points are ignored at 12:16:00 and the alarm transitions into the state according to how you specified the alarm to treat missing data. For more information, see Evaluating an alarm.

- We recommend that you create these alarms to take actions when they transition to the `INSUFFICIENT_DATA` state, because several Lambda function failure use cases will transition the alarm to `INSUFFICIENT_DATA` regardless of the way that you set the alarm to treat missing data.
- If the Lambda function returns an error:
  - If there is a permission problem with calling the Lambda function, the alarm begins having missing data transitions according to how you specified the alarm to treat missing data when you created it.
  - Any other error coming from the Lambda function causes the alarm to transition to `INSUFFICIENT_DATA`.
- If the Lambda function returns partial data:
  - The alarm continues to be evaluated on the data points that are returned.
  - You can use the following methods to find whether an alarm on a Lambda function is currently evaluating its alarm state based on partial data:
    - In the console, choose an alarm and choose the **Details** page. If you see the message **Evaluation warning: Not evaluating all data appears on that page**, it is evaluating on partial data.
    - If you see the value `PARTIAL_DATA` in the `EvaluationState` field when you use the `describe-alarms` Amazon CLI command or the DescribeAlarms API, it is evaluating on partial data.
  - An alarm also publishes events to Amazon EventBridge when it goes into the partial data state.
- If the metric requested by the Lambda function has some delay so that the last data point is always missing, you should use a workaround. You can create an M out of N alarm or increase the evaluation period of the alarm. For more information about M out of N alarms, see Evaluating an alarm.

Create a CloudWatch alarm based on anomaly detection

You can create an alarm based on CloudWatch anomaly detection, which analyzes past metric data and creates a model of expected values. The expected values take into account the typical hourly, daily, and weekly patterns in the metric.

You set a value for the anomaly detection threshold, and CloudWatch uses this threshold with the model to determine the "normal" range of values for the metric. A higher value for the threshold produces a thicker band of "normal" values.

You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or either above or below the band.

You also can create anomaly detection alarms on single metrics and the outputs of metric math expressions. You can use these expressions to create graphs that visualize anomaly detection bands.

In an account set up as a monitoring account for CloudWatch cross-account observability, you can create anomaly detectors on metrics in source accounts in addition to metrics in the monitoring account.

For more information, see Using CloudWatch anomaly detection.

> **Note**
>
> If you're already using anomaly detection for visualization purposes on a metric in the Metrics console and you create an anomaly detection alarm on that same metric, then the threshold that you set for the alarm doesn't change the threshold that you already set for visualization. For more information, see Creating a graph.

To create an alarm that's based on anomaly detection

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Do one of the following:
   - Choose the service namespace that contains your metric, and then continue choosing options as they appear to narrow down your options. When a list of metrics appears, select the check box that's next to your metric.
   - In the search box, enter the name of a metric, dimension, or resource ID. Select one of the results, and then continue choosing options as they appear until a list of metrics appears. Select the check box that's next to your metric.

6. Choose **Graphed metric**.

   a. (Optional) For *Statistic*, choose the dropdown, and then select one of the predefined statistics or percentiles. You can use the search box in the dropdown to specify a custom percentile, such as **p95.45**.

   b. (Optional) For *Period*, choose the dropdown, and then select one of the predefined evaluation periods.

      > **Note**
      >
      > When CloudWatch evaluates your alarm, it aggregates the period into a single datapoint. For an anomaly detection alarm, the evaluation period must be one minute or longer.

7. Choose **Next**.

8. Under ***Conditions***, specify the following:

   a. Choose **Anomaly detection**.

      If the model for this metric and statistic already exists, CloudWatch displays a preview of the anomaly detection band in the graph at the top of the screen. After you create your alarm, it can take up to 15 minutes for the actual anomaly detection band to appear in the graph. Before that, the band that you see is an approximation of the anomaly detection band.

      > **Tip**
      >
      > To see the graph at the top of the screen in a longer time frame, choose **Edit** at the top-right of the screen.

      If the model for this metric and statistic doesn't already exist, CloudWatch generates the anomaly detection band after you finish creating your alarm. For new models, it can take up to 3 hours for the actual anomaly detection band to appear in your graph. It can take up to two weeks for the new model to train, so the anomaly detection band shows more accurate expected values.

   b. For **Whenever *metric* is**, specify when to trigger the alarm. For example, when the metric is greater than, lower than, or outside the band (in either direction).

   c. For **Anomaly detection threshold**, choose the number to use for the anomaly detection threshold. A higher number creates a thicker band of "normal" values that is more tolerant of metric changes. A lower number creates a thinner band that will go to `ALARM` state with smaller metric deviations. The number does not have to be a whole number.

   d. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

      To create an M out of N alarm, specify a number for the first value that is lower than the number for the second value. For more information, see [Evaluating an alarm](#).

   e. For **Missing data treatment**, choose how the alarm behaves when some data points are missing. For more information, see [Configuring how CloudWatch alarms treat missing data](#).

   f. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **Ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see [Percentile-based CloudWatch alarms and low data samples](#).

9. Choose **Next**.

10. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    Choose **Remove** if you don't want the alarm to send notifications.

11. You can set up the alarm to perform EC2 actions or invoke a Lambda function when it changes state, or to create a Systems Manager OpsItem or incident when it goes into ALARM state. To do this, choose the appropriate button and then choose the alarm state and action to perform.

    If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    For more information about Systems Manager actions, see [Configuring CloudWatch to create OpsItems from alarms](#) and [Incident creation](#).

> **Note**
>
> To create an alarm that performs an Amazon Systems Manager Incident Manager action, you must have certain permissions. For more information, see [Identity-based policy examples for Amazon Systems Manager Incident Manager](#).

12. Choose **Next**.
13. Under ***Name and description***, enter a name and description for your alarm, and choose **Next**. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

> **Tip**
>
> The alarm name must contain only UTF-8 characters, and can't contain ASCII control characters

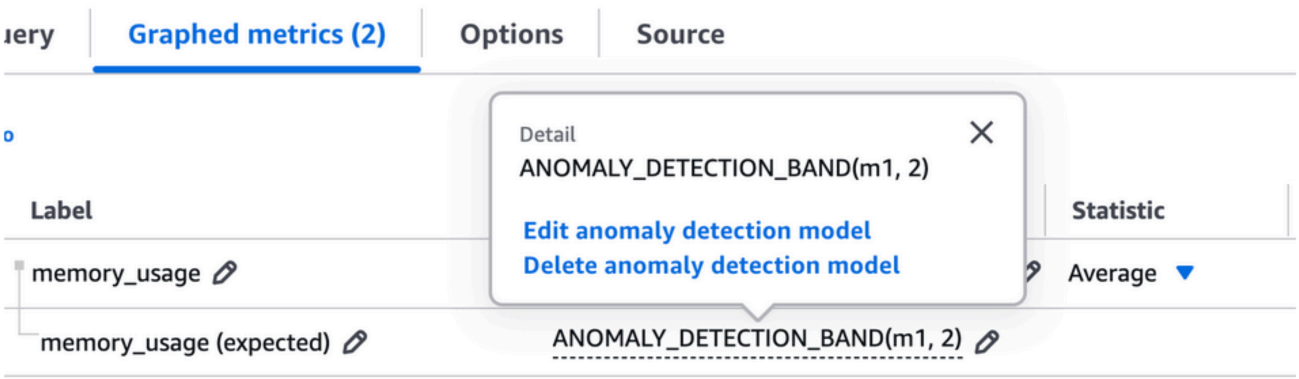
14. Under ***Preview and create***, confirm that your alarm's information and conditions are correct, and choose **Create alarm**.

Editing an anomaly detection model

After you create an alarm, you can adjust the anomaly detection model. You can exclude certain time periods from being used in the model creation. It is critical that you exclude unusual events such as system outages, deployments, and holidays from the training data. You can also specify whether to adjust the model for Daylight Savings Time changes.

To edit the anomaly detection model for an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose the name of the alarm. If necessary, use the search box to find the alarm.
4. Choose **View**, **In metrics**.
5. In the **Details** column, choose the **ANOMALY_DETECTION_BAND** keyword, and then choose **Edit anomaly detection model** in the popup.



6. To exclude a time period from being used to produce the model, choose the calendar icon by **End date**. Then, select or enter the days and times to exclude from training and choose **Apply**.
7. If the metric is sensitive to Daylight Savings Time changes, select the appropriate time zone in the **Metric timezone** box.
8. Choose **Update**.

Deleting an anomaly detection model

Using anomaly detection for an alarm accrues charges. As a best practice, if your alarm no longer needs an anomaly detection model, delete the alarm first and the model second. When anomaly detection alarms are evaluated, any missing anomaly detectors are created on your behalf. If you delete the model without deleting the alarm, the alarm automatically recreates the model.

To delete an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose the name of the alarm.
4. Choose **Actions**, **Delete**.
5. In the confirmation box, choose **Delete**.

To delete an anomaly detection model that was used for an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**, and then choose **All metrics**.

3. Choose **Browse**, and then select the metric that includes the anomaly detection model. You can search for your metric in the search box or select your metric by choosing through the options.

   - (Optional) If you're using the original interface, choose **All metrics**, and then choose the metric that includes the anomaly detection model. You can search for your metric in the search box or select your metric by choosing through the options.

4. Choose **Graphed metrics**.

5. In the **Graphed metrics** tab, in the **Details** column, choose the **ANOMALY_DETECTION_BAND** keyword, and then choose **Delete anomaly detection model** in the popup.

   - (Optional) If you're using the original interface, choose **Edit model**. You're directed to a new screen. On the new screen, choose **Delete model**, and then choose **Delete**.

Alarming on logs

The steps in the following sections explain how to create CloudWatch alarms on logs.

Create a CloudWatch alarm based on a log group-metric filter

The procedure in this section describes how to create an alarm based on a log group-metric filter. With metric filters, you can look for terms and patterns in log data as the data is sent to CloudWatch. For more information, see Create metrics from log events using filters in the *Amazon CloudWatch Logs User Guide*. Before you create an alarm based on a log group-metric filter, you must complete the following actions:

- Create a log group. For more information, see Working with log groups and log streams in the *Amazon CloudWatch Logs User Guide*.

- Create a metric filter. For more information, see [Create a metric filter for a log group]() in the *Amazon CloudWatch Logs User Guide*.

To create an alarm based on a log group-metric filter

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. From the navigation pane, choose **Logs**, and then choose **Log groups**.
3. Choose the log group that includes your metric filter.
4. Choose **Metric filters**.
5. In the metric filters tab, select the box for the metric filter that you want to base your alarm on.
6. Choose **Create alarm**.
7. (Optional) Under **Metric**, edit **Metric name**, **Statistic**, and **Period**.
8. Under **Conditions**, specify the following:

   a. For **Threshold type**, choose **Static** or **Anomaly detection**.

   b. For **Whenever *`your-metric-name`* is . . .**, choose **Greater**, **Greater/Equal**, **Lower/Equal** , or **Lower**.

   c. For **than . . .**, specify a number for your threshold value.
9. Choose **Additional configuration**.

   a. For **Data points to alarm**, specify how many data points trigger your alarm to go into the `ALARM` state. If you specify matching values, your alarm goes into the `ALARM` state if that many consecutive periods are breaching. To create an M-out-of-N alarm, specify a number for the first value that's lower than the number you specify for the second value. For more information, see Using Amazon CloudWatch alarms.

   b. For **Missing data treatment**, select an option to specify how to treat missing data when your alarm is evaluated.
10. Choose **Next**.
11. For **Notification**, specify an Amazon SNS topic to notify when your alarm is in the `ALARM`, `OK`, or `INSUFFICIENT_DATA` state.

    a. (Optional) To send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    b. (Optional) To not send notifications, choose **Remove**.

12. To have the alarm perform Auto Scaling, EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

    Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see [Configuring CloudWatch to create OpsItems from alarms] and [Incident creation].

    > **Note**
    >
    > To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see [Identity-based policy examples for Amazon Systems Manager Incident Manager].

13. Choose **Next**.
14. For **Name and description**, enter a name and description for your alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
15. For **Preview and create**, check that your configuration is correct, and choose **Create alarm**.

Combining alarms

With CloudWatch, you can combine several alarms into one *composite alarm* to create a summarized, aggregated health indicator over a whole application or group of resources. Composite alarms are alarms that determine their state by monitoring the states of other alarms. You define rules to combine the status of those monitored alarms using Boolean logic.

You can use composite alarms to reduce alarm noise by taking actions only at an aggregated level. For example, you can create a composite alarm to send a notification to your web server team if any alarm related to your web server triggers. When any of those alarms goes into the ALARM state, the composite alarm goes itself in the ALARM state and sends a notification to your team. If other alarms related to your web server also go into the ALARM state, your team does not get overloaded with new notifications since the composite alarm has already notified them about the existing situation.

You can also use composite alarms to create complex alarming conditions and take actions only when many different conditions are met. For example, you can create a composite alarm that combines a CPU alarm and a memory alarm, and would only notify your team if both the CPU and the memory alarms have triggered.

Using composite alarms

When you use composite alarms, you have two options:

- Configure the actions you want to take only at the composite alarm level, and create the underlying monitored alarms without actions
- Configure a different set of actions at the composite alarm level. For example, the composite alarm actions could engage a different team in case of a widespread issue.

Composite alarms can take only the following actions:

- Notify Amazon SNS topics
- Invoke Lambda functions
- Create OpsItems in Systems Manager Ops Center
- Create incidents in Systems Manager Incident Manager

> **Note**
>
> All the underlying alarms in your composite alarm must be in the same account and the same Region as your composite alarm. However, if you set up a composite alarm in a CloudWatch cross-account observability monitoring account, the underlying alarms can watch metrics in different source accounts and in the monitoring account itself. For more information, see [CloudWatch cross-account observability]().
> A single composite alarm can monitor 100 underlying alarms, and 150 composite alarms can monitor a single underlying alarm.

Rule expressions

All composite alarms contain rule expressions. Rule expressions tell composite alarms which other alarms to monitor and determine their states from. Rule expressions can refer to metric alarms and composite alarms. When you reference an alarm in a rule expression, you designate a function to the alarm that determines which of the following three states the alarm will be in:

- ALARM

  ALARM ("alarm-name or alarm-ARN") is TRUE if the alarm is in ALARM state.
- OK

  OK ("alarm-name or alarm-ARN") is TRUE if the alarm is in OK state.
- INSUFFICIENT_DATA

  INSUFFICIENT_DATA (“alarm-name or alarm-ARN") is TRUE if the named alarm is in INSUFFICIENT_DATA state.

> **Note**
>
> TRUE always evaluates to TRUE, and FALSE always evaluates to FALSE.

Example expressions

The request parameter `AlarmRule` supports the use of the logical operators `AND`, `OR`, and `NOT`, so you can combine multiple functions into a single expressions. The following example expressions show how you can configure the underlying alarms in your composite alarm:

- `ALARM(CPUUtilizationTooHigh) AND ALARM(DiskReadOpsTooHigh)`

  The expression specifies that the composite alarm goes into `ALARM` only if `CPUUtilizationTooHigh` and `DiskReadOpsTooHigh` are in `ALARM`.
- `ALARM(CPUUtilizationTooHigh) AND NOT ALARM(DeploymentInProgress)`

  The expression specifies that the composite alarm goes into `ALARM` if `CPUUtilizationTooHigh` is in `ALARM` and `DeploymentInProgress` is not in `ALARM`. This is an example of a composite alarm that reduces alarm noise during a deployment window.
- `(ALARM(CPUUtilizationTooHigh) OR ALARM(DiskReadOpsTooHigh)) AND OK(NetworkOutTooHigh)`

The expression specifies that the composite alarm goes into ALARM if (ALARM(CPUUtilizationTooHigh) or (DiskReadOpsTooHigh) is in ALARM and (NetworkOutTooHigh) is in OK. This is an example of a composite alarm that reduces alarm noise by not sending you notifications when either of the underlying alarms aren't in ALARM while a network issue is occurring.

Topics

Create a composite alarm

The steps in this section explain how to use the CloudWatch console to create a composite alarm. You can also use the API or Amazon CLI to create a composite alarm. For more information, see PutCompositeAlarm or put-composite-alarm

To create a composite alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. From the list of alarms, select the check box next to each of the existing alarms that you want to reference in your rule expression, and then choose **Create composite alarm**.
4. Under **Specify composite alarm conditions**, specify the rule expression for your new composite alarm.

> **Note**
>
> Automatically, the alarms that you selected from the list of alarms are listed in the **Conditions** box. By default, the ALARM function has been designated to each of your alarms, and each of your alarms is joined by the logical operator OR.

You can use the following substeps to modify your rule expression:

a. You can change the required state for each of your alarms from ALARM to OK or INSUFFICIENT_DATA.

b. You can change the logical operator in your rule expression from `OR` to `AND` or `NOT`, and you can add parentheses to group your functions.

c. You can include other alarms in your rule expression or delete alarms from your rule expression.

Example: Rule expression with conditions

```
(ALARM("CPUUtilizationTooHigh") OR
ALARM("DiskReadOpsTooHigh")) AND
OK("NetworkOutTooHigh")
```

In the example rule expression where the composite alarm goes into `ALARM` when ALARM ("CPUUtilizationTooHigh" or ALARM("DiskReadOpsTooHigh") is in `ALARM` at the same time as OK("NetworkOutTooHigh") is in `OK`.

5. When finished, choose **Next**.

6. Under **Configure actions**, you can choose from the following:

For ***Notification***

- **Select an exisiting SNS topic**, **Create a new SNS topic**, or **Use a topic ARN** to define the SNS topic that will receive the notification.
- **Add notification**, so your alarm can send multiple notifications for the same alarm state or different alarm states.
- **Remove** to stop your alarm from sending notifications or taking actions.

(Optional) To have the alarm invoke a Lambda function when it changes state, choose **Add Lambda action**. Then specify the function name or ARN, and optionally choose a specific version of the function.

For ***Systems Manager action***

- **Add Systems Manager action**, so your alarm can perform an SSM action when it goes into ALARM.

To learn more about Systems Manager actions, see [Configuring CloudWatch to create OpsItems from alarms] in the *Amazon Systems Manager User Guide* and [Incident creation] in the *Incident Manager User Guide*. To create an alarm that performs an SSM Incident Manager action, you must have the correct permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager in the *Incident Manager User Guide*.

To have the alarm start an investigation, choose **Add investigation action** and then select your investigation group. For more information about Amazon Q Developer operational investigations, see Amazon Q Developer operational investigations (Preview).

7. When finished, choose **Next**.
8. Under **Add name and description**, enter an alarm name and *optional* description for your new composite alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
9. When finished, choose **Next**.
10. Under **Preview and create**, confirm your information, and then choose **Create composite alarm**.

> **Note**
>
> You can create a cycle of composite alarms, where one composite alarm and another composite alarm depend on each other. If you find yourself in this scenario, your composite alarms stop being evaluated, and you can't delete your composite alarms because they're dependent on each other. The easiest way to break the cycle of dependecy between your composite alarms is to change the function `AlarmRule` in one of your composite alarms to `False`.

Suppressing composite alarm actions

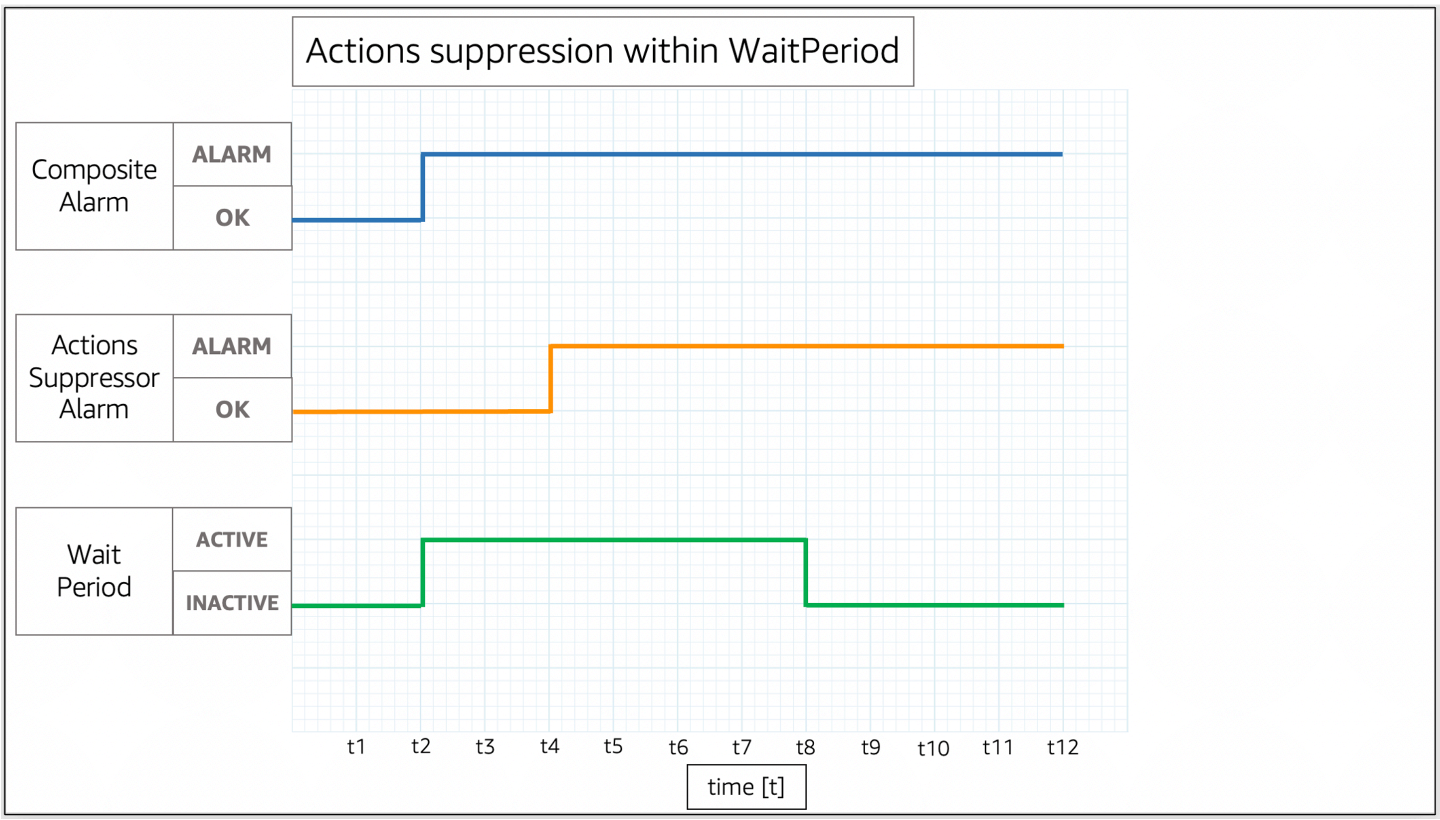
Because composite alarms allow you to get an aggregated view of your health across multiple alarms, there are common situations where it is expected for those alarms to trigger. For example, during a maintenance window of your application or when you investigate an ongoing incident. In such situations, you may want to suppress the actions of your composite alarms, to prevent unwanted notifications or the creation of new incident tickets

With composite alarm action suppression, you define alarms as suppressor alarms. Suppressor alarms prevent composite alarms from taking actions. For example, you can specify a suppressor alarm that represents the status of a supporting resource. If the supporting resource is down, the suppressor alarm prevents the composite alarm from sending notifications. Composite alarm action suppression helps you reduce alarm noise, so you spend less time managing your alarms and more time focusing on your operations.

You specify suppressor alarms when you configure composite alarms. Any alarm can function as a suppressor alarm. When a suppressor alarm changes states from `OK` to `ALARM`, its composite alarm stops taking actions. When a suppressor alarm changes states from `ALARM` to `OK`, its composite alarm resumes taking actions.

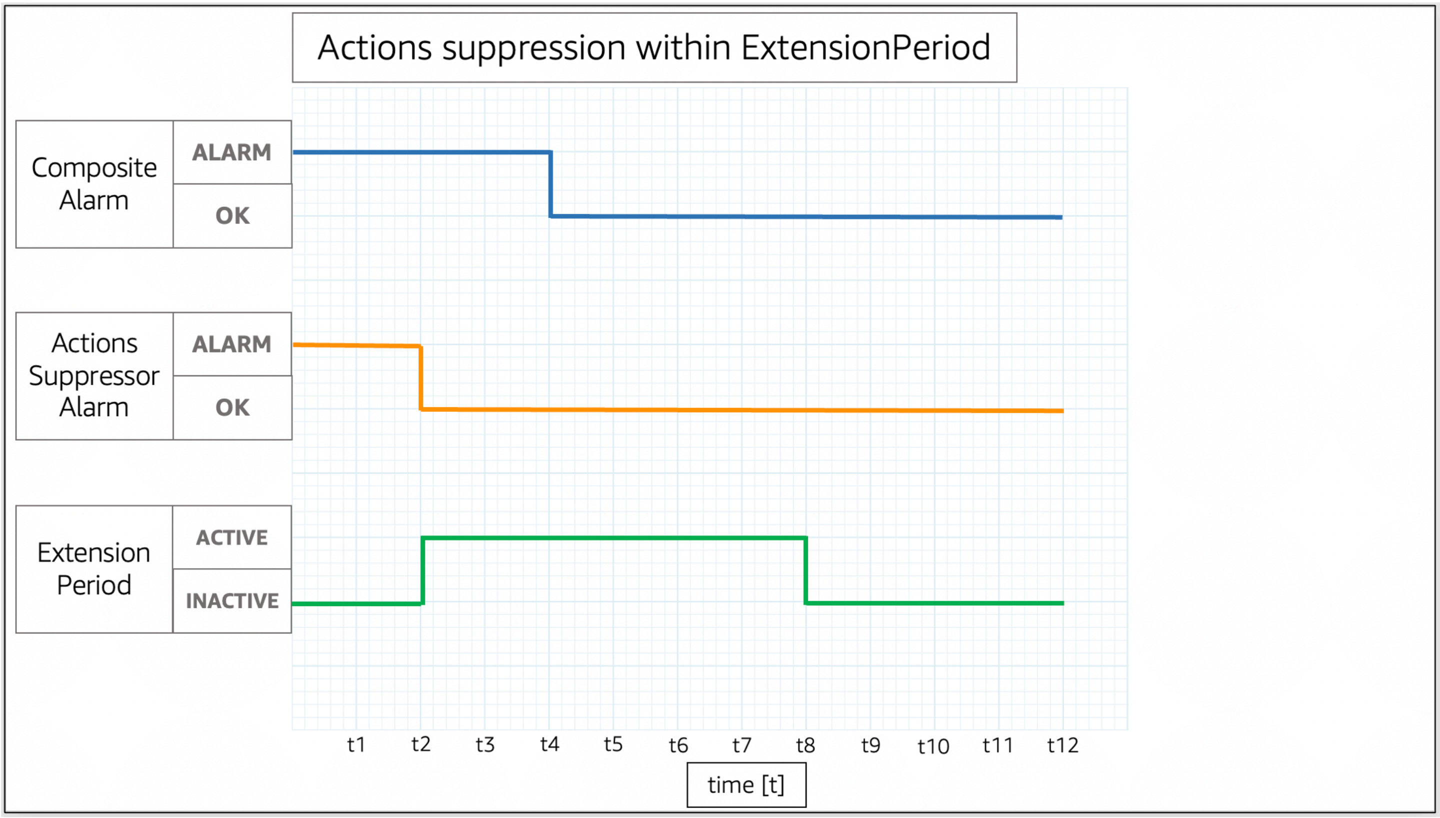
`WaitPeriod` and `ExtensionPeriod`

When you specify a suppressor alarm, you set the parameters `WaitPeriod` and `ExtensionPeriod`. These parameters prevent composite alarms from taking actions unexpectedly while suppressor alarms change states. Use `WaitPeriod` to compensate for any delays that can occur when a suppressor alarm changes from `OK` to `ALARM`. For example, if a suppressor alarm changes from `OK` to `ALARM` within 60 seconds, set `WaitPeriod` to 60 seconds.



In the image, the composite alarm changes from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t8. This gives the suppressor alarm time to change states from `OK` to `ALARM` at t4 before it suppresses the composite alarm's actions when the `WaitPeriod` expires at t8.

Use `ExtensionPeriod` to compensate for any delays that can occur when a composite alarm changes to `OK` following a suppressor alarm changing to `OK`. For example, if a composite alarm changes to `OK` within 60 seconds of a suppressor alarm changing to `OK`, set `ExtensionPeriod` to 60 seconds.



In the image, the suppressor alarm changes from `ALARM` to `OK` at t2. An `ExtensionPeriod` starts at t2 and ends at t8. This gives the composite alarm time to change from `ALARM` to `OK` before the `ExtensionPeriod` expires at t8.

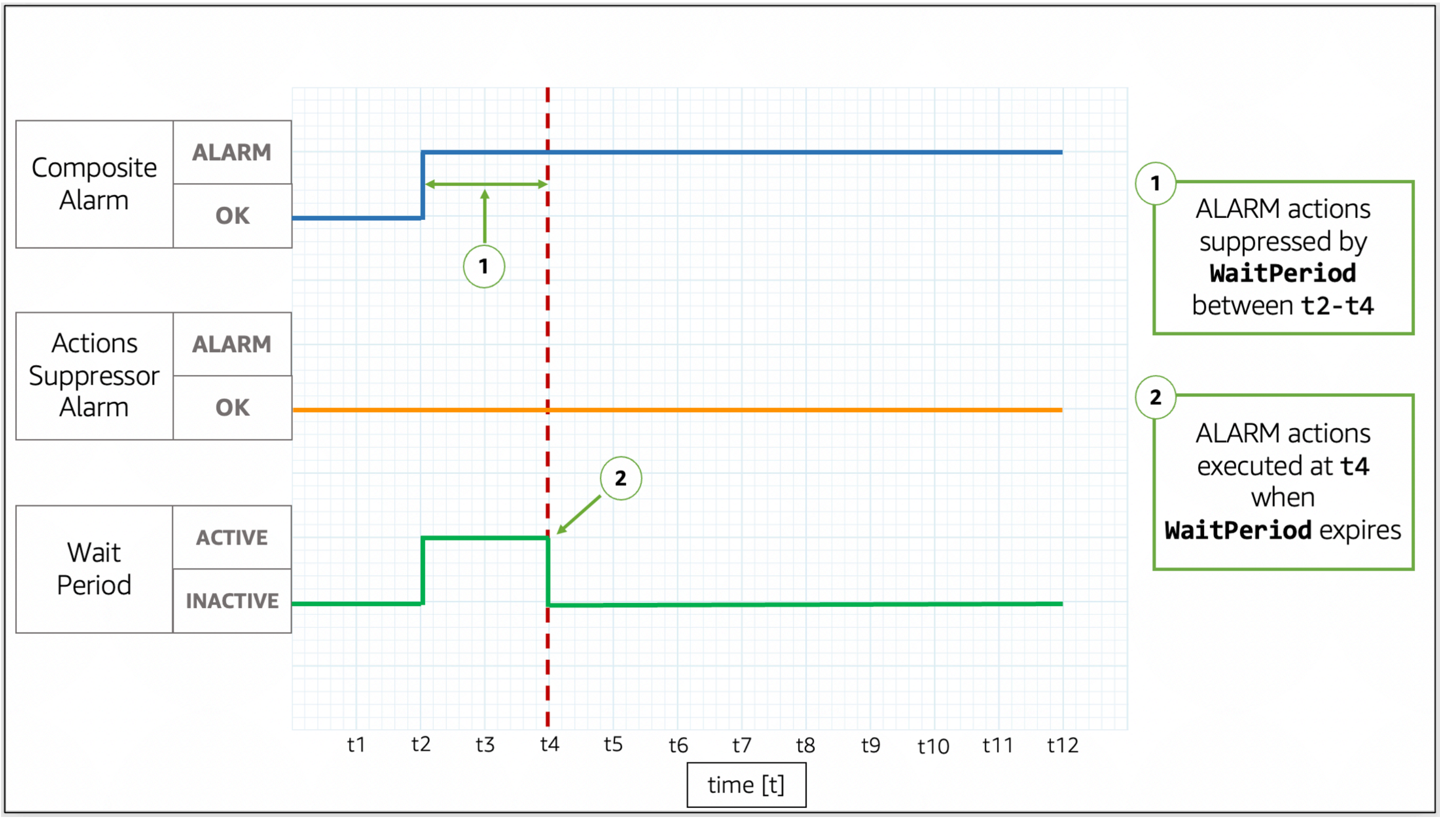
Composite alarms don't take actions when `WaitPeriod` and `ExtensionPeriod` become active. Composite alarms take actions that are based on their currents states when `ExtensionPeriod` and `WaitPeriod` become inactive. We recommend that you set the value for each parameter to 60 seconds, as CloudWatch evaluates metric alarms every minute. You can set the parameters to any integer in seconds.

The following examples describe in more detail how `WaitPeriod` and `ExtensionPeriod` prevent composite alarms from taking actions unexpectedly.

> **Note**
>
> In the following examples, `WaitPeriod` is configured as 2 time units, and `ExtensionPeriod` is configured as 3 time units.

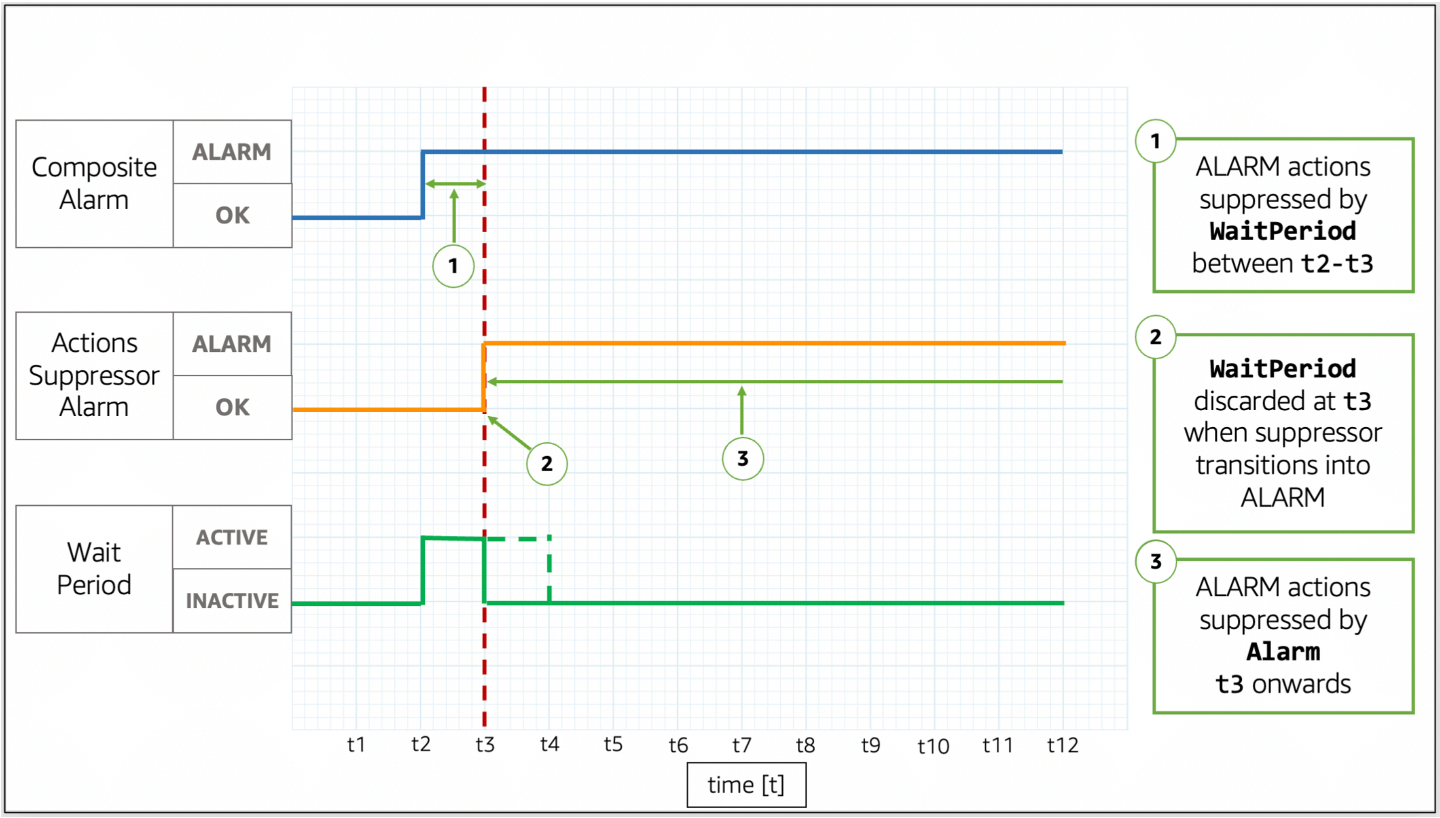
Examples

Example 1: Actions are not suppressed after `WaitPeriod`



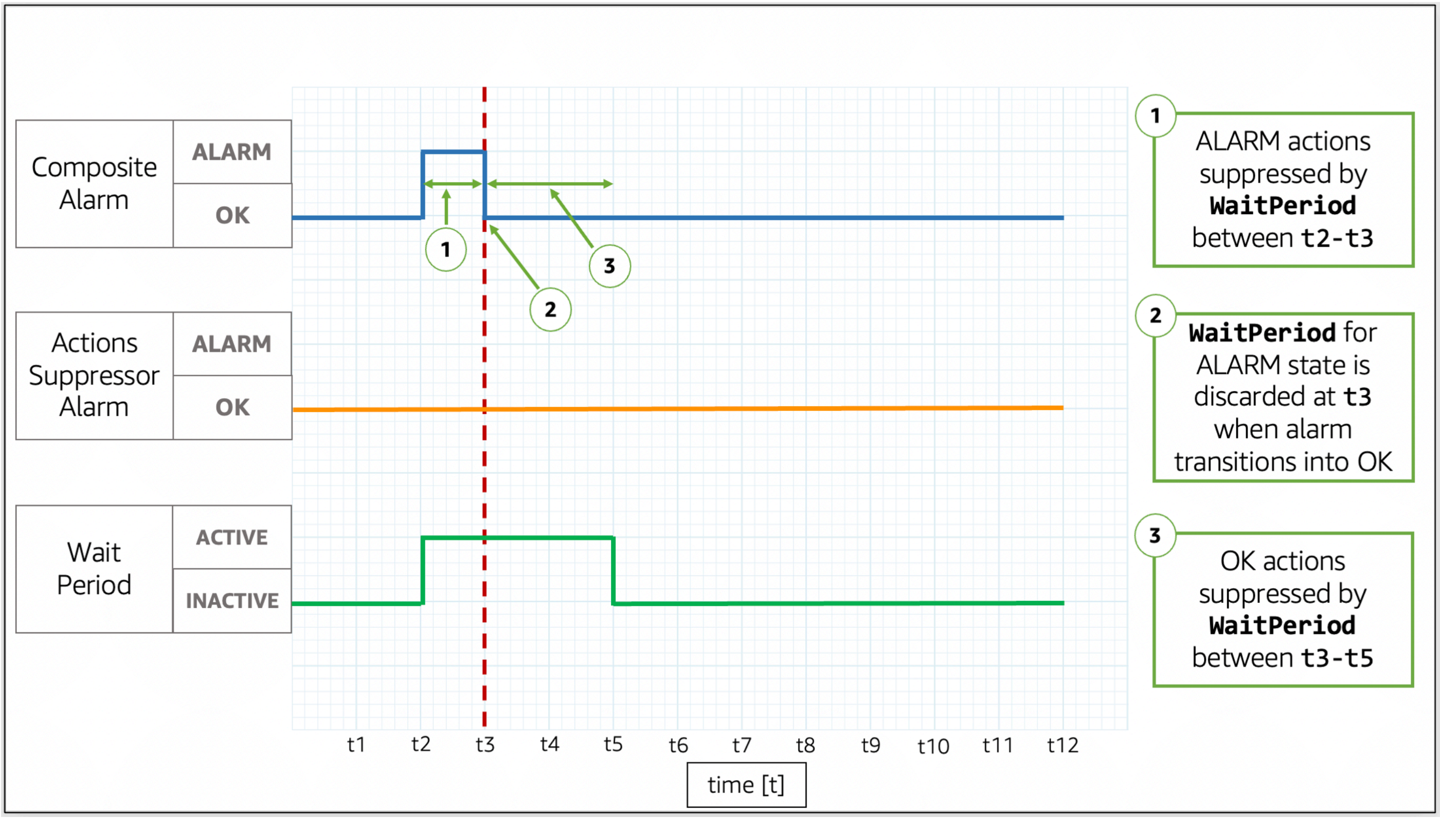
In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4, so it can prevent the composite alarm from taking actions. After the `WaitPeriod` expires at t4, the composite alarm takes its actions because the suppressor alarm is still in `OK`.

Example 2: Actions are suppressed by alarm before `WaitPeriod` expires



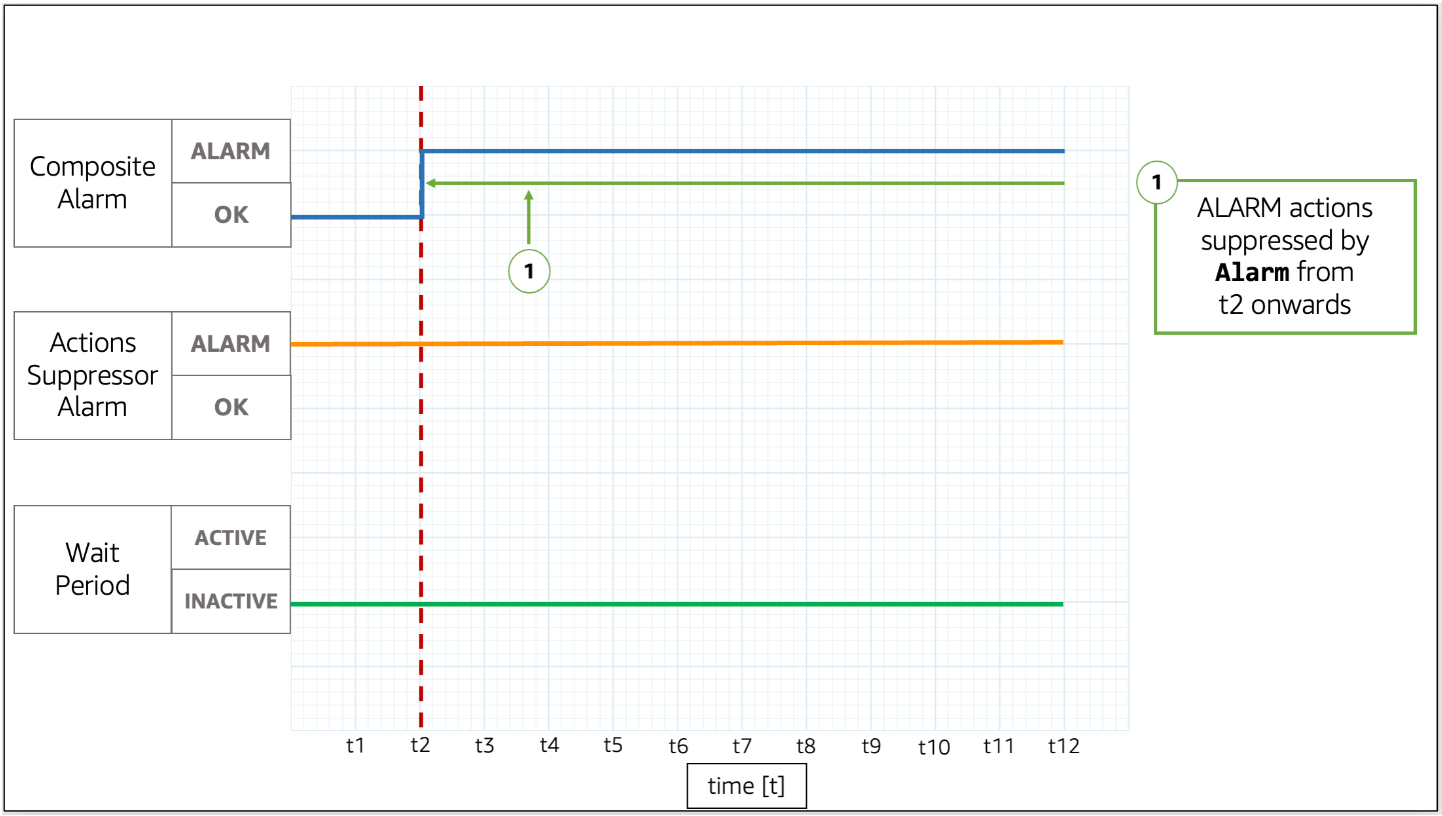
In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from `OK` to `ALARM` at t3. Because the suppressor alarm changes states from `OK` to `ALARM` at t3, the `WaitPeriod` that started at t2 is discarded, and the suppressor alarm now stops the composite alarm from taking actions.

Example 3: State transition when actions are suppressed by `WaitPeriod`



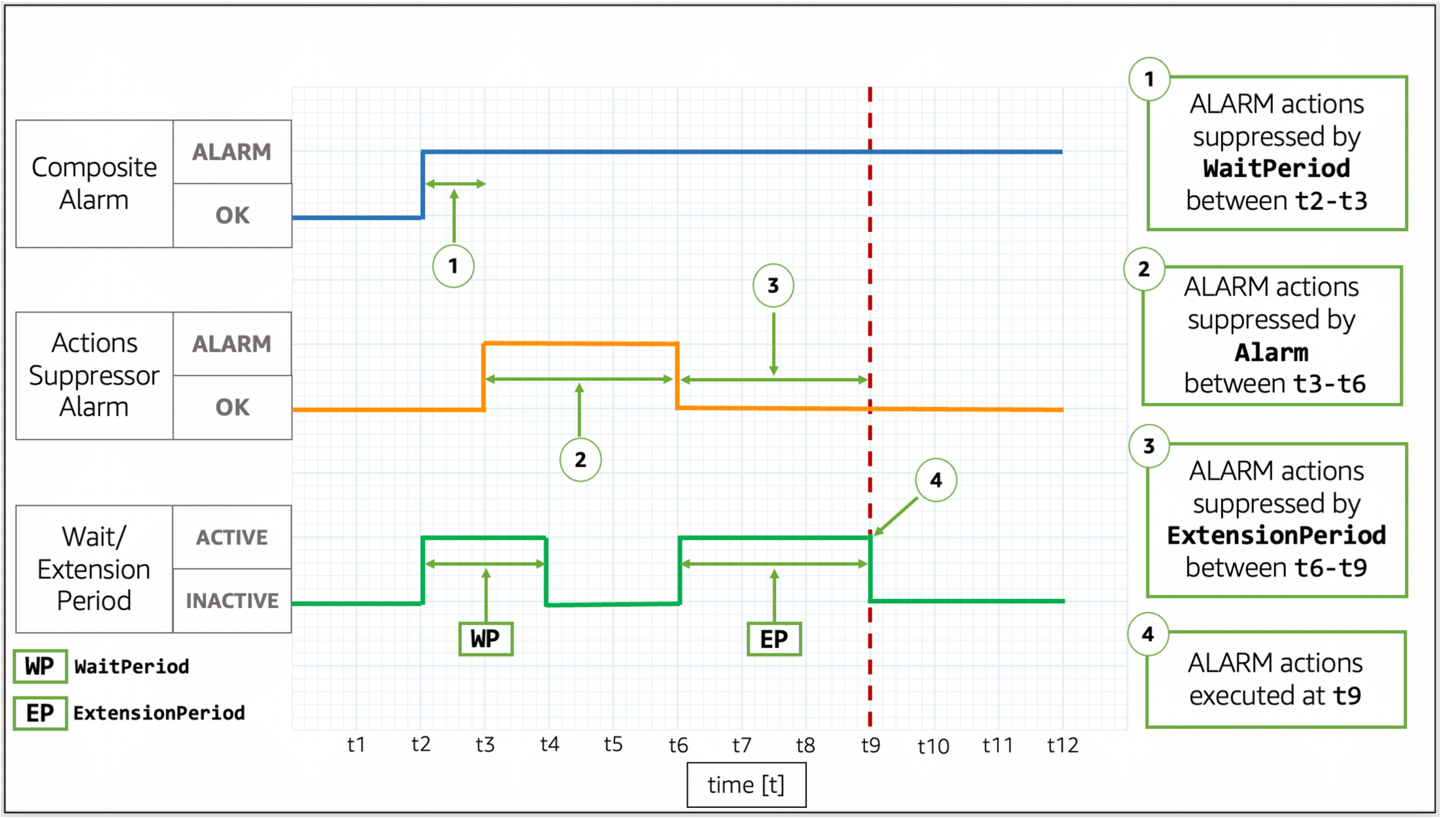
In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states. The composite alarm changes back to `OK` at t3, so the `WaitPeriod` that started at t2 is discarded. A new `WaitPeriod` starts at t3 and ends at t5. After the new `WaitPeriod` expires at t5, the composite alarm takes its actions.

Example 4: State transition when actions are suppressed by alarm



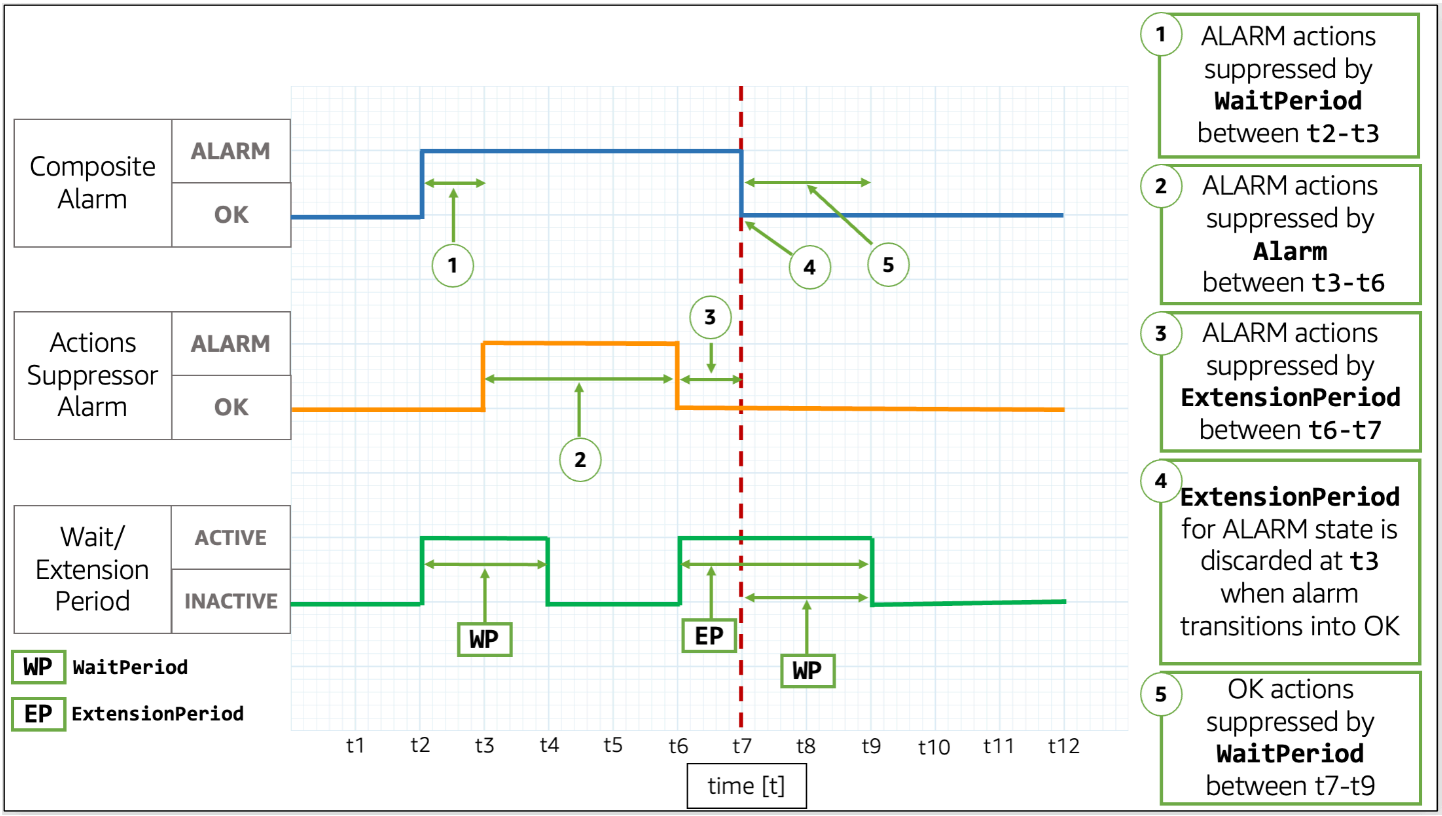
In the image, the composite alarm changes states from `OK` to `ALARM` at t2. The suppressor alarm is already in `ALARM`. The suppressor alarm stops the composite alarm from taking actions.

Example 5: Actions are not suppressed after `ExtensionPeriod`



In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from `OK` to `ALARM` at t3 before it suppresses the composite alarm's actions until t6. Because the suppressor alarm changes states from `OK` to `ALARM` at t3, the `WaitPeriod` that started at t2 is discarded. At t6, the suppressor alarm changes to `OK`. An `ExtensionPeriod` starts at t6 and ends at t9. After the `ExtensionPeriod` expires, the composite alarm takes its actions.

Example 6: State transition when actions are suppressed by `ExtensionPeriod`



In the image, the composite alarm changes states from `OK` to `ALARM` at t2. A `WaitPeriod` starts at t2 and ends at t4. This gives the suppressor alarm time to change states from `OK` to `ALARM` at t3 before it suppresses the composite alarm's actions until t6. Because the suppressor alarm changes states from `OK` to `ALARM` at t3, the `WaitPeriod` that started at t2 is discarded. At t6, the suppressor alarm changes back to `OK`. An `ExtensionPeriod` starts at t6 and ends at t9. When the composite alarm changes back to `OK` at t7, the `ExtensionPeriod` is discarded, and a new `WaitPeriod` starts at t7 and ends at t9.

> **Tip**
>
> If you replace the action suppressor alarm, any active `WaitPeriod` or `ExtensionPeriod` is discarded.

Acting on alarm changes

CloudWatch can notify users on two types of alarm changes: when an alarm changes state, and when the configuration of an alarm gets updated.

When an alarm evaluates, it might change from one state to another, such as ALARM, OK or INSUFFICIENT_DATA. These alarm state changes can signal a possible incident, a return to normal, or a metric being unavailable. In such cases, you might want to the alarm to automatically take one of the following actions

- Send a notification to a SNS topic as part of the alarm's actions. An SNS topic can then be configured for application-to-application (A2A) messaging as well as application-to-person (A2P) notifications, including channels such as email notifications and SMS. All the destinations that you define for your SNS topic receive the alarm notification. For more information, see Amazon SNS event destinations.
- You can configure notifications for alarm state change events. Amazon User Notifications offers a native way to configure such notifications and is the recommended approach.
- Reboot, stop, recover, or terminate an Amazon EC2 instance. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.
- Scale the capacity of an Amazon EC2 Auto Scaling group. For more information, see Step and simple scaling policies for Amazon EC2 Auto Scaling.
- Start an investigation in Amazon Q operational investigations. For more information, see Start an investigation in Amazon Q operational investigations from an alarm
- Invoke a Lambda function.
- Create an incident in Systems Manager Incident Manager. For more information, see Creating incidents automatically with CloudWatch alarms.
- Create an OpsItem in Systems Manager OpsCenter. For more information, see Configure CloudWatch alarms to create OpsItems.

Additionally, CloudWatch sends events to Amazon EventBridge whenever alarms change state, and when alarms are created, deleted, or updated. You can write EventBridge rules to take actions or be notified when EventBridge receives these events.

Topics

Notifying users on alarm changes

This section explains how you can use Amazon User Notifications or Amazon Simple Notification Service to have users be notified of alarm changes.

Setting up Amazon User Notifications

You can use Amazon User Notifications to set up delivery channels to get notified about CloudWatch alarm state change and configuration change events. You receive a notification when an event matches a rule that you specify. You can receive notifications for events through multiple channels, including email, Amazon Chatbot chat notifications, or Amazon Console Mobile Application push notifications. You can also see notifications in the at Console Notifications Center. User Notifications supports aggregation, which can reduce the number of notifications you receive during specific events.

The notification configurations you create with Amazon User Notifications do not count towards the limit on the number of actions you can configure per target alarm state. As Amazon User Notifications matches the events emitted to Amazon EventBridge, it sends notifications for all the alarms in your account and selected Regions, unless you specify an advanced filter to allowlist or denylist specific alarms or patterns.

The following example of an advanced filter matches an alarm state change from OK to ALARM on the alarm named `ServerCpuTooHigh`.

```
{
"detail": {
    "alarmName": ["ServerCpuTooHigh"],
    "previousState": { "value": ["OK"] },
    "state": { "value": ["ALARM"] }
  }
}
```

You can use any of the properties published by an alarm in EventBridge events to create a filter. For more information, see Alarm events and EventBridge.

Setting up Amazon SNS notifications

You can use Amazon Simple Notification Service to send both application-to-application (A2A) messaging and application-to-person (A2P) messaging, including mobile text messaging (SMS) and email messages. For more information, see Amazon SNS event destinations.

For every state that an alarm can take, you can configure the alarm to send a message to an SNS topic. Every Amazon SNS topic you configure for a state on a given alarm counts towards the limit on the number of actions you can configure for that alarm and state. You can send messages to the same Amazon SNS topic from any alarms in your account, and use the same Amazon SNS topic for both application (A2A) and person (A2P) consumers. Because this configuration is done at the alarm level, only the alarms you have configured send messages to the selected Amazon SNS topic.

First, create a topic, then subscribe to it. You can optionally publish a test message to the topic. For an example, see Setting up an Amazon SNS topic using the Amazon Web Services Management Console. Or for more information, see Getting started with Amazon SNS.

Alternatively, if you plan to use the Amazon Web Services Management Console to create your CloudWatch alarm, you can skip this procedure because you can create the topic when you create the alarm.

When you create a CloudWatch alarm, you can add actions for any target state the alarm enters. Add an Amazon SNS notification for the state you want to be notified about, and select the Amazon SNS topic you created in the previous step to send an email notification when the alarm enters the selected state.

> **Note**
>
> When you create an Amazon SNS topic, you choose to make it a *standard topic* or a *FIFO topic*. CloudWatch guarantees the publication of all alarm notifications to both types of topics. However, even if you use a FIFO topic, in rare cases CloudWatch sends the notifications to the topic out of order. If you use a FIFO topic, the alarm sets the message group ID of the alarm notifications to be a hash of the ARN of the alarm.

- Setting up an SNS topic using the Amazon CLI

Preventing confused deputy security issues

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In Amazon, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, Amazon provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, and `aws:SourceOrgPaths` global condition context keys in resource policies to limit the permissions that Amazon SNS gives another service to the resource. Use `aws:SourceArn` to associate only one resource with cross-service access. Use `aws:SourceAccount` to let any resource in that account be associated with the cross-service use. Use `aws:SourceOrgID` to allow any resource from any account within an organization be associated with the cross-service use. Use `aws:SourceOrgPaths` to associate any resource from accounts within an Amazon Organizations path with the cross-service use. For more information about using and understanding paths, see aws:SourceOrgPaths in the IAM User Guide.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcard characters (*) for the unknown portions of the ARN. For example, `arn:aws-cn:servicename:*:123456789012:*`.

If the `aws:SourceArn` value does not contain the account ID, such as an Amazon S3 bucket ARN, you must use both `aws:SourceAccount` and `aws:SourceArn` to limit permissions.

To protect against the confused deputy problem at scale, use the `aws:SourceOrgID` or `aws:SourceOrgPaths` global condition context key with the organization ID or organization path of the resource in your resource-based policies. Policies that include the `aws:SourceOrgID` or `aws:SourceOrgPaths` key will automatically include the correct accounts and you don't have to manually update the policies when you add, remove, or move accounts in your organization.

The value of `aws:SourceArn` must be the ARN of the alarm that is sending notifications.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in CloudWatch to prevent the confused deputy problem.

```
{
    "Statement": [{
        "Effect": "Allow",
```

```
        "Principal": {
            "Service": "cloudwatch.amazonaws.com"
        },
        "Action": "SNS:Publish",
        "Resource": "arn:aws:sns:us-east-2:444455556666:MyTopic",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:cloudwatch:us-east-2:111122223333:alarm:*"
            },
            "StringEquals": {
                "aws:SourceAccount": "111122223333"
            }
        }
    }]
}
```

If an alarm ARN includes any non-ASCII characters, use only the `aws:SourceAccount` global condition key to limit the permissions.

Setting up an Amazon SNS topic using the Amazon Web Services Management Console

First, create a topic, then subscribe to it. You can optionally publish a test message to the topic.

To create an SNS topic

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. On the Amazon SNS dashboard, under **Common actions**, choose **Create Topic**.
3. In the **Create new topic** dialog box, for **Topic name**, enter a name for the topic (for example, **`my-topic`**).
4. Choose **Create topic**.
5. Copy the **Topic ARN** for the next task (for example, arn:aws:sns:us-east-1:111122223333:my-topic).

To subscribe to an SNS topic

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In the navigation pane, choose **Subscriptions**, **Create subscription**.
3. In the **Create subscription** dialog box, for **Topic ARN**, paste the topic ARN that you created in the previous task.

4. For **Protocol**, choose **Email**.
5. For **Endpoint**, enter an email address that you can use to receive the notification, and then choose **Create subscription**.
6. From your email application, open the message from Amazon Notifications and confirm your subscription.

   Your web browser displays a confirmation response from Amazon SNS.

To publish a test message to an SNS topic

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. On the **Topics** page, select a topic and choose **Publish to topic**.
4. In the **Publish a message** page, for **Subject**, enter a subject line for your message, and for **Message**, enter a brief message.
5. Choose **Publish Message**.
6. Check your email to confirm that you received the message.

Setting up an SNS topic using the Amazon CLI

First, you create an SNS topic, and then you publish a message directly to the topic to test that you have properly configured it.

To set up an SNS topic

1. Create the topic using the create-topic command as follows.

   ```
   aws sns create-topic --name my-topic
   ```

   Amazon SNS returns a topic ARN with the following format:

   ```
   {
       "TopicArn": "arn:aws:sns:us-east-1:111122223333:my-topic"
   }
   ```

2. Subscribe your email address to the topic using the subscribe command. If the subscription request succeeds, you receive a confirmation email message.

```
aws sns subscribe --topic-arn arn:aws:sns:us-east-1:111122223333:my-topic --
protocol email --notification-endpoint my-email-address
```

Amazon SNS returns the following:

```
{
    "SubscriptionArn": "pending confirmation"
}
```

3. From your email application, open the message from Amazon Notifications and confirm your subscription.

   Your web browser displays a confirmation response from Amazon Simple Notification Service.

4. Check the subscription using the list-subscriptions-by-topic command.

```
aws sns list-subscriptions-by-topic --topic-arn arn:aws:sns:us-
east-1:111122223333:my-topic
```

   Amazon SNS returns the following:

```
{
  "Subscriptions": [
    {
        "Owner": "111122223333",
        "Endpoint": "me@mycompany.com",
        "Protocol": "email",
        "TopicArn": "arn:aws:sns:us-east-1:111122223333:my-topic",
        "SubscriptionArn": "arn:aws:sns:us-east-1:111122223333:my-topic:64886986-
bf10-48fb-a2f1-dab033aa67a3"
    }
  ]
}
```

5. (Optional) Publish a test message to the topic using the publish command.

```
aws sns publish --message "Verification" --topic arn:aws:sns:us-
east-1:111122223333:my-topic
```

   Amazon SNS returns the following.

```
{
    "MessageId": "42f189a0-3094-5cf6-8fd7-c2dde61a4d7d"
}
```

6. Check your email to confirm that you received the message.

Schema of Amazon SNS notifications when alarms change state

This section lists the schemas of the notifications sent to Amazon SNS topics when alarms change their state.

Schema when a metric alarm changes state

```
{
  "AlarmName": "string",
  "AlarmDescription": "string",
  "AWSAccountId": "string",
  "AlarmConfigurationUpdatedTimestamp": "string",
  "NewStateValue": "string",
  "NewStateReason": "string",
  "StateChangeTime": "string",
  "Region": "string",
  "AlarmArn": "string",
  "OldStateValue": "string",
  "OKActions": ["string"],
  "AlarmActions": ["string"],
  "InsufficientDataActions": ["string"],
  "Trigger": {
    "MetricName": "string",
    "Namespace": "string",
    "StatisticType": "string",
    "Statistic": "string",
    "Unit": "string or null",
    "Dimensions": [
      {
        "value": "string",
        "name": "string"
      }
    ],
    "Period": "integer",
    "EvaluationPeriods": "integer",
    "DatapointsToAlarm": "integer",
```

```
    "ComparisonOperator": "string",
    "Threshold": "number",
    "TreatMissingData": "string",
    "EvaluateLowSampleCountPercentile": "string or null"
  }
}
```

Schema when a composite alarm changes state

```
{
  "AlarmName": "string",
  "AlarmDescription": "string",
  "AWSAccountId": "string",
  "NewStateValue": "string",
  "NewStateReason": "string",
  "StateChangeTime": "string",
  "Region": "string",
  "AlarmArn": "string",
  "OKActions": [String],
  "AlarmActions": [String],
  "InsufficientDataActions": [String],
  "OldStateValue": "string",
  "AlarmRule": "string",
  "TriggeringChildren": [String]
}
```

Alarm events and EventBridge

CloudWatch sends events to Amazon EventBridge whenever a CloudWatch alarm is created, updated, deleted, or changes alarm state. You can use EventBridge and these events to write rules that take actions, such as notifying you, when an alarm changes state. For more information, see [What is Amazon EventBridge?](#)

CloudWatch guarantees the delivery of alarm state change events to EventBridge.

Sample events from CloudWatch

This section includes example events from CloudWatch.

State change for a single-metric alarm

```
{
    "version": "0",
```

```
    "id": "c4c1c1c9-6542-e61b-6ef0-8c4d36933a92",

Start an investigation in Amazon Q operational investigations from an alarm

You can start an investigation in Amazon Q operational investigations from the current state of a CloudWatch alarm, or from any point in the last two weeks of a CloudWatch alarm's history.

For more information about Amazon Q operational investigations, see [Amazon Q Developer operational investigations (Preview)](#).

To start an investigation from a CloudWatch alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **Alarms**, **All alarms**.
3. Choose the name of the alarm.
4. Choose the time period in the alarm history that you want to investigate.
5. Choose **Investigate**, **Start new investigation**.
6. For **New investigation title**, enter a name for the investigation. Then choose **Start investigation**.

   The Amazon Q investigations assistant starts. It scans your telemetry data to find data that might be associated with this situation.
7. In the CloudWatch console's navigation pane, choose **Investigations**, then choose the name of the investigation that you just started.

   The **Findings** section displays a natural-language summary of the alarm's status and the reason that it was triggered.
8. (Optional) In the graph of the alarm, you can right-click and then choose to deep-dive into the alarm or the metric that it watches.
9. On the right side of the screen, choose the **Suggestions** tab.

   You see a list of other telemetry that Amazon Q operational investigations has discovered and that might be relevant to the investigation. These findings can include other metrics and CloudWatch Logs Insights query results. Amazon Q operational investigations ran these queries based on the alarm.

   - For each finding, you can choose **Add to findings** or **Discard**.

When you choose **Add to findings**, the telemetry is added to the **Findings** section, and Amazon Q operational investigations uses this information to direct it's further scanning and suggestions.

- For a CloudWatch Logs Insights query result, to change or edit the query and re-run it, you can open the context (right-click) menu for by the results, and then choose **Open in Logs Insights**. For more information, see [Analyzing log data with CloudWatch Logs Insights](#).

  If you want to run a different query, when you get to the Logs Insights page you can choose to use query assist to be able to use natural language to form a query. For more information, see [Use natural language to generate and update CloudWatch Logs Insights queries](#).
- (Optional) If you know of telemetry in another Amazon service that might apply to this investigation, you can go to that service's console and add the telemetry to the investigation. For example, to add a Lambda metric to the investigation, you can do the following:

  1. Open the Lambda console.
  2. In the **Monitor** section, find the metric.
  3. Open the context menu for the metric, choose **Investigate**, **Add to investigation** Then, in the **Investigate** pane, select the name of the investigation.

10. Amazon Q might also add hypotheses to the list in the **Suggestions** tab. These hypotheses are generated by the investigation in natural language.

    For each hyypotheses, you can choose **Add to findings** or **Discard**.
11. When you think you have completed the investigation and found the root cause of the issue, you can choose the **Overview** tab and then choose **Investigation summary**. Amazon Q investigations then creates a natural-language summary of the important findings and hypotheses from the investigation.

Managing alarms

Edit or delete a CloudWatch alarm

You can edit or delete an existing alarm.

You can't change the name of an existing alarm. You can copy an alarm and give the new alarm a different name. To copy an alarm, select the check box next to the alarm name in the alarm list and choose **Action**, **Copy**.

To edit an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose the name of the alarm.
4. To add or remove tags, choose the **Tags** tab and then choose **Manage tags**.
5. To edit other parts of the alarm, choose **Actions**, **Edit**.

   The **Specify metric and conditions** page appears, showing a graph and other information about the metric and statistic that you selected.
6. To change the metric, choose **Edit**, choose the **All metrics** tab, and do one of the following:
   - Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.

   Choose **Select metric**.
7. To change other aspects of the alarm, choose the appropriate options. To change how many data points must be breaching for the alarm to go into `ALARM` state or to change how missing data is treated, choose **Additional configuration**.
8. Choose **Next**.
9. Under **Notification**, **Auto Scaling action**, and **EC2 action**, optionally edit the actions taken when the alarm is triggered. Then choose **Next**.
10. Optionally change the alarm description.

    You can't change the name of an existing alarm. You can copy an alarm and give the new alarm a different name. To copy an alarm, select the check box next to the alarm name in the alarm list and choose **Action**, **Copy**.
11. Choose **Next**.

12. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Update alarm**.

To update an email notification list that was created using the Amazon SNS console

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In the navigation pane, choose **Topics** and then select the ARN for your notification list (topic).
3. Do one of the following:
    - To add an email address, choose **Create subscription**. For **Protocol**, choose **Email**. For **Endpoint**, enter the email address of the new recipient. Choose **Create subscription**.
    - To remove an email address, choose the **Subscription ID**. Choose **Other subscription actions**, **Delete subscriptions**.
4. Choose **Publish to topic**.

To delete an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**.
3. Select the check box to the left of the name of the alarm, and choose **Actions**, **Delete**.
4. Choose **Delete**.

Hide Auto Scaling alarms

When you view your alarms in the Amazon Web Services Management Console, you can hide the alarms related to both Amazon EC2 Auto Scaling and Application Auto Scaling. This feature is available only in the Amazon Web Services Management Console.

To temporarily hide Auto Scaling alarms

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**, and select **Hide Auto Scaling alarms**.

Alarm use cases and examples

The following sections provides examples and tutorials for alarms for common use cases.

Topics

Create a billing alarm to monitor your estimated Amazon charges

You can monitor your estimated Amazon charges by using Amazon CloudWatch. When you enable the monitoring of estimated charges for your Amazon account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

The alarm triggers when your account billing exceeds the threshold you specify. It triggers only when the current billing exceeds the threshold. It doesn't use projections based on your usage so far in the month.

If you create a billing alarm at a time when your charges have already exceeded the threshold, the alarm goes to the `ALARM` state immediately.

> **Note**
>
> For information about analyzing CloudWatch charges that you have already been billed for, see Analyzing, optimizing, and reducing CloudWatch costs.

Tasks

Enabling billing alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated Amazon charges and create an alarm using billing metric data. After you enable billing alerts, you can't disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in using account root user credentials or as an IAM user that has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.
- In a consolidated billing account, member linked account metrics are captured only if the payer account enables the **Receive Billing Alerts** preference. If you change which account is your management/payer account, you must enable the billing alerts in the new management/payer account.
- The account must not be part of the Amazon Partner Network (APN) because billing metrics are not published to CloudWatch for APN accounts. For more information, see Amazon Partner Network.

To enable the monitoring of estimated charges

1. Open the Amazon Billing and Cost Management console at https://console.amazonaws.cn/costmanagement/.
2. In the navigation pane, choose **Billing Preferences**.
3. By **Alert preferences** choose **Edit**.
4. Choose **Receive CloudWatch Billing Alerts**.
5. Choose **Save preferences**.

Create a billing alarm

> **Important**
>
> Before you create a billing alarm, you must set your Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges. You also must enable billing alerts for your account or in the management/payer account (if you are using consolidated billing). For more information, see Enabling billing alerts.

In this procedure, you create an alarm that sends a notification when your estimated charges for Amazon exceed a defined threshold.

To create a billing alarm using the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**. In **Amazon Namespaces**, choose **Billing**, and then choose **Total Estimated Charge**.

   > **Note**
   >
   > If you don't see the **Billing/Total Estimated Charge** metric, enable billing alerts, and change your Region to US East (N. Virginia). For more information, see Enabling billing alerts.

5. Select the box for the **EstimatedCharges** metric, and then choose **Select metric**.
6. For **Statistic**, choose **Maximum**.
7. For **Period**, choose **6 hours**.
8. For **Threshold type**, choose **Static**.
9. For **Whenever EstimatedCharges is . . .**, choose **Greater**.
10. For **than . . .**, define the value that you want to cause your alarm to trigger. For example, **200** USD.

    The **EstimatedCharges** metric values are only in US dollars (USD), and the currency conversion is provided by Amazon Services LLC. For more information, see What is Amazon Billing?.

> **Note**
>
> After you define a threshold value, the preview graph displays your estimated charges for the current month.

11. Choose **Additional Configuration** and do the following:

    - For **Datapoints to alarm**, specify **1 out of 1**.
    - For **Missing data treatment**, choose **Treat missing data as missing**.

12. Choose **Next**.
13. Under **Notification**, ensure that **In alarm** is selected. Then specify an Amazon SNS topic to be notified when your alarm is in the `ALARM` state. The Amazon SNS topic can include your email address so that you receive email when the billing amount crosses the threshold that you specified.

    You can select an existing Amazon SNS topic, create a new Amazon SNS topic, or use a topic ARN to notify other account. If you want your alarm to send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

14. Choose **Next**.
15. Under **Name and description**, enter a name for your alarm. The name must contain only UTF-8 characters, and can't contain ASCII control characters.

    - (Optional) Enter a description of your alarm. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

16. Choose **Next**.
17. Under **Preview and create**, make sure that your configuration is correct, and then choose **Create alarm**.

Deleting a billing alarm

You can delete your billing alarm when you no longer need it.

To delete a billing alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Select the check box next to the alarm and choose **Actions**, **Delete**.
4. When prompted for confirmation, choose **Yes, Delete**.

Create a CPU usage alarm

You can create an CloudWatch alarm that sends a notification using Amazon SNS when the alarm changes state from `OK` to `ALARM`.

The alarm changes to the `ALARM` state when the average CPU use of an EC2 instance exceeds a specified threshold for consecutive specified periods.

Setting up a CPU usage alarm using the Amazon Web Services Management Console

Use these steps to use the Amazon Web Services Management Console to create a CPU usage alarm.

To create an alarm based on CPU usage

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**.
5. In the **All metrics** tab, choose **EC2 metrics**.
6. Choose a metric category (for example, **Per-Instance Metrics**).
7. Find the row with the instance that you want listed in the **InstanceId** column and **CPUUtilization** in the **Metric Name** column. Select the check box next to this row, and choose **Select metric**.
8. Under **Specify metric and conditions**, for **Statistic** choose **Average**, choose one of the predefined percentiles, or specify a custom percentile (for example, **`p95.45`**).
9. Choose a period (for example, **`5 minutes`**).
10. Under **Conditions**, specify the following:

    a. For **Threshold type**, choose **Static**.

b. For **Whenever CPUUtilization is**, specify **Greater**. Under **than...**, specify the threshold that is to trigger the alarm to go to ALARM state if the CPU utilization exceeds this percentage. For example, 70.

c. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an alarm.

d. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring how CloudWatch alarms treat missing data.

e. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-based CloudWatch alarms and low data samples.

11. Choose **Next**.

12. Under **Notification**, choose **In alarm** and select an SNS topic to notify when the alarm is in `ALARM` state

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.

13. When finished, choose **Next**.

14. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.

15. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Setting up a CPU usage alarm using the Amazon CLI

Use these steps to use the Amazon CLI to create a CPU usage alarm.

To create an alarm based on CPU usage

1. Set up an SNS topic. For more information, see Setting up Amazon SNS notifications.
2. Create an alarm using the put-metric-alarm command as follows.

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70%" --metric-name CPUUtilization --namespace AWS/EC2 --statistic
 Average --period 300 --threshold 70 --comparison-operator GreaterThanThreshold --
dimensions  Name=InstanceId,Value=i-12345678 --evaluation-periods 2 --alarm-actions
 arn:aws:sns:us-east-1:111122223333:my-topic --unit Percent
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

   a. Change the alarm state from `INSUFFICIENT_DATA` to `OK`.

   ```
   aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason
    "initializing" --state-value OK
   ```

   b. Change the alarm state from `OK` to `ALARM`.

   ```
   aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason
    "initializing" --state-value ALARM
   ```

   c. Check that you have received a notification about the alarm.

Create a load balancer latency alarm that sends email

You can set up an Amazon SNS notification and configure an alarm that monitors latency exceeding 100 ms for your Classic Load Balancer.

Setting up a latency alarm using the Amazon Web Services Management Console

Use these steps to use the Amazon Web Services Management Console to create a load balancer latency alarm.

To create a load balancer latency alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Under **CloudWatch Metrics by Category**, choose the **ELB Metrics** category.
5. Select the row with the Classic Load Balancer and the **Latency** metric.
6. For the statistic, choose **Average**, choose one of the predefined percentiles, or specify a custom percentile (for example, **`p95.45`**).
7. For the period, choose **1 Minute**.
8. Choose **Next**.
9. Under **Alarm Threshold**, enter a unique name for the alarm (for example, **`myHighCpuAlarm`**) and a description of the alarm (for example, **`Alarm when Latency exceeds 100s`**). Alarm names must contain only UTF-8 characters, and can't contain ASCII control characters

   The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
10. Under **Whenever**, for **is**, choose **>** and enter **`0.1`**. For **for**, enter **`3`**.
11. Under **Additional settings**, for **Treat missing data as**, choose **ignore (maintain alarm state)** so that missing data points don't trigger alarm state changes.

    For **Percentiles with low samples**, choose **ignore (maintain the alarm state)** so that the alarm evaluates only situations with adequate numbers of data samples.
12. Under **Actions**, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic or create a new one.

    To create an SNS topic, choose **New list**. For **Send notification to**, enter a name for the SNS topic (for example, **`myHighCpuAlarm`**), and for **Email list**, enter a comma-separated list of email addresses to be notified when the alarm changes to the `ALARM` state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent.
13. Choose **Create Alarm**.

Setting up a latency alarm using the Amazon CLI

Use these steps to use the Amazon CLI to create a load balancer latency alarm.

To create a load balancer latency alarm

1. Set up an SNS topic. For more information, see Setting up Amazon SNS notifications.
2. Create the alarm using the put-metric-alarm command as follows:

```
aws cloudwatch put-metric-alarm --alarm-name lb-mon --alarm-description "Alarm
 when Latency exceeds 100s" --metric-name Latency --namespace AWS/ELB --statistic
 Average --period 60 --threshold 100 --comparison-operator GreaterThanThreshold --
dimensions Name=LoadBalancerName,Value=my-server --evaluation-periods 3 --alarm-
actions arn:aws:sns:us-east-1:111122223333:my-topic --unit Seconds
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

   a. Change the alarm state from `INSUFFICIENT_DATA` to `OK`.

   ```
   aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason
    "initializing" --state-value OK
   ```

   b. Change the alarm state from `OK` to `ALARM`.

   ```
   aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason
    "initializing" --state-value ALARM
   ```

   c. Check that you have received an email notification about the alarm.

Create a storage throughput alarm that sends email

You can set up an SNS notification and configure an alarm that is triggered when Amazon EBS exceeds 100 MB throughput.

Setting up a storage throughput alarm using the Amazon Web Services Management Console

Use these steps to use the Amazon Web Services Management Console to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All Alarms**.
3. Choose **Create alarm**.
4. Under **EBS Metrics**, choose a metric category.
5. Select the row with the volume and the **VolumeWriteBytes** metric.
6. For the statistic, choose **Average**. For the period, choose **5 Minutes**. Choose **Next**.
7. Under **Alarm Threshold**, enter a unique name for the alarm (for example, **`myHighWriteAlarm`**) and a description of the alarm (for example, **`VolumeWriteBytes exceeds 100,000 KiB/s`**). The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
8. Under **Whenever**, for **is**, choose **>** and enter **`100000`**. For **for**, enter **15** consecutive periods.

   A graphical representation of the threshold is shown under **Alarm Preview**.
9. Under **Additional settings**, for **Treat missing data as**, choose **ignore (maintain alarm state)** so that missing data points don't trigger alarm state changes.
10. Under **Actions**, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic or create one.

    To create an SNS topic, choose **New list**. For **Send notification to**, enter a name for the SNS topic (for example, **`myHighCpuAlarm`**), and for **Email list**, enter a comma-separated list of email addresses to be notified when the alarm changes to the `ALARM` state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.
11. Choose **Create Alarm**.

Setting up a storage throughput alarm using the Amazon CLI

Use these steps to use the Amazon CLI to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm

1. Create an SNS topic. For more information, see [Setting up Amazon SNS notifications](#).

2. Create the alarm.

```
aws cloudwatch put-metric-alarm --alarm-name ebs-mon --alarm-description "Alarm
 when EBS volume exceeds 100MB throughput" --metric-name VolumeReadBytes --
namespace AWS/EBS --statistic Average --period 300 --threshold 100000000 --
comparison-operator GreaterThanThreshold --dimensions Name=VolumeId,Value=my-
volume-id --evaluation-periods 3 --alarm-actions arn:aws:sns:us-
east-1:111122223333:my-alarm-topic --insufficient-data-actions arn:aws:sns:us-
east-1:111122223333:my-insufficient-data-topic
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.

   a. Change the alarm state from INSUFFICIENT_DATA to OK.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value OK
   ```

   b. Change the alarm state from OK to ALARM.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value ALARM
   ```

   c. Change the alarm state from ALARM to INSUFFICIENT_DATA.

   ```
   aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason
    "initializing" --state-value INSUFFICIENT_DATA
   ```

   d. Check that you have received an email notification about the alarm.

Create an alarm on Performance Insights counter metrics from an Amazon database

CloudWatch includes a **DB_PERF_INSIGHTS** metric math function which you can use to bring Performance Insights counter metrics into CloudWatch from Amazon Relational Database Service and Amazon DocumentDB (with MongoDB compatibility). **DB_PERF_INSIGHTS** also brings in the DBLoad metric at sub-minute intervals. You can set CloudWatch alarms on these metrics.

For more information about Amazon RDS Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS.

For more information about Amazon DocumentDB Performance Insights, see [Monitoring with Performance Insights](#).

Anomaly detection is not supported for alarms based on the **DB_PERF_INSIGHTS** function.

> **Note**
>
> High-resolution metrics with sub-minute granularity retrieved by **DB_PERF_INSIGHTS** are only applicable to the **DBLoad** metric, or for operating system metrics if you have enabled Enhanced Monitoring at a higher resolution. For more information about Amazon RDS enhanced monitoring, see [Monitoring OS metrics with Enhanced Monitoring.](#).
> You can create a high-resolution alarm using the **DB_PERF_INSIGHTS** function. The maximum evaluation range for a high-resolution alarm is three hours. You can use the CloudWatch console to graph metrics retrieved with the **DB_PERF_INSIGHTS** function for any time range.

To create an alarm that's based on Performance Insights metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. Choose the **Add math** dropdown, and then select **All functions**, **DB_PERF_INSIGHTS** from the list.

   After you choose **DB_PERF_INSIGHTS**, a math expression box appears where you apply or edit math expressions.
6. In the math expression box, enter your **DB_PERF_INSIGHTS** math expression, and then choose **Apply**.

   For example, `DB_PERF_INSIGHTS(‘RDS’, ‘db-ABCDEFGHIJKLMNOPQRSTUVWXY1’, ‘os.cpuUtilization.user.avg’)`

   > **Important**
   >
   > When you use the **DB_PERF_INSIGHTS** math expression, you must specify the Unique Database Resource ID of the database. This is different than the database identifier. To

find the database resource ID in the Amazon RDS console, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is displayed in the **Configuration** section.

For information about the **DB_PERF_INSIGHTS** function and other functions that are available for metric math, see [Metric math syntax and functions](#).

7. Choose **Select metric**.

   The **Specify metric and conditions** page appears, showing a graph and other information about the math expression that you have selected.

8. For **Whenever *`expression`* is**, specify whether the expression must be greater than, less than, or equal to the threshold. Under **than...**, specify the threshold value.

9. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the `ALARM` state to trigger the alarm. If the two values here match, you create an alarm that goes to `ALARM` state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see [Evaluating an alarm](#).

10. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see [Configuring how CloudWatch alarms treat missing data](#).

11. Choose **Next**.

12. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.

    To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

    To have the alarm not send notifications, choose **Remove**.

13. To have the alarm perform Auto Scaling, EC2, Lambda, or Systems Manager actions, choose the appropriate button and choose the alarm state and action to perform. If you choose a Lambda function as an alarm action, you specify the function name or ARN, and you can optionally choose a specific version of the function.

Alarms can perform Systems Manager actions only when they go into ALARM state. For more information about Systems Manager actions, see see Configuring CloudWatch to create OpsItems from alarms and Incident creation.

> **Note**
>
> To create an alarm that performs an SSM Incident Manager action, you must have certain permissions. For more information, see Identity-based policy examples for Amazon Systems Manager Incident Manager.

14. When finished, choose **Next**.
15. Enter a name and description for the alarm. Then choose **Next**.

    The name must contain only UTF-8 characters, and can't contain ASCII control characters. The description can include markdown formatting, which is displayed only in the alarm **Details** tab in the CloudWatch console. The markdown can be useful to add links to runbooks or other internal resources.
16. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Create alarms to stop, terminate, reboot, or recover an EC2 instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your EC2 instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which helps you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily restart a stopped instance if you need to run it again later. You can also keep the same instance ID and root volume. However, you cannot restart a terminated instance. Instead, you must launch a new instance.

You can add the stop, terminate, or reboot, actions to any alarm that is set on an Amazon EC2 per-instance metric, including basic and detailed monitoring metrics provided by Amazon CloudWatch (in the AWS/EC2 namespace), in addition to any custom metrics that include the "InstanceId=" dimension, as long as the InstanceId value refers to a valid running Amazon EC2 instance. You can also add the recover action to alarms that is set on any Amazon EC2 per-instance metric except for `StatusCheckFailed_Instance`.

> **Important**
>
> Alarms configured on Amazon EC2 metrics can temporarily enter the INSUFFICIENT_DATA state if there are missing metric data points. This is rare, but can happen when the metric reporting is interrupted, even when the Amazon EC2 instance is healthy. For alarms on Amazon EC2 metrics that are configured to take stop, terminate, reboot, or recover actions, we recommend that you configure those alarms to treat missing data as `missing`, and to have these alarms trigger only when in the ALARM state.
> For more information about how you can configure CloudWatch to act on missing metrics that have alarms set on them, see Configuring how CloudWatch alarms treat missing data.

To set up a CloudWatch alarm action that can reboot, stop, or terminate an instance, you must use a service-linked IAM role, *AWSServiceRoleForCloudWatchEvents*. The AWSServiceRoleForCloudWatchEvents IAM role enables Amazon to perform alarm actions on your behalf.

To create the service-linked role for CloudWatch Events, use the following command:

```
aws iam create-service-linked-role --aws-service-name events.amazonaws.com
```

Console support

You can create alarms using the CloudWatch console or the Amazon EC2 console. The procedures in this documentation use the CloudWatch console. For procedures that use the Amazon EC2 console, see Create alarms that stop, terminate, reboot, or rcover an instance in the *Amazon EC2 User Guide*.

Permissions

If you are using an Amazon Identity and Access Management (IAM) account to create or modify an alarm that performs EC2 actions or Systems Manager OpsItem actions, you must have the `iam:CreateServiceLinkedRole` permission.

Contents

Adding stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an SNS notification, so that you will receive an email when the alarm is triggered.

Amazon EC2 instances that use an Amazon Elastic Block Store volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated.

To create an alarm to stop an idle instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select Metric**.
5. For **Amazon namespaces**, choose **EC2**.
6. Do the following:

    a. Choose **Per-Instance Metrics**.

    b. Select the check box in the row with the correct instance and the **CPUUtilization** metric.

    c. Choose the **Graphed metrics** tab.

   d. For the statistic, choose **Average**.
   e. Choose a period (for example, **1 Hour**).
   f. Choose **Select metric**.
7. Under **Conditions**, do the following:
   a. Choose **Static**.
   b. Under **Whenever CPUUtilization is**, choose **Lower**.
   c. For **than**, type **10**.
   d. Choose **Next**.
   e. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

      To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Stop_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the `ALARM` state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.
   f. Choose **Add EC2 Action**.
   g. For **Alarm state trigger**, choose **In alarm**. For **Take the following action**, choose **Stop this instance**.
   h. Choose **Next**.
   i. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
   j. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

Adding terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don't need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information about enabling and disabling termination protection for an instance, see Enabling Termination Protection for an Instance in the *Amazon EC2 User Guide*.

To create an alarm to terminate an idle instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **Create Alarm**.
3. For the **Select Metric** step, do the following:

   a. Under **EC2 Metrics**, choose **Per-Instance Metrics**.

   b. Select the row with the instance and the **CPUUtilization** metric.

   c. For the statistic, choose **Average**.

   d. Choose a period (for example, **`1 Hour`**).

   e. Choose **Next**.
4. For the **Define Alarm** step, do the following:

   a. Under **Alarm Threshold**, type a unique name for the alarm (for example, Terminate EC2 instance) and a description of the alarm (for example, Terminate EC2 instance when CPU is idle for too long). Alarm names must contain only ASCII characters.

   b. Under **Whenever**, for **is**, choose **<** and type **`10`**. For **for**, type **24** consecutive periods.

      A graphical representation of the threshold is shown under **Alarm Preview**.

   c. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

      To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Terminate_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the `ALARM` state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

   d. Choose **EC2 Action**.

   e. For **Whenever this alarm**, choose **State is ALARM**. For **Take this action**, choose **Terminate this instance**.

   f. Choose **Create Alarm**.

Adding reboot actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health

Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing hour, unlike stopping and restarting your instance. For more information about rebooting an instance, see Reboot Your Instance in the *Amazon EC2 User Guide*.

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each.

To create an alarm to reboot an instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **Create Alarm**.
3. For the **Select Metric** step, do the following:
   a. Under **EC2 Metrics**, choose **Per-Instance Metrics**.
   b. Select the row with the instance and the **StatusCheckFailed_Instance** metric.
   c. For the statistic, choose **Minimum**.
   d. Choose a period (for example, **`1 Minute`**).
   e. Choose **Next**.
4. For the **Define Alarm** step, do the following:
   a. Under **Alarm Threshold**, type a unique name for the alarm (for example, Reboot EC2 instance) and a description of the alarm (for example, Reboot EC2 instance when health checks fail). Alarm names must contain only ASCII characters.
   b. Under **Whenever**, for **is**, choose **>** and type **`0`**. For **for**, type **3** consecutive periods.

      A graphical representation of the threshold is shown under **Alarm Preview**.

c. Under **Notification**, for **Send notification to**, choose an existing SNS topic or create a new one.

   To create an SNS topic, choose **New list**. For **Send notification to**, type a name for the SNS topic (for example, Reboot_EC2_Instance). For **Email list**, type a comma-separated list of email addresses to be notified when the alarm changes to the `ALARM` state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

d. Choose **EC2 Action**.

e. For **Whenever this alarm**, choose **State is ALARM**. For **Take this action**, choose **Reboot this instance**.

f. Choose **Create Alarm**.

Adding recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires Amazon involvement to repair. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

When the `StatusCheckFailed_System` alarm is triggered, and the recover action is initiated, you will be notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic will receive an email notification that includes the status of the recovery attempt and any further instructions. You will notice an instance reboot on the recovered instance.

The recover action can be used only with `StatusCheckFailed_System`, not with `StatusCheckFailed_Instance`.

Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host

- Hardware issues on the physical host that impact network reachability

The recover action is supported only on some instance types. For more information about supported instance types and other requirements, see [Recover your instance] and [Requirements].

> **Important**
>
> To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each and reboot alarms to three evaluation periods of one minute each.

To create an alarm to recover an instance using the Amazon CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, **All alarms**.
3. Choose **Create Alarm**.
4. Choose **Select Metric** and then do the following:

    a. Choose **EC2 Metrics**, **Per-Instance Metrics**.

    b. Select the row with the instance and the **StatusCheckFailed_System** metric, and then choose **Select metric**.

    c. For the statistic, choose **Minimum**.

    d. Choose a period (for example, **`1 Minute`**).

    > **Important**
    >
    > To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each.

5. For **Conditions**, do the following:

    a. Under **Threshold type**, choose **Static**.

    b. Under **Whenever**, choose **Greater** and enter **`0`** for **than...**.

c. Choose **Additional configuration**, then for **Datapoints to alarm** specify 2 **out of** 2.

6. Choose **Next**.
7. Under **Notification**, do the following:

   a. For **Alarm state trigger**, choose **In alarm**.
   b. For **Send notification to the following SNS topic**, choose an existing SNS topic or create a new one.
   c. Choose **Add EC2 Action**.
   d. For **Alarm state trigger**, choose **In alarm**.
   e. For **Take the following action**, choose **Recover this instance**.
   f. Choose **Next**.
8. For **Alarm name**, type a unique name for the alarm (for example, **`Recover EC2 instance`**) and a description of the alarm (for example, **`Recover EC2 instance when health checks fail`**). Alarm names must contain only ASCII characters.
9. Choose **Next**.
10. Choose **Create Alarm**.

Viewing the history of triggered alarms and actions

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last 30 days of alarm and action history.

To view the history of triggered alarms and actions

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms** and select an alarm.
3. To view the most recent state transition along with the time and metric values, choose **Details**.
4. To view the most recent history entries, choose **History**.

Alarms and tagging

Tags are key-value pairs that can help you organize and categorize your resources. You can also use them to scope user permissions by granting a user permission to access or change only resources with certain tag values. For more general information about tagging resources, see [Tagging your Amazon resources]

The following list explains some details about how tagging works with CloudWatch alarms.

- To be able to set or update tags for a CloudWatch resource, you must be signed on to an account that has the `cloudwatch:TagResource` permission. For example, to create an alarm and set tags for it, you must have the `cloudwatch:TagResource` permission in addition to the `the cloudwatch:PutMetricAlarm` permission. We recommend that you make sure anyone in your organization who will create or update CloudWatch resources has the `cloudwatch:TagResource` permission.
- Tags can be used for tag-based authorization control. For example, IAM user or role permissions can include conditions to limit CloudWatch calls to specific resources based on their tags. However, keep in mind the following
  - Tags with names that start with `aws:` can't be used for tag-based authorization control.
  - Composite alarms do not support tag-based authorization control.

Auditing CloudWatch telemetry configurations

You can use Amazon CloudWatch to discover and understand the state of telemetry configuration for your Amazon resources from a central view in the CloudWatch console. This simplifies the process of auditing your telemetry collection configurations across multiple resource types within an account or across multiple accounts in Organizations. With a consolidated view, you can easily review and manage telemetry settings, helping you to ensure proper monitoring and data collection across your Amazon environment.

CloudWatch can help you identify telemetry configuration for the following types of Amazon resource types:

- Amazon EC2 instances that provide detailed metrics. For more information, see Manage detailed monitoring for your EC2 instances in the Amazon EC2 User Guide.
- Amazon VPC virtual networks that provide flow logs. For more information, see Logging IP traffic using VPC Flow Logs in the Amazon VPC User Guide.
- Lambda functions that provide traces. For more information, see Visualize Lambda function invocations using Amazon X-Ray in the Amazon X-Ray Developer Guide.

To begin auditing your telemetry configurations, you must first turn on the telemetry auditing experience for your Amazon Web Services account or organization. Enabling this feature creates Amazon Config service-linked configuration recorders that discover resources and their associated telemetry configuration metadata. For more information, see Configuration Recorder in the Amazon Config Developer Guide.

> **Note**
>
> Amazon Config periodically takes inventory of, or discovers, all the resources in your account as an anti-entropy behavior, regardless of the resource types in scope for your configuration recorders. The inventory includes deleted resources and resources that Amazon Config is not currently recording. This behavior helps maintain data consistency. This means that although the service-linked configuration recorder for the CloudWatch telemetry auditing feature is configured to record three resource types (Amazon EC2 instances, Amazon EC2 VPC virtual networks, and Lambda functions), you might see describe calls from `ConfigResourceCompositionSession` and `AWSConfig-Describe`

in Amazon CloudTrail. For more information, see Non-recorded Resources in the Amazon Config Developer Guide.

The telemetry auditing experience uses this information and offers visibility into the configuration status, at the resource type level and at more granular telemetry detail levels. You can customize your view of the resources or telemetry details using filters, and modify the telemetry configuration directly from the resource's console page.

Turning on the telemetry auditing experience does not incur any additional costs.

Topics

- Turning on CloudWatch telemetry auditing
- Viewing Amazon resource telemetry in CloudWatch
- Turning off CloudWatch telemetry auditing

Turning on CloudWatch telemetry auditing

Use the CloudWatch console to turn on telemetry auditing for your Amazon Web Services account or organization. For an organization, CloudWatch uses a management account or a delegated administrator account to discover Amazon resources and the telemetry configurations for all of the member accounts in the organization. Turning on the telemetry auditing experience does not incur any additional cost.

Telemetry auditing remains on until you turn it off. For more information, see Turning off CloudWatch telemetry auditing.

Topics

- Auditing telemetry configurations for your organization
- Turning on telemetry auditing for your account
- Deregistering a delegated administrator account
- Turning off trusted access for Organizations

Auditing telemetry configurations for your organization

To turn on telemetry configuration for your organization, you must use a management account or a delegated administrator account. CloudWatch uses this account to discover your organization's Amazon resources and their telemetry configurations.

Before you can turn on telemetry auditing for your organization, you need to turn on trusted access between Amazon Organizations and CloudWatch. When you turn on trusted access, CloudWatch creates a service-linked role named **AWSServiceRoleForObservabilityAdmin** to support resource and telemetry configuration discovery for the organization. The role is created in all member accounts of the organization. For more information about the service-linked role, see Service-linked role permissions for CloudWatch telemetry config. For more information about Amazon Organizations, see Amazon CloudWatch and Amazon Organizations in the Amazon Organizations User Guide.

To use a management account for telemetry configuration, log in with the account, turn on trusted access, and then turn on telemetry auditing. For more information, see Turning on telemetry auditing for your Amazon Organizations.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pain, choose **Settings**.
3. Choose the **Organizations** tab.
4. In **Organizational Management Settings**, choose **Turn on**. The **Enable trusted access** page appears.
5. To review the role policy, choose **View permission details** and the role policy appears in a window. Choose **Enable trusted access**. The telemetry configuration **Overview** page appears and CloudWatch begins discovering Amazon resources in the organization. As CloudWatch discovers resources, it updates information on the **Overview** page.

> **Note**
>
> The time delay before resources appear on the **Overview** page depends on the number of member accounts and resources in your organization or account.

Registering a delegated administrator account for your organization

A delegated administrator account is a member account that shares administrator access for service-managed permissions. The account that you register as a delegated administrator must be in your organization. A delegated administrator account for your organization can be used outside of CloudWatch, so make sure that you understand this account type before you follow this procedure. For more information, see [Amazon CloudWatch and Amazon Organizations]() in the Amazon Organizations User Guide.

To remove or change the delegated administrator account, deregister the account first. For more information, see [Deregistering a delegated administrator account]().

To register a delegated administrator account

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. Choose **Register delegated administrator**.
5. On the **Register delegated administrator** page, for **Delegated administrator account ID**, enter the 12-digit account ID for an organization member.
6. Choose **Register delegated administrator**. At the top of the page, a message appears indicating the account was registered successfully. The **Organization Settings** page appears. To see information about the delegated administrator account, hover over the number below **Delegated administrators**.

Turning on telemetry auditing for your Amazon Organizations

Turn on telemetry auditing for your Amazon Organizations to monitor the telemetry for the Amazon resources across all your member accounts. This also turns on the telemetry auditing experience for individual accounts. You can also turn on the telemetry auditing experience for only your account. For more information, see [Turning on telemetry auditing for your account]().

You can turn off trusted access across all your member accounts. For more information, see [Turning off trusted access for Organizations]().

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Telemetry config**.

3. Choose **Turn on**, and then choose the **Organization** tab. The telemetry config **Overview** page appears and CloudWatch begins discovering Amazon resources in your account. As CloudWatch discovers resources, it updates information in the **Overview** page.

> **Note**
>
> The delay before resources appear on the **Overview** page depends on the number of member accounts and resources in your organization or account.

Turning on telemetry auditing for your account

Turn on telemetry auditing for your Amazon Web Services account to monitor telemetry for the Amazon resources in that account. If you have an organization in Amazon Organizations, turn on telemetry configuration for your organization instead. For more information, see [Turning on telemetry auditing for your Amazon Organizations](#).

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**, **Telemetry config**.
3. Choose **Turn on**, then **This account**, if you are using a management account or a delegated administrator account. The telemetry configuration **Overview** page appears and CloudWatch begins discovering Amazon resources in your account. As CloudWatch discovers resources, it updates information on the **Overview** page.

> **Note**
>
> The delay before resources appear on the **Overview** page depends on the number of member accounts and resources in your organization or account.

Deregistering a delegated administrator account

Deregister the delegated administrator account before turning off trusted access for Organizations. You can also deregister a delegated administrator account if it no longer has access to the appropriate Amazon resources for telemetry auditing or to choose a different member account to be the delegated administrator. This account will not be able to perform account management tasks for Organizations. For more information, see [Amazon CloudWatch and Amazon Organizations] in the Amazon Organizations User Guide.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. On the **Organization** tab, choose **Deregister**.
4. On the **Deregister delegated administrator** page, choose **Deregister**.

To register an account as a delegated administrator, see Registering a delegated administrator account for your organization.

Turning off trusted access for Organizations

Trusted access extends the functionality of the management account in Amazon Organizations to other Amazon services. When you turn off trusted access, trusted access between your organization and all Amazon services—not just CloudWatch—will stop.

If you no longer want trusted access turned on for your organization, you can turn it off. For more information, see Amazon CloudWatch and Amazon Organizations in the Amazon Organizations User Guide.

> **Note**
>
> Before turning off trusted access for an organization, deregister the delegated administrator account. For more information, see Deregistering a delegated administrator account.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. In the **Organizational Management Settings** section, select **Turn off**.

Viewing Amazon resource telemetry in CloudWatch

Telemetry configuration displays Amazon resources in two places: As an overview, on the **Telemetry config** page and in detail, on the **Discovered resources** page.

- **Telemetry config** – This page shows the percentage of resources with telemetry that are configured for each resource type and the number of resources detected as providing metrics, as well as the total number of resources in your account or organization. You can filter the display of resources in the **Telemetry config** page by account ID or by the tags applied to your resources.
- **Discovered resources** – This page shows details about each resource that has been discovered by telemetry configuration, including the resource ID, the type of telemetry each resource is providing, and the time when information about the resource was last refreshed by telemetry configuration. You can filter the display of resource on the **Discovered resources** page by any of the information provided about the resource.

  For each Amazon resource tracked by telemetry configuration, the **Discovered resources** page shows the status of its telemetry by providing the following information:

  - For telemetry types that CloudWatch detects that the resource is providing, the **Discovered resources** page shows **On**.
  - For telemetry types that CloudWatch detects the resource is not providing, the **Discovered resources** page shows **Off**.
  - For telemetry types that are not supported for a resource, the **Discovered resources** page shows **NS**, that is, not supported.

To view resources on the Telemetry config page

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Telemetry config**.
3. The **Telemetry config** page shows the total number of each resource that was discovered by telemetry config, the number of resources providing telemetry, and the percentage of discovered resources that are providing telemetry.
4. To see recent changes to resources, choose **Refresh**.

To view resources on the Discovered resources page

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Telemetry config**.
3. Do one of the following to view all resource types discovered by telemetry configuration or to view one resource type:

   a. To view all resources that have been discovered by telemetry configuration, choose **View resources**. The **Discovered resources** page appears and shows all resources discovered by telemetry configuration.

   b. To view one resource type, at the bottom of the page, choose a type of Amazon resource. The **Discovered resources** page appears. The **Discovered resources** page shows all discovered resources for that resource type.

4. On the **Discovered resources** page, do one or more of the following:

   - To view information about the resource or to change its telemetry settings, choose a resource ID. The console page for the resource appears.

     > **Note**
     >
     > You can only view a resource on its console page if the resource belongs to your account. To determine if the resource belongs to your account, check the **Amazon Web Services account** column. If the **Amazon Web Services account** column does not appear, change your the **Discovered resources** page preferences. For more information, see Changing preferences for Discovered resource page.

   - To view other pages of resources, choose a page number, or navigate by using **<** or **>** to view next or previous pages.

   - To see the latest information about resources in the page, choose **Refresh**.

Filtering discovered resources

You can use one or more filters on the **Telemetry config** page or the **Discovered resources** page to change your view of the resources. Your filter settings persist across both pages.

To filter resources on the Telemetry config page

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Settings**, and then choose **Telemetry config**.

3. You can filter the discovered resources that are displayed on the page by specifying an account ID or tag value.

   a. Choose **Find resource**.

   b. Choose **Account ID** or **Tag value**, and then choose additional options for the filter. Statistics about telemetry coverage for each resource change based on your filter options.

4. To remove a filter, in the filter text box, choose **X**.

To filter resources on the Discovered resources page

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Telemetry config**.
3. To view all resource types discovered by telemetry configuration or to view one resource type, do one of the following:

   a. To view all resources discovered by telemetry configuration, choose **View resources**. The **Discovered resources** page appears and shows all resources discovered by telemetry configuration.

   b. To view one resource type, at the bottom of the page, choose a type of Amazon resource. The **Discovered resources** page appears. The **Discovered resources** page filters all discovered resources for that resource type.

4. You can filter the resources displayed in the page based on any of the columns in the page. You can change the columns in the page by changing your preferences for the **Discovered resources** page. For more information, see Changing preferences for Discovered resource page.

   a. Choose **Find resource**. Filters for each column in the page appear. Choose one, then choose additional options to define the filter. Resources appear in the page that match the filter settings.

   b. To further filter the resources displayed in the page, choose **Find resources** again, choose another filter, and choose additional options. Resources appear in the page that match all of the filter settings.

5. To remove one of the filters, in the filter text box, choose **X**.
6. To remove all of the filters and see all resource types discovered by telemetry configuration, choose **Clear filters**.

Changing preferences for Discovered resource page

You can change your preferences for the **Discovered resources** page to control how many resources appear per page and which detailed metrics appear in the page. Only detailed metrics in view can be used to filter the resources displayed in the discovered resources page. For more information, see Filtering discovered resources.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Telemetry config**.
3. Choose **View resources**. The **Discovered resources** page appears.
4. Choose the gear icon.
5. In the **Preferences** dialog box, choose the number of resources per page and the visible content to show as columns.
6. Choose **Confirm**.

Turning off CloudWatch telemetry auditing

When you no longer need telemetry configuration, turn it off. When telemetry configuration is turned off, it no longer shows the status of telemetry for resources in your account or organization. You can turn on telemetry configuration at any time. For more information, see Turning on CloudWatch telemetry auditing.

1. Open the CloudWatch console.
2. In the navigation pane, choose **Telemetry config**.
3. Choose **Turn off**.

Infrastructure monitoring

The topics in this section explain CloudWatch features that can help you gain operational visibility into your Amazon resources.

Topics

Container Insights

Use CloudWatch Container Insights to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. Container Insights is available for Amazon Elastic Container Service (Amazon ECS), Amazon Elastic Kubernetes Service (Amazon EKS), RedHat OpenShift on Amazon (ROSA), and Kubernetes platforms on Amazon EC2. Container Insights supports collecting metrics from clusters deployed on Amazon Fargate for both Amazon ECS and Amazon EKS.

CloudWatch automatically collects metrics for many resources, such as CPU, memory, disk, and network. Container Insights also provides diagnostic information, such as container restart failures, to help you isolate issues and resolve them quickly. You can also set CloudWatch alarms on metrics that Container Insights collects.

Container Insights collects data as *performance log events* using embedded metric format. These performance log events are entries that use a structured JSON schema that enables high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates aggregated metrics at the cluster, node, pod, task, and service level as CloudWatch metrics. The metrics that Container Insights collects are available in CloudWatch automatic dashboards, and are also viewable in the **Metrics** section of the CloudWatch console. Metrics are not visible until the container tasks have been running for some time.

When you deploy Container Insights, it automatically creates a log group for the performance log events. You don't need to create this log group yourself.

To help you manage your Container Insights costs, CloudWatch does not automatically create all possible metrics from the log data. However, you can view additional metrics and additional levels of granularity by using CloudWatch Logs Insights to analyze the raw performance log events.

With the original version of Container Insights, metrics collected and logs ingested are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics and logs are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

In Amazon EKS, RedHatOpenshift on Amazon, and Kubernetes, Container Insights uses a containerized version of the CloudWatch agent to discover all of the running containers in a cluster. It then collects performance data at every layer of the performance stack.

Container Insights supports encryption with the Amazon KMS key for the logs and metrics that it collects. To enable this encryption, you must manually enable Amazon KMS encryption for the log group that receives Container Insights data. This causes Container Insights to encrypt this data using the provided KMS key. Only symmetric keys are supported. Do not use asymmetric KMS keys to encrypt your log groups.

For more information, see Encrypt Log Data in CloudWatch Logs Using Amazon KMS.

Supported platforms

Container Insights is available for Amazon Elastic Container Service, Amazon Elastic Kubernetes Service, RedHat OpenShift on Amazon, and Kubernetes platforms on Amazon EC2 instances.

- For Amazon ECS, Container Insights collects metrics at the cluster, task, and service levels on both Linux and Windows Server instances. Container Insights collects metrics at the instance level only on Linux instances. Network metrics are available for containers that use `bridge` network mode and `awsvpc` network mode, but are not available for containers that use `host` network mode.
- For Amazon Elastic Kubernetes Service, and Kubernetes platforms on Amazon EC2 instances, Container Insights is supported on both Linux and Windows instances.

Container Insights with enhanced observability for Amazon ECS

On December 2, 2024, Amazon released Container Insights with enhanced observability for Amazon ECS. This version supports enhanced observability for Amazon ECS clusters using the

Amazon EC2 and Fargate launch types. After you configure Container Insights with enhanced observability on Amazon ECS, Container Insights auto-collects detailed infrastructure telemetry from the cluster level down to the container level in your environment and displays these critical performance data in curated dashboards removing the heavy lifting in observability set-up. For information about how to set up Container Insights with enhanced observability, see Setting up Container Insights on Amazon ECS.

Container Insights with enhanced observability provides all of the Container Insights metrics, plus additional task and container metrics. For more information, see Amazon ECS Container Insights with enhanced observability metrics.

Container Insights with enhanced observability also supports CloudWatch cross-account observability. You can use a single monitoring account to monitor and troubleshoot applications that span multiple Amazon accounts within a single Region. For more information, see CloudWatch cross-account observability.

Container Insights with enhanced observability for Amazon EKS

On November 6, 2023, a new version of Container Insights was released. This version supports enhanced observability for Amazon EKS clusters running on Amazon EC2 and can collect more detailed metrics from these clusters. After installation, it automatically collects detailed infrastructure telemetry and container logs for your Amazon EKS clusters. You can then use curated, immediately usable dashboards to drill down into application and infrastructure telemetry.

Container Insights with enhanced observability for Amazon EKS collects granular health, performance, and status metrics up to the container level, and also control plane metrics. For more information about the additional metrics and dimensions collected, see Amazon EKS and Kubernetes Container Insights with enhanced observability metrics.

If you installed Container Insights by using the CloudWatch agent on an Amazon EKS cluster on Amazon EC2 after November 6, 2023, you have Container Insights with enhanced observability for Amazon EKS. Otherwise, you can upgrade an Amazon EKS cluster to this new version by following the instructions in Upgrading to Container Insights with enhanced observability for Amazon EKS in CloudWatch.

Container Insights supports CloudWatch cross-account observability. You use a single monitoring account to monitor and troubleshoot your applications that span multiple Amazon accounts within a single Region. For more information, see CloudWatch cross-account observability.

Container Insights with enhanced observability for Amazon EKS also supports Windows worker nodes.

Container Insights with enhanced observability for Amazon EKS is not supported on Fargate.

> **Note**
>
> You can find whether you have clusters that can be upgraded to Container Insights with enhanced observability for Amazon EKS by navigating to the Container Insights console. To do so, choose **Insights**, **Container Insights** in the navigation pane of the CloudWatch console. In the Container Insights console, a banner informs you if you have any Amazon EKS clusters that can be upgraded, and links to the upgrade page.

CloudWatch agent container image

Amazon provides a CloudWatch agent container image on Amazon Elastic Container Registry. For more information, see cloudwatch-agent on Amazon ECR.

Setting up Container Insights

The Container Insights setup process is different for Amazon ECS and Amazon EKS and Kubernetes.

Topics

Setting up Container Insights on Amazon ECS

You can use one or both of the following options to enable Container Insights on Amazon ECS clusters:

- Use the Amazon Web Services Management Console or the Amazon CLI to start collecting cluster-level, task-level, and service-level metrics.
- Deploy the CloudWatch agent as a daemon service to start collecting of instance-level metrics on clusters that are hosted on Amazon EC2 instances.

Topics

Setting up Container Insights on Amazon ECS

You can set up Container Insights with enhanced observability or Container Insights on new and existing Amazon ECS clusters using either the Amazon ECS console or the Amazon CLI. Container Insights collects metrics at the cluster, task, and service levels. Container Insights with enhanced observability provides additional dimensions and metrics, allowing you to deep dive down to container level visibility.

If you're using Amazon ECS on an Amazon EC2 instance, launch that instance using an AMI that includes Amazon ECS agent version 1.29 or later. For information about updating your agent version, see Updating the Amazon ECS Container Agent.

> **Note**
>
> If the customer managed Amazon KMS key that you use for your Amazon ECS Container Insights metrics is not already configured to work with CloudWatch, you must update the key policy to allow for encrypted logs in CloudWatch Logs. You must also associate your own Amazon KMS key with the log group in `/aws/ecs/containerinsights/`*`ClusterName`*`/performance`. For more information, see Encrypt log data in CloudWatch Logs using Amazon Key Management Service.

We recommend that you use Container Insights with enhanced observability instead of Container Insights as it provides detailed visibility in your container environment, reducing the mean time to resolution.

Set up Container Insights with enhanced observability

You can turn on Container Insights with enhanced observability using the Amazon ECS console or Amazon CLI.

Amazon CLI

Use the following command to turn on Container Insights with enhanced observability.

Set the `containerInsights` account setting to `enhanced`

```
aws ecs put-account-setting --name containerInsights --value enhanced
```

Example output

```
{
    "setting": {
        "name": "containerInsights",
        "value": "enhanced",
        "principalArn": "arn:aws:iam::123456789012:johndoe",
         "type": user
    }
}
```

> **Note**
>
> By default, the `put-account-setting` applies only to the currently authenticated user. To enable the setting account-wide for all users and roles, use the root user as in the following example.
>
> ```
> aws ecs put-account-setting --name containerInsights --value enhanced --
> principal-arn arn:aws:iam::accountID:root
> ```

After you set this account setting, all new clusters automatically use Container Insights with enhanced observability. Use the `update-cluster-settings` command to add Container Insights with enhanced observability to existing cluster, or to upgrade clusters that currently use Container Insights to Container Insights with enhanced observability.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
 name=containerInsights,value=enhanced
```

Amazon ECS console

1. Open the console at https://console.amazonaws.cn/ecs/v2.

2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. To use Container Insights with enhanced observability, choose **Container Insights with enhanced observability**.
6. Choose **Save changes**.
7. On the confirmation screen, choose **Confirm** to save the selection.

After you set this, all new clusters automatically use Container Insights with enhanced observability. You can add Container Insights with enhanced observability to existing clusters, or update clusters that currently use Container Insights to Container Insights with enhanced observability. For more information, see Updating an Amazon ECS cluster in the *Amazon Elastic Container Service Developer Guide*.

Set up Container Insights

You can turn on Container Insights using the Amazon ECS console or Amazon CLI.

Amazon CLI

To use Container Insights, set the `container Insights` account setting to `enabled`. Use the following command to turn on Container Insights.

```
aws ecs put-account-setting --name containerInsights --value enabled
```

Example output

```
{
    "setting": {
        "name": "container Insights",
        "value": "enabled",
        "principalArn": "arn:aws:iam::123456789012:johndoe",
         "type": user
    }
}
```

When you set the `container Insights` account setting to `enabled`, all new clusters have Container Insights enabled by default. Use the `update-cluster-settings` command to add Container Insights to an existing cluster.

```
aws ecs update-cluster-settings --cluster cluster-name --settings
 name=containerInsights,value=enabled
```

Amazon ECS console

1. Open the console at https://console.amazonaws.cn/ecs/v2.
2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose **Account Settings**.
4. Choose **Update**.
5. To use Container Insights, choose **Container Insights**.
6. Choose **Save changes**.
7. On the confirmation screen, choose **Confirm** to save the selection.

After you set this, all new clusters automatically use Container Insights. Update existing clusters to add Container Insights. For more information, see Updating an Amazon ECS cluster in the *Amazon Elastic Container Service Developer Guide*.

Setting up Container Insights on Amazon ECS using Amazon Distro for OpenTelemetry

Use this section if you want to use Amazon Distro for OpenTelemetry to set up CloudWatch Container Insights on an Amazon ECS cluster. For more information about Amazon Distro for Open Telemetry, see Amazon Distro for OpenTelemetry.

These steps assume that you already have a cluster running Amazon ECS. For more information about using Amazon Distro for Open Telemetry with Amazon ECS and setting up an Amazon ECS cluster for this purpose, see Setting up Amazon Distro for OpenTelemetry Collector in Amazon Elastic Container Service.

Step 1: Create a task role

The first step is creating a task role in the cluster that the Amazon OpenTelemetry Collector will use.

To create a task role for Amazon Distro for OpenTelemetry

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Policies** and then choose **Create policy**.
3. Choose the **JSON** tab and copy in the following policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:DescribeLogGroups",
                "ssm:GetParameters"
            ],
            "Resource": "*"
        }
    ]
}
```

4. Choose **Review policy**.
5. For name, enter **`AWSDistroOpenTelemetryPolicy`**, and then choose **Create policy**.
6. In the left navigation pane, choose **Roles** and then choose **Create role**.
7. In the list of services, choose **Elastic Container Service**.
8. Lower on the page, choose **Elastic Container Service Task** and then choose **Next: Permissions**.
9. In the list of policies, search for **AWSDistroOpenTelemetryPolicy**.
10. Select the check box next to **AWSDistroOpenTelemetryPolicy**.
11. Choose **Next: Tags** and then choose **Next: Review.**
12. For **Role name** enter **`AWSOpenTelemetryTaskRole`** and then choose **Create role**.

Step 2: Create a task execution role

The next step is creating a task execution role for the Amazon OpenTelemetry Collector.

To create a task execution role for Amazon Distro for OpenTelemetry

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the left navigation pane, choose **Roles** and then choose **Create role**.
3. In the list of services, choose **Elastic Container Service**.
4. Lower on the page, choose **Elastic Container Service Task** and then choose **Next: Permissions**.
5. In the list of policies, search for **AmazonECSTaskExecutionRolePolicy** and then select the check box next to **AmazonECSTaskExecutionRolePolicy**.
6. In the list of policies, search for **CloudWatchLogsFullAccess** and then select the check box next to **CloudWatchLogsFullAccess**.
7. In the list of policies, search for **AmazonSSMReadOnlyAccess** and then select the check box next to **AmazonSSMReadOnlyAccess**.
8. Choose **Next: Tags** and then choose **Next: Review.**
9. For **Role name** enter **`AWSOpenTelemetryTaskExecutionRole`** and then choose **Create role**.

Step 3: Create a task definition

The next step is creating a task definition.

To create a task definition for Amazon Distro for OpenTelemetry

1. Open the console at https://console.amazonaws.cn/ecs/v2.
2. In the navigation pane, choose **Task definitions**
3. Choose **Create new task definition**, **Create new task definition**.
4. For **Task definition family**, specify a unique name for the task definition.
5. Configure your containers, and then choose **Next**.
6. Under **Metrics and logging**, select **Use metric collection**.
7. Choose **Next**.
8. Choose **Create**.

For more information about using the Amazon OpenTelemetry collector with Amazon ECS, see Setting up Amazon Distro for OpenTelemetry Collector in Amazon Elastic Container Service.

Step 4: Run the task

The final step is running the task that you've created.

To run the task for Amazon Distro for OpenTelemetry

1. Open the console at https://console.amazonaws.cn/ecs/v2.
2. In the left navigation pane, choose **Task Definitions** and then select the task that you just created.
3. Choose **Actions**, **Deploy**, **Run task**.
4. Choose **Deploy**, **Run task**.
5. In the **Compute options** section, from **Existing cluster**, choose the cluster.
6. Choose **Create**.
7. Next, you can check for the new metrics in the CloudWatch console.
8. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
9. In the left navigation pane, choose **Metrics**.

   You should see a **ECS/ContainerInsights** namespace. Choose that namespace and you should see eight metrics.

Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS

To deploy the CloudWatch agent to collect instance-level metrics from Amazon ECS clusters that are hosted on EC2 instance, use a quick start setup with a default configuration, or install the agent manually to be able to customize it.

Both methods require that you already have at least one Amazon ECS cluster deployed with an EC2 launch type and that the CloudWatch agent continer has access to the Amazon EC2 Instance Metadata Service (IMDS). For more information about IMDS, see [Instance metadata and user data](#).

These methods also assume that you have the Amazon CLI installed. Additionally, to run the commands in the following procedures, you must be logged on to an account or role that has the **IAMFullAccess** and **AmazonECS_FullAccess** policies.

Topics

- [Quick setup using Amazon CloudFormation](#)

- Manual and custom setup

Quick setup using Amazon CloudFormation

To use the quick setup, enter the following command to use Amazon CloudFormation to install the agent. Replace *cluster-name* and *cluster-region* with the name and Region of your Amazon ECS cluster.

This command creates the IAM roles **CWAgentECSTaskRole** and **CWAgentECSExecutionRole**. If these roles already exist in your account, use `ParameterKey=CreateIAMRoles,ParameterValue=False` instead of `ParameterKey=CreateIAMRoles,ParameterValue=True` when you enter the command. Otherwise, the command will fail.

```
ClusterName=cluster-name
Region=cluster-region
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-ecs-instance-metric/cloudformation-quickstart/cwagent-ecs-instance-metric-cfn.json
aws cloudformation create-stack --stack-name CWAgentECS-${ClusterName}-${Region} \
    --template-body file://cwagent-ecs-instance-metric-cfn.json \
    --parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
                 ParameterKey=CreateIAMRoles,ParameterValue=True \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${Region}
```

(Alternative) Using your own IAM roles

If you want to use your own custom ECS task role and ECS task execution role instead of the **CWAgentECSTaskRole** and **CWAgentECSExecutionRole** roles, first make sure that the role to be used as the ECS task role has **CloudWatchAgentServerPolicy** attached. Also, make sure that the role to be used as the ECS task execution role has both the **CloudWatchAgentServerPolicy** and **AmazonECSTaskExecutionRolePolicy** policies attached. Then enter the following command. In the command, replace *task-role-arn* with the ARN of your custom ECS task role, and replace *execution-role-arn* with the ARN of your custom ECS task execution role.

```
ClusterName=cluster-name
Region=cluster-region
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
```

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-ecs-instance-metric/cloudformation-quickstart/cwagent-ecs-instance-metric-cfn.json
aws cloudformation create-stack --stack-name CWAgentECS-${ClusterName}-${Region} \
    --template-body file://cwagent-ecs-instance-metric-cfn.json \
    --parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
                 ParameterKey=TaskRoleArn,ParameterValue=${TaskRoleArn} \
                 ParameterKey=ExecutionRoleArn,ParameterValue=${ExecutionRoleArn} \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${Region}
```

Troubleshooting the quick setup

To check the status of the Amazon CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stacks --stack-name CWAgentECS-$ClusterName-$Region --region $Region
```

If you see the `StackStatus` is other than `CREATE_COMPLETE` or `CREATE_IN_PROGRESS`, check the stack events to find the error. Enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack-events --stack-name CWAgentECS-$ClusterName-$Region
 --region $Region
```

To check the status of the `cwagent` daemon service, enter the following command. In the output, you should see that the `runningCount` is equal to the `desiredCount` in the `deployment` section. If it isn't equal, check the `failures` section in the output.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs describe-services --services cwagent-daemon-service --cluster $ClusterName --region $Region
```

You can also use the CloudWatch Logs console to check the agent log. Look for the **/ecs/ecs-cwagent-daemon-service** log group.

Deleting the Amazon CloudFormation stack for the CloudWatch agent

If you need to delete the Amazon CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation delete-stack --stack-name CWAgentECS-${ClusterName}-${Region} --
region ${Region}
```

Manual and custom setup

Follow the steps in this section to manually deploy the CloudWatch agent to collect instance-level metrics from your Amazon ECS clusters that are hosted on EC2 instances.

Necessary IAM roles and policies

Two IAM roles are required. You must create them if they don't already exist. For more information about these roles, see IAM roles for Tasks and Amazon ECS Task Execution Role.

- An *ECS task role*, which is used by the CloudWatch agent to publish metrics. If this role already exists, you must make sure it has the `CloudWatchAgentServerPolicy` policy attached.
- An *ECS task execution role*, which is used by Amazon ECS agent to launch the CloudWatch agent. If this role already exists, you must make sure it has the `AmazonECSTaskExecutionRolePolicy` and `CloudWatchAgentServerPolicy` policies attached.

If you do not already have these roles, you can use the following commands to create them and attach the necessary policies. This first command creates the ECS task role.

```
aws iam create-role --role-name CWAgentECSTaskRole \
    --assume-role-policy-document "{\"Version\": \"2012-10-17\",\"Statement\": [{\"Sid
\": \"\",\"Effect\": \"Allow\",\"Principal\": {\"Service\": \"ecs-tasks.amazonaws.com
\"},\"Action\": \"sts:AssumeRole\"}]}"
```

After you enter the previous command, note the value of `Arn` from the command output as "TaskRoleArn". You'll need to use it later when you create the task definition. Then enter the following command to attach the necessary policies.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
CloudWatchAgentServerPolicy \
    --role-name CWAgentECSTaskRole
```

This next command creates the ECS task execution role.

```
aws iam create-role --role-name CWAgentECSExecutionRole \
    --assume-role-policy-document "{\"Version\": \"2012-10-17\",\"Statement\": [{\"Sid
\": \"\",\"Effect\": \"Allow\",\"Principal\": {\"Service\": \"ecs-tasks.amazonaws.com
\"},\"Action\": \"sts:AssumeRole\"}]}"
```

After you enter the previous command, note the value of `Arn` from the command output as "ExecutionRoleArn". You'll need to use it later when you create the task definition. Then enter the following commands to attach the necessary policies.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
CloudWatchAgentServerPolicy \
    --role-name CWAgentECSExecutionRole

aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/service-role/
AmazonECSTaskExecutionRolePolicy \
    --role-name CWAgentECSExecutionRole
```

Create the task definition and launch the daemon service

Create a task definition and use it to launch the CloudWatch agent as a daemon service. To create the task definition, enter the following command. In the first lines, replace the placeholders with the actual values for your deployment. *`logs-region`* is the Region where CloudWatch Logs is located, and *`cluster-region`* is the Region where your cluster is located. *`task-role-arn`* is the Arn of the ECS task role that you are using, and *`execution-role-arn`* is the Arn of the ECS task execution role.

```
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
AWSLogsRegion=logs-region
Region=cluster-region
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-
ecs-instance-metric/cwagent-ecs-instance-metric.json \
    | sed "s|{{task-role-arn}}|${TaskRoleArn}|;s|{{execution-role-arn}}|
${ExecutionRoleArn}|;s|{{awslogs-region}}|${AWSLogsRegion}|" \
    | xargs -0 aws ecs register-task-definition --region ${Region} --cli-input-json
```

Then run the following command to launch the daemon service. Replace *`cluster-name`* and *`cluster-region`* with the name and Region of your Amazon ECS cluster.

> **Important**
>
> Remove all capacity provider strategies before you run this command. Otherwise, the command won't work.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs create-service \
    --cluster ${ClusterName} \
    --service-name cwagent-daemon-service \
    --task-definition ecs-cwagent-daemon-service \
    --scheduling-strategy DAEMON \
    --region ${Region}
```

If you see this error message, `An error occurred (InvalidParameterException) when calling the CreateService operation: Creation of service was not idempotent`, you have already created a daemon service named `cwagent-daemon-service`. You must delete that service first, using the following command as an example.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs delete-service \
    --cluster ${ClusterName} \
    --service cwagent-daemon-service \
    --region ${Region} \
    --force
```

(Optional) Advanced configuration

Optionally, you can use SSM to specify other configuration options for the CloudWatch agent in your Amazon ECS clusters that are hosted on EC2 instances. These options are as follows:

- `metrics_collection_interval` – How often in seconds that the CloudWatch agent collects metrics. The default is 60. The range is 1–172,000.
- `endpoint_override` – (Optional) Specifies a different endpoint to send logs to. You might want to do this if you're publishing from a cluster in a VPC and you want the logs data to go to a VPC endpoint.

  The value of `endpoint_override` must be a string that is a URL.

- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5 seconds.
- `region` – By default, the agent publishes metrics to the same Region where the Amazon ECS container instance is located. To override this, you can specify a different Region here. For example, `"region" : "us-east-1"`

The following is an example of a customized configuration:

```
{
    "agent": {
        "region": "us-east-1"
    },
    "logs": {
        "metrics_collected": {
            "ecs": {
                "metrics_collection_interval": 30
            }
        },
        "force_flush_interval": 5
    }
}
```

To customize your CloudWatch agent configuration in your Amazon ECS containers

1. Make sure that the **AmazonSSMReadOnlyAccess** policy is attached to your Amazon ECS Task Execution role. You can enter the following command to do so. This example assumes that your Amazon ECS Task Execution role is CWAgentECSExecutionRole. If you are using a different role, substitute that role name in the following command.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
AmazonSSMReadOnlyAccess \
        --role-name CWAgentECSExecutionRole
```

2. Create the customized configuration file similar to the preceding example. Name this file `/tmp/ecs-cwagent-daemon-config.json`.

3. Run the following command to put this configuration into the Parameter Store. Replace *cluster-region* with the Region of your Amazon ECS cluster. To run this command, you must be logged on to a user or role that has the **AmazonSSMFullAccess** policy.

```
Region=cluster-region
aws ssm put-parameter \
    --name "ecs-cwagent-daemon-service" \
    --type "String" \
    --value "`cat /tmp/ecs-cwagent-daemon-config.json`" \
    --region $Region
```

4. Download the task definition file to a local file, such as `/tmp/cwagent-ecs-instance-metric.json`

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/daemon-service/cwagent-ecs-instance-metric/cwagent-ecs-instance-metric.json -o /tmp/cwagent-ecs-instance-metric.json
```

5. Modify the task definition file. Remove the following section:

```
"environment": [
                {
                    "name": "USE_DEFAULT_CONFIG",
                    "value": "True"
                }
            ],
```

Replace that section with the following:

```
"secrets": [
                {
                    "name": "CW_CONFIG_CONTENT",
                    "valueFrom": "ecs-cwagent-daemon-service"
                }
            ],
```

6. Restart the agent as a daemon service by following these steps:

    a. Run the following command.

```
TaskRoleArn=task-role-arn
ExecutionRoleArn=execution-role-arn
AWSLogsRegion=logs-region
Region=cluster-region
cat /tmp/cwagent-ecs-instance-metric.json \
    | sed "s|{{task-role-arn}}|${TaskRoleArn}|;s|{{execution-role-arn}}|
${ExecutionRoleArn}|;s|{{awslogs-region}}|${AWSLogsRegion}|" \
    | xargs -0 aws ecs register-task-definition --region ${Region} --cli-input-
json
```

b. Run the following command to launch the daemon service. Replace *`cluster-name`* and *`cluster-region`* with the name and Region of your Amazon ECS cluster.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs create-service \
    --cluster ${ClusterName} \
    --service-name cwagent-daemon-service \
    --task-definition ecs-cwagent-daemon-service \
    --scheduling-strategy DAEMON \
    --region ${Region}
```

If you see this error message, `An error occurred (InvalidParameterException) when calling the CreateService operation: Creation of service was not idempotent`, you have already created a daemon service named `cwagent-daemon-service`. You must delete that service first, using the following command as an example.

```
ClusterName=cluster-name
Region=Region
aws ecs delete-service \
    --cluster ${ClusterName} \
    --service cwagent-daemon-service \
    --region ${Region} \
    --force
```

Deploying the Amazon Distro for OpenTelemetry to collect EC2 instance-level metrics on Amazon ECS clusters

Use the steps in this section to use Amazon Distro for OpenTelemetry to collect EC2 instance-level metrics on an Amazon ECS cluster. For more information about the Amazon Distro for OpenTelemetry, see Amazon Distro for OpenTelemetry.

These steps assume that you already have a cluster running Amazon ECS. This cluster must be deployed with the EC2 launch type. For more information about using Amazon Distro for Open Telemetry with Amazon ECS and setting up an Amazon ECS cluster for this purpose, see Setting up Amazon Distro for OpenTelemetry Collector in Amazon Elastic Container Service for ECS EC2 instance level metrics.

Topics

Quick setup using Amazon CloudFormation

Download the Amazon CloudFormation template file for installing the Amazon Distro for OpenTelemetry collector for Amazon ECS on EC2. Run the following curl command.

```
curl -O https://raw.githubusercontent.com/aws-observability/aws-otel-collector/main/
deployment-template/ecs/aws-otel-ec2-instance-metrics-daemon-deployment-cfn.yaml
```

After you download the template file, open it and replace *PATH_TO_CloudFormation_TEMPLATE* with the path where you saved the template file. Then export the following parameters and run the Amazon CloudFormation command, as shown in the following command.

- **Cluster_Name**– The Amazon ECS cluster name
- **AWS_Region**– The Region where the data will be sent
- **PATH_TO_CloudFormation_TEMPLATE**– The path where you saved the Amazon CloudFormation template file.
- **command**– To enable the Amazon Distro for OpenTelemetry collector to collect the instance-level metrics for Amazon ECS on Amazon EC2, you must specify `--config=/etc/ecs/otel-instance-metrics-config.yaml` for this parameter.

```
ClusterName=Cluster_Name
Region=AWS_Region
command=--config=/etc/ecs/otel-instance-metrics-config.yaml
aws cloudformation create-stack --stack-name AOCECS-${ClusterName}-${Region} \
--template-body file://PATH_TO_CloudFormation_TEMPLATE \
--parameters ParameterKey=ClusterName,ParameterValue=${ClusterName} \
ParameterKey=CreateIAMRoles,ParameterValue=True \
ParameterKey=command,ParameterValue=${command} \
--capabilities CAPABILITY_NAMED_IAM \
--region ${Region}
```

After running this command, use the Amazon ECS console to see if the task is running.

Troubleshooting the quick setup

To check the status of the Amazon CloudFormation stack, enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack --stack-name AOCECS-$ClusterName-$Region --region
 $Region
```

If the value of `StackStatus` is anything other than `CREATE_COMPLETE` or `CREATE_IN_PROGRESS`, check the stack events to find the error. Enter the following command.

```
ClusterName=cluster-name
Region=cluster-region
aws cloudformation describe-stack-events --stack-name AOCECS-$ClusterName-$Region --
region $Region
```

To check the status of the `AOCECS` daemon service, enter the following command. In the output, you should see that `runningCount` is equal to the `desiredCount` in the deployment section. If it isn't equal, check the failures section in the output.

```
ClusterName=cluster-name
Region=cluster-region
aws ecs describe-services --services AOCECS-daemon-service --cluster $ClusterName --
region $Region
```

You can also use the CloudWatch Logs console to check the agent log. Look for the **/aws/ecs/containerinsights/{ClusterName}/performance** log group.

Manual and custom setup

Follow the steps in this section to manually deploy the Amazon Distro for OpenTelemetry to collect instance-level metrics from your Amazon ECS clusters that are hosted on Amazon EC2 instances.

Step 1: Necessary roles and policies

Two IAM roles are required. You must create them if they don't already exist. For more information about these roles, see Create IAM policy and Create IAM role.

Step 2: Create the task definition

Create a task definition and use it to launch the Amazon Distro for OpenTelemetry as a daemon service.

To use the task definition template to create the task definition, follow the instructions in Create ECS EC2 Task Definition for EC2 instance with Amazon OTel Collector.

To use the Amazon ECS console to create the task definition, follow the instructions in Install Amazon OTel Collector by creating Task Definition through Amazon console for Amazon ECS EC2 instance metrics.

Step 3: Launch the daemon service

To launch the Amazon Distro for OpenTelemetry as a daemon service, follow the instructions in Run your task on the Amazon Elastic Container Service (Amazon ECS) using daemon service.

(Optional) Advanced configuration

Optionally, you can use SSM to specify other configuration options for the Amazon Distro for OpenTelemetry in your Amazon ECS clusters that are hosted on Amazon EC2 instances. For more information, about creating a configuration file, see Custom OpenTelemetry Configuration. For more information about the options that you can use in the configuration file, see Amazon Container Insights Receiver.

Set up FireLens to send logs to CloudWatch Logs

FireLens for Amazon ECS enables you to use task definition parameters to route logs to Amazon CloudWatch Logs for log storage and analytics. FireLens works with Fluent Bit and Fluentd. We provide an Amazon for Fluent Bit image, or you can use your own Fluent Bit or Fluentd image.

Creating Amazon ECS task definitions with a FireLens configuration is supported using the Amazon SDKs, Amazon CLI, and Amazon Web Services Management Console. For more information about CloudWatch Logs, see What is CloudWatch Logs?.

There are key considerations when using FireLens for Amazon ECS. For more information, see Considerations.

To find the Amazon for Fluent Bit images, see Using the Amazon for Fluent Bit image.

To create a task definition that uses a FireLens configuration, see Creating a task definition that uses a FireLens configuration.

Example

The following task definition example demonstrates how to specify a log configuration that forwards logs to a CloudWatch Logs log group. For more information, see What Is Amazon CloudWatch Logs? in the *Amazon CloudWatch Logs User Guide*.

In the log configuration options, specify the log group name and the Region it exists in. To have Fluent Bit create the log group on your behalf, specify `"auto_create_group":"true"`. You can also specify the task ID as the log stream prefix, which assists in filtering. For more information, see Fluent Bit Plugin for CloudWatch Logs.

```
{
 "family": "firelens-example-cloudwatch",
 "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
 "containerDefinitions": [
  {
   "essential": true,
   "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:latest",
   "name": "log_router",
   "firelensConfiguration": {
    "type": "fluentbit"
   },
   "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
     "awslogs-group": "firelens-container",
     "awslogs-region": "us-west-2",
     "awslogs-create-group": "true",
     "awslogs-stream-prefix": "firelens"
    }
```

```
    },
    "memoryReservation": 50
    },
    {
     "essential": true,
     "image": "nginx",
     "name": "app",
     "logConfiguration": {
      "logDriver":"awsfirelens",
      "options": {
      "Name": "cloudwatch_logs",
      "region": "us-west-2",

cluster/application",
      "auto_create_group": "true",
      "log_stream_name": "my-task-id"
     }
    },
    "memoryReservation": 100
   }
  ]
}
```

Setting up Container Insights on Amazon EKS and Kubernetes

Container Insights is supported on Amazon EKS versions 1.23 and later. The quick start method of installation is supported only on versions 1.24 and later.

The overall process for setting up Container Insights on Amazon EKS or Kubernetes is as follows:

1. Verify that you have the necessary prerequisites.
2. Set up the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent, or Amazon Distro for OpenTelemetry on your cluster to send metrics to CloudWatch.

> **Note**
>
> To use Container Insights with enhanced observability for Amazon EKS, you must use the Amazon CloudWatch Observability EKS add-on or the CloudWatch agent. For more information about this version of Container Insights, see Container Insights with enhanced observability for Amazon EKS.

To use Container Insights with Fargate, you must use Amazon Distro for OpenTelemetry. Container Insights with enhanced observability for Amazon EKS is not supported on Fargate.

Note

Container Insights now supports Windows worker nodes in an Amazon EKS cluster. Container Insights with enhanced observability for Amazon EKS is also supported on Windows. For information about enabling Container Insights on Windows, see Using the CloudWatch agent with Container Insights enhanced observability enabled.

Set up Fluent Bit or Fluentd to send logs to CloudWatch Logs. (This is enabled by default if you install the Amazon CloudWatch Observability EKS add-on.)

You can perform these steps at once as part of the quick start setup if you are using the CloudWatch agent, or do them separately.

3. (Optional) Set up Amazon EKS control plane logging.
4. (Optional) Set up the CloudWatch agent as a StatsD endpoint on the cluster to send StatsD metrics to CloudWatch.
5. (Optional) Enable App Mesh Envoy Access Logs.

With the original version of Container Insights, metrics collected and logs ingested are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics and logs are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Topics

Verifying prerequisites for Container Insights in CloudWatch

Before you install Container Insights on Amazon EKS or Kubernetes, verify the following. These prerequisites apply whether you are using the CloudWatch agent or Amazon Distro for OpenTelemetry to set up Container Insights on Amazon EKS clusters.

- You have a functional Amazon EKS or Kubernetes cluster with nodes attached in one of the Regions that supports the Container Insights for Amazon EKS and Kubernetes. For the list of supported Regions, see Container Insights.
- You have `kubectl` installed and running. For more information, see Installing `kubectl` in the *Amazon EKS User Guide*.
- If you're using Kubernetes running on Amazon instead of using Amazon EKS, the following prerequisites are also necessary:
  - Be sure that your Kubernetes cluster has enabled role-based access control (RBAC). For more information, see Using RBAC Authorization in the Kubernetes Reference.
  - Your kubelet has enabled Webhook authorization mode. For more information, see Kubelet authentication/authorization in the Kubernetes Reference.

You must also grant IAM permissions to enable your Amazon EKS worker nodes to send metrics and logs to CloudWatch. There are two ways to do this:

- Attach a policy to the IAM role of your worker nodes. This works for both Amazon EKS clusters and other Kubernetes clusters.
- Use an IAM role for service accounts for the cluster, and attach the policy to this role. This works only for Amazon EKS clusters.

The first option grants permissions to CloudWatch for the entire node, while using an IAM role for the service account gives CloudWatch access to only the appropriate daemonset pods.

Attaching a policy to the IAM role of your worker nodes

Follow these steps to attach the policy to the IAM role of your worker nodes. This works for both Amazon EKS clusters and Kubernetes clusters outside of Amazon EKS.

To attach the necessary policy to the IAM role for your worker nodes

1. Open the Amazon EC2 console at https://console.amazonaws.cn/ec2/.

2. Select one of the worker node instances and choose the IAM role in the description.
3. On the IAM role page, choose **Attach policies**.
4. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find this policy.
5. Choose **Attach policies**.

If you're running a Kubernetes cluster outside Amazon EKS, you might not already have an IAM role attached to your worker nodes. If not, you must first attach an IAM role to the instance and then add the policy as explained in the previous steps. For more information on attaching a role to an instance, see Attaching an IAM Role to an Instance in the *Amazon EC2 User Guide*.

If you're running a Kubernetes cluster outside Amazon EKS and you want to collect EBS volume IDs in the metrics, you must add another policy to the IAM role attached to the instance. Add the following as an inline policy. For more information, see Adding and Removing IAM Identity Permissions in the *IAM User Guide*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ec2:DescribeVolumes"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

Using an IAM service account role

This method works only on Amazon EKS clusters.

To grant permission to CloudWatch using an IAM service account role

1. If you haven't already, enable IAM roles for service accounts on your cluster. For more information, see Enabling IAM roles for service accounts on your cluster .

2. If you haven't already, configure the service account to use an IAM role. For more information, see Configuring a Kubernetes service account to assume an IAM role.

   When you create the role, attach the **CloudWatchAgentServerPolicy** IAM policy to the role in addition to the policy that you create for the role. Also, the associated Kubernetes Service Account that is linked to this role should be created in the `amazon-cloudwatch` namespace, where the CloudWatch and Fluent Bit daemonsets will be deployed in the upcoming steps
3. If you haven't already, associate the IAM role with a service account in your cluster. For more information, see Configuring a Kubernetes service account to assume an IAM role.

Using the CloudWatch agent with Container Insights enhanced observability enabled

Use the instructions in one of the following sections to set up Container Insights on an Amazon EKS cluster or Kubernetes cluster by using the CloudWatch agent. The quick start instructions are supported only on Amazon EKS versions 1.24 and later.

> **Note**
>
> You can install Container Insights by following the instructions in any one of the following sections. You don't need to follow all three sets of instructions.

Topics

- Quick start with the Amazon CloudWatch Observability EKS add-on
- Quick Start setup for Container Insights on Amazon EKS and Kubernetes
- Setting up the CloudWatch agent to collect cluster metrics

Quick start with the Amazon CloudWatch Observability EKS add-on

You can use the Amazon EKS add-on to install Container Insights with enhanced observability for Amazon EKS. The add-on installs the CloudWatch agent to send infrastructure metrics from the cluster, installs Fluent Bit to send container logs, and also enables CloudWatch Application Signals to send application performance telemetry.

When you use the Amazon EKS add-on version 1.5.0 or later, Container Insights is enabled on both Linux and Windows worker nodes in the cluster. Currently, Application Signals is not supported on Windows in Amazon EKS.

The Amazon EKS add-on is not supported for clusters running Kubernetes instead of Amazon EKS.

For more information about the Amazon CloudWatch Observability EKS add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

If you use version 3.1.0 or later of the add-on, you can use EKS Pod Identity to grant the required permissions to the add-on. EKS Pod Identity is the recommended option and provides benefits such as least privilege, credential rotation, and auditability. Additionally, using EKS Pod Identity allows you to install the EKS add-on as part of the cluster creation itself.

To install the Amazon CloudWatch Observability EKS add-on

1. Follow the EKS Pod Identity association steps to create the IAM role and set up the EKS Pod Identity agent.
2. Attach an IAM policy that grants the required permissions to your role. Replace *my-role* with the name of your IAM role from the previous step.

```
aws iam attach-role-policy \
 --role-name my-role \
--policy-arn=arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

3. Enter the following command, using with the IAM role you created in the previous step:

```
aws eks create-addon \
--addon-name amazon-cloudwatch-observability \
--cluster-name my-cluster-name \
--pod-identity-associations serviceAccount=cloudwatch-
agent,roleArn=arn:aws:iam::111122223333:role/my-role
```

Quick Start setup for Container Insights on Amazon EKS and Kubernetes

> **Important**
>
> If you are installing Container Insights on an Amazon EKS cluster, we recommend that you use the Amazon CloudWatch Observability EKS add-on for the installation, instead of using the instructions in this section. Additionally, to retrieve accelerated computing networks, you must use the Amazon CloudWatch Observability EKS add-on. For more information and instructions, see Quick start with the Amazon CloudWatch Observability EKS add-on.

To complete the setup of Container Insights, you can follow the quick start instructions in this section. If you are installing in an Amazon EKS cluster and you use the instructions in this section on or after November 6, 2023, you install Container Insights with enhanced observability for Amazon EKS in the cluster.

> **Important**
>
> Before completing the steps in this section, you must have verified the prerequisites including IAM permissions. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

Alternatively, you can instead follow the instructions in the following two sections, Setting up the CloudWatch agent to collect cluster metrics and Send logs to CloudWatch Logs. Those sections provide more configuration details on how the CloudWatch agent works with Amazon EKS and Kubernetes, but require you to perform more installation steps.

With the original version of Container Insights, metrics collected and logs ingested are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics and logs are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

> **Note**
>
> Amazon has now launched Fluent Bit as the default log solution for Container Insights with significant performance gains. We recommend that you use Fluent Bit instead of Fluentd.

Quick Start with the CloudWatch agent operator and Fluent Bit

There are two configurations for Fluent Bit: an optimized version and a version that provides an experience more similar to Fluentd. The Quick Start configuration uses the optimized version. For more details about the Fluentd-compatible configuration, see Set up Fluent Bit as a DaemonSet to send logs to CloudWatch Logs.

The CloudWatch agent operator is an additional container that gets installed to an Amazon EKS cluster. It is modeled after the OpenTelemetry Operator for Kubernetes. The operator manages the lifecycle of Kubernetes resources in a cluster. It installs the CloudWatch Agent, DCGM Exporter

(NVIDIA), and the Amazon Neuron Monitor on an Amazon EKS cluster and manages them. Fluent Bit and the CloudWatch Agent for Windows are installed directly to an Amazon EKS cluster without the operator managing them.

For a more secure and feature-rich certificate authority solution, the CloudWatch agent operator requires cert-manager, a widely-adopted solution for TLS certificate management in Kubernetes. Using cert-manager simplifies the process of obtaining, renewing, managing and using these certificates. It ensures that certificates are valid and up to date, and attempts to renew certificates at a configured time before expiry. cert-manager also facilitates issuing certificates from a variety of supported sources, including Amazon Certificate Manager Private Certificate Authority.

To deploy Container Insights using the quick start

1. Install cert-manager if it is not already installed in the cluster. For more information, see [cert-manager Installation](https://cert-manager.io/docs/installation/).
2. Install the custom resource definitions (CRD) by entering the following commmand.

   ```
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/main/k8s-quickstart/cwagent-custom-resource-definitions.yaml | kubectl
    apply --server-side -f -
   ```

3. Install the operator by entering the following command. Replace *my-cluster-name* with the name of your Amazon EKS or Kubernetes cluster, and replace *my-cluster-region* with the name of the Region where the logs are published. We recommend that you use the same Region where your cluster is deployed to reduce the Amazon outbound data transfer costs.

   ```
   ClusterName=my-cluster-name
   RegionName=my-cluster-region
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/main/k8s-quickstart/cwagent-operator-rendered.yaml | sed 's/{{cluster_name}}/'${ClusterName}'/g;s/{{region_name}}/'${RegionName}'/g' | kubectl
    apply -f -
   ```

   For example, to deploy Container Insights on the cluster named `MyCluster` and publish the logs and metrics to US West (Oregon), enter the following command.

   ```
   ClusterName='MyCluster'
   RegionName='us-west-2'
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/main/k8s-quickstart/cwagent-operator-rendered.yaml | sed 's/
   ```

```
{{cluster_name}}/'${ClusterName}'/g;s/{{region_name}}/'${RegionName}'/g' | kubectl
 apply -f -
```

Migrating from Container Insights

If you already have Container Insights configured in an Amazon EKS cluster and you want to migrate to Container Insights with enhanced observability for Amazon EKS, see [Upgrading to Container Insights with enhanced observability for Amazon EKS in CloudWatch](#)

Deleting Container Insights

If you want to remove Container Insights after using the quick start setup, enter the following commands.

```
ClusterName=my-cluster-name
RegionName=my-cluster-region
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/main/k8s-quickstart/cwagent-operator-rendered.yaml | sed 's/
{{cluster_name}}/'${ClusterName}'/g;s/{{region_name}}/'${RegionName}'/g' | kubectl
 delete -f -
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/main/k8s-quickstart/cwagent-custom-resource-definitions.yaml | kubectl delete
 -f -
```

Setting up the CloudWatch agent to collect cluster metrics

> **Important**
>
> If you are installing Container Insights on on Amazon EKS cluster, we recommend that you use the Amazon CloudWatch Observability EKS add-on for the installation, instead of using the instructions in this section. For more information and instructions, see [Quick start with the Amazon CloudWatch Observability EKS add-on](#).

To set up Container Insights to collect metrics, you can follow the steps in [Quick Start setup for Container Insights on Amazon EKS and Kubernetes](#) or you can follow the steps in this section. In the following steps, you set up the CloudWatch agent to be able to collect metrics from your clusters.

If you are installing in an Amazon EKS cluster and you use the instructions in this section on or after November 6, 2023, you install Container Insights with enhanced observability for Amazon EKS in the cluster.

Step 1: Create a namespace for CloudWatch

Use the following step to create a Kubernetes namespace called `amazon-cloudwatch` for CloudWatch. You can skip this step if you have already created this namespace.

To create a namespace for CloudWatch

- Enter the following command.

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/cloudwatch-namespace.yaml
```

Step 2: Create a service account in the cluster

Use one of the following methods to create a service account for the CloudWatch agent, if you do not already have one.

- Use `kubectl`
- Use a `kubeconfig` file

Use `kubectl` for authentication

To use `kubectl` to create a service account for the CloudWatch agent

- Enter the following command.

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/cwagent/cwagent-serviceaccount.yaml
```

If you didn't follow the previous steps, but you already have a service account for the CloudWatch agent that you want to use, you must ensure that it has the following rules. Additionally, in the rest of the steps in the Container Insights installation, you must use the name of that service account instead of `cloudwatch-agent`.

```
rules:
  - apiGroups: [""]
    resources: ["pods", "nodes", "endpoints"]
    verbs: ["list", "watch"]
  - apiGroups: [ "" ]
    resources: [ "services" ]
    verbs: [ "list", "watch" ]
  - apiGroups: ["apps"]
    resources: ["replicasets", "daemonsets", "deployments", "statefulsets"]
    verbs: ["list", "watch"]
  - apiGroups: ["batch"]
    resources: ["jobs"]
    verbs: ["list", "watch"]
  - apiGroups: [""]
    resources: ["nodes/proxy"]
    verbs: ["get"]
  - apiGroups: [""]
    resources: ["nodes/stats", "configmaps", "events"]
    verbs: ["create", "get"]
  - apiGroups: [""]
    resources: ["configmaps"]
    resourceNames: ["cwagent-clusterleader"]
    verbs: ["get","update"]
  - nonResourceURLs: ["/metrics"]
    verbs: ["get", "list", "watch"]
```

Use `kubeconfig` for authentication

Alternatively, you can use a `kubeconfig` file for authentication. This method allows you to bypass the need for a service account b directly specifying the `kubeconfig` path in your CloudWatch agent configuration. It also allows you to remove your dependency on the Kubernetes control plane API for authentication, streamlining your setup and potentially increasing security by managing authentication through your kubeconfig file.

To use this method, update your CloudWatch agent configuration file to specify the path to your `kubeconfig` file, as in the following example.

```
{
  "logs": {
```

```
    "metrics_collected": {
      "kubernetes": {
        "cluster_name": "YOUR_CLUSTER_NAME",
        "enhanced_container_insights": false,
        "accelerated_compute_metrics": false,
        "tag_service": false,
        "kube_config_path": "/path/to/your/kubeconfig"
        "host_ip": "HOSTIP"
      }
    }
  }
}
```

To create a `kubeconfig` file, create a Certificate Signing Request (CSR) for the `admin/{create_your_own_user}` user with the `system:masters` Kubernetes role. Then sign with Kubernetes cluster's Certificate Authority (CA) and create the `kubeconfig` file.

Step 3: Create a ConfigMap for the CloudWatch agent

Use the following steps to create a ConfigMap for the CloudWatch agent.

To create a ConfigMap for the CloudWatch agent

1. Download the ConfigMap YAML to your `kubectl` client host by running the following command:

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/cwagent/cwagent-configmap-enhanced.yaml
   ```

2. Edit the downloaded YAML file, as follows:

   - **cluster_name** – In the `kubernetes` section, replace `{{cluster_name}}` with the name of your cluster. Remove the `{{}}` characters. Alternatively, if you're using an Amazon EKS cluster, you can delete the `"cluster_name"` field and value. If you do, the CloudWatch agent detects the cluster name from the Amazon EC2 tags.

3. (Optional) Make further changes to the ConfigMap based on your monitoring requirements, as follows:

- **metrics_collection_interval** – In the `kubernetes` section, you can specify how often the agent collects metrics. The default is 60 seconds. The default cadvisor collection interval in kubelet is 15 seconds, so don't set this value to less than 15 seconds.
- **endpoint_override** – In the `logs` section, you can specify the CloudWatch Logs endpoint if you want to override the default endpoint. You might want to do this if you're publishing from a cluster in a VPC and you want the data to go to a VPC endpoint.
- **force_flush_interval** – In the `logs` section, you can specify the interval for batching log events before they are published to CloudWatch Logs. The default is 5 seconds.
- **region** – By default, the agent published metrics to the Region where the worker node is located. To override this, you can add a `region` field in the `agent` section: for example, `"region":"us-west-2"`.
- **statsd** section – If you want the CloudWatch Logs agent to also run as a StatsD listener in each worker node of your cluster, you can add a `statsd` section to the `metrics` section, as in the following example. For information about other StatsD options for this section, see [Retrieve custom metrics with StatsD](#).

```
"metrics": {
  "metrics_collected": {
    "statsd": {
      "service_address":":8125"
    }
  }
}
```

A full example of the JSON section is as follows. If you're using a `kubeconfig` file for authentication, add the `kube_config_path` parameter to specify the path to your kubeconfig file.

```
{
    "agent": {
        "region": "us-east-1"
    },
    "logs": {
        "metrics_collected": {
            "kubernetes": {
                "cluster_name": "MyCluster",
                "metrics_collection_interval": 60,
```

```
                "kube_config_path": "/path/to/your/kubeconfig" //if using
 kubeconfig for authentication
            }
        },
        "force_flush_interval": 5,
        "endpoint_override": "logs.us-east-1.amazonaws.com"
    },
    "metrics": {
        "metrics_collected": {
            "statsd": {
                "service_address": ":8125"
            }
        }
    }
}
```

4. Create the ConfigMap in the cluster by running the following command.

```
kubectl apply -f cwagent-configmap-enhanced.yaml
```

Step 4: Deploy the CloudWatch agent as a DaemonSet

To finish the installation of the CloudWatch agent and begin collecting container metrics, use the following steps.

To deploy the CloudWatch agent as a DaemonSet

1. • If you do not want to use StatsD on the cluster, enter the following command.

   ```
   kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-
   cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/
   deployment-mode/daemonset/container-insights-monitoring/cwagent/cwagent-
   daemonset.yaml
   ```

   • If you do want to use StatsD, follow these steps:

     a. Download the DaemonSet YAML to your `kubectl` client host by running the following command.

```
curl -O  https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/latest/k8s-deployment-manifest-templates/deployment-
mode/daemonset/container-insights-monitoring/cwagent/cwagent-daemonset.yaml
```

b. Uncomment the `port` section in the `cwagent-daemonset.yaml` file as in the following:

```
ports:
  - containerPort: 8125
    hostPort: 8125
    protocol: UDP
```

c. Deploy the CloudWatch agent in your cluster by running the following command.

```
kubectl apply -f cwagent-daemonset.yaml
```

d. Deploy the CloudWatch agent on Windows nodes in your cluster by running the following command. The StatsD listener is not supported on the CloudWatch agent on Windows.

```
kubectl apply -f cwagent-daemonset-windows.yaml
```

2. Validate that the agent is deployed by running the following command.

```
kubectl get pods -n amazon-cloudwatch
```

When complete, the CloudWatch agent creates a log group named `/aws/containerinsights/Cluster_Name/performance` and sends the performance log events to this log group. If you also set up the agent as a StatsD listener, the agent also listens for StatsD metrics on port 8125 with the IP address of the node where the application pod is scheduled.

Troubleshooting

If the agent doesn't deploy correctly, try the following:

- Run the following command to get the list of pods.

```
kubectl get pods -n amazon-cloudwatch
```

- Run the following command and check the events at the bottom of the output.

```
kubectl describe pod pod-name -n amazon-cloudwatch
```

- Run the following command to check the logs.

```
kubectl logs pod-name  -n amazon-cloudwatch
```

Using Amazon Distro for OpenTelemetry

You can set up Container Insights to collect metrics from Amazon EKS clusters by using the Amazon Distro for OpenTelemetry collector. For more information about the Amazon Distro for OpenTelemetry, see Amazon Distro for OpenTelemetry.

> **Important**
>
> If you install using Amazon Distro for OpenTelemetry, you install Container Insights but do not get Container Insights with enhanced observability for Amazon EKS. You will not collect the detailed metrics supported in Container Insights with enhanced observability for Amazon EKS.

How you set up Container Insights depends on whether the cluster is hosted on Amazon EC2 instances or on Amazon Fargate.

Amazon EKS clusters hosted on Amazon EC2

If you have not already done so, make sure that you have fulfilled the prerequisites including the necessary IAM roles. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

Amazon provides a Helm chart that you can use to set up the monitoring of Amazon Elastic Kubernetes Service on Amazon EC2. This monitoring uses the Amazon Distro for OpenTelemetry(ADOT) Collector for metrics and Fluent Bit for logs. Therefore, the Helm chart is useful for customers who use Amazon EKS on Amazon EC2 and want to collect metrics and logs to send to CloudWatch Container Insights. For more information about this Helm chart, see ADOT Helm chart for EKS on EC2 metrics and logs to Amazon CloudWatch Container Insights.

Alternatively, you can also use the instructions in the rest of this section.

First, deploy the Amazon Distro for OpenTelemetry collector as a DaemonSet by entering the following command.

```
curl https://raw.githubusercontent.com/aws-observability/aws-otel-collector/main/
deployment-template/eks/otel-container-insights-infra.yaml |
kubectl apply -f -
```

To confirm that the collector is running, enter the following command.

```
kubectl get pods -l name=aws-otel-eks-ci -n aws-otel-eks
```

If the output of this command includes multiple pods in the `Running` state, the collector is running and collecting metrics from the cluster. The collector creates a log group named `aws/containerinsights/`*`cluster-name`*`/performance` and sends the performance log events to it.

For information about how to see your Container Insights metrics in CloudWatch, see Viewing Container Insights metrics.

Amazon has also provided documentation on GitHub for this scenario. If you want to customize the metrics and logs published by Container Insights, see https://aws-otel.github.io/docs/getting-started/container-insights/eks-infra.

Amazon EKS clusters hosted on Fargate

For instructions for how to configure and deploy an ADOT Collector to collect system metrics from workloads deployed to an Amazon EKS cluster on Fargate and send them to CloudWatch Container Insights, see Container Insights EKS Fargate in the Amazon Distro for OpenTelemetry documentation.

Send logs to CloudWatch Logs

To send logs from your containers to Amazon CloudWatch Logs, you can use Fluent Bit. For more information, see Fluent Bit.

> **Note**
>
> As of February 10 2025, Amazon has deprecated support for FluentD as a log forwarder to CloudWatch Logs. We recommend that you use Fluent Bit, which is a lightweight and resource-efficient alternative. Existing FluentD deployments will continue to function.

Migrate your logging pipeline to Fluent Bit to ensure continued support and optimal performance.
Container Insights previously also supported using FluentD to send logs from your containers. FluentD has been deprecated and is now not supported for Container Insights. Use Fluent Bit instead.

Topics

- Set up Fluent Bit as a DaemonSet to send logs to CloudWatch Logs
- (Optional) Set up Amazon EKS control plane logging
- (Optional) Enable the Use_Kubelet feature for large clusters

Set up Fluent Bit as a DaemonSet to send logs to CloudWatch Logs

The following sections help you deploy Fluent Bit to send logs from containers to CloudWatch Logs.

Topics

- Setting up Fluent Bit
- Multi-line log support
- (Optional) Reducing the log volume from Fluent Bit
- Troubleshooting
- Dashboard

Setting up Fluent Bit

To set up Fluent Bit to collect logs from your containers, you can follow the steps in Quick Start setup for Container Insights on Amazon EKS and Kubernetes or you can follow the steps in this section.

With either method, the IAM role that is attached to the cluster nodes must have sufficient permissions. For more information about the permissions required to run an Amazon EKS cluster, see Amazon EKS IAM Policies, Roles, and Permissions in the *Amazon EKS User Guide*.

In the following steps, you set up Fluent Bit as a daemonSet to send logs to CloudWatch Logs. When you complete this step, Fluent Bit creates the following log groups if they don't already exist.

> **Important**
>
> If you already have FluentD configured in Container Insights and the FluentD DaemonSet is not running as expected (this can happen if you use the `containerd` runtime), you must uninstall it before installing Fluent Bit to prevent Fluent Bit from processing the FluentD error log messages. Otherwise, you must uninstall FluentD immediately after you have successfully installed Fluent Bit. Uninstalling Fluentd after installing Fluent Bit ensures continuity in logging during this migration process. Only one of Fluent Bit or FluentD is needed to send logs to CloudWatch Logs.

Log group name	Log source
`/aws/containerinsights/ Cluster_Name /application`	All log files in `/var/log/containers`
`/aws/containerinsights/ Cluster_Name /host`	Logs from `/var/log/dmesg` , `/var/log/secure` , and `/var/log/messages`
`/aws/containerinsights/ Cluster_Name /dataplane`	The logs in `/var/log/journal` for `kubelet.service` , `kubeproxy.service` , and `docker.service` .

To install Fluent Bit to send logs from containers to CloudWatch Logs

1. If you don't already have a namespace called `amazon-cloudwatch`, create one by entering the following command:

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/cloudwatch-namespace.yaml
```

2. Run the following command to create a ConfigMap named `cluster-info` with the cluster name and the Region to send logs to. Replace *`cluster-name`* and *`cluster-region`* with your cluster's name and Region.

```
ClusterName=cluster-name
RegionName=cluster-region
```

```
FluentBitHttpPort='2020'
FluentBitReadFromHead='Off'
[[ ${FluentBitReadFromHead} = 'On' ]] && FluentBitReadFromTail='Off'||
 FluentBitReadFromTail='On'
[[ -z ${FluentBitHttpPort} ]] && FluentBitHttpServer='Off' ||
 FluentBitHttpServer='On'
kubectl create configmap fluent-bit-cluster-info \
--from-literal=cluster.name=${ClusterName} \
--from-literal=http.server=${FluentBitHttpServer} \
--from-literal=http.port=${FluentBitHttpPort} \
--from-literal=read.head=${FluentBitReadFromHead} \
--from-literal=read.tail=${FluentBitReadFromTail} \
--from-literal=logs.region=${RegionName} -n amazon-cloudwatch
```

In this command, the `FluentBitHttpServer` for monitoring plugin metrics is on by default. To turn it off, change the third line in the command to `FluentBitHttpPort=''` (empty string) in the command.

Also by default, Fluent Bit reads log files from the tail, and will capture only new logs after it is deployed. If you want the opposite, set `FluentBitReadFromHead='On'` and it will collect all logs in the file system.

3. Download and deploy the Fluent Bit daemonset to the cluster by running one of the following commands.

   - If you want the Fluent Bit optimized configuration for Linux computers, run this command.

     ```
     kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-bit.yaml
     ```

   - If you want the Fluent Bit optimized configuration for Windows computers, run this command.

     ```
     kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-bit-windows.yaml
     ```

- If you are using Linux computers and want the Fluent Bit configuration that is more similar to Fluentd, run this command.

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/container-insights-monitoring/fluent-bit/fluent-bit-compatible.yaml
```

Important

The Fluent Bit daemonset configuration by default sets the log level to INFO, which can result in higher CloudWatch Logs ingestion costs. If you want to reduce log ingestion volume and costs, you can change the log level to ERROR.
For more information about how to reduce the log volume, see (Optional) Reducing the log volume from Fluent Bit

4. Validate the deployment by entering the following command. Each node should have one pod named **fluent-bit-***.

```
kubectl get pods -n amazon-cloudwatch
```

The above steps create the following resources in the cluster:

- A service account named `Fluent-Bit` in the `amazon-cloudwatch` namespace. This service account is used to run the Fluent Bit daemonSet. For more information, see Managing Service Accounts in the Kubernetes Reference.
- A cluster role named `Fluent-Bit-role` in the `amazon-cloudwatch` namespace. This cluster role grants `get`, `list`, and `watch` permissions on pod logs to the `Fluent-Bit` service account. For more information, see API Overview in the Kubernetes Reference.
- A ConfigMap named `Fluent-Bit-config` in the `amazon-cloudwatch` namespace. This ConfigMap contains the configuration to be used by Fluent Bit. For more information, see Configure a Pod to Use a ConfigMap in the Kubernetes Tasks documentation.

If you want to verify your Fluent Bit setup, follow these steps.

Verify the Fluent Bit setup

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Log groups**.
3. Make sure that you're in the Region where you deployed Fluent Bit.
4. Check the list of log groups in the Region. You should see the following:
   - `/aws/containerinsights/Cluster_Name/application`
   - `/aws/containerinsights/Cluster_Name/host`
   - `/aws/containerinsights/Cluster_Name/dataplane`
5. Navigate to one of these log groups and check the **Last Event Time** for the log streams. If it is recent relative to when you deployed Fluent Bit, the setup is verified.

   There might be a slight delay in creating the `/dataplane` log group. This is normal as these log groups only get created when Fluent Bit starts sending logs for that log group.

Multi-line log support

For information on how to use Fluent Bit with multi-line logs, see the following sections of the Fluent Bit documentation:

- Multiline Parsing
- Multiline and Containers (v1.8)
- Multiline Core (v1.8)
- Always use multiline in the tail input

(Optional) Reducing the log volume from Fluent Bit

By default, we send Fluent Bit application logs and Kubernetes metadata to CloudWatch. If you want to reduce the volume of data being sent to CloudWatch, you can stop one or both of these data sources from being sent to CloudWatch. If you have followed the steps on this page to set up Fluent Bit, download the Kubernetes manifest YAML file from the kubectl `apply` command that you previously ran and modify it with your changes, which you can then re-apply to your cluster. Alternatively, if you are using the Amazon CloudWatch Observability EKS add-on or Helm chart, see (Optional) Additional configuration for information about managing the Fluent Bit configuration by using the add-on’s advanced config or the Helm chart.

To stop Fluent Bit application logs, remove the following section from the `Fluent Bit configuration` file.

```
[INPUT]
        Name                tail
        Tag                 application.*
        Path                /var/log/containers/fluent-bit*
        Parser              docker
        DB                  /fluent-bit/state/flb_log.db
        Mem_Buf_Limit       5MB
        Skip_Long_Lines     On
        Refresh_Interval    10
```

To remove Kubernetes metadata from being appended to log events that are sent to CloudWatch, add the following filters to the `application-log.conf` section in the Fluent Bit configuration. Replace *`<Metadata_1>`* and the similar fields with with the actual metadata identifiers.

```
application-log.conf: |
    [FILTER]
        Name                nest
        Match               application.*
        Operation           lift
        Nested_under        kubernetes
        Add_prefix          Kube.

    [FILTER]
        Name                modify
        Match               application.*
        Remove              Kube.<Metadata_1>
        Remove              Kube.<Metadata_2>
        Remove              Kube.<Metadata_3>

    [FILTER]
        Name                nest
        Match               application.*
        Operation           nest
        Wildcard            Kube.*
        Nested_under        kubernetes
        Remove_prefix       Kube.
```

Troubleshooting

If you don't see these log groups and are looking in the correct Region, check the logs for the Fluent Bit daemonSet pods to look for the error.

Run the following command and make sure that the status is `Running`.

```
kubectl get pods -n amazon-cloudwatch
```

If the logs have errors related to IAM permissions, check the IAM role that is attached to the cluster nodes. For more information about the permissions required to run an Amazon EKS cluster, see Amazon EKS IAM Policies, Roles, and Permissions in the *Amazon EKS User Guide*.

If the pod status is `CreateContainerConfigError`, get the exact error by running the following command.

```
kubectl describe pod pod_name -n amazon-cloudwatch
```

Dashboard

You can create a dashboard to monitor metrics of each running plugin. You can see data for input and output bytes and for record processing rates as well as output errors and retry/failed rates. To view these metrics, you will need to install the CloudWatch agent with Prometheus metrics collection for Amazon EKS and Kubernetes clusters. For more information about how to set up the dashboard, see Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters.

> **Note**
>
> Before you can set up this dashboard, you must set up Container Insights for Prometheus metrics. For more information, see Container Insights Prometheus metrics monitoring.

To create a dashboard for the Fluent Bit Prometheus metrics

1. Create environment variables, replacing the values on the right in the following lines to match your deployment.

   ```
   DASHBOARD_NAME=your_cw_dashboard_name
   REGION_NAME=your_metric_region_such_as_us-west-1
   ```

```
CLUSTER_NAME=your_kubernetes_cluster_name
```

2. Create the dashboard by running the following command.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_cloudwatch_dashboards/fluent-bit/cw_dashboard_fluent_bit.json \
| sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
| xargs -0 aws cloudwatch put-dashboard --dashboard-name ${DASHBOARD_NAME} --
dashboard-body
```

(Optional) Set up Amazon EKS control plane logging

If you're using Amazon EKS, you can optionally enable Amazon EKS control plane logging, to provide audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs. For more information, see Amazon EKS Control Plane Logging.

(Optional) Enable the Use_Kubelet feature for large clusters

By default, the Use_Kubelet feature is disabled in the FluentBit Kubernetes plugin. Enabling this feature can reduce traffic to the API server and mitigate the issue of the API Server being a bottleneck. We recommend that you enable this feature for large clusters.

To enable Use_Kubelet, first add the nodes and nodes/proxy permissions to the clusterRole config.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: fluent-bit-role
rules:
  - nonResourceURLs:
      - /metrics
    verbs:
      - get
  - apiGroups: [""]
    resources:
      - namespaces
      - pods
      - pods/logs
      - nodes
      - nodes/proxy
```

```
    verbs: ["get", "list", "watch"]
```

In the DaemonSet configuration, this feature needs host network access. The image version for `amazon/aws-for-fluent-bit` should 2.12.0 or later, or the fluent bit image version should be 1.7.2 or later.

```
apiVersion: apps/v1
kind: DaemonSet
metadata:
  name: fluent-bit
  namespace: amazon-cloudwatch
  labels:
    k8s-app: fluent-bit
    version: v1
    kubernetes.io/cluster-service: "true"
spec:
  selector:
    matchLabels:
      k8s-app: fluent-bit
  template:
    metadata:
      labels:
        k8s-app: fluent-bit
        version: v1
        kubernetes.io/cluster-service: "true"
    spec:
      containers:
      - name: fluent-bit
        image: amazon/aws-for-fluent-bit:2.19.0
        imagePullPolicy: Always
        env:
            - name: AWS_REGION
              valueFrom:
                configMapKeyRef:
                  name: fluent-bit-cluster-info
                  key: logs.region
            - name: CLUSTER_NAME
              valueFrom:
                configMapKeyRef:
                  name: fluent-bit-cluster-info
                  key: cluster.name
            - name: HTTP_SERVER
              valueFrom:
```

```
              configMapKeyRef:
                name: fluent-bit-cluster-info
                key: http.server
          - name: HTTP_PORT
            valueFrom:
              configMapKeyRef:
                name: fluent-bit-cluster-info
                key: http.port
          - name: READ_FROM_HEAD
            valueFrom:
              configMapKeyRef:
                name: fluent-bit-cluster-info
                key: read.head
          - name: READ_FROM_TAIL
            valueFrom:
              configMapKeyRef:
                name: fluent-bit-cluster-info
                key: read.tail
          - name: HOST_NAME
            valueFrom:

                fieldPath: spec.nodeName
          - name: HOSTNAME
            valueFrom:
              fieldRef:
                apiVersion: v1
                fieldPath: metadata.name
          - name: CI_VERSION
            value: "k8s/1.3.8"
      resources:
          limits:
            memory: 200Mi
          requests:
            cpu: 500m
            memory: 100Mi
      volumeMounts:
      # Please don't change below read-only permissions
      - name: fluentbitstate
        mountPath: /var/fluent-bit/state
      - name: varlog
        mountPath: /var/log
        readOnly: true
      - name: varlibdockercontainers
        mountPath: /var/lib/docker/containers
```

```
            readOnly: true
          - name: fluent-bit-config
            mountPath: /fluent-bit/etc/
          - name: runlogjournal
            mountPath: /run/log/journal
            readOnly: true
          - name: dmesg
            mountPath: /var/log/dmesg
            readOnly: true
        terminationGracePeriodSeconds: 10
        hostNetwork: true
        dnsPolicy: ClusterFirstWithHostNet
        volumes:
        - name: fluentbitstate
          hostPath:
            path: /var/fluent-bit/state
        - name: varlog
          hostPath:
            path: /var/log
        - name: varlibdockercontainers
          hostPath:
            path: /var/lib/docker/containers
        - name: fluent-bit-config
          configMap:
            name: fluent-bit-config
        - name: runlogjournal
          hostPath:
            path: /run/log/journal
        - name: dmesg
          hostPath:
            path: /var/log/dmesg
        serviceAccountName: fluent-bit
        tolerations:
        - key: node-role.kubernetes.io/master
          operator: Exists
          effect: NoSchedule
        - operator: "Exists"
          effect: "NoExecute"
        - operator: "Exists"
          effect: "NoSchedule"
```

The Kubernetes Plugin configuration should be similar to the following:

```
[FILTER]
        Name                kubernetes
        Match               application.*
        Kube_URL            https://kubernetes.default.svc:443
        Kube_Tag_Prefix     application.var.log.containers.
        Merge_Log           On
        Merge_Log_Key       log_processed
        K8S-Logging.Parser  On
        K8S-Logging.Exclude Off
        Labels              Off
        Annotations         Off
        Use_Kubelet         On
        Kubelet_Port        10250
        Buffer_Size         0
```

Updating or deleting Container Insights on Amazon EKS and Kubernetes

Use the steps in these sections to update your CloudWatch agent container image, or to remove Container Insights from an Amazon EKS or Kubernetes cluster.

Topics

- Upgrading to Container Insights with enhanced observability for Amazon EKS in CloudWatch
- Updating the CloudWatch agent container image
- Deleting the CloudWatch agent and Fluent Bit for Container Insights

Upgrading to Container Insights with enhanced observability for Amazon EKS in CloudWatch

> **Important**
>
> If you are upgrading or installing Container Insights on an Amazon EKS cluster, we recommend that you use the Amazon CloudWatch Observability EKS add-on for the installation, instead of using the instructions in this section. Additionally, to retrieve accelerated computing metrics, you must use the Amazon CloudWatch Observability EKS add-on. For more information and instructions, see Quick start with the Amazon CloudWatch Observability EKS add-on.

Container Insights with enhanced observability for Amazon EKS is the newest version of Container Insights. It collects detailed metrics from clusters running Amazon EKS and offers curated, immediately usable dashboards to drill down into application and infrastructure telemetry. For more information about this version of Container Insights, see [Container Insights with enhanced observability for Amazon EKS](#).

If you have installed the original version of Container Insights in an Amazon EKS cluster and you want to upgrade it to the newer version with enhanced observability, follow the instructions in this section.

> **Important**
>
> Before completing the steps in this section, you must have verified the prerequisites including cert-manager. For more information, see [Quick Start with the CloudWatch agent operator and Fluent Bit](#).

To upgrade an Amazon EKS cluster to Container Insights with enhanced observability for Amazon EKS

1. Install the CloudWatch agent operator by entering the following command. Replace *my-cluster-name* with the name of your Amazon EKS or Kubernetes cluster, and replace *my-cluster-region* with the name of the Region where the logs are published. We recommend that you use the same Region where your cluster is deployed to reduce the Amazon outbound data transfer costs.

   ```
   ClusterName=my-cluster-name
   RegionName=my-cluster-region
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/main/k8s-quickstart/cwagent-operator-rendered.yaml | sed 's/{{cluster_name}}/'${ClusterName}'/g;s/{{region_name}}/'${RegionName}'/g' | kubectl apply -f -
   ```

   If you notice a failure caused by conflicting resources, it is likely because you already have the CloudWatch agent and Fluent Bit with its associated components such as the ServiceAccount, the ClusterRole and the ClusterRoleBinding installed on the cluster. When the CloudWatch agent operator tries to install the CloudWatch agent and its associated components, if it detects any change in the contents, it by default fails the installation or update to avoid overwriting the state of the resources on the cluster. We recommend that you delete any existing CloudWatch agent with Container Insights setup that you had previously installed on the cluster, and then install the CloudWatch agent operator.

2. (Optional) To apply an existing custom Fluent Bit configuration, you must update the configmap associated with the Fluent Bit daemonset. The CloudWatch agent operator provides a default configuration for Fluent Bit, and you can override or modify the default configuration as needed. To apply a custom configuration, follow these steps.

   a. Open the existing configuration by entering the following command.

   ```
   kubectl edit cm fluent-bit-config -n amazon-cloudwatch
   ```

   b. Make your changes in the file, then enter `:wq` to save the file and exit edit mode.

   c. Restart Fluent Bit by entering the following command.

   ```
   kubectl rollout restart ds fluent-bit -n amazon-cloudwatch
   ```

Updating the CloudWatch agent container image

> **Important**
>
> If you are upgrading or installing Container Insights on an Amazon EKS cluster, we recommend that you use the Amazon CloudWatch Observability EKS add-on for the installation, instead of using the instructions in this section. Additionally, to retrieve accelerated computing metrics, you must use the Amazon CloudWatch Observability EKS add-on or the CloudWatch agent operator. For more information and instructions, see [Quick start with the Amazon CloudWatch Observability EKS add-on](#).

If you need to update your container image to the latest version, use the steps in this section.

To update your container image

1. Verify if the `amazoncloudwatchagent` Customer Resource Definition (CRD) already exists by entering the following command.

   ```
   kubectl get crds amazoncloudwatchagents.cloudwatch.aws.amazon.com -n amazon-
   cloudwatch
   ```

   If this command returns an error that the CRD is missing, the cluster doesn't have Container Insights with enhanced observabilit for Amazon EKS configured with the CloudWatch agent operator. In this case, see Upgrading to Container Insights with enhanced observability for Amazon EKS in CloudWatch.

2. Apply the latest `cwagent-version.yaml` file by entering the following command.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/main/k8s-quickstart/cwagent-version.yaml | kubectl apply -f -
```

Deleting the CloudWatch agent and Fluent Bit for Container Insights

If you installed Container Insights by using installing the CloudWatch Observability add-on for Amazon EKS, you can delete Container Insights and the CloudWatch agent by entering the following command:

> **Note**
>
> The Amazon EKS add-on now supports Container Insights on Windows worker nodes. If you delete the Amazon EKS add-on, Container Insights for Windows is also deleted.

```
aws eks delete-addon —cluster-name my-cluster —addon-name amazon-cloudwatch-
observability
```

Otherwise, to delete all resources related to the CloudWatch agent and Fluent Bit, enter the following command. In this command, *My_Cluster_Name* is the name of your Amazon EKS or Kubernetes cluster, and *My_Region* is the name of the Region where the logs are published.

```
ClusterName=My_Cluster_Name
RegionName=My-Region
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/main/k8s-quickstart/cwagent-operator-rendered.yaml | sed 's/
{{cluster_name}}/'${ClusterName}'/g;s/{{region_name}}/'${RegionName}'/g' | kubectl
 delete -f -
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/main/k8s-quickstart/cwagent-custom-resource-definitions.yaml | kubectl delete
 -f -
```

Setting up Container Insights on RedHat OpenShift on Amazon (ROSA)

CloudWatch Container Insights with enhanced observability supports RedHat OpenShift on Amazon (ROSA). This version supports enhanced observability for ROSA clusters. After you install the CloudWatch agent operator Helm chart, Container Insights auto-collects detailed infrastructure telemetry from the cluster level down to the container level in your environment. It then displays this performance data in curated dashboards removing the heavy lifting in observability setup.

> **Note**
>
> For RedHat for OpenShift on Amazon (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default also enabled to receive both metrics and traces from your applications that are instrumented for Application Signals. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) [Additional configuration], as outlined in (Optional) Additional configuration.

To install Container Insights with enhanced observability on a RedHat OpenShift on Amazon (ROSA) cluster

1. If necessary, install Helm. For more information, see Quickstart Guide in the Helm documentation.
2. Install the CloudWatch agent operator by entering the following commands. Replace *my-cluster-name* with the name of your cluster, and replace *my-cluster-region* with the Region that the cluster runs in.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm repo update aws-observability
helm install --wait --create-namespace \
    --namespace amazon-cloudwatch amazon-cloudwatch-observability \
    aws-observability/amazon-cloudwatch-observability \
    --set clusterName=my-cluster-name \
    --set region=my-cluster-region \
    --set k8sMode=ROSA
```

3. Set up authorization for the agent operator by following the steps in Option 1, Option 2, or Option 3 in Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

Viewing Container Insights metrics

After you have Container Insights set up and it is collecting metrics, you can view those metrics in the CloudWatch console.

For Container Insights metrics to appear on your dashboard, you must complete the Container Insights setup. For more information, see Setting up Container Insights.

This procedure explains how to view the metrics that Container Insights automatically generates from the collected log data. The rest of this section explains how to further dive into your data and use CloudWatch Logs Insights to see more metrics at more levels of granularity.

To view Container Insights metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Insights**, **Container Insights**.
3. Use the drop-down boxes near the top to select the type of resource to view, as well as the specific resource.

You can set a CloudWatch alarm on any metric that Container Insights collects. For more information, see Using Amazon CloudWatch alarms

> **Note**
>
> If you have already set up CloudWatch Application Insights to monitor your containerized applications, the Application Insights dashboard appears below the Container Insights dashboard. If you have not already enabled Application Insights, you can do so by choosing **Auto-configure Application Insights** below the performance view in the Container Insights dashboard.
> For more information about Application Insights and containerized applications, see Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring.

Viewing the top contributors

For some of the views in Container Insights performance monitoring, you can also see the top contributors by memory or CPU, or the most recently active resources. This is available when you select any of the following dashboards in the drop-down box near the top of the page:

- ECS Services
- ECS Tasks
- EKS Namespaces
- EKS Services
- EKS Pods

When you are viewing one of these types of resources, the bottom of the page displays a table sorted initially by CPU usage. You can change it to sort by memory usage or recent activity. To see more about one of the rows in the table, you can select the checkbox next to that row and then choose **Actions** and choose one of the options in the **Actions** menu.

Using CloudWatch Logs Insights to view Container Insights data

Container Insights collects metrics by using performance log events with using embedded metric format. The logs are stored in CloudWatch Logs. CloudWatch generates several metrics automatically from the logs which you can view in the CloudWatch console. You can also do a deeper analysis of the performance data that is collected by using CloudWatch Logs Insights queries.

For more information about CloudWatch Logs Insights, see Analyze Log Data with CloudWatch Logs Insights. For more information about the log fields you can use in queries, see Container Insights performance log events for Amazon EKS and Kubernetes.

To use CloudWatch Logs Insights to query your container metric data

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Logs**, **Logs Insights**.

   Near the top of the screen is the query editor. When you first open CloudWatch Logs Insights, this box contains a default query that returns the 20 most recent log events.
3. In the box above the query editor, select one of the Container Insights log groups to query. For the following example queries to work, the log group name must end with **performance**.

   When you select a log group, CloudWatch Logs Insights automatically detects fields in the data in the log group and displays them in **Discovered fields** in the right pane. It also displays a bar graph of log events in this log group over time. This bar graph shows the distribution of events in the log group that matches your query and time range, not only the events displayed in the table.

4. In the query editor, replace the default query with the following query and choose **Run query**.

```
STATS avg(node_cpu_utilization) as avg_node_cpu_utilization by NodeName
| SORT avg_node_cpu_utilization DESC
```

This query shows a list of nodes, sorted by average node CPU utilization.

5. To try another example, replace that query with another query and choose **Run query**. More sample queries are listed later on this page.

```
STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by
 PodName
| SORT avg_number_of_container_restarts DESC
```

This query displays a list of your pods, sorted by average number of container restarts.

6. If you want to try another query, you can use include fields in the list at the right of the screen. For more information about query syntax, see CloudWatch Logs Insights Query Syntax.

To see lists of your resources

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Resources**.
3. The default view is a list of your resources being monitored by Container Insights, and alarms that you have set on these resources. To see a visual map of the resources, choose **Map view**.
4. From the map view, you can pause your pointer over any resource in the map to see basic metrics about that resource. You can choose any resource to see more detailed graphs about the resource.

Use case: Seeing task-level metrics in Amazon ECS containers

The following example illustrates how to use CloudWatch Logs Insights to dive deeper into your Container Insights logs. For more examples, see the blog Introducing Amazon CloudWatch Container Insights for Amazon ECS.

Container Insights does not automatically generate metrics at the Task level of granularity. The following query displays task-level metrics for CPU and memory usage.

```
stats avg(CpuUtilized) as CPU, avg(MemoryUtilized) as Mem by TaskId, ContainerName
```

```
| sort Mem, CPU desc
```

Other sample queries for Container Insights

List of your pods, sorted by average number of container restarts

```
STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by PodName
| SORT avg_number_of_container_restarts DESC
```

Pods requested vs. pods running

```
fields @timestamp, @message
| sort @timestamp desc
| filter Type="Pod"
| stats min(pod_number_of_containers) as requested,
 min(pod_number_of_running_containers) as running, ceil(avg(pod_number_of_containers-
pod_number_of_running_containers)) as pods_missing by kubernetes.pod_name
| sort pods_missing desc
```

Count of cluster node failures

```
stats avg(cluster_failed_node_count) as CountOfNodeFailures
| filter Type="Cluster"
| sort @timestamp desc
```

Application log errors by container name

```
stats count() as countoferrors by kubernetes.container_name
| filter stream="stderr"
| sort countoferrors desc
```

Metrics collected by Container Insights

Container Insights collects one set of metrics for Amazon ECS and Amazon Fargate on Amazon ECS, and a different set for Amazon EKS, Amazon Fargate on Amazon EKS, RedHat OpenShift on Amazon (ROSA), and Kubernetes.

Metrics are not visible until the container tasks have been running for some time.

Topics

- Amazon EKS and Kubernetes Container Insights metrics

Amazon ECS Container Insights with enhanced observability metrics

The following table lists the metrics and dimensions that Container Insights with enhanced observability collects for Amazon ECS. These metrics are in the `ECS/ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights with enhanced observability. Metrics do not appear before Container Insights with enhanced observability has been set up completely. For more information, see Set up Container Insights with enhanced observability.

The following metrics are available for all launch types.

Metric name	Dimensions	Description
`ContainerInstanceCount`	`ClusterName`	The number of EC2 instances running the Amazon ECS agent that are registered with a cluster. This metric is collected only for container instances that are running Amazon ECS tasks in the cluster. It is not collected for empty container instances that do not have any Amazon ECS tasks. Unit: Count

Metric name	Dimensions	Description

`ContainerCpuUtilized`	`ClusterName`
	
	`ContainerName` , `TaskId`, `ServiceName` , `ClusterName`
	
	`ContainerName` , `TaskDefinitionFamily` , `ClusterName` , `TaskId`
	
	`TaskDefinitionFamily` , `ClusterName` , `ContainerName`
	
	`ServiceName` , `ClusterName` , `ContainerName`
		The CPU units used by containers in the resource that is specified by the dimension set that you're using.
		
		Unit: None

`ContainerCpuReserved`	`ClusterName`
	
	`ContainerName` , `TaskId`, `ServiceName` , `ClusterName`
	
	`ContainerName` , `TaskDefinitionFamily` , `ClusterName` , `TaskId`
	
	`TaskDefinitionFamily` , `ClusterName` , `ContainerName`
	
	`ServiceName` , `ClusterName` , `ContainerName`
		The CPU units reserved by containers in the resource that is specified by the dimension set that you're using. This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used.
		
		Unit: None

Metric name	Dimensions	Description
ContainerCpuUtilization	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId	The total percentage of CPU units being used by containers in the resource that is specified by the dimension set that you're using. Unit: Percent
ContainerMemoryUtilized	ClusterName ContainerName , TaskId, ServiceName , ClusterName ContainerName , TaskDefinitionFamily , ClusterName , TaskId TaskDefinitionFamily , ClusterName , ContainerName ServiceName , ClusterName , ContainerName	The memory being used by containers in the resource that is specified by the dimension set that you're using. Unit: Megabytes

Metric name	Dimensions	Description

`ContainerMemoryReserved`	`ClusterName`
	
	`ContainerName` , `TaskId`, `ServiceName` , `ClusterName`
	
	`ContainerName` , `TaskDefinitionFamily` , `ClusterName` , `TaskId`
	
	`TaskDefinitionFamily` , `ClusterName` , `ContainerName`
	
	`ServiceName` , `ClusterName` , `ContainerName`
		The memory that is reserved by containers in the resource that is specified by the dimension set that you're using.
		
		This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used.
		
		Unit: Megabytes

Metric name	Dimensions	Description

`ContainerMemoryUtilization`	`ClusterName`
	
	`ContainerName` , `TaskId`, `ServiceName` , `ClusterName`
	
	`ContainerName` , `TaskDefinitionFamily` , `ClusterName` , `TaskId`
	
	`TaskDefinitionFamily` , `ClusterName` , `ContainerName`
	
	`ServiceName` , `ClusterName` , `ContainerName`
		The total percentage of memory being used by containers in the resource that is specified by the dimension set that you're using.
		
		Unit: Percent

`ContainerNetworkRxBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes received by the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		This metric is available only for containers in tasks using the `awsvpc` or `bridge` network modes.
		
		Unit: Bytes/Second

Metric name	Dimensions	Description

`ContainerNetworkTxBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes transmitted by the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		This metric is available only for containers in tasks using the `awsvpc` or `bridge` network modes.
		
		Unit: Bytes/Second

`ContainerStorageReadBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes read from storage on the container in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime.
		
		Unit: Bytes

Metric name	Dimensions	Description

`ContainerStorageWriteBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes written to storage in the container that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		Unit: Bytes

`CpuUtilized`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The CPU units used by tasks in the resource that is specified by the dimension set that you're using.
		
		Unit: None

Metric name	Dimensions	Description

`CpuReserved`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The CPU units reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used.
		
		Unit: None

`DeploymentCount`	`ServiceName` , `ClusterName`	The number of deployments in an Amazon ECS service. Unit: Count
`DesiredTaskCount`	`ServiceName` , `ClusterName`	The desired number of tasks for an Amazon ECS service. Unit: Count

Metric name	Dimensions	Description

`EBSFilesystemSize`	`ClusterName ,TaskDefinitionFamily , VolumeName`
	
	`TaskDefinitionFamily ,ClusterName`
	
	`ServiceName , ClusterName`
		The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is allocated to the resources specified by the dimensions you're using.
		
		This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version `1.4.0` or Amazon EC2 instances using container agent version `1.79.0` or later.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description

`EBSFilesystemUtilized`	`ClusterName` ,`TaskDefinitionFamily` , `VolumeName`
	
	`TaskDefinitionFamily` ,`ClusterName`
	
	`ServiceName` , `ClusterName`
		The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is being used by the resources specified by the dimensions that you're using.
		
		This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version `1.4.0` or Amazon EC2 instances using container agent version `1.79.0` or later.
		
		For tasks run on Fargate, Fargate reserves space on the disk that is only used by Fargate. There is no cost associated with the space Fargate uses, but you will see this additional storage using tools like `df`.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description

`EphemeralStorageReserved` [1]	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes reserved from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can’t be changed in a running task.
		
		This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description
MemoryUtilized	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The memory being used by tasks in the resource that is specified by the dimension set that you're using. Unit: Megabytes
MemoryReserved	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName ,TaskId ClusterName , TaskDefinitionFamily ,TaskId	The memory that is reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used. Unit: Megabytes

Metric name	Dimensions	Description

`NetworkRxBytes`	`TaskDefinitionFamily`, `ClusterName`
	
	`ServiceName`, `ClusterName`
	
	`ClusterName`
	
	`ClusterName`, `ServiceName`, `TaskId`
	
	`ClusterName`, `TaskDefinitionFamily`, `TaskId`
		The number of bytes received by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		This metric is available only for containers in tasks using the `awsvpc` or `bridge` network modes.
		
		Unit: Bytes/Second

`NetworkTxBytes`	`TaskDefinitionFamily`, `ClusterName`
	
	`ServiceName`, `ClusterName`
	
	`ClusterName`
	
	`ClusterName`, `ServiceName`, `TaskId`
	
	`ClusterName`, `TaskDefinitionFamily`, `TaskId`
		The number of bytes transmitted by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		This metric is available only for containers in tasks using the `awsvpc` or `bridge` network modes.
		
		Unit: Bytes/Second

Metric name	Dimensions	Description
PendingTaskCount	ServiceName , ClusterName	The number of tasks currently in the PENDING state. Unit: Count
RunningTaskCount	ServiceName , ClusterName	The number of tasks currently in the RUNNING state. Unit: Count
RestartCount	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId	The number of times a container in an Amazon ECS task has been restarted. This metric is collected only for containers that have a restart policy enabled. Unit: Count
ServiceCount	ClusterName	The number of services in the cluster. Unit: Count

Metric name	Dimensions	Description

`StorageReadBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes read from storage on the instance in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime.
		
		Unit: Bytes

`StorageWriteBytes`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `ServiceName` , `TaskId`
	
	`ClusterName` , `TaskDefinitionFamily` , `TaskId`
		The number of bytes written to storage in the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		Unit: Bytes

`TaskCount`	`ClusterName`	The number of tasks running in the cluster. Unit: Count

Metric name	Dimensions	Description
TaskCpuUtilization	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId	The total percentage of CPU units being used by a task. Unit: Percent
TaskEphemeralStorageUtilization	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId	The total percentage of ephemeral storage being used by a task. Unit: Percent

Metric name	Dimensions	Description
TaskMemoryUtilization	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName ClusterName , ServiceName , TaskId ClusterName , TaskDefinitionFamily , TaskId	The total percentage of memory being used by a task. Unit: Percent
TaskSetCount	ServiceName , ClusterName	The number of task sets in the service. Unit: Count

> **Note**
>
> The EphemeralStorageReserved and EphemeralStorageUtilized metrics are only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
> Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as df.

The following metrics are available when you complete the steps in Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS and use the EC2 launch type.

Metric name	Dimensions	Description
instance_cpu_limit	ClusterName	The maximum number of CPU

Metric name	Dimensions	Description
		units that can be assigned to a single EC2 instance in the cluster. Unit: None

`instance_cpu_reserved_capacity`	`ClusterName`
	
	`InstanceId` , `ContainerInstanceId` , `ClusterName`
		The percentage of CPU currently being reserved on a single EC2 instance in the cluster.
		
		Unit: Percent

`instance_cpu_usage_total`	`ClusterName`	The number of CPU units being used on a Single EC2 instance in the cluster. Unit: None

`instance_cpu_utilization`	`ClusterName`
	
	`InstanceId` , `ContainerInstanceId` , `ClusterName`
		The total percentage of CPU units being used on a single EC2 instance in the cluster.
		
		Unit: Percent

Metric name	Dimensions	Description
instance_filesystem_utilization	ClusterName InstanceId , ContainerInstanceId , ClusterName	The total percentage of file system capacity being used on a single EC2 instance in the cluster. Unit: Percent
instance_memory_limit	ClusterName	The maximum amount of memory, in bytes, that can be assigned to a single EC2 instance in this cluster. Unit: Bytes
instance_memory_reserved_capacity	ClusterName InstanceId , ContainerInstanceId , ClusterName	The percentage of Memory currently being reserved on a single EC2 instance in the cluster. Unit: Percent

Metric name	Dimensions	Description
instance_memory_utilization	ClusterName InstanceId , ContainerInstanceId , ClusterName	The total percentage of memory being used on a single EC2 instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Percent

Metric name	Dimensions	Description
instance_memory_working_set	ClusterName	The amount of memory, in bytes, being used on a single EC2 instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Bytes
instance_network_total_bytes	ClusterName	The total number of bytes per second transmitted and received over the network on a single EC2 instance in the cluster. Unit: Bytes/second
instance_number_of_running_tasks	ClusterName	The number of running tasks on a single EC2 instance in the cluster. Unit: Count

Amazon ECS Container Insights metrics

The following table lists the metrics and dimensions that Container Insights collects for Amazon ECS. These metrics are in the `ECS/ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Setting up Container Insights.

The following metrics are available when you complete the steps in Setting up Container Insights on Amazon ECS.

Metric name	Dimensions	Description
`ContainerInstanceCount`	`ClusterName`	The number of EC2 instances running the Amazon ECS agent that are registered with a cluster. This metric is collected only for container instances that are running Amazon ECS tasks in the cluster. It is not collected for empty container instances that do not have any Amazon ECS tasks. Unit: Count

`CpuUtilized`	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
		The CPU units used by tasks in the resource that is specified by the dimension set that you're using.

Metric name	Dimensions	Description
	ClusterName	Unit: None
CpuReserved	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The CPU units reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the CPU reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance CPU reservation is used. Unit: None
DeploymentCount	ServiceName , ClusterName	The number of deployments in an Amazon ECS service. Unit: Count
DesiredTaskCount	ServiceName , ClusterName	The desired number of tasks for an Amazon ECS service. Unit: Count

Metric name	Dimensions	Description

`EBSFilesystemSize`	`VolumeName` , `TaskDefinitionFamily` , `ClusterName`
	
	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
		The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is allocated to the resources specified by the dimensions you're using.
		
		This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version `1.4.0` or Amazon EC2 instances using container agent version `1.79.0` or later.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description

`EBSFilesystemUtilized`	`VolumeName` , `TaskDefinitionFamily` , `ClusterName`
	
	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
		The total amount, in gigabytes (GB), of Amazon EBS filesystem storage that is being used by the resources specified by the dimensions that you're using.
		
		This metric is only available for tasks that run on Amazon ECS infrastructure running on Fargate using platform version `1.4.0` or Amazon EC2 instances using container agent version `1.79.0` or later.
		
		For tasks run on Fargate, Fargate reserves space on the disk that is only used by Fargate. There is no cost associated with the space Fargate uses, but you will see this additional storage using tools like `df`.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description

`EphemeralStorageReserved` [1]	`TaskDefinitionFamily ,ClusterName`
	
	`ServiceName , ClusterName`
	
	`ClusterName`
		The number of bytes reserved from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task.
		
		This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description

`EphemeralStorageUtilized` [1]	`TaskDefinitionFamily` , `ClusterName`
	
	`ServiceName` , `ClusterName`
	
	`ClusterName`
		The number of bytes used from ephemeral storage in the resource that is specified by the dimensions that you're using. Ephemeral storage is used for the container root filesystem and any bind mount host volumes defined in the container image and task definition. The amount of ephemeral storage can't be changed in a running task.
		
		This metric is only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
		
		Unit: Gigabytes (GB)

Metric name	Dimensions	Description
MemoryUtilized	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The memory being used by tasks in the resource that is specified by the dimension set that you're using. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Megabytes

Metric name	Dimensions	Description
MemoryReserved	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The memory that is reserved by tasks in the resource that is specified by the dimension set that you're using. This metric is collected based on the memory reservation defined in the task definition, for example, at the task or all containers level. If this is not specified in the task definition, then the instance memory reservation is used. Unit: Megabytes
NetworkRxBytes	TaskDefinitionFamily ,ClusterName ServiceName , ClusterName ClusterName	The number of bytes received by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime. This metric is available only for containers in tasks using the awsvpc or bridge network modes. Unit: Bytes/Second

Metric name	Dimensions	Description

`NetworkTxBytes`	`TaskDefinitionFamily ,ClusterName`
	
	`ServiceName , ClusterName`
	
	`ClusterName`
		The number of bytes transmitted by the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		This metric is available only for containers in tasks using the `awsvpc` or `bridge` network modes.
		
		Unit: Bytes/Second

`PendingTaskCount`	`ServiceName , ClusterName`	The number of tasks currently in the `PENDING` state. Unit: Count
`RunningTaskCount`	`ServiceName , ClusterName`	The number of tasks currently in the `RUNNING` state. Unit: Count

Metric name	Dimensions	Description
RestartCount	ClusterName ClusterName , ServiceName ClusterName , TaskDefinitionFamily	The number of times a container in an Amazon ECS task has been restarted. This metric is collected only for containers that have a restart policy enabled. Unit: Count
ServiceCount	ClusterName	The number of services in the cluster. Unit: Count
StorageReadBytes	TaskDefinitionFamily , ClusterName ServiceName , ClusterName ClusterName	The number of bytes read from storage on the instance in the resource that is specified by the dimensions that you're using. This does not include read bytes for your storage devices. This metric is obtained from the Docker runtime. Unit: Bytes

Metric name	Dimensions	Description

`StorageWriteBytes`	`TaskDefinitionFamily , ClusterName`
	
	`ServiceName , ClusterName`
	
	`ClusterName`
		The number of bytes written to storage in the resource that is specified by the dimensions that you're using. This metric is obtained from the Docker runtime.
		
		Unit: Bytes

`TaskCount`	`ClusterName`	The number of tasks running in the cluster. Unit: Count
`TaskSetCount`	`ServiceName , ClusterName`	The number of task sets in the service. Unit: Count

> **Note**
>
> The `EphemeralStorageReserved` and `EphemeralStorageUtilized` metrics are only available for tasks that run on Fargate Linux platform version 1.4.0 or later.
> Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as `df`.

The following metrics are available when you complete the steps in [Deploying the CloudWatch agent to collect EC2 instance-level metrics on Amazon ECS](#)

Metric name	Dimensions	Description
`instance_cpu_limit`	`ClusterName`	The maximum number of CPU

Metric name	Dimensions	Description
		units that can be assigned to a single EC2 Instance in the cluster. Unit: None

`instance_cpu_reserved_capacity`	`ClusterName`
	
	`InstanceId` , `ContainerInstanceId` , `ClusterName`
		The percentage of CPU currently being reserved on a single EC2 instance in the cluster.
		
		Unit: Percent

`instance_cpu_usage_total`	`ClusterName`	The number of CPU units being used on a Single EC2 instance in the cluster. Unit: None

`instance_cpu_utilization`	`ClusterName`
	
	`InstanceId` , `ContainerInstanceId` , `ClusterName`
		The total percentage of CPU units being used on a single EC2 instance in the cluster.
		
		Unit: Percent

Metric name	Dimensions	Description
instance_filesystem_utilization	ClusterName InstanceId , ContainerInstanceId , ClusterName	The total percentage of file system capacity being used on a single EC2 instance in the cluster. Unit: Percent
instance_memory_limit	ClusterName	The maximum amount of memory, in bytes, that can be assigned to a single EC2 Instance in this cluster. Unit: Bytes
instance_memory_reserved_capacity	ClusterName InstanceId , ContainerInstanceId , ClusterName	The percentage of Memory currently being reserved on a single EC2 Instance in the cluster. Unit: Percent

Metric name	Dimensions	Description

`instance_memory_utilization`	`ClusterName`
	
	`InstanceId` , `ContainerInstanceId` , `ClusterName`
		The total percentage of memory being used on a single EC2 Instance in the cluster.
		
		Note
		If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate.
		
		Unit: Percent

Metric name	Dimensions	Description
instance_memory_working_set	ClusterName	The amount of memory, in bytes, being used on a single EC2 Instance in the cluster. **Note** If you're using the Java ZGC garbage collector for your application, this metric might be inaccurate. Unit: Bytes
instance_network_total_bytes	ClusterName	The total number of bytes per second transmitted and received over the network on a single EC2 Instance in the cluster. Unit: Bytes/second
instance_number_of_running_tasks	ClusterName	The number of running tasks on a single EC2 Instance in the cluster. Unit: Count

Amazon EKS and Kubernetes Container Insights with enhanced observability metrics

The following tables list the metrics and dimensions that Container Insights with enhanced observability collects for Amazon EKS and Kubernetes. These metrics are in the `ContainerInsights` namespace. For more information, see Metrics.

If you do not see any Container Insights with enhanced observability metrics in your console, be sure that you have completed the setup of Container Insights with enhanced observability. Metrics do not appear before Container Insights with enhanced observability has been set up completely. For more information, see Setting up Container Insights.

If you are using version 1.5.0 or later of the Amazon EKS add-on or version 1.300035.0 of the CloudWatch agent, most metrics listed in the following table are collected for both Linux and Windows nodes. See the **Metric Name** column of the table to see which metrics are not collected for Windows.

With the earlier version of Container Insights which delivers aggregated metrics at Cluster and Service level, the metrics are charged as custom metrics. With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics are charged per observation instead of being charged per metric stored or log ingested. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

> **Note**
>
> On Windows, network metrics such as `pod_network_rx_bytes` and `pod_network_tx_bytes` are not collected for host process containers.
> On RedHat OpenShift on Amazon (ROSA) clusters , diskio metrics such as `node_diskio_io_serviced_total` and `node_diskio_io_service_bytes_total` are not collected.

Metric name	Dimensions	Description
`cluster_failed_node_count`	`ClusterName`	The number of failed worker nodes in the cluster. A node is considered failed if it is suffering from any *node*

Metric name	Dimensions	Description
		conditions. For more information, see [Conditions](#) in the Kubernetes documentation.
`cluster_node_count`	`ClusterName`	The total number of worker nodes in the cluster.
`namespace_number_of_running_pods`	`Namespace ClusterName` `ClusterName`	The number of pods running per namespace in the resource that is specified by the dimensions that you're using.
`node_cpu_limit`	`ClusterName` `ClusterName ,InstanceId ,NodeName`	The maximum number of CPU units that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description
node_cpu_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of CPU units that are reserved for node components, such as kubelet, kube-proxy, and Docker. Formula: node_cpu_request / node_cpu_limit **Note** node_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_cpu_usage_total	ClusterName ClusterName , InstanceId , NodeName	The number of CPU units being used on the nodes in the cluster.
node_cpu_utilization	NodeName, ClusterName , InstanceId ClusterName	The total percentage of CPU units being used on the nodes in the cluster. Formula: node_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description

`node_filesystem_utilization`	`NodeName`, `ClusterName` , `InstanceId`
	
	`ClusterName`
		The total percentage of file system capacity being used on nodes in the cluster.
		
		Formula: `node_filesystem_usage / node_filesystem_capacity`
		
		Note
		`node_filesystem_usage` and `node_filesystem_capacity` are not reported directly as metrics, but are fields in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

`node_memory_limit`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The maximum amount of memory, in bytes, that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description

`node_filesystem_inodes`
 	
It is not available on Windows.
	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The total number of inodes (used and unused) on a node.

`node_filesystem_inodes_free`
 	
It is not available on Windows.
	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The number of unused inodes on a node.

`node_gpu_limit`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The total number of GPU(s) available on the node.

`node_gpu_usage_total`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The number of GPU(s) being used by the running pods on the node.

`node_gpu_reserved_capacity`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`	

Metric name	Dimensions	Description
node_memory_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used on the nodes in the cluster. Formula: node_memory_request / node_memory_limit **Note** node_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_utilization	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used by the node or nodes. It is the percentage of node memory usage divided by the node memory limitation. Formula: node_memory_working_set / node_memory_limit .

Metric name	Dimensions	Description
node_memory_working_set	ClusterName ClusterName , InstanceId , NodeName	The amount of memory, in bytes, being used in the working set of the nodes in the cluster.
node_network_total_bytes	NodeName, ClusterName , InstanceId ClusterName	The total number of bytes per second transmitted and received over the network per node in a cluster. Formula: node_network_rx_bytes + node_network_tx_bytes **Note** node_network_rx_bytes and node_network_tx_bytes are not reported directly as metrics, but are fields in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().
node_number_of_running_containers	NodeName, ClusterName , InstanceId ClusterName	The number of running containers per node in a cluster.

Metric name	Dimensions	Description

`node_number_of_running_pods`	`NodeName`, `ClusterName` , `InstanceId`
	
	`ClusterName`
		The number of running pods per node in a cluster.

`node_status_allocatable_pods`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The number of pods that can be assigned to a node based on its allocatable resources, which is defined as the remainder of a node's capacity after accounting for system daemons reservations and hard eviction thresholds.

`node_status_capacity_pods`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The number of pods that can be assigned to a node based on its capacity.

`node_status_condition_ready`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates whether the node status condition `Ready` is true for Amazon EC2 nodes.

`node_status_condition_memory_pressure`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates whether the node status condition `MemoryPressure` is true.

`node_status_condition_pid_pressure`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates whether the node status condition `PIDPressure` is true.

`node_status_condition_disk_pressure`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates whether the node status condition `OutOfDisk` is true.

Metric name	Dimensions	Description
node_status_condit ion_unknown	ClusterName ClusterName , InstanceI d , NodeName	Indicates whether any of the node status conditions are Unknown.
node_interface_net work_rx_dropped	ClusterName ClusterName , InstanceI d , NodeName	The number of packets which were received and subsequen tly dropped by a network interface on the node.
node_interface_net work_tx_dropped	ClusterName ClusterName , InstanceI d , NodeName	The number of packets which were due to be transmitt ed but were dropped by a network interface on the node.
node_diskio_io_ser vice_bytes_total It is not available on Windows or on ROSA clusters.	ClusterName ClusterName , InstanceI d , NodeName	The total number of bytes transferred by all I/O operations on the node.
node_diskio_io_ser viced_total It is not available on Windows or on ROSA clusters.	ClusterName ClusterName , InstanceI d , NodeName	The total number of I/O operations on the node.

Metric name	Dimensions	Description
pod_cpu_reserved_capacity	PodName, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , Service	The CPU capacity that is reserved per pod in a cluster. Formula: pod_cpu_request / node_cpu_limit **Note** pod_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().
pod_cpu_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of CPU units being used by pods. Formula: pod_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description
pod_cpu_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of CPU units being used by pods relative to the pod limit. Formula: pod_cpu_usage_total / pod_cpu_limit
pod_memory_reserved_capacity	PodName, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , Service	The percentage of memory that is reserved for pods. Formula: pod_memory_request / node_memory_limit **Note** pod_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of memory currently being used by the pod or pods. Formula: pod_memory_working_set / node_memory_limit
pod_memory_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The percentage of memory that is being used by pods relative to the pod limit. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: pod_memory_working_set / pod_memory_limit

Metric name	Dimensions	Description

`pod_network_rx_bytes`	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName`
	
	`Service`, `Namespace` , `ClusterName`
	
	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The number of bytes per second being received over the network by the pod.
		
		Formula: `sum(pod_interface_network_rx_bytes)`
		
		Note
		
		`pod_interface_network_rx_bytes` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_network_tx_bytes	PodName, Namespace , ClusterName Namespace, ClusterName Service, Namespace , ClusterName ClusterName ClusterName , Namespace , PodName, FullPodName	The number of bytes per second being transmitted over the network by the pod. Formula: sum(pod_interface_network_tx_bytes) **Note** pod_interface_network_tx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description

`pod_cpu_request`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The CPU requests for the pod.
		
		Formula: `sum(container_cpu_request)`
		
		Note
		
		`pod_cpu_request` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

Metric name	Dimensions	Description

`pod_memory_request`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The memory requests for the pod.
		
		Formula: `sum(container_memory_request)`
		
		Note
		
		`pod_memory_request` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description

`pod_cpu_limit`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The CPU limit defined for the containers in the pod. If any containers in the pod don't have a CPU limit defined, this metric doesn't appear.
		
		Formula: `sum(container_cpu_limit)`
		
		Note
		
		`pod_cpu_limit` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_memory_limit	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	The memory limit defined for the containers in the pod. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: sum(container_memory_limit) **Note** pod_cpu_limit is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_status_failed	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Indicates that all containers in the pod have terminated, and at least one container has terminated with a non-zero status or was terminated by the system.

Metric name	Dimensions	Description

`pod_status_ready`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		Indicates that all containers in the pod are ready, having reached the condition of `ContainerReady` .

`pod_status_running`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		Indicates that all containers in the pod are running.

`pod_status_scheduled`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		Indicates that the pod has been scheduled to a node.

Metric name	Dimensions	Description
pod_status_unknown	ClusterName PodName, Namespace , ClusterName Namespace , ClusterNa me , Service ClusterName , Namespace , PodName, FullPodName	Indicates that status of the pod can't be obtained.
pod_status_pending	ClusterName PodName, Namespace , ClusterName Namespace , ClusterNa me , Service ClusterName , Namespace , PodName, FullPodName	Indicates that the pod has been accepted by the cluster but one or more of the containers has not become ready yet.
pod_status_succeeded	ClusterName PodName, Namespace , ClusterName Namespace , ClusterNa me , Service ClusterName , Namespace , PodName, FullPodName	Indicates that all containers in the pod have successfully terminated and will not be restarted.

Metric name	Dimensions	Description
pod_number_of_containers	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers defined in the pod specification.
pod_number_of_running_containers	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are currently in the Running state.
pod_container_status_terminated	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Terminated state.

Metric name	Dimensions	Description
pod_container_status_running	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Running state.
pod_container_status_waiting	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Waiting state.
pod_container_status_waiting_reason_crash_loop_back_off	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending because of a CrashLoopBackOff error, where a container repeatedly fails to start.

Metric name	Dimensions	Description
pod_container_status_waiting_reason_create_container_config_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason CreateContainerConfigError . This is because of an error while creating the container configuration.
pod_container_status_waiting_reason_create_container_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason CreateContainerError because of an error while creating the container.
pod_container_status_waiting_reason_image_pull_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending because of ErrImagePull , ImagePullBackOff , or InvalidImageName . These situations are because of an error while pulling the container image.

Metric name	Dimensions	Description
pod_container_status_waiting_reason_oom_killed	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are in the Terminated state because of running out of memory (OOM killed).
pod_container_status_waiting_reason_start_error	ClusterName PodName, Namespace , ClusterName Namespace , ClusterName , Service ClusterName , Namespace , PodName, FullPodName	Reports the number of containers in the pod which are pending with the reason being StartError because of an error while starting the container.
pod_container_status_terminated_reason_oom_killed	ContainerName , FullPodName , PodName, Namespace , ClusterName ContainerName , PodName, Namespace , ClusterName ClusterName	Indicates a pod was terminated for exceeding the memory limit. This metric is only displayed when this issue occurs.

Metric name	Dimensions	Description

`pod_interface_network_rx_dropped`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The number of packets which were received and subsequently dropped a network interface for the pod.

`pod_interface_network_tx_dropped`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The number of packets which were due to be transmitted but were dropped for the pod.

`pod_memory_working_set`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`
	
	`ClusterName` , `Namespace` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The memory in bytes that is currently being used by a pod.

Metric name	Dimensions	Description

`pod_cpu_usage_total`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`
	
	`ClusterName` , `Namespace` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
		The number of CPU units used by a pod.

`container_cpu_utilization`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName` , `FullPodName`
		The percentage of CPU units being used by the container.
		
		Formula: `container_cpu_usage_total / node_cpu_limit`
		
		Note
		
		`container_cpu_utilization` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description

`container_cpu_utilization_over_container_limit`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName` , `FullPodName`
		The percentage of CPU units being used by the container relative to the container limit. If the container doesn't have a CPU limit defined, this metric doesn't appear.
		
		Formula: `container_cpu_usage_total / container_cpu_limit`
		
		Note
		`container_cpu_utilization_over_container_limit` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

Metric name	Dimensions	Description

`container_memory_utilization`	`ClusterName`
	
	`PodName`, `Namespace`, `ClusterName`, `ContainerName`
	
	`PodName`, `Namespace`, `ClusterName`, `ContainerName`, `FullPodName`
		The percentage of memory units being used by the container.
		
		Formula: `container_memory_working_set / node_memory_limit`
		
		Note
		`container_memory_utilization` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

Metric name	Dimensions	Description

`container_memory_utilization_over_container_limit`	`ClusterName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName`
	
	`PodName`, `Namespace` , `ClusterName` , `ContainerName` , `FullPodName`
		The percentage of memory units being used by the container relative to the container limit. If the container doesn't have a memory limit defined, this metric doesn't appear.
		
		Formula: `container_memory_working_set / container_memory_limit`
		
		Note
		`container_memory_utilization_over_container_limit` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
`container_memory_failures_total` It is not available on Windows.	`ClusterName` PodName, `Namespace` , `ClusterName` , `ContainerName` PodName, `Namespace` , `ClusterName` , `ContainerName` , `FullPodName`	The number of memory allocation failures experienced by the container.
`pod_number_of_container_restarts`	PodName, `Namespace` , `ClusterName`	The total number of container restarts in a pod.
`service_number_of_running_pods`	Service, `Namespace` , `ClusterName` `ClusterName`	The number of pods running the service or services in the cluster.
`replicas_desired`	`ClusterName` PodName, `Namespace` , `ClusterName`	The number of pods desired for a workload as defined in the workload specification.
`replicas_ready`	`ClusterName` PodName, `Namespace` , `ClusterName`	The number of pods for a workload that have reached the ready status.
`status_replicas_available`	`ClusterName` PodName, `Namespace` , `ClusterName`	The number of pods for a workload which are available . A pod is available when it has been ready for the `minReadySeconds` defined in the workload specification.

Metric name	Dimensions	Description
status_replicas_un available	ClusterName PodName, Namespace , ClusterName	The number of pods for a workload which are unavailab le. A pod is available when it has been ready for the minReadySeconds defined in the workload specification. Pods are unavailable if they have not met this criterion.
apiserver_storage_ objects	ClusterName ClusterName , resource	The number of objects stored in etcd at the time of the last check.
apiserver_storage_ db_total_size_in_b ytes	ClusterName ClusterName , endpoint	Total size of the storage database file physically allocated in bytes. This metric is experimental and might change in future releases of Kubernetes. Unit: Bytes Meaningful statistics: Sum, Average, Minimum, Maximum
apiserver_request_ total	ClusterName ClusterName , code, verb	The total number of API requests to the Kubernetes API server.
apiserver_request_ duration_seconds	ClusterName ClusterName , verb	Responce latency for API requests to the Kubernetes API server.

Metric name	Dimensions	Description
apiserver_admission_controller_admission_duration_seconds	ClusterName ClusterName , operation	Admission controller latency in seconds. An admission controller is code which intercepts requests to the Kubernetes API server.
rest_client_request_duration_seconds	ClusterName ClusterName , operation	Reponse latency experienced by clients calling the Kubernetes API server. This metric is experimental and may change in future releases of Kubernetes.
rest_client_requests_total	ClusterName ClusterName , code, method	The total number of API requests to the Kubernetes API server made by clients. This metric is experimental and may change in future releases of Kubernetes.
etcd_request_duration_seconds	ClusterName ClusterName , operation	Response latency of API calls to Etcd. This metric is experimental and may change in future releases of Kubernetes.
apiserver_storage_size_bytes	ClusterName ClusterName , endpoint	Size of the storage database file physically allocated in bytes. This metric is experimental and may change in future releases of Kubernetes.
apiserver_longrunning_requests	ClusterName ClusterName , resource	The number of active long-running requests to the Kubernetes API server.

Metric name	Dimensions	Description

`apiserver_current_inflight_requests`	`ClusterName`
	
	`ClusterName` , `request_kind`
		The number of requests that are being processed by Kubernetes API server.

`apiserver_admission_webhook_admission_duration_seconds`	`ClusterName`
	
	`ClusterName` , `name`
		Admission webhook latency in seconds. Admission webhooks are HTTP callbacks that receive admission requests and do something with them.

`apiserver_admission_step_admission_duration_seconds`	`ClusterName`
	
	`ClusterName` , `operation`
		Admission sub-step latency in seconds.

`apiserver_requested_deprecated_apis`	`ClusterName`
	
	`ClusterName` , `group`
		Number of requests to deprecated APIs on the Kubernetes API server.

`apiserver_request_total_5xx`	`ClusterName`
	
	`ClusterName` , `code`, `verb`
		Number of requests to the Kubernetes API server which were responded to with a 5XX HTTP response code.

`apiserver_storage_list_duration_seconds`	`ClusterName`
	
	`ClusterName` , `resource`
		Response latency of listing objects from Etc. This metric is experimental and may change in future releases of Kubernetes.

`apiserver_flowcontrol_request_concurrency_limit`	`ClusterName`
	
	`ClusterName` , `priority_level`
		The number of threads used by the currently executing requests in the API Priority and Fairness subsystem.

Metric name	Dimensions	Description

`apiserver_flowcontrol_rejected_requests_total`	`ClusterName`
	
	`ClusterName` , `reason`
		Number of requests rejected by API Priority and Fairness subsystem. This metric is experimental and may change in future releases of Kubernetes.

`apiserver_current_inqueue_requests`	`ClusterName`
	
	`ClusterName` , `request_kind`
		The number queued requests queued by the Kubernetes API server. This metric is experimental and may change in future releases of Kubernetes.

NVIDIA GPU metrics

Beginning with version `1.300034.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects NVIDIA GPU metrics from EKS workloads by default. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version `v1.3.0-eksbuild.1` or later. For more information, see [Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart](). These NVIDIA GPU metrics that are collected are listed in the table in this section.

For Container Insights to collect NVIDIA GPU metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version `v1.3.0-eksbuild.1` or later.
- [The NVIDIA device plugin for Kubernetes]() must be installed in the cluster.
- [The NVIDIA container toolkit]() must be installed on the nodes of the cluster. For example, the Amazon EKS optimized accelerated AMIs are built with the necessary components.

You can opt out of collecting NVIDIA GPU metrics by setting the `accelerated_compute_metrics` option in the beginn CloudWatch agent configuration file to `false`. For more information and an example opt-out configuration, see [(Optional) Additional configuration]().

Metric name	Dimensions	Description
container_gpu_memory_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the container.
container_gpu_memory_used	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the container.
container_gpu_memory_utilization	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName	The percentage of frame buffer used of the GPU(s) allocated to the container.

Metric name	Dimensions	Description
	ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	
container_gpu_power_draw	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The power usage in watts of the GPU(s) allocated to the container.
container_gpu_temperature	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , GpuDevice	The temperature in degrees celsius of the GPU(s) allocated to the container.

Metric name	Dimensions	Description
container_gpu_utilization	ClusterName ClusterName ,Namespace , PodName, ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ClusterName ,Namespace ,PodName, FullPodName , ContainerName ,GpuDevice	The percentage utilization of the GPU(s) allocated to the container.
node_gpu_memory_total	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the node.
node_gpu_memory_used	ClusterName ClusterName ,InstanceId , NodeName ClusterName ,InstanceId , InstanceType ,NodeName, GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the node.

Metric name	Dimensions	Description
node_gpu_memory_utilization	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, GpuDevice	The percentage of frame buffer used on the GPU(s) allocated to the node.
node_gpu_power_draw	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, GpuDevice	The power usage in watts of the GPU(s) allocated to the node.
node_gpu_temperature	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, GpuDevice	The temperature in degrees celsius of the GPU(s) allocated to the node.
node_gpu_utilization	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, GpuDevice	The percentage utilization of the GPU(s) allocated to the node.

Metric name	Dimensions	Description
pod_gpu_memory_total	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The total frame buffer size, in bytes, on the GPU(s) allocated to the pod.
pod_gpu_memory_used	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName . GpuDevice	The bytes of frame buffer used on the GPU(s) allocated to the pod.

Metric name	Dimensions	Description
pod_gpu_memory_utilization	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName . GpuDevice	The percentage of frame buffer used of the GPU(s) allocated to the pod.
pod_gpu_power_draw	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName . GpuDevice	The power usage in watts of the GPU(s) allocated to the pod.

Metric name	Dimensions	Description

`pod_gpu_temperature`	`ClusterName`
	
	`ClusterName` , `Namespace`
	
	`ClusterName` , `Namespace` , `Service`
	
	`ClusterName` , `Namespace` , `PodName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` . `GpuDevice`
		The temperature in degrees Celsius of the GPU(s) allocated to the pod.

`pod_gpu_utilization`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName` , `GpuDevice`
		The percentage utilization of the GPU(s) allocated to the pod.

Amazon Neuron metrics for Amazon Trainium and Amazon Inferentia

Beginning with version `1.300036.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects accelerated computing metrics from Amazon Trainium and Amazon Inferentia accelerators by default. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version `v1.5.0-eksbuild.1` or later. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch

Observability EKS add-on or the Helm chart. For more information about Amazon Trainium, see Amazon Trainium. For more information about Amazon Inferentia, see Amazon Inferentia.

For Container Insights to collect Amazon Neuron metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version `v1.5.0-eksbuild.1` or later.
- The Neuron driver must be installed on the nodes of the cluster.
- The Neuron device plugin must be installed on the cluster. For example, the Amazon EKS optimized accelerated AMIs are built with the necessary components.

The metrics that are collected are listed in the table in this section. The metrics are collected for Amazon Trainium, Amazon Inferentia, and Amazon Inferentia2.

The CloudWatch agent collects these metrics from the Neuron monitor and does the necessary Kubernetes resource correlation to deliver metrics at the pod and container levels

Metric name	Dimensions	Description

`container_neuronco re_utiliz ation`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName` , `NeuronDev ice` , `NeuronCore`
		NeuronCore utilization, during the captured period of the NeuronCore allocated to the container.
		
		Unit: Percent

`container_neuronco re_memory`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
		The amount of device memory used for constants during training by the NeuronCore that is allocated

Metric name	Dimensions	Description
_usage_constants	ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	to the container (or weights during inference). Unit: Bytes
container_neuroncore_memory_usage_model_code	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The amount of device memory used for the models' executable code by the NeuronCore that is allocated to the container. Unit: Bytes
container_neuroncore_memory_usage_model_shared_scratchpad	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the container. This memory region is reserved for the models. Unit: Bytes

Metric name	Dimensions	Description

`container_neuroncore_memory_usage_runtime_memory`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName` , `NeuronDevice` , `NeuronCore`
		The amount of device memory used for the Neuron runtime by the NeuronCore allocated to the container.
		
		Unit: Bytes

`container_neuroncore_memory_usage_tensors`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`, `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName`
	
	`ClusterName` , `Namespace` , `PodName`, `FullPodName` , `ContainerName` , `NeuronDevice` , `NeuronCore`
		The amount of device memory used for tensors by the NeuronCore allocated to the container.
		
		Unit: Bytes

Metric name	Dimensions	Description
container_neuroncore_memory_usage_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice , NeuronCore	The total amount of memory used by the NeuronCore allocated to the container. Unit: Bytes
container_neurondevice_hw_ecc_events_total	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device on the node. Unit: Count

Metric name	Dimensions	Description
pod_neuroncore_utilization	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The NeuronCore utilization during the captured period of the NeuronCore allocated to the pod. Unit: Percent
pod_neuroncore_memory_usage_constants	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The amount of device memory used for constants during training by the NeuronCore that is allocated to the pod (or weights during inference). Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_model_code	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for the models' executable code by the NeuronCore that is allocated to the pod. Unit: Bytes
pod_neuroncore_memory_usage_model_shared_scratchpad	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the pod. This memory region is reserved for the models. Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_runtime_memory	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for the Neuron runtime by the NeuronCore allocated to the pod. Unit: Bytes
pod_neuroncore_memory_usage_tensors	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NeuronDevice ,NeuronCore	The amount of device memory used for tensors by the NeuronCore allocated to the pod. Unit: Bytes

Metric name	Dimensions	Description
pod_neuroncore_memory_usage_total	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice , NeuronCore	The total amount of memory used by the NeuronCore allocated to the pod. Unit: Bytes
pod_neurondevice_hw_ecc_events_total	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device allocated to a pod. Unit: Bytes

Metric name	Dimensions	Description

`node_neuroncore_utilization`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
	
	`ClusterName` , `InstanceType` , `InstanceId` , `NodeName`, `NeuronDevice` , `NeuronCore`
		The NeuronCore utilization during the captured period of the NeuronCore allocated to the node.
		
		Unit: Percent

`node_neuroncore_memory_usage_constants`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
	
	`ClusterName` , `InstanceType` , `InstanceId` , `NodeName`, `NeuronDevice` , `NeuronCore`
		The amount of device memory used for constants during training by the NeuronCore that is allocated to the node (or weights during inference).
		
		Unit: Bytes

`node_neuroncore_memory_usage_model_code`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
	
	`ClusterName` , `InstanceType` , `InstanceId` , `NodeName`, `NeuronDevice` , `NeuronCore`
		The amount of device memory used for models' executable code by the NeuronCore that is allocated to the node.
		
		Unit: Bytes

`node_neuroncore_memory_usage_model_shared_scratchpad`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
	
	`ClusterName` , `InstanceType` , `InstanceId` , `NodeName`, `NeuronDevice` , `NeuronCore`
		The amount of device memory used for the scratchpad shared of the models by the NeuronCore that is allocated to the node. This is a memory region reserved for the models.
		
		Unit: Bytes

Metric name	Dimensions	Description
node_neuroncore_memory_usage_runtime_memory	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceType , InstanceId , NodeName, NeuronDevice , NeuronCore	The amount of device memory used for the Neuron runtime by the NeuronCore that is allocated to the node. Unit: Bytes
node_neuroncore_memory_usage_tensors	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceType , InstanceId , NodeName, NeuronDevice , NeuronCore	The amount of device memory used for tensors by the NeuronCore that is allocated to the node. Unit: Bytes
node_neuroncore_memory_usage_total	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceType , InstanceId , NodeName, NeuronDevice , NeuronCore	The total amount of memory used by the NeuronCore that is allocated to the node. Unit: Bytes
node_neuron_execution_errors_total	ClusterName ClusterName , InstanceId , NodeName	The total number of execution errors on the node. This is calculated by the CloudWatch agent by aggregating the errors of the following types: generic, numerical , transient , model, runtime, and hardware Unit: Count

Metric name	Dimensions	Description
node_neurondevice_runtime_memory_used_bytes	ClusterName ClusterName , InstanceId , NodeName	The total Neuron device memory usage in bytes on the node. Unit: Bytes
node_neuron_execution_latency	ClusterName ClusterName , InstanceId , NodeName	In seconds, the latency for an execution on the node as measured by the Neuron runtime. Unit: Seconds
node_neurondevice_hw_ecc_events_total	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , NodeName, NeuronDevice	The number of corrected and uncorrected ECC events for the on-chip SRAM and device memory of the Neuron device on the node. Unit: Count

Amazon Elastic Fabric Adapter (EFA) metrics

Beginning with version `1.300037.0` of the CloudWatch agent, Container Insights with enhanced observability for Amazon EKS collects Amazon Elastic Fabric Adapter (EFA) metrics from Amazon EKS clusters on Linux instances. The CloudWatch agent must be installed using the CloudWatch Observability EKS add-on version `v1.5.2-eksbuild.1` or later. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about Amazon Elastic Fabric Adapter, see Elastic Fabric Adapter.

For Container Insights to collect Amazon Elastic Fabric adapter metrics, you must meet the following prerequisites:

- You must be using Container Insights with enhanced observability for Amazon EKS, with the Amazon CloudWatch Observability EKS add-on version `v1.5.2-eksbuild.1` or later.

- The EFA device plugin must be installed on the cluster. For more information, see [aws-efa-k8s-device-plugin](https://github.com/aws-samples/aws-efa-eks) on GitHub.

The metrics that are collected are listed in the following table.

Metric name	Dimensions	Description

`container_efa_rx_bytes`	`ClusterName`
	
	`ClusterName`, `Namespace`, `PodName`, `ContainerName`
	
	`ClusterName`, `Namespace`, `PodName`, `FullPodName`, `ContainerName`
	
	`ClusterName`, `Namespace`, `PodName`, `FullPodName`, `ContainerName`, `NetworkInterfaceId`
		The number of bytes per second received by the EFA device(s) allocated to the container.
		
		Unit: Bytes/Second

`container_efa_tx_bytes`	`ClusterName`
	
	`ClusterName`, `Namespace`, `PodName`, `ContainerName`
	
	`ClusterName`, `Namespace`, `PodName`, `FullPodName`, `ContainerName`
	
	`ClusterName`, `Namespace`, `PodName`, `FullPodName`, `ContainerName`, `NetworkInterfaceId`
		The number of bytes per second transmitted by the EFA device(s) allocated to the container.
		
		Unit: Bytes/Second

`container_efa_rx_dropped`	`ClusterName`
	
	`ClusterName`, `Namespace`, `PodName`, `ContainerName`
		The number of packets that were received and then dropped by the EFA device(s) allocated to the container.

Metric name	Dimensions	Description
	ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	Unit: Count/Second
container_efa_rdma_read_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the container. Unit: Bytes/Second
container_efa_rdma_write_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the container. Unit: Bytes/Second

Metric name	Dimensions	Description
container_efa_rdma_write_recv_bytes	ClusterName ClusterName , Namespace , PodName, ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName ClusterName , Namespace , PodName, FullPodName , ContainerName , NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the container. Unit: Bytes/Second
pod_efa_rx_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received by the EFA device(s) allocated to the pod. Unit: Bytes/Second

Metric name	Dimensions	Description
pod_efa_tx_bytes	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second transmitted by the EFA device(s) allocated to the pod. Unit: Bytes/Second
pod_efa_rx_dropped	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NetworkInterfaceId	The number of packets that were received and then dropped by the EFA device(s) allocated to the pod. Unit: Count/Second

Metric name	Dimensions	Description
pod_efa_rdma_read_bytes	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
pod_efa_rdma_write_bytes	ClusterName ClusterName ,Namespace ClusterName ,Namespace , Service ClusterName ,Namespace , PodName ClusterName ,Namespace , PodName, FullPodName ClusterName ,Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second

Metric name	Dimensions	Description
pod_efa_rdma_write_recv_bytes	ClusterName ClusterName , Namespace ClusterName , Namespace , Service ClusterName , Namespace , PodName ClusterName , Namespace , PodName, FullPodName ClusterName , Namespace , PodName, FullPodName , NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
node_efa_rx_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second received by the EFA device(s) allocated to the node. Unit: Bytes/Second
node_efa_tx_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second transmitted by the EFA device(s) allocated to the node. Unit: Bytes/Second

Metric name	Dimensions	Description
node_efa_rx_dropped	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of packets that were received and then dropped by the EFA device(s) allocated to the node. Unit: Count/Second
node_efa_rdma_read_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second received using remote direct memory access read operations by the EFA device(s) allocated to the node. Unit: Bytes/Second
node_efa_rdma_write_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second transmitted using remote direct memory access read operations by the EFA device(s) allocated to the pod. Unit: Bytes/Second
node_efa_rdma_write_recv_bytes	ClusterName ClusterName , InstanceId , NodeName ClusterName , InstanceId , InstanceType , NodeName, NetworkInterfaceId	The number of bytes per second received during remote direct memory access write operations by the EFA device(s) allocated to the node. Unit: Bytes/Second

Amazon SageMaker AI HyperPod metrics

Beginning with version `v2.0.1-eksbuild.1` of the the CloudWatch Observability EKS add-on, Container Insights with enhanced observability for Amazon EKS automatically collects Amazon SageMaker AI HyperPod metrics from Amazon EKS clusters. For more information about the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about Amazon SageMaker AI HyperPod, see Amazon SageMaker AI HyperPod.

The metrics that are collected are listed in the following table.

Metric name	Dimensions	Description

`hyperpod_node_health_status_unschedulable`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `Unschedulable` by Amazon SageMaker AI HyperPod. This means that the node is running deep health checks and is not available for running workloads.
		
		Unit: Count

`hyperpod_node_health_status_schedulable`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `Schedulable` by Amazon SageMaker AI HyperPod. This means that the node has passed basic health checks or deep health checks and is available for running workloads.
		
		Unit: Count

`hyperpod_node_health_status_unschedulable_pen`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		Indicates if a node is labeled as `UnschedulablePendingReplacement` by HyperPod. This means that the node has failed deep health checks or health monitoring agent checks and requires a replacement.

Metric name	Dimensions	Description
ding_repl acement		If automatic node recovery is enabled, the node will be automatic ally replaced by Amazon SageMaker AI HyperPod. Unit: Count
hyperpod_ node_heal th_status _unschedu lable_pen ding_rebo ot	ClusterName ClusterName , InstanceId , NodeName	Indicates if a node is labeled as UnschedulablePendi ngReboot by Amazon SageMaker AI HyperPod. This means that the node is running deep health checks and requires a reboot. If automatic node recovery is enabled, the node will be automatic ally rebooted by Amazon SageMaker AI HyperPod. Unit: Count

Amazon EKS and Kubernetes Container Insights metrics

The following tables list the metrics and dimensions that Container Insights collects for Amazon EKS and Kubernetes. These metrics are in the ContainerInsights namespace. For more information, see Metrics.

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Setting up Container Insights.

Metric name	Dimensions	Description
cluster_failed_nod e_count	ClusterName	The number of failed worker nodes in the cluster. A node is considered failed if it is

Metric name	Dimensions	Description
		suffering from any *node conditions*. For more information, see Conditions in the Kubernetes documentation.
`cluster_node_count`	`ClusterName`	The total number of worker nodes in the cluster.

`namespace_number_of_running_pods`	`Namespace ClusterName`
	
	`ClusterName`
		The number of pods running per namespace in the resource that is specified by the dimensions that you're using.

`node_cpu_limit`	`ClusterName`	The maximum number of CPU units that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description

`node_cpu_reserved_capacity`	`NodeName`, `ClusterName` , `InstanceId`
	
	`ClusterName`
		The percentage of CPU units that are reserved for node components, such as kubelet, kube-proxy, and Docker.
		
		Formula: `node_cpu_request / node_cpu_limit`
		
		Note
		`node_cpu_request` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

`node_cpu_usage_total`	`ClusterName`	The number of CPU units being used on the nodes in the cluster.

`node_cpu_utilization`	`NodeName`, `ClusterName` , `InstanceId`
	
	`ClusterName`
		The total percentage of CPU units being used on the nodes in the cluster.
		
		Formula: `node_cpu_usage_total / node_cpu_limit`

Metric name	Dimensions	Description

`node_gpu_limit`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The total number of GPU(s) available on the node.

`node_gpu_usage_total`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The number of GPU(s) being used by the running pods on the node.

`node_gpu_reserved_capacity`	`ClusterName`
	
	`ClusterName` , `InstanceId` , `NodeName`
		The percentage of GPU currently being reserved on the node. The formula is, `node_gpu_request / node_gpu_limit` .
		
		Note
		`node_gpu_request` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

Metric name	Dimensions	Description

`node_filesystem_utilization`	`NodeName`, `ClusterName` , `InstanceId`
	
	`ClusterName`
		The total percentage of file system capacity being used on nodes in the cluster.
		
		Formula: `node_filesystem_usage / node_filesystem_capacity`
		
		Note
		`node_filesystem_usage` and `node_filesystem_capacity` are not reported directly as metrics, but are fields in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

`node_memory_limit`	`ClusterName`	The maximum amount of memory, in bytes, that can be assigned to a single node in this cluster.

Metric name	Dimensions	Description
node_memory_reserved_capacity	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used on the nodes in the cluster. Formula: node_memory_request / node_memory_limit **Note** node_memory_request is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
node_memory_utilization	NodeName, ClusterName , InstanceId ClusterName	The percentage of memory currently being used by the node or nodes. It is the percentage of node memory usage divided by the node memory limitation. Formula: node_memory_working_set / node_memory_limit .

Metric name	Dimensions	Description
node_memory_working_set	ClusterName	The amount of memory, in bytes, being used in the working set of the nodes in the cluster.
node_network_total_bytes	NodeName, ClusterName , InstanceId ClusterName	The total number of bytes per second transmitted and received over the network per node in a cluster. Formula: node_network_rx_bytes + node_network_tx_bytes **Note** node_network_rx_bytes and node_network_tx_bytes are not reported directly as metrics, but are fields in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().
node_number_of_running_containers	NodeName, ClusterName , InstanceId ClusterName	The number of running containers per node in a cluster.

Metric name	Dimensions	Description
node_number_of_running_pods	NodeName, ClusterName , InstanceId ClusterName	The number of running pods per node in a cluster.
pod_cpu_reserved_capacity	PodName, Namespace , ClusterName ClusterName	The CPU capacity that is reserved per pod in a cluster. Formula: pod_cpu_request / node_cpu_limit **Note** pod_cpu_request is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes].
pod_cpu_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of CPU units being used by pods. Formula: pod_cpu_usage_total / node_cpu_limit

Metric name	Dimensions	Description
pod_cpu_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of CPU units being used by pods relative to the pod limit. Formula: pod_cpu_usage_total / pod_cpu_limit
pod_gpu_request	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The GPU requests for the pod. This value must always be equal to pod_gpu_limit .
pod_gpu_limit	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The maximum number of GPU(s) that can be assigned to the pod in a node.
pod_gpu_usage_total	ClusterName ClusterName , Namespace , PodName ClusterName , FullPodName , Namespace , PodName	The number of GPU(s) being allocated on the pod.

Metric name	Dimensions	Description

`pod_gpu_reserved_capacity`	`ClusterName`
	
	`ClusterName` , `Namespace` , `PodName`
	
	`ClusterName` , `FullPodName` , `Namespace` , `PodName`
		The percentage of GPU currently being reserved for the pod. The formula is - pod_gpu_request / node_gpu_reserved_capacity.

`pod_memory_reserved_capacity`	`PodName`, `Namespace` , `ClusterName`
	
	`ClusterName`
		The percentage of memory that is reserved for pods.
		
		Formula: `pod_memory_request / node_memory_limit`
		
		Note
		
		`pod_memory_request` is not reported directly as a metric, but is a field in performance log events. For more information, see [Relevant fields in performance log events for Amazon EKS and Kubernetes]().

Metric name	Dimensions	Description
pod_memory_utilization	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of memory currently being used by the pod or pods. Formula: pod_memory_working_set / node_memory_limit
pod_memory_utilization_over_pod_limit	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The percentage of memory that is being used by pods relative to the pod limit. If any containers in the pod don't have a memory limit defined, this metric doesn't appear. Formula: pod_memory_working_set / pod_memory_limit

Metric name	Dimensions	Description

`pod_network_rx_bytes`	`PodName`, `Namespace` , `ClusterName`
	
	`Namespace` , `ClusterName`
	
	`Service`, `Namespace` , `ClusterName`
	
	`ClusterName`
		The number of bytes per second being received over the network by the pod.
		
		Formula: `sum(pod_interface_network_rx_bytes)`
		
		Note
		
		`pod_interface_network_rx_bytes` is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.

Metric name	Dimensions	Description
pod_network_tx_bytes	PodName, Namespace , ClusterName Namespace , ClusterName Service, Namespace , ClusterName ClusterName	The number of bytes per second being transmitted over the network by the pod. Formula: sum(pod_interface_network_tx_bytes) **Note** pod_interface_network_tx_bytes is not reported directly as a metric, but is a field in performance log events. For more information, see Relevant fields in performance log events for Amazon EKS and Kubernetes.
pod_number_of_container_restarts	PodName, Namespace , ClusterName	The total number of container restarts in a pod.
service_number_of_running_pods	Service, Namespace , ClusterName ClusterName	The number of pods running the service or services in the cluster.

Kueue metrics

Beginning with version v2.4.0-eksbuild.1 of the the CloudWatch Observability EKS add-on, Container Insights for Amazon EKS supports collecting Kueue metrics from Amazon EKS clusters.

For more information about the add-on, see [Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart](#).

For information about enabling the metrics, see [Enable Kueue metrics](#) to enable them.

The Kueue metrics that are collected are listed in the following table. These metrics are published into the `ContainerInsights/Prometheus` namespace in CloudWatch. Some of these metrics use the following dimensions:

- `ClusterQueue` is the name of the ClusterQueue
- The possible values of `Status` are `active` and `inadmissible`
- The possible values of `Reason` are `Preempted`, `PodsReadyTimeout`, `AdmissionCheck`, `ClusterQueueStopped`, and `InactiveWorkload`
- `Flavor` is the referenced flavor.
- `Resource` refers to cluster computer resources, such as `cpu`, `memory`, `gpu`, and so on.

Metric name	Dimensions	Description

`kueue_pending_workloads`	`ClusterName` , `ClusterQueue` , `Status`
	
	`ClusterName` , `ClusterQueue`
	
	`ClusterName` , `Status`
	
	`ClusterName`
		The number of pending workloads.

`kueue_evicted_workloads_total`	`ClusterName` , `ClusterQueue` , `Reason`
	
	`ClusterName` , `ClusterQueue`
	
	`ClusterName` , `Reason`
	
	`ClusterName`
		The total number of evicted workloads.

`kueue_admitted_active`	`ClusterName` , `ClusterQueue`
	
	`ClusterName`
		The number of admitted workloads that are active (unsuspended and not finished).

Metric name	Dimensions	Description
ive_workl oads		
kueue_clu ster_queu e_resourc e_usage	ClusterName , ClusterQueue , Resource, Flavor ClusterName , ClusterQueue , Resource ClusterName , ClusterQueue , Flavor ClusterName , ClusterQueue ClusterName	Reports the total resource usage of the ClusterQueue.
kueue_clu ster_queu e_nominal _quota	ClusterName , ClusterQueue , Resource, Flavor ClusterName , ClusterQueue , Resource ClusterName , ClusterQueue , Flavor ClusterName , ClusterQueue ClusterName	Reports the resource quota of the ClusterQueue.

Container Insights performance log reference

This section includes reference information about how Container Insights uses performance log events to collect metrics. When you deploy Container Insights, it automatically creates a log group for the performance log events. You don't need to create this log group yourself.

Topics

- Container Insights performance log events for Amazon ECS

- [Container Insights performance log events for Amazon EKS and Kubernetes]
- [Relevant fields in performance log events for Amazon EKS and Kubernetes]

Container Insights performance log events for Amazon ECS

The following are examples of the performance log events that Container Insights collects from Amazon ECS.

These logs are in CloudWatch Logs, in a log group named `/aws/ecs/containerinsights/CLUSTER_NAME/performance`. Within that log group, each container instance will has a log stream named `AgentTelemetry-CONTAINER_INSTANCE_ID`.

You can query these logs using queries such as `{ $.Type = "Container" }` to view all container log events.

Type: Container

```
{
 "Version":"0",

Relevant fields in performance log events for Amazon EKS and Kubernetes

For Amazon EKS and Kubernetes, the containerized CloudWatch agent emits data as performance log events. This enables CloudWatch to ingest and store high-cardinality data. CloudWatch uses the data in the performance log events to create aggregated CloudWatch metrics at the cluster, node, and pod levels without the need to lose granular details.

The following table lists the fields in these performance log events that are relevant to the collection of Container Insights metric data. You can use CloudWatch Logs Insights to query for any of these fields to collect data or investigate issues. For more information, see Analyze Log Data With CloudWatch Logs Insights.

Type	Log field	Source	Formula or notes
Pod	`pod_cpu_utilization`	Calculated	Formula: `pod_cpu_usage_total / node_cpu_limit`
Pod	`pod_cpu_usage_total` `pod_cpu_usage_total` is reported in millicores.	cadvisor	
Pod	`pod_cpu_limit`	Calculated	Formula: `sum(container_cpu_limit)` `sum(container_cpu_limit)` includes already-completed pods. If any containers in the pod don't have a CPU limit defined, this field doesn't appear in the log event. This

Type	Log field	Source	Formula or notes
			includes [init containers]().
Pod	`pod_cpu_request`	Calculated	Formula: `sum(container_cpu_request)` `container_cpu_request` isn't guaranteed to be set. Only the ones that are set are included in the sum.
Pod	`pod_cpu_utilization_over_pod_limit`	Calculated	Formula: `pod_cpu_usage_total / pod_cpu_limit`
Pod	`pod_cpu_reserved_capacity`	Calculated	Formula: `pod_cpu_request / node_cpu_limit`

Type	Log field	Source	Formula or notes
Pod	`pod_memory_utilization`	Calculated	Formula: `pod_memory_working_set / node_memory_limit` It is the percentage of pod memory usage over the node memory limitation.
Pod	`pod_memory_working_set`	cadvisor	
Pod	`pod_memory_limit`	Calculated	Formula: `sum(container_memory_limit)` If any containers in the pod don't have a memory limit defined, this field doesn't appear in the log event. This includes [init containers](https://kubernetes.io/docs/concepts/workloads/pods/init-containers/).

Type	Log field	Source	Formula or notes
Pod	`pod_memory_request`	Calculated	Formula: `sum(container_memory_request)` `container_memory_request` isn't guaranteed to be set. Only the ones that are set are included in the sum.
Pod	`pod_memory_utilization_over_pod_limit`	Calculated	Formula: `pod_memory_working_set / pod_memory_limit` If any containers in the pod don't have a memory limit defined, this field doesn't appear in the log event. This includes init containers.

Type	Log field	Source	Formula or notes
Pod	pod_memory_reserved_capacity	Calculated	Formula: pod_memory_request / node_memory_limit
Pod	pod_network_tx_bytes	Calculated	Formula: sum(pod_interface_network_tx_bytes) This data is available for all the network interfaces per pod. The CloudWatch agent calculates the total and adds metric extraction rules.
Pod	pod_network_rx_bytes	Calculated	Formula: sum(pod_interface_network_rx_bytes)

Type	Log field	Source	Formula or notes
Pod	pod_network_total_bytes	Calculated	Formula: pod_network_rx_bytes + pod_network_tx_bytes
PodNet	pod_interface_network_rx_bytes	cadvisor	This data is network rx bytes per second of a pod network interface.
PodNet	pod_interface_network_tx_bytes	cadvisor	This data is network tx bytes per second of a pod network interface.
Container	container_cpu_usage_total	cadvisor	
Container	container_cpu_limit	cadvisor	Not guaranteed to be set. It's not emitted if it's not set.
Container	container_cpu_request	cadvisor	Not guaranteed to be set. It's not emitted if it's not set.
Container	container_memory_working_set	cadvisor	

Type	Log field	Source	Formula or notes
Container	`container_memory_limit`	pod	Not guaranteed to be set. It's not emitted if it's not set.
Container	`container_memory_request`	pod	Not guaranteed to be set. It's not emitted if it's not set.
Node	`node_cpu_utilization`	Calculated	Formula: `node_cpu_usage_total / node_cpu_limit`
Node	`node_cpu_usage_total`	cadvisor	
Node	`node_cpu_limit`	/proc	

Type	Log field	Source	Formula or notes
Node	`node_cpu_request`	Calculated	Formula: `sum(pod_cpu_request)` For cronjobs, `node_cpu_request` also includes requests from completed pods. This can lead to a high value for `node_cpu_reserved_capacity` .
Node	`node_cpu_reserved_capacity`	Calculated	Formula: `node_cpu_request / node_cpu_limit`
Node	`node_memory_utilization`	Calculated	Formula: `node_memory_working_set / node_memory_limit`
Node	`node_memory_working_set`	cadvisor	
Node	`node_memory_limit`	/proc	

Type	Log field	Source	Formula or notes
Node	`node_memory_request`	Calculated	Formula: `sum(pod_memory_request)`
Node	`node_memory_reserved_capacity`	Calculated	Formula: `node_memory_request / node_memory_limit`
Node	`node_network_rx_bytes`	Calculated	Formula: `sum(node_interface_network_rx_bytes)`
Node	`node_network_tx_bytes`	Calculated	Formula: `sum(node_interface_network_tx_bytes)`
Node	`node_network_total_bytes`	Calculated	Formula: `node_network_rx_bytes + node_network_tx_bytes`
Node	`node_number_of_running_pods`	Pod List	

Type	Log field	Source	Formula or notes
Node	node_number_of_running_containers	Pod List	
NodeNet	node_interface_network_rx_bytes	cadvisor	This data is network rx bytes per second of a worker node network interface.
NodeNet	node_interface_network_tx_bytes	cadvisor	This data is network tx bytes per second of a worker node network interface.
NodeFS	node_filesystem_capacity	cadvisor	
NodeFS	node_filesystem_usage	cadvisor	
NodeFS	node_filesystem_utilization	Calculated	Formula: node_filesystem_usage / node_filesystem_capacity This data is available per device name.

Type	Log field	Source	Formula or notes
Cluster	`cluster_failed_node_count`	API Server	
Cluster	`cluster_node_count`	API Server	
Service	`service_number_of_running_pods`	API Server	
Namespace	`namespace_number_of_running_pods`	API Server	

Metrics calculation examples

This section includes examples that show how some of the values in the preceding table are calculated.

Suppose that you have a cluster in the following state.

```
Node1
   node_cpu_limit = 4
   node_cpu_usage_total = 3

   Pod1
     pod_cpu_usage_total = 2

     Container1
        container_cpu_limit = 1
        container_cpu_request = 1
        container_cpu_usage_total = 0.8

     Container2
        container_cpu_limit = null
        container_cpu_request = null
        container_cpu_usage_total = 1.2

   Pod2
     pod_cpu_usage_total = 0.4

     Container3
```

```
        container_cpu_limit = 1
        container_cpu_request = 0.5
        container_cpu_usage_total = 0.4

Node2
   node_cpu_limit = 8
   node_cpu_usage_total = 1.5

   Pod3
     pod_cpu_usage_total = 1

     Container4
        container_cpu_limit = 2
        container_cpu_request = 2
        container_cpu_usage_total = 1
```

The following table shows how pod CPU metrics are calculated using this data.

Metric	Formula	Pod1	Pod2	Pod3
`pod_cpu_utilization`	`pod_cpu_usage_total / node_cpu_limit`	2 / 4 = 50%	0.4 / 4 = 10%	1 / 8 = 12.5%
`pod_cpu_utilization_over_pod_limit`	`pod_cpu_usage_total / sum(container_cpu_limit)`	N/A because CPU limit for `Container2` isn't defined	0.4 / 1 = 40%	1 / 2 = 50%
`pod_cpu_reserved_capacity`	`sum(container_cpu_request) / node_cpu_limit`	(1 + 0) / 4 = 25%	0.5 / 4 = 12.5%	2 / 8 = 25%

The following table shows how node CPU metrics are calculated using this data.

Metric	Formula	Node1	Node2
node_cpu_utilization	node_cpu_usage_total / node_cpu_limit	3 / 4 = 75%	1.5 / 8 = 18.75%
node_cpu_reserved_capacity	sum(pod_cpu_request) / node_cpu_limit	1.5 / 4 = 37.5%	2 / 8 = 25%

Container Insights Prometheus metrics monitoring

CloudWatch Container Insights monitoring for Prometheus automates the discovery of Prometheus metrics from containerized systems and workloads. Prometheus is an open-source systems monitoring and alerting toolkit. For more information, see What is Prometheus? in the Prometheus documentation.

Discovering Prometheus metrics is supported for Amazon Elastic Container Service, Amazon Elastic Kubernetes Service and Kubernetes clusters running on Amazon EC2 instances. The Prometheus counter, gauge, and summary metric types are collected.

For Amazon ECS and Amazon EKS clusters, both the EC2 and Fargate launch types are supported. Container Insights automatically collects metrics from several workloads, and you can configure it to collect metrics from any workload.

You can adopt Prometheus as an open-source and open-standard method to ingest custom metrics in CloudWatch. The CloudWatch agent with Prometheus support discovers and collects Prometheus metrics to monitor, troubleshoot, and alarm on application performance degradation and failures faster. This also reduces the number of monitoring tools required to improve observability.

Container Insights Prometheus support involves pay-per-use of metrics and logs, including collecting, storing, and analyzing. For more information, see Amazon CloudWatch Pricing.

Pre-built dashboards for some workloads

The Container Insights Prometheus solution includes pre-built dashboards for the popular workloads that are listed in this section. For sample configurations for these workloads, see (Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing and (Optional) Set up sample containerized Amazon EKS workloads for Prometheus metric testing.

You can also configure Container Insights to collect Prometheus metrics from other containerized services and applications by editing the agent configuration file.

Workloads with pre-built dashboards for Amazon EKS clusters and Kubernetes clusters running on Amazon EC2 instances:

- Amazon App Mesh
- NGINX
- Memcached
- Java/JMX
- HAProxy

Workloads with pre-built dashboards for Amazon ECS clusters:

- Amazon App Mesh
- Java/JMX
- NGINX
- NGINX Plus

Set up and configure Prometheus metrics collection on Amazon ECS clusters

To collect Prometheus metrics from Amazon ECS clusters, you can use the CloudWatch agent as a collector or use the Amazon Distro for OpenTelemetry collector. For information about using the Amazon Distro for OpenTelemetry collector, see https://aws-otel.github.io/docs/getting-started/container-insights/ecs-prometheus.

The following sections explain how to use the CloudWatch agent as the collector to retrieve Prometheus metrics. You install the CloudWatch agent with Prometheus monitoring on clusters running Amazon ECS, and you can optionally configure the agent to scrape additional targets. These sections also provide optional tutorials for setting up sample workloads to use for testing with Prometheus monitoring.

Container Insights on Amazon ECS supports the following launch type and network mode combinations for Prometheus metrics:

Amazon ECS launch type	Network modes supported
EC2 (Linux)	bridge, host, and awsvpc
Fargate	awsvpc

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

- Install the CloudWatch agent with Prometheus metrics collection on Amazon ECS clusters
- Scraping additional Prometheus sources and importing those metrics
- (Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing

Install the CloudWatch agent with Prometheus metrics collection on Amazon ECS clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon ECS. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- Amazon App Mesh
- Java/JMX

You can also configure the agent to scrape and import metrics from additional Prometheus workloads and sources.

Set up IAM roles

You need two IAM roles for the CloudWatch agent task definition. If you specify **`CreateIAMRoles=True`** in the Amazon CloudFormation stack to have Container Insights create these roles for you, the roles will be created with the correct permissions. If you want to create them yourself or use existing roles, the following roles and permissions are required.

- **CloudWatch agent ECS task role**— The CloudWatch agent container uses this role. It must include the **CloudWatchAgentServerPolicy** policy and a customer-managed policy which contains the following read-only permissions:
  - `ec2:DescribeInstances`
  - `ecs:ListTasks`
  - `ecs:ListServices`
  - `ecs:DescribeContainerInstances`
  - `ecs:DescribeServices`
  - `ecs:DescribeTasks`
  - `ecs:DescribeTaskDefinition`
- **CloudWatch agent ECS task execution role**— This is the role that Amazon ECS requires to launch and execute your containers. Ensure that your task execution role has the **AmazonSSMReadOnlyAccess**, **AmazonECSTaskExecutionRolePolicy**, and **CloudWatchAgentServerPolicy** policies attached. If you want to store more sensitive data for Amazon ECS to use, see [Specifying sensitive data](#).

Install the CloudWatch agent with Prometheus monitoring by using Amazon CloudFormation

You use Amazon CloudFormation to install the CloudWatch agent with Prometheus monitoring for Amazon ECS clusters. The following list shows the parameters you will use in the Amazon CloudFormation template.

- **ECSClusterName**— Specifies the target Amazon ECS cluster.
- **CreateIAMRoles**— Specify **`True`** to create new roles for the Amazon ECS task role and Amazon ECS task execution role. Specify **`False`** to reuse existing roles.
- **TaskRoleName**— If you specified **`True`** for **CreateIAMRoles**, this specifies the name to use for the new Amazon ECS task role. If you specified **`False`** for **CreateIAMRoles**, this specifies the existing role to use as the Amazon ECS task role.
- **ExecutionRoleName**— If you specified **`True`** for **CreateIAMRoles**, this specifies the name to use for the new Amazon ECS task execution role. If you specified **`False`** for **CreateIAMRoles**, this specifies the existing role to use as the Amazon ECS task execution role.
- **ECSNetworkMode**— If you are using EC2 launch type, specify the network mode here. It must be either **`bridge`** or **`host`**.
- **ECSLaunchType**— Specify either **`fargate`** or **EC2**.

- **SecurityGroupID**— If the **ECSNetworkMode** is **awsvpc**, specify the security group ID here.
- **SubnetID**— If the **ECSNetworkMode** is **awsvpc**, specify the subnet ID here.

Command samples

This section includes sample Amazon CloudFormation commands to install Container Insights with Prometheus monitoring in various scenarios.

Create Amazon CloudFormation stack for an Amazon ECS cluster in bridge network mode

```
export AWS_PROFILE=your_aws_config_profile_eg_default
export AWS_DEFAULT_REGION=your_aws_region_eg_ap-southeast-1
export ECS_CLUSTER_NAME=your_ec2_ecs_cluster_name
export ECS_NETWORK_MODE=bridge
export CREATE_IAM_ROLES=True
export ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
export ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-
prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=${ECS_CLUSTER_NAME} \
                 ParameterKey=CreateIAMRoles,ParameterValue=${CREATE_IAM_ROLES} \
                 ParameterKey=ECSNetworkMode,ParameterValue=${ECS_NETWORK_MODE} \

```

Amazon resources created by the Amazon CloudFormation stack

The following table lists the Amazon resources that are created when you use Amazon CloudFormation to set up Container Insights with Prometheus monitoring on an Amazon ECS cluster.

Resource type	Resource name	Comments
AWS::SSM::Parameter	AmazonCloudWatch-CWAgentConfig-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	This is the CloudWatch agent with the default App Mesh and Java/JMX embedded metric format definition.
AWS::SSM::Parameter	AmazonCloudWatch-PrometheusConfigName-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	This is the Prometheus scraping configuration.
AWS::IAM::Role	**$ECS_TASK_ROLE_NAME**.	The Amazon ECS task role. This is created only if you specified **`True`** for `CREATE_IAM_ROLES` .
AWS::IAM::Role	**${ECS_EXECUTION_ROLE_NAME}**	The Amazon ECS task execution role. This is created only if you specified **`True`** for `CREATE_IAM_ROLES` .
AWS::ECS::TaskDefinition	cwagent-prometheus-$*ECS_CLUSTER_NAME* -$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	
AWS::ECS::Service	cwagent-prometheus-replica-service-$*ECS_LAUNCH_TYPE* -$*ECS_NETWORK_MODE*	

Deleting the Amazon CloudFormation stack for the CloudWatch agent with Prometheus monitoring

To delete the CloudWatch agent from an Amazon ECS cluster, enter these commands.

```
export AWS_PROFILE=your_aws_config_profile_eg_default
export AWS_DEFAULT_REGION=your_aws_region_eg_ap-southeast-1
export CLOUDFORMATION_STACK_NAME=your_cloudformation_stack_name

aws cloudformation delete-stack \
--stack-name ${CLOUDFORMATION_STACK_NAME} \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Scraping additional Prometheus sources and importing those metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config> in the Prometheus documentation. The other is for the CloudWatch agent configuration.

For Amazon ECS clusters, the configurations are integrated with the Parameter Store of Amazon Systems Manager by the secrets in the Amazon ECS task definition:

- The secret `PROMETHEUS_CONFIG_CONTENT` is for the Prometheus scrape configuration.
- The secret `CW_CONFIG_CONTENT` is for the CloudWatch agent configuration.

To scrape additional Prometheus metrics sources and import those metrics to CloudWatch, you modify both the Prometheus scrape configuration and the CloudWatch agent configuration, and then re-deploy the agent with the updated configuration.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. By default, the sample configuration file contains the following global configuration lines:

```
global:
  scrape_interval: 1m
  scrape_timeout: 10s
```

- **scrape_interval**— Defines how frequently to scrape targets.
- **scrape_timeout**— Defines how long to wait before a scrape request times out.

You can also define different values for these settings at the job level, to override the global configurations.

Prometheus scraping jobs

The CloudWatch agent YAML files already have some default scraping jobs configured. For example, in the YAML files for Amazon ECS such as `cwagent-ecs-prometheus-metric-for-bridge-host.yaml`, the default scraping jobs are configured in the `ecs_service_discovery` section.

```
"ecs_service_discovery": {
                  "sd_frequency": "1m",
                  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
                  "docker_label": {
                  },
                  "task_definition_list": [
                    {
                      "sd_job_name": "ecs-appmesh-colors",
                      "sd_metrics_ports": "9901",
                      "sd_task_definition_arn_pattern": ".*:task-definition\/.*-
ColorTeller-(white):[0-9]+",
                      "sd_metrics_path": "/stats/prometheus"
                    },
                    {
                      "sd_job_name": "ecs-appmesh-gateway",
                      "sd_metrics_ports": "9901",
                      "sd_task_definition_arn_pattern": ".*:task-definition/.*-
ColorGateway:[0-9]+",
                      "sd_metrics_path": "/stats/prometheus"
                    }
                  ]
                }
```

Each of these default targets are scraped, and the metrics are sent to CloudWatch in log events using embedded metric format. For more information, see [Embedding metrics within logs](#).

Log events from Amazon ECS clusters are stored in the **/aws/ecs/containerinsights/*`cluster_name`*/prometheus** log group.

Each scraping job is contained in a different log stream in this log group.

To add a new scraping target, you add a new entry in the `task_definition_list` section under the `ecs_service_discovery` section. of the YAML file, and restart the agent. For an example of this process, see [Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics](#).

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file has a `prometheus` section under `metrics_collected` for the Prometheus scraping configuration. It includes the following configuration options:

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional. If you omit it, the agent can detect the Amazon ECS cluster name.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics. This field is optional. If you omit it, CloudWatch uses **/aws/ecs/containerinsights/*`cluster_name`*/prometheus** for logs from Amazon ECS clusters.
- **prometheus_config_path**— specifies the Prometheus scrape configuration file path. If the value of this field starts with `env:` the Prometheus scrape configuration file contents will be retrieved from the container's environment variable. Do not change this field.
- **ecs_service_discovery**— is the section to specify the configurations of the Amazon ECS Prometheus target auto-discovery functions. Two modes are supported to discover the Prometheus targets: discovery based on the container's docker label or discovery based on the Amazon ECS task definition ARN regular expression. You can use the two modes together and the CloudWatch agent will de-duplicate the discovered targets based on: *{private_ip}:{port}/{metrics_path}*.

  The `ecs_service_discovery` section can contain the following fields:

  - `sd_frequency` is the frequency to discover the Prometheus exporters. Specify a number and a unit suffix. For example, `1m` for once per minute or `30s` for once per 30 seconds. Valid unit suffixes are `ns`, `us`, `ms`, `s`, `m`, and `h`.

    This field is optional. The default is 60 seconds (1 minute).

- `sd_target_cluster` is the target Amazon ECS cluster name for auto-discovery. This field is optional. The default is the name of the Amazon ECS cluster where the CloudWatch agent is installed.
- `sd_cluster_region` is the target Amazon ECS cluster's Region. This field is optional. The default is the Region of the Amazon ECS cluster where the CloudWatch agent is installed. .
- `sd_result_file` is the path of the YAML file for the Prometheus target results. The Prometheus scrape configuration will refer to this file.
- `docker_label` is an optional section that you can use to specify the configuration for docker label-based service discovery. If you omit this section, docker label-based discovery is not used. This section can contain the following fields:
  - `sd_port_label` is the container's docker label name that specifies the container port for Prometheus metrics. The default value is `ECS_PROMETHEUS_EXPORTER_PORT`. If the container does not have this docker label, the CloudWatch agent will skip it.
  - `sd_metrics_path_label` is the container's docker label name that specifies the Prometheus metrics path. The default value is `ECS_PROMETHEUS_METRICS_PATH`. If the container does not have this docker label, the agent assumes the default path `/metrics`.
  - `sd_job_name_label` is the container's docker label name that specifies the Prometheus scrape job name. The default value is `job`. If the container does not have this docker label, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- `task_definition_list` is an optional section that you can use to specify the configuration of task definition-based service discovery. If you omit this section, task definition-based discovery is not used. This section can contain the following fields:
  - `sd_task_definition_arn_pattern` is the pattern to use to specify the Amazon ECS task definitions to discover. This is a regular expression.
  - `sd_metrics_ports` lists the containerPort for the Prometheus metrics. Separate the containerPorts with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.
  - `sd_metrics_path` specifies the Prometheus metric path. If you omit this, the agent assumes the default path `/metrics`
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.

- `service_name_list_for_tasks` is an optional section that you can use to specify the configuration of service name-based discovery. If you omit this section, service name-based discovery is not used. This section can contain the following fields:
  - `sd_service_name_pattern` is the pattern to use to specify the Amazon ECS service where tasks are to be discovered. This is a regular expression.
  - `sd_metrics_ports` Lists the `containerPort` for the Prometheus metrics. Separate multiple `containerPorts` with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.
  - `sd_metrics_path` specifies the Prometheus metrics path. If you omit this, the agent assumes that the default path `/metrics`.
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
  - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.

    If you have multiple labels specified in `source_labels`, we recommend that you do not use ^ or $ characters in the regular expression for `label_matcher`.
  - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
  - `label_separator` specifies the separator to be used in the `label_matcher` line if multiple `source_labels` are specified. The default is `;`. You can see this default used in the `label_matcher` line in the following example.
  - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
  - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

See the following `metric_declaration` example.

```
"metric_declaration": [
  {
     "source_labels":[ "Service", "Namespace"],
     "label_matcher":"(.*node-exporter.*|.*kube-dns.*);kube-system$",
     "dimensions":[
        ["Service", "Namespace"]
     ],
     "metric_selectors":[
        "^coredns_dns_request_type_count_total$"
     ]
  }
]
```

This example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of `Service` contains either `node-exporter` or `kube-dns`.
- The value of `Namespace` is `kube-system`.
- The Prometheus metric `coredns_dns_request_type_count_total` contains both `Service` and `Namespace` labels.

The log event that is sent includes the following highlighted section:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"coredns_dns_request_type_count_total"
            }
         ],
         "Dimensions":[
            [
               "Namespace",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "Namespace":"kube-system",
```

```
    "Service":"kube-dns",
    "coredns_dns_request_type_count_total":2562,
    "eks_amazonaws_com_component":"kube-dns",
    "instance":"192.168.61.254:9153",
    "job":"kubernetes-service-endpoints",
    ...
}
```

Detailed guide for autodiscovery on Amazon ECS clusters

Prometheus provides dozens of dynamic service-discovery mechanisms as described in <scrape_config>. However there is no built-in service discovery for Amazon ECS. The CloudWatch agent adds this mechanism.

When the Amazon ECS Prometheus service discovery is enabled, the CloudWatch agent periodically makes the following API calls to Amazon ECS and Amazon EC2 frontends to retrieve the metadata of the running ECS tasks in the target ECS cluster.

```
EC2:DescribeInstances
ECS:ListTasks
ECS:ListServices
ECS:DescribeContainerInstances
ECS:DescribeServices
ECS:DescribeTasks
ECS:DescribeTaskDefinition
```

The metadata is used by the CloudWatch agent to scan the Prometheus targets within the ECS cluster. The CloudWatch agent supports three service discovery modes:

- Container docker label-based service discovery
- ECS task definition ARN regular expression-based service discovery
- ECS service name regular expression-based service discovery

All modes can be used together. CloudWatch agent de-duplicates the discovered targets based on: `{private_ip}:{port}/{metrics_path}`.

All discovered targets are written into a result file specified by the `sd_result_file` configuration field within the CloudWatch agent container. The following is a sample result file:

```
- targets:
```

```
  - 10.6.1.95:32785
  labels:
    __metrics_path__: /metrics
    ECS_PROMETHEUS_EXPORTER_PORT: "9406"
    ECS_PROMETHEUS_JOB_NAME: demo-jar-ec2-bridge-dynamic
    ECS_PROMETHEUS_METRICS_PATH: /metrics
    InstanceType: t3.medium
    LaunchType: EC2
    SubnetId: subnet-123456789012
    TaskDefinitionFamily: demo-jar-ec2-bridge-dynamic-port
    TaskGroup: family:demo-jar-ec2-bridge-dynamic-port
    TaskRevision: "7"
    VpcId: vpc-01234567890
    container_name: demo-jar-ec2-bridge-dynamic-port
    job: demo-jar-ec2-bridge-dynamic
- targets:
  - 10.6.3.193:9404
  labels:
    __metrics_path__: /metrics
    ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_B: "9404"
    ECS_PROMETHEUS_JOB_NAME: demo-tomcat-ec2-bridge-mapped-port
    ECS_PROMETHEUS_METRICS_PATH: /metrics
    InstanceType: t3.medium
    LaunchType: EC2
    SubnetId: subnet-123456789012
    TaskDefinitionFamily: demo-tomcat-ec2-bridge-mapped-port
    TaskGroup: family:demo-jar-tomcat-bridge-mapped-port
    TaskRevision: "12"
    VpcId: vpc-01234567890
    container_name: demo-tomcat-ec2-bridge-mapped-port
    job: demo-tomcat-ec2-bridge-mapped-port
```

You can directly integrate this result file with Prometheus file-based service discovery. For more information about Prometheus file-based service discovery, see <file_sd_config>.

Suppose the result file is written to `/tmp/cwagent_ecs_auto_sd.yaml` The following Prometheus scrape configuration will consume it.

```
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: cwagent-ecs-file-sd-config
```

```
    sample_limit: 10000
    file_sd_configs:
      - files: [ "/tmp/cwagent_ecs_auto_sd.yaml" ]
```

The CloudWatch agent also adds the following additional labels for the discovered targets.

- `container_name`
- `TaskDefinitionFamily`
- `TaskRevision`
- `TaskGroup`
- `StartedBy`
- `LaunchType`
- `job`
- `__metrics_path__`
- Docker labels

When the cluster has the EC2 launch type, the following three labels are added.

- `InstanceType`
- `VpcId`
- `SubnetId`

> **Note**
>
> Docker labels that don't match the regular expression `[a-zA-Z_][a-zA-Z0-9_]*` are filtered out. This matches the Prometheus conventions as listed in `label_name` in [Configuration file](#) in the Prometheus documentation.

ECS service discovery configuration examples

This section includes examples that demonstrate ECS service discovery.

Example 1

```
"ecs_service_discovery": {
```

```
  "sd_frequency": "1m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
  }
}
```

This example enables docker label-based service discovery. The CloudWatch agent will query the ECS tasks' metadata once per minute and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

The default value of `sd_port_label` in the `docker_label` section is `ECS_PROMETHEUS_EXPORTER_PORT`. If any running container in the ECS tasks has a `ECS_PROMETHEUS_EXPORTER_PORT` docker label, the CloudWatch agent uses its value as `container port` to scan all exposed ports of the container. If there is a match, the mapped host port plus the private IP of the container are used to construct the Prometheus exporter target in the following format: `private_ip:host_port`.

The default value of `sd_metrics_path_label` in the `docker_label` section is `ECS_PROMETHEUS_METRICS_PATH`. If the container has this docker label, its value will be used as the `__metrics_path__` . If the container does not have this label, the default value `/metrics` is used.

The default value of `sd_job_name_label` in the `docker_label` section is `job`. If the container has this docker label, its value will be appended as one of the labels for the target to replace the default job name specified in the Prometheus configuration. The value of this docker label is used as the log stream name in the CloudWatch Logs log group.

Example 2

```
"ecs_service_discovery": {
  "sd_frequency": "15s",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
    "sd_port_label": "ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_A",
    "sd_job_name_label": "ECS_PROMETHEUS_JOB_NAME"
  }
}
```

This example enables docker label-based service discovery. THe CloudWatch agent will query the ECS tasks' metadata every 15 seconds and write the discovered targets into the `/tmp/`

`cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container. The containers with a docker label of `ECS_PROMETHEUS_EXPORTER_PORT_SUBSET_A` will be scanned. The value of the docker label `ECS_PROMETHEUS_JOB_NAME` is used as the job name.

Example 3

```
"ecs_service_discovery": {
  "sd_frequency": "5m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "task_definition_list": [
    {
      "sd_job_name": "java-prometheus",
      "sd_metrics_path": "/metrics",
      "sd_metrics_ports": "9404; 9406",
      "sd_task_definition_arn_pattern": ".*:task-definition/.*javajmx.*:[0-9]+"
    },
    {
      "sd_job_name": "envoy-prometheus",
      "sd_metrics_path": "/stats/prometheus",
      "sd_container_name_pattern": "^envoy$",
      "sd_metrics_ports": "9901",
      "sd_task_definition_arn_pattern": ".*:task-definition/.*appmesh.*:23"
    }
  ]
}
```

This example enables ECS task definition ARN regular expression-based service discovery. The CloudWatch agent will query the ECS tasks' metadata every five minutes and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

Two task definition ARN regular expresion sections are defined:

- For the first section, the ECS tasks with `javajmx` in their ECS task definition ARN are filtered for the container port scan. If the containers within these ECS tasks expose the container port on 9404 or 9406, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/metrics`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/metrics`, the scraped metrics are sent to the `java-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.

- For the second section, the ECS tasks with `appmesh` in their ECS task definition ARN and with `version` of `:23` are filtered for the container port scan. For containers with a name of `envoy` that expose the container port on `9901`, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value within these ECS tasks expose the container port on 9404 or 9406, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/stats/prometheus`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/stats/prometheus`, and send the scraped metrics to the `envoy-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.

Example 4

```
"ecs_service_discovery": {
  "sd_frequency": "5m",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "service_name_list_for_tasks": [
    {
      "sd_job_name": "nginx-prometheus",
      "sd_metrics_path": "/metrics",
      "sd_metrics_ports": "9113",
      "sd_service_name_pattern": "^nginx-.*"
    },
    {
      "sd_job_name": "haproxy-prometheus",
      "sd_metrics_path": "/stats/metrics",
      "sd_container_name_pattern": "^haproxy$",
      "sd_metrics_ports": "8404",
      "sd_service_name_pattern": ".*haproxy-service.*"
    }
  ]
}
```

This example enables ECS service name regular expression-based service discovery. The CloudWatch agent will query the ECS services' metadata every five minutes and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

Two service name regular expresion sections are defined:

- For the first section, the ECS tasks that are associated with ECS services that have names matching the regular expression `^nginx-.*` are filtered for the container port scan. If the containers within these ECS tasks expose the container port on 9113, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/metrics`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/metrics`, and the scraped metrics are sent to the `nginx-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.
- or the second section, the ECS tasks that are associated with ECS services that have names matching the regular expression `.*haproxy-service.*` are filtered for the container port scan. For containers with a name of `haproxy` expose the container port on 8404, the mapped host port along with the private IP of the container are used to create the Prometheus exporter targets. The value of `sd_metrics_path` sets `__metrics_path__` to `/stats/metrics`. So the CloudWatch agent will scrape the Prometheus metrics from `private_ip:host_port/stats/metrics`, and the scraped metrics are sent to the `haproxy-prometheus` log stream in CloudWatch Logs in the log group `/aws/ecs/containerinsights/cluster_name/prometheus`.

Example 5

```
"ecs_service_discovery": {
  "sd_frequency": "1m30s",
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
  "docker_label": {
    "sd_port_label": "MY_PROMETHEUS_EXPORTER_PORT_LABEL",
    "sd_metrics_path_label": "MY_PROMETHEUS_METRICS_PATH_LABEL",
    "sd_job_name_label": "MY_PROMETHEUS_METRICS_NAME_LABEL"
  }
  "task_definition_list": [
    {
      "sd_metrics_ports": "9150",
      "sd_task_definition_arn_pattern": "*memcached.*"
    }
  ]
}
```

This example enables both ECS service discovery modes. The CloudWatch agent will query the ECS tasks' metadata every 90 seconds and write the discovered targets into the `/tmp/cwagent_ecs_auto_sd.yaml` file within the CloudWatch agent container.

For the docker-based service discovery configuration:

- The ECS tasks with docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` will be filtered for Prometheus port scan. The target Prometheus container port is specified by the value of the label `MY_PROMETHEUS_EXPORTER_PORT_LABEL`.
- The value of the docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` is used for `__metrics_path__`. If the container does not have this docker label, the default value `/metrics` is used.
- The value of the docker label `MY_PROMETHEUS_EXPORTER_PORT_LABEL` is used as the job label. If the container does not have this docker label, the job name defined in the Prometheus configuration is used.

For the ECS task definition ARN regular expression-based service discovery configuration:

- The ECS tasks with `memcached` in the ECS task definition ARN are filtered for container port scan. The target Prometheus container port is 9150 as defined by `sd_metrics_ports`. The default metrics path `/metrics` is used. The job name defined in the Prometheus configuration is used.

(Optional) Set up sample containerized Amazon ECS workloads for Prometheus metric testing

To test the Prometheus metric support in CloudWatch Container Insights, you can set up one or more of the following containerized workloads. The CloudWatch agent with Prometheus support automatically collects metrics from each of these workloads. To see the metrics that are collected by default, see Prometheus metrics collected by the CloudWatch agent.

Topics

- Tutorial for scraping Redis OSS Prometheus metrics on Amazon ECS Fargate

Sample App Mesh workload for Amazon ECS clusters

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Setting up Container Insights on Amazon ECS.

First, follow this walkthrough to deploy the sample color app on your Amazon ECS cluster. After you finish, you will have App Mesh Prometheus metrics exposed on port 9901.

Next, follow these steps to install the CloudWatch agent with Prometheus monitoring on the same Amazon ECS cluster where you installed the color app. The steps in this section install the CloudWatch agent in bridge network mode.

The environment variables `ENVIRONMENT_NAME`, `AWS_PROFILE`, and `AWS_DEFAULT_REGION` that you set in the walkthrough will also be used in the following steps.

To install the CloudWatch agent with Prometheus monitoring for testing

1. Download the Amazon CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-
bridge-host.yaml
```

2. Set the network mode by entering the following commands.

```
export ECS_CLUSTER_NAME=${ENVIRONMENT_NAME}
export ECS_NETWORK_MODE=bridge
```

3. Create the Amazon CloudFormation stack by entering the following commands.

```
aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=${ECS_CLUSTER_NAME} \
                 ParameterKey=CreateIAMRoles,ParameterValue=True \
                 ParameterKey=ECSNetworkMode,ParameterValue=${ECS_NETWORK_MODE} \
                 ParameterKey=TaskRoleName,ParameterValue=CWAgent-Prometheus-
TaskRole-${ECS_CLUSTER_NAME} \
```

```
                 ParameterKey=ExecutionRoleName,ParameterValue=CWAgent-Prometheus-ExecutionRole-${ECS_CLUSTER_NAME} \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION} \
    --profile ${AWS_PROFILE}
```

4. (Optional) When the Amazon CloudFormation stack is created, you see a `CREATE_COMPLETE` message. If you to check the status before you see that message, enter the following command.

```
aws cloudformation describe-stacks \
--stack-name CWAgent-Prometheus-ECS-${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
--query 'Stacks[0].StackStatus' \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Troubleshooting

The steps in the walkthrough use jq to parse the output result of the Amazon CLI. For more information about installing jq, see [jq](). Use the following command to set the default output format of your Amazon CLI to JSON so jq can parse it correctly.

```
$ aws configure
```

When the response gets to `Default output format`, enter **`json`**.

Uninstall the CloudWatch agent with Prometheus monitoring

When you are finished testing, enter the following command to uninstall the CloudWatch agent by deleting the Amazon CloudFormation stack.

```
aws cloudformation delete-stack \
--stack-name CWAgent-Prometheus-ECS-${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
--region ${AWS_DEFAULT_REGION} \
--profile ${AWS_PROFILE}
```

Sample Java/JMX workload for Amazon ECS clusters

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent with Prometheus support scrapes the Java/JMX Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the JMX Exporter to expose the metrics on a different port or metrics_path. If you do change the port or path, update the default `ecs_service_discovery` section in the CloudWatch agent configuration.

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Setting up Container Insights on Amazon ECS.

To install the Java/JMX sample workload for Amazon ECS clusters

1. Follow the steps in these sections to create your Docker images.

   - Example: Java Jar Application Docker image with Prometheus metrics
   - Example: Apache Tomcat Docker image with Prometheus metrics
2. Specify the following two docker labels in the Amazon ECS task definition file. You can then run the task definition as an Amazon ECS service or Amazon ECS task in the cluster.

   - Set `ECS_PROMETHEUS_EXPORTER_PORT` to point to the containerPort where the Prometheus metrics are exposed.
   - Set `Java_EMF_Metrics` to `true`. The CloudWatch agent uses this flag to generated the embedded metric format in the log event.

   The following is an example:

```
{
  "family": "workload-java-ec2-bridge",
  "taskRoleArn": "{{task-role-arn}}",
  "executionRoleArn": "{{execution-role-arn}}",
  "networkMode": "bridge",
  "containerDefinitions": [
    {
      "name": "tomcat-prometheus-workload-java-ec2-bridge-dynamic-port",
      "image": "your_docker_image_tag_for_tomcat_with_prometheus_metrics",
      "portMappings": [
        {
          "hostPort": 0,
          "protocol": "tcp",
          "containerPort": 9404
```

```
        }
      ],
      "dockerLabels": {
        "ECS_PROMETHEUS_EXPORTER_PORT": "9404",
        "Java_EMF_Metrics": "true"
      }
    }
  ],
  "requiresCompatibilities": [
    "EC2"  ],
  "cpu": "256",
  "memory": "512"
  }
```

The default setting of the CloudWatch agent in the Amazon CloudFormation template enables both docker label-based service discovery and task definition ARN-based service discovery. To view these default settings, see line 65 of the CloudWatch agent YAML configuration file. The containers with the `ECS_PROMETHEUS_EXPORTER_PORT` label will be auto-discovered based on the specified container port for Prometheus scraping.

The default setting of the CloudWatch agent also has the `metric_declaration` setting for Java/JMX at line 112 of the same file. All docker labels of the target containers will be added as additional labels in the Prometheus metrics and sent to CloudWatch Logs. For the Java/JMX containers with docker label `Java_EMF_Metrics="true"`, the embedded metric format will be generated.

Sample NGINX workload for Amazon ECS clusters

The NGINX Prometheus exporter can scrape and expose NGINX data as Prometheus metrics. This example uses the exporter in tandem with the NGINX reverse proxy service for Amazon ECS.

For more information about the NGINX Prometheus exporter, see nginx-prometheus-exporter on Github. For more information about the NGINX reverse proxy, see ecs-nginx-reverse-proxy on Github.

The CloudWatch agent with Prometheus support scrapes the NGINX Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the NGINX Prometheus Exporter to expose the metrics on a different port or path. If you change the port or path, update the `ecs_service_discovery` section in the CloudWatch agent configuration file.

Install the NGINX reverse proxy sample workload for Amazon ECS clusters

Follow these steps to install the NGINX reverse proxy sample workload.

Create the Docker images

To create the Docker images for the NGINX reverse proxy sample workload

1. Download the following folder from the NGINX reverse proxy repo: https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/.
2. Find the `app` directory and build an image from that directory:

   ```
   docker build -t web-server-app ./path-to-app-directory
   ```

3. Build a custom image for NGINX. First, create a directory with the following two files:

   - A sample Dockerfile:

     ```
     FROM nginx
     COPY nginx.conf /etc/nginx/nginx.conf
     ```

   - An `nginx.conf` file, modified from https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/:

     ```
     events {
       worker_connections 768;
     }

     http {
       # Nginx will handle gzip compression of responses from the app server
       gzip on;
       gzip_proxied any;
       gzip_types text/plain application/json;
       gzip_min_length 1000;

       server{
         listen 8080;
         location /stub_status {
             stub_status   on;
         }
       }
     ```

```
    server {
      listen 80;

      # Nginx will reject anything not matching /api
      location /api {
        # Reject requests with unsupported HTTP method
        if ($request_method !~ ^(GET|POST|HEAD|OPTIONS|PUT|DELETE)$) {
          return 405;
        }

        # Only requests matching the whitelist expectations will
        # get sent to the application server
        proxy_pass http://app:3000;
        proxy_http_version 1.1;
        proxy_set_header Upgrade $http_upgrade;
        proxy_set_header Connection 'upgrade';
        proxy_set_header Host $host;
        proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
        proxy_cache_bypass $http_upgrade;
      }
    }
  }
```

Note

`stub_status` must be enabled on the same port that `nginx-prometheus-exporter` is configured to scrape metrics from. In our example task definition, `nginx-prometheus-exporter` is configured to scrape metrics from port 8080.

4. Build an image from files in your new directory:

```
docker build -t nginx-reverse-proxy ./path-to-your-directory
```

5. Upload your new images to an image repository for later use.

Create the task definition to run NGINX and the web server app in Amazon ECS

Next, you set up the task definition.

This task definition enables the collection and export of NGINX Prometheus metrics. The NGINX container tracks input from the app, and exposes that data to port 8080, as set in `nginx.conf`.

The NGINX prometheus exporter container scrapes these metrics, and posts them to port 9113, for use in CloudWatch.

To set up the task definition for the NGINX sample Amazon ECS workload

1. Create a task definition JSON file with the following content. Replace *your-customized-nginx-iamge* with the image URI for your customized NGINX image, and replace *your-web-server-app-image* with the image URI for your web server app image.

```
{
  "containerDefinitions": [
    {
      "name": "nginx",
      "image": "your-customized-nginx-image",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "protocol": "tcp"
        }
      ],
      "links": [
        "app"
      ]
    },
    {
      "name": "app",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 256,
      "essential": true
    },
    {
      "name": "nginx-prometheus-exporter",
      "image": "docker.io/nginx/nginx-prometheus-exporter:0.8.0",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "command": [
        "-nginx.scrape-uri",
        "http://nginx:8080/stub_status"
```

```
    ],
    "links":[
      "nginx"
    ],
      "portMappings":[
        {
          "containerPort": 9113,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "networkMode": "bridge",
  "placementConstraints": [],
  "family": "nginx-sample-stack"
}
```

2. Register the task definition by entering the following command.

```
aws ecs register-task-definition --cli-input-json file://path-to-your-task-definition-json
```

3. Create a service to run the task by entering the following command:

   Be sure not to change the service name. We will be running a CloudWatch agent service using a configuration that searches for tasks using the name patterns of the services that started them. For example, for the CloudWatch agent to find the task launched by this command, you can specify the value of `sd_service_name_pattern` to be `^nginx-service$`. The next section provides more details.

```
aws ecs create-service \
 --cluster your-cluster-name \
 --service-name nginx-service \
 --task-definition nginx-sample-stack:1 \
 --desired-count 1
```

Configure the CloudWatch agent to scrape NGINX Prometheus metrics

The final step is to configure the CloudWatch agent to scrape the NGINX metrics. In this example, the CloudWatch agent discovers the task via the service name pattern, and the port 9113, where the exporter exposes the prometheus metrics for NGINX. With the task discovered and the metrics available, the CloudWatch agent begins posting the collected metrics to the log stream **nginx-prometheus-exporter**.

To configure the CloudWatch agent to scrape the NGINX metrics

1. Download the latest version of the necessary YAML file by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent confguration in the `value` key in the `resource:CWAgentConfigSSMParameter` section. Then, in the `ecs_service_discovery` section, add the following `service_name_list_for_tasks` section.

```
"service_name_list_for_tasks": [
  {
    "sd_job_name": "nginx-prometheus-exporter",
    "sd_metrics_path": "/metrics",
    "sd_metrics_ports": "9113",
    "sd_service_name_pattern": "^nginx-service$"
   }
],
```

3. In the same file, add the following section in the `metric_declaration` section to allow NGINX metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["job"],
  "label_matcher": ".*nginx.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName"]],
  "metric_selectors": [
    "^nginx_.*$"
  ]
},
```

4. If you don't already have the CloudWatch agent deployed in this cluster, skip to step 8.

   If you already have the CloudWatch agent deployed in the Amazon ECS cluster by using Amazon CloudFormation, you can create a change set by entering the following commands:

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name nginx-scraping-support
```

5. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.

6. Revew the newly-created changeset **nginx-scraping-support**. You should see one change applied to the **CWAgentConfigSSMParameter** resource. Run the changeset and restart the CloudWatch agent task by entering the following command:

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

8. If you are installing the CloudWatch agent with Prometheus metric collecting on the cluster for the first time, enter the following commands.

```
ECS_CLUSTER_NAME=your_cluster_name
```

```
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your NGINX metrics and logs

You can now view the NGINX metrics being collected.

To view the metrics for your sample NGINX workload

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **ContainerInsights/Prometheus** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **/aws/containerinsights/*your_cluster_name*/prometheus**, in the log stream *nginx-prometheus-exporter*.

Sample NGINX Plus workload for Amazon ECS clusters

NGINX Plus is the commerical version of NGINX. You must have a licence to use it. For more information, see NGINX Plus

The NGINX Prometheus exporter can scrape and expose NGINX data as Prometheus metrics. This example uses the exporter in tandem with the NGINX Plus reverse proxy service for Amazon ECS.

For more information about the NGINX Prometheus exporter, see [nginx-prometheus-exporter] on Github. For more information about the NGINX reverse proxy, see [ecs-nginx-reverse-proxy] on Github.

The CloudWatch agent with Prometheus support scrapes the NGINX Plus Prometheus metrics based on the service discovery configuration in the Amazon ECS cluster. You can configure the NGINX Prometheus Exporter to expose the metrics on a different port or path. If you change the port or path, update the `ecs_service_discovery` section in the CloudWatch agent configuration file.

Install the NGINX Plus reverse proxy sample workload for Amazon ECS clusters

Follow these steps to install the NGINX reverse proxy sample workload.

Create the Docker images

To create the Docker images for the NGINX Plus reverse proxy sample workload

1. Download the following folder from the NGINX reverse proxy repo: https://github.com/awslabs/ecs-nginx-reverse-proxy/tree/master/reverse-proxy/.
2. Find the app directory and build an image from that directory:

```
docker build -t web-server-app ./path-to-app-directory
```

3. Build a custom image for NGINX Plus. Before you can build the image for NGINX Plus, you need to obtain the key named `nginx-repo.key` and the SSL certificate `nginx-repo.crt` for your licensed NGINX Plus. Create a directory and store in it your `nginx-repo.key` and `nginx-repo.crt` files.

   In the directory that you just created, create the following two files:

   - A sample Dockerfile with the following content. This docker file is adopted from a sample file provided at https://docs.nginx.com/nginx/admin-guide/installing-nginx/installing-nginx-docker/#docker_plus_image. The important change that we make is that we load a separate file, called `nginx.conf`, which will be created in the next step.

```
FROM debian:buster-slim

LABEL maintainer="NGINX Docker Maintainers <docker-maint@nginx.com>“

# Define NGINX versions for NGINX Plus and NGINX Plus modules
```

```
# Uncomment this block and the versioned nginxPackages block in the main RUN
# instruction to install a specific release
# ENV NGINX_VERSION 21
# ENV NJS_VERSION 0.3.9
# ENV PKG_RELEASE 1~buster

# Download certificate and key from the customer portal (https://cs.nginx.com
 (https://cs.nginx.com/))
# and copy to the build context
COPY nginx-repo.crt /etc/ssl/nginx/
COPY nginx-repo.key /etc/ssl/nginx/
# COPY nginx.conf /etc/ssl/nginx/nginx.conf

RUN set -x \
# Create nginx user/group first, to be consistent throughout Docker variants
&& addgroup --system --gid 101 nginx \
&& adduser --system --disabled-login --ingroup nginx --no-create-home --home /

        proxy_set_header Host $host;
        proxy_set_header X-Forwarded-For $proxy_add_x_forwarded_for;
        proxy_cache_bypass $http_upgrade;
      }
    }
  }
```

4. Build an image from files in your new directory:

```
docker build -t nginx-plus-reverse-proxy ./path-to-your-directory
```

5. Upload your new images to an image repository for later use.

Create the task definition to run NGINX Plus and the web server app in Amazon ECS

Next, you set up the task definition.

This task definition enables the collection and export of NGINX Plus Prometheus metrics. The NGINX container tracks input from the app, and exposes that data to port 8080, as set in `nginx.conf`. The NGINX prometheus exporter container scrapes these metrics, and posts them to port 9113, for use in CloudWatch.

To set up the task definition for the NGINX sample Amazon ECS workload

1. Create a task definition JSON file with the following content. Replace *your-customized-nginx-plus-image* with the image URI for your customized NGINX Plus image, and replace *your-web-server-app-image* with the image URI for your web server app image.

```
{
  "containerDefinitions": [
    {
      "name": "nginx",
      "image": "your-customized-nginx-plus-image",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "portMappings": [
        {
          "containerPort": 80,
          "protocol": "tcp"
```

```
        }
      ],
      "links": [
        "app",
        "app2"
      ]
    },
    {
      "name": "app",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 128,
      "essential": true
    },
    {
      "name": "app2",
      "image": "your-web-server-app-image",
      "memory": 256,
      "cpu": 128,
      "essential": true
    },
    {
      "name": "nginx-prometheus-exporter",
      "image": "docker.io/nginx/nginx-prometheus-exporter:0.8.0",
      "memory": 256,
      "cpu": 256,
      "essential": true,
      "command": [
        "-nginx.plus",
        "-nginx.scrape-uri",
         "http://nginx:8080/api"
    ],
    "links":[
      "nginx"
    ],
      "portMappings":[
        {
          "containerPort": 9113,
          "protocol": "tcp"
        }
      ]
    }
  ],
  "networkMode": "bridge",
```

```
  "placementConstraints": [],
  "family": "nginx-plus-sample-stack"
}
```

2. Register the task definition:

```
aws ecs register-task-definition --cli-input-json file://path-to-your-task-definition-json
```

3. Create a service to run the task by entering the following command:

```
aws ecs create-service \
 --cluster your-cluster-name \
 --service-name nginx-plus-service \
 --task-definition nginx-plus-sample-stack:1 \
 --desired-count 1
```

   Be sure not to change the service name. We will be running a CloudWatch agent service using a configuration that searches for tasks using the name patterns of the services that started them. For example, for the CloudWatch agent to find the task launched by this command, you can specify the value of `sd_service_name_pattern` to be `^nginx-plus-service$`. The next section provides more details.

Configure the CloudWatch agent to scrape NGINX Plus Prometheus metrics

The final step is to configure the CloudWatch agent to scrape the NGINX metrics. In this example, the CloudWatch agent discovers the task via the service name pattern, and the port 9113, where the exporter exposes the prometheus metrics for NGINX. With the task discovered and the metrics available, the CloudWatch agent begins posting the collected metrics to the log stream **nginx-prometheus-exporter**.

To configure the CloudWatch agent to scrape the NGINX metrics

1. Download the latest version of the necessary YAML file by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-bridge-host.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent confguration in the `value` key in the `resource:CWAgentConfigSSMParameter` section. Then, in the `ecs_service_discovery` section, add the following `service_name_list_for_tasks` section.

```
"service_name_list_for_tasks": [
  {
    "sd_job_name": "nginx-plus-prometheus-exporter",
    "sd_metrics_path": "/metrics",
    "sd_metrics_ports": "9113",
    "sd_service_name_pattern": "^nginx-plus.*"
   }
],
```

3. In the same file, add the following section in the `metric_declaration` section to allow NGINX Plus metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName"]],
  "metric_selectors": [
    "^nginxplus_connections_accepted$",
    "^nginxplus_connections_active$",
    "^nginxplus_connections_dropped$",
    "^nginxplus_connections_idle$",
    "^nginxplus_http_requests_total$",
    "^nginxplus_ssl_handshakes$",
    "^nginxplus_ssl_handshakes_failed$",
    "^nginxplus_up$",
    "^nginxplus_upstream_server_health_checks_fails$"
  ]
},
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName",
 "upstream"]],
  "metric_selectors": [
    "^nginxplus_upstream_server_response_time$"
  ]
},
```

```
{
  "source_labels": ["job"],
  "label_matcher": "^nginx-plus.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily", "ServiceName", "code"]],
  "metric_selectors": [
    "^nginxplus_upstream_server_responses$",
    "^nginxplus_server_zone_responses$"
  ]
},
```

4. If you don't already have the CloudWatch agent deployed in this cluster, skip to step 8.

   If you already have the CloudWatch agent deployed in the Amazon ECS cluster by using Amazon CloudFormation, you can create a change set by entering the following commands:

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name nginx-plus-scraping-support
```

5. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.

6. Revew the newly-created changeset **nginx-plus-scraping-support**. You should see one change applied to the **CWAgentConfigSSMParameter** resource. Run the changeset and restrt the CloudWatch agent task by entering the following command:

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
```

```
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

8. If you are installing the CloudWatch agent with Prometheus metric collecting on the cluster for the first time, enter the following commands.

```
ECS_CLUSTER_NAME=your_cluster_name
AWS_REGION=your_aws_region
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your NGINX Plus metrics and logs

You can now view the NGINX Plus metrics being collected.

To view the metrics for your sample NGINX workload

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **ContainerInsights/Prometheus** namespace to see the metrics.

3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **/aws/containerinsights/*your_cluster_name*/prometheus**, in the log stream *nginx-plus-prometheus-exporter*.

Tutorial for adding a new Prometheus scrape target: Memcached on Amazon ECS

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Memcached application on an Amazon Amazon ECS cluster with the EC2 launch type. The Memcached Prometheus exporter target will be auto-discovered by the CloudWatch agent by ECS task definition-based service discovery.

Memcached is a general-purpose distributed memory caching system. It is often used to speed up dynamic database-driven websites by caching data and objects in RAM to reduce the number of times an external data source (such as a database or API) must be read. For more infromation, see [What is Memcached?](#)

The [memchached_exporter](#) (Apache License 2.0) is one of the Prometheus official exporters. By default the memcache_exporter serves on port 0.0.0.0:9150 at `/metrics.`

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- [Memcached](#)
- [prom/memcached-exporter](#)

Prerequisite

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see [Setting up Container Insights on Amazon ECS](#).

Topics

- [Set the Amazon ECS EC2 cluster environment variables](#)
- [Install the sample Memcached workload](#)
- [Configure the CloudWatch agent to scrape Memcached Prometheus metrics](#)
- [Viewing your Memcached metrics](#)

Set the Amazon ECS EC2 cluster environment variables

To set the Amazon ECS EC2 cluster environment variables

1. Install the Amazon ECS CLI if you haven't already done so. For more information, see [Installing the Amazon ECS CLI](#).
2. Set the new Amazon ECS cluster name and Region. For example:

```
ECS_CLUSTER_NAME=ecs-ec2-memcached-tutorial
AWS_DEFAULT_REGION=ca-central-1
```

3. (Optional) If you don't already have an Amazon ECS cluster with the EC2 launch type where you want to install the sample Memcached workload and CloudWatch agent, you can create one by entering the following command.

```
ecs-cli up --capability-iam --size 1 \
--instance-type t3.medium \
--cluster $ECS_CLUSTER_NAME \
--region $AWS_REGION
```

The expected result of this command is as follows:

```
WARN[0000] You will not be able to SSH into your EC2 instances without a key pair.
INFO[0000] Using recommended Amazon Linux 2 AMI with ECS Agent 1.44.4 and Docker
 version 19.03.6-ce
INFO[0001] Created cluster                               cluster=ecs-ec2-memcached-
tutorial region=ca-central-1
INFO[0002] Waiting for your cluster resources to be created...
INFO[0002] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
INFO[0063] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
INFO[0124] Cloudformation stack status
 stackStatus=CREATE_IN_PROGRESS
VPC created: vpc-xxxxxxxxxxxxxxxxx
Security Group created: sg-xxxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxx
Cluster creation succeeded.
```

Install the sample Memcached workload

To install the sample Memcached workload which exposes the Prometheus metrics

1. Download the Memcached Amazon CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/sample_traffic/memcached/memcached-traffic-sample.yaml
```

2. Set the IAM role names to be created for Memcached by entering the following commands.

```
MEMCACHED_ECS_TASK_ROLE_NAME=memcached-prometheus-demo-ecs-task-role-name
MEMCACHED_ECS_EXECUTION_ROLE_NAME=memcached-prometheus-demo-ecs-execution-role-name
```

3. Install the sample Memcached workload by entering the following command. This sample installs the workload in `host` network mode.

```
MEMCACHED_ECS_NETWORK_MODE=host

aws cloudformation create-stack --stack-name Memcached-Prometheus-Demo-ECS-$ECS_CLUSTER_NAME-EC2-$MEMCACHED_ECS_NETWORK_MODE \
    --template-body file://memcached-traffic-sample.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=ECSNetworkMode,ParameterValue=$MEMCACHED_ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$MEMCACHED_ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=$MEMCACHED_ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

The Amazon CloudFormation stack creates four resources:

- One ECS task role
- One ECS task execution role
- One Memcached task definition
- One Memcached service

In the Memcached task definition, two containers are defined:

- The primary container runs a simple Memcached application and opens port 11211 for access.
- The other container runs the Redis OSS exporter process to expose the Prometheus metrics on port 9150. This is the container to be discovered and scraped by the CloudWatch agent.

Configure the CloudWatch agent to scrape Memcached Prometheus metrics

To configure the CloudWatch agent to scrape Memcached Prometheus metrics

1. Download the latest version of `cwagent-ecs-prometheus-metric-for-awsvpc.yaml` by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/
cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-
awsvpc.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent configuration behind the `value` key in the `resource:CWAgentConfigSSMParameter` section.

   Then, in the `ecs_service_discovery` section, add the following configuration into the `task_definition_list` section.

```
{
    "sd_job_name": "ecs-memcached",
    "sd_metrics_ports": "9150",
    "sd_task_definition_arn_pattern": ".*:task-definition/memcached-prometheus-
demo.*:[0-9]+"
},
```

   For the `metric_declaration` section, the default setting does not allow any Memcached metrics. Add the following section to allow Memcached metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["container_name"],
  "label_matcher": "memcached-exporter-.*",
  "dimensions": [["ClusterName", "TaskDefinitionFamily"]],
  "metric_selectors": [
```

```
      "^memcached_current_(bytes|items|connections)$",
      "^memcached_items_(reclaimed|evicted)_total$",
      "^memcached_(written|read)_bytes_total$",
      "^memcached_limit_bytes$",
      "^memcached_commands_total$"
    ]
  },
  {
    "source_labels": ["container_name"],
    "label_matcher": "memcached-exporter-.*",
    "dimensions": [["ClusterName", "TaskDefinitionFamily","status","command"],
   ["ClusterName", "TaskDefinitionFamily","command"]],
    "metric_selectors": [
      "^memcached_commands_total$"
    ]
  },
```

3. If you already have the CloudWatch agent deployed in the Amazon ECS cluster by Amazon CloudFormation, you can create a change set by entering the following commands.

```
ECS_NETWORK_MODE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name memcached-scraping-support
```

4. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
5. Review the newly created changeset `memcached-scraping-support`. You should see one change applied to the `CWAgentConfigSSMParameter` resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

6. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-EC2-$ECS_NETWORK_MODE \
--region $AWS_REGION
```

7. If you are installing the CloudWatch agent with Prometheus metric collecting for the cluster for the first time, please enter the following commands:

```
ECS_NETWORK_MODEE=bridge
CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION
```

Viewing your Memcached metrics

This tutorial sends the following metrics to the **ECS/ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric name	Dimensions
memcached _current_items	ClusterName , TaskDefinitionFamily
memcached _current_ connections	ClusterName , TaskDefinitionFamily
memcached _limit_bytes	ClusterName , TaskDefinitionFamily
memcached _current_bytes	ClusterName , TaskDefinitionFamily
memcached _written_ bytes_total	ClusterName , TaskDefinitionFamily
memcached _read_byt es_total	ClusterName , TaskDefinitionFamily
memcached _items_ev icted_total	ClusterName , TaskDefinitionFamily
memcached _items_re claimed_total	ClusterName , TaskDefinitionFamily
memcached _commands _total	ClusterName , TaskDefinitionFamily ClusterName , TaskDefinitionFamily, command ClusterName , TaskDefinitionFamily, status, command

> **Note**
>
> The value of the **command** dimension can be: `delete`, `get`, `cas`, `set`, `decr`, `touch`, `incr`, or `flush`.
> The value of the **status** dimension can be `hit`, `miss`, or `badval`.

You can also create a CloudWatch dashboard for your Memcached Prometheus metrics.

To create a dashboard for Memcached Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_memcached_cw_dashboard_name
ECS_TASK_DEF_FAMILY=memcached-prometheus-demo-$ECS_CLUSTER_NAME-EC2-
$MEMCACHED_ECS_NETWORK_MOD
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-
container-insights/latest/ecs-task-definition-templates/deployment-mode/
replica-service/cwagent-prometheus/sample_cloudwatch_dashboards/memcached/
cw_dashboard_memcached.json \
| sed "s/{{YOUR_AWS_REGION}}/$AWS_REGION/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/$ECS_CLUSTER_NAME/g" \
| sed "s/{{YOUR_TASK_DEF_FAMILY}}/$ECS_TASK_DEF_FAMILY/g" \
| xargs -0 aws cloudwatch put-dashboard --dashboard-name ${DASHBOARD_NAME} --region
 $AWS_REGION --dashboard-body
```

Tutorial for scraping Redis OSS Prometheus metrics on Amazon ECS Fargate

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Redis OSS application in an Amazon ECS Fargate cluster. The Redis OSS Prometheus exporter target will be auto-discovered by the CloudWatch agent with Prometheus metric support based on the container's docker labels.

Redis OSS (https://redis.io/) is an open source (BSD licensed), in-memory data structure store, used as a database, cache and message broker. For more information, see redis.

redis_exporter (MIT License licensed) is used to expose the Redis OSS prometheus metrics on the specified port (default: 0.0.0.0:9121). For more information, see [redis_exporter].

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- redis
- redis_exporter

Prerequisite

To collect metrics from a sample Prometheus workload for Amazon ECS, you must be running Container Insights in the cluster. For information about installing Container Insights, see Setting up Container Insights on Amazon ECS.

Topics

- Set the Amazon ECS Fargate cluster environment variable
- Set the network environment variables for the Amazon ECS Fargate cluster
- Install the sample Redis OSS workload
- Configure the CloudWatch agent to scrape Redis OSS Prometheus metrics
- Viewing your Redis OSS metrics

Set the Amazon ECS Fargate cluster environment variable

To set the Amazon ECS Fargate cluster environment variable

1. Install the Amazon ECS CLI if you haven't already done so. For more information, see Installing the Amazon ECS CLI.
2. Set the new Amazon ECS cluster name and Region. For example:

```
ECS_CLUSTER_NAME=ecs-fargate-redis-tutorial
AWS_DEFAULT_REGION=ca-central-1
```

3. (Optional) If you don't already have an Amazon ECS Fargate cluster where you want to install the sample Redis OSS workload and CloudWatch agent, you can create one by entering the following command.

```
ecs-cli up --capability-iam \
```

```
--cluster $ECS_CLUSTER_NAME \
--launch-type FARGATE \
--region $AWS_DEFAULT_REGION
```

The expected result of this command is as follows:

```
INFO[0000] Created cluster   cluster=ecs-fargate-redis-tutorial region=ca-central-1
INFO[0001] Waiting for your cluster resources to be created...
INFO[0001] Cloudformation stack status   stackStatus=CREATE_IN_PROGRESS
VPC created: vpc-xxxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxxx
Subnet created: subnet-xxxxxxxxxxxxxxxxx
Cluster creation succeeded.
```

Set the network environment variables for the Amazon ECS Fargate cluster

To set the network environment variables for the Amazon ECS Fargate cluster

1. Set your VPC and subnet ID of the Amazon ECS cluster. If you created a new cluster in the previous procedure, you'll see these values in the result of the final command. Otherwise, use the IDs of the existing cluster that you are going to use with Redis.

```
ECS_CLUSTER_VPC=vpc-xxxxxxxxxxxxxxxxx
ECS_CLUSTER_SUBNET_1=subnet-xxxxxxxxxxxxxxxxx
ECS_CLUSTER_SUBNET_2=subnet-xxxxxxxxxxxxxxxxx
```

2. In this tutorial, we are going to install the Redis OSS application and the CloudWatch agent in the default security group of the Amazon ECS cluster's VPC. The default security group allows all network connection within the same security group so the CloudWatch agent can scrape the Prometheus metrics exposed on the Redis OSS containers. In a real production environment, you might want to create dedicated security groups for the Redis OSS application and CloudWatch agent and set customized permissions for them.

Enter the following command to get the default security group ID.

```
aws ec2 describe-security-groups \
--filters Name=vpc-id,Values=$ECS_CLUSTER_VPC  \
--region $AWS_DEFAULT_REGION
```

Then set the Fargate cluster deafult security group variable by entering the following command, replacing *my-default-security-group* with the value you found from the previous command.

```
ECS_CLUSTER_SECURITY_GROUP=my-default-security-group
```

Install the sample Redis OSS workload

To install the sample Redis OSS workload which exposes the Prometheus metrics

1. Download the Redis OSS Amazon CloudFormation template by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/sample_traffic/redis/redis-traffic-sample.yaml
```

2. Set the IAM role names to be created for Redis OSS by entering the following commands.

```
REDIS_ECS_TASK_ROLE_NAME=redis-prometheus-demo-ecs-task-role-name
REDIS_ECS_EXECUTION_ROLE_NAME=redis-prometheus-demo-ecs-execution-role-name
```

3. Install the sample Redis OSS workload by entering the following command.

```
aws cloudformation create-stack --stack-name Redis-Prometheus-Demo-ECS-$ECS_CLUSTER_NAME-fargate-awsvpc \
    --template-body file://redis-traffic-sample.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=SecurityGroupID,ParameterValue=$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET_1 \
                 ParameterKey=TaskRoleName,ParameterValue=$REDIS_ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=$REDIS_ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_DEFAULT_REGION
```

The Amazon CloudFormation stack creates four resources:

- One ECS task role
- One ECS task execution role
- One Redis OSS task definition
- One Redis OSS service

In the Redis OSS task definition, two containers are defined:

- The primary container runs a simple Redis OSS application and opens port 6379 for access.
- The other container runs the Redis OSS exporter process to expose the Prometheus metrics on port 9121. This is the container to be discovered and scraped by the CloudWatch agent. The following docker label is defined so that the CloudWatch agent can discover this container based on it.

```
ECS_PROMETHEUS_EXPORTER_PORT: 9121
```

Configure the CloudWatch agent to scrape Redis OSS Prometheus metrics

To configure the CloudWatch agent to scrape Redis OSS Prometheus metrics

1. Download the latest version of `cwagent-ecs-prometheus-metric-for-awsvpc.yaml` by entering the following command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/ecs-task-definition-templates/deployment-mode/replica-service/cwagent-prometheus/cloudformation-quickstart/cwagent-ecs-prometheus-metric-for-awsvpc.yaml
```

2. Open the file with a text editor, and find the full CloudWatch agent configuration behind the `value` key in the `resource:CWAgentConfigSSMParameter` section.

   Then, in the `ecs_service_discovery` section shown here, the `docker_label`-based service discovery is enabled with the default settings which are based on `ECS_PROMETHEUS_EXPORTER_PORT`, which matches the docker label we defined in the Redis OSS ECS task definition. So we do not need to make any changes in this section:

```
ecs_service_discovery": {
  "sd_frequency": "1m",
```

```
  "sd_result_file": "/tmp/cwagent_ecs_auto_sd.yaml",
*  "docker_label": {
  },*
  ...
```

For the `metric_declaration` section, the default setting does not allow any Redis OSS metrics. Add the following section to allow Redis OSS metrics. Be sure to follow the existing indentation pattern.

```
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily"]],
  "metric_selectors": [
    "^redis_net_(in|out)put_bytes_total$",
    "^redis_(expired|evicted)_keys_total$",
    "^redis_keyspace_(hits|misses)_total$",
    "^redis_memory_used_bytes$",
    "^redis_connected_clients$"
  ]
},
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily","cmd"]],
  "metric_selectors": [
    "^redis_commands_total$"
  ]
},
{
  "source_labels": ["container_name"],
  "label_matcher": "^redis-exporter-.*$",
  "dimensions": [["ClusterName","TaskDefinitionFamily","db"]],
  "metric_selectors": [
    "^redis_db_keys$"
  ]
},
```

3. If you already have the CloudWatch agent deployed in the Amazon ECS cluster by Amazon CloudFormation, you can create a change set by entering the following commands.

```
ECS_LAUNCH_TYPE=FARGATE
```

```
CREATE_IAM_ROLES=True
ECS_CLUSTER_SUBNET=$ECS_CLUSTER_SUBNET_1
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-
$ECS_CLUSTER_NAME-$ECS_LAUNCH_TYPE-awsvpc \
    --template-body file://cwagent-ecs-prometheus-metric-for-awsvpc.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSLaunchType,ParameterValue=$ECS_LAUNCH_TYPE \
                 ParameterKey=SecurityGroupID,ParameterValue=
$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION} \
    --change-set-name redis-scraping-support
```

4. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
5. Review the newly created changeset `redis-scraping-support`. You should see one change applied to the `CWAgentConfigSSMParameter` resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service cwagent-prometheus-replica-service-$ECS_LAUNCH_TYPE-awsvpc \
--region ${AWS_DEFAULT_REGION}
```

6. Wait about 10 seconds, and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service cwagent-prometheus-replica-service-$ECS_LAUNCH_TYPE-awsvpc \
--region ${AWS_DEFAULT_REGION}
```

7. If you are installing the CloudWatch agent with Prometheus metric collecting for the cluster for the first time, please enter the following commands:

```
ECS_LAUNCH_TYPE=FARGATE
```

```
CREATE_IAM_ROLES=True
ECS_CLUSTER_SUBNET=$ECS_CLUSTER_SUBNET_1
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name

aws cloudformation create-stack --stack-name CWAgent-Prometheus-ECS-
$ECS_CLUSTER_NAME-$ECS_LAUNCH_TYPE-awsvpc \
    --template-body file://cwagent-ecs-prometheus-metric-for-awsvpc.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSLaunchType,ParameterValue=$ECS_LAUNCH_TYPE \
                 ParameterKey=SecurityGroupID,ParameterValue=
$ECS_CLUSTER_SECURITY_GROUP \
                 ParameterKey=SubnetID,ParameterValue=$ECS_CLUSTER_SUBNET \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=
$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region ${AWS_DEFAULT_REGION}
```

Viewing your Redis OSS metrics

This tutorial sends the following metrics to the **ECS/ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric Name	Dimensions	
`redis_net_input_bytes_total`	ClusterName, `TaskDefinitionFamily`	
`redis_net_output_bytes_total`	ClusterName, `TaskDefinitionFamily`	
`redis_expired_keys_total`	ClusterName, `TaskDefinitionFamily`	

Metric Name	Dimensions
redis_evicted_keys_total	ClusterName, TaskDefinitionFamily
redis_keyspace_hits_total	ClusterName, TaskDefinitionFamily
redis_keyspace_misses_total	ClusterName, TaskDefinitionFamily
redis_memory_used_bytes	ClusterName, TaskDefinitionFamily
redis_connected_clients	ClusterName, TaskDefinitionFamily
redis_commands_total	ClusterName , TaskDefinitionFamily , cmd
redis_db_keys	ClusterName , TaskDefinitionFamily , db

Note

The value of the **cmd** dimension can be: append, client, command, config, dbsize, flushall, get, incr, info, latency, or slowlog.
The value of the **db** dimension can be db0 to db15.

You can also create a CloudWatch dashboard for your Redis OSS Prometheus metrics.

To create a dashboard for Redis OSS Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_cw_dashboard_name
ECS_TASK_DEF_FAMILY=redis-prometheus-demo-$ECS_CLUSTER_NAME-fargate-awsvpc
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_cloudwatch_dashboards/redis/cw_dashboard_redis.json \
| sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
| sed "s/{{YOUR_NAMESPACE}}/${NAMESPACE}/g" \
```

Set up and configure Prometheus metrics collection on Amazon EKS and Kubernetes clusters

To collect Prometheus metrics from clusters running Amazon EKS or Kubernetes, you can use the CloudWatch agent as a collector or use the Amazon Distro for OpenTelemetry collector. For information about using the Amazon Distro for OpenTelemetry collector, see https://aws-otel.github.io/docs/getting-started/container-insights/eks-prometheus.

The following sections explain how to collect Prometheus metrics using the CloudWatch agent. They explain how to install the CloudWatch agent with Prometheus monitoring on clusters running Amazon EKS or Kubernetes, and how to configure the agent to scrape additional targets. They also provide optional tutorials for setting up sample workloads to use for testing with Prometheus monitoring.

Topics

Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon EKS or Kubernetes. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- Amazon App Mesh

- NGINX
- Memcached
- Java/JMX
- HAProxy
- Fluent Bit

You can also configure the agent to scrape and import additional Prometheus workloads and sources.

Before following these steps to install the CloudWatch agent for Prometheus metric collection, you must have a cluster running on Amazon EKS or a Kubernetes cluster running on an Amazon EC2 instance.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

Install the CloudWatch agent with Prometheus metrics collection on Amazon EKS and Kubernetes clusters

This section explains how to set up the CloudWatch agent with Prometheus monitoring in a cluster running Amazon EKS or Kubernetes. After you do this, the agent automatically scrapes and imports metrics for the following workloads running in that cluster.

- Amazon App Mesh
- NGINX
- Memcached

- Java/JMX
- HAProxy
- Fluent Bit

You can also configure the agent to scrape and import additional Prometheus workloads and sources.

Before following these steps to install the CloudWatch agent for Prometheus metric collection, you must have a cluster running on Amazon EKS or a Kubernetes cluster running on an Amazon EC2 instance.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

Setting up IAM roles

The first step is to set up the necessary IAM role in the cluster. There are two methods:

- Set up an IAM role for a service account, also known as a *service role*. This method works for both the EC2 launch type and the Fargate launch type.
- Add an IAM policy to the IAM role used for the cluster. This works only for the EC2 launch type.

Set up a service role (EC2 launch type and Fargate launch type)

To set up a service role, enter the following command. Replace *MyCluster* with the name of the cluster.

```
eksctl create iamserviceaccount \
 --name cwagent-prometheus \
```

```
--namespace amazon-cloudwatch \
 --cluster MyCluster \
--attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
--approve \
--override-existing-serviceaccounts
```

Add a policy to the node group's IAM role (EC2 launch type only)

To set up the IAM policy in a node group for Prometheus support

1. Open the Amazon EC2 console at https://console.amazonaws.cn/ec2/.
2. In the navigation pane, choose **Instances**.
3. You need to find the prefix of the IAM role name for the cluster. To do this, select the check box next to the name of an instance that is in the cluster, and choose **Actions**, **Security**, **Modify IAM Role**. Then copy the prefix of the IAM role, such as `eksctl-dev303-workshop-nodegroup`.
4. Open the IAM console at https://console.amazonaws.cn/iam/.
5. In the navigation pane, choose **Roles**.
6. Use the search box to find the prefix that you copied earlier in this procedure, and choose that role.
7. Choose **Attach policies**.
8. Use the search box to find **CloudWatchAgentServerPolicy**. Select the check box next to **CloudWatchAgentServerPolicy**, and choose **Attach policy**.

Installing the CloudWatch agent to collect Prometheus metrics

You must install the CloudWatch agent in the cluster to collect the metrics. How to install the agent differs for Amazon EKS clusters and Kubernetes clusters.

Delete previous versions of the CloudWatch agent with Prometheus support

If you have already installed a version of the CloudWatch agent with Prometheus support in your cluster, you must delete that version by entering the following command. This is necessary only for previous versions of the agent with Prometheus support. You do not need to delete the CloudWatch agent that enables Container Insights without Prometheus support.

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

Installing the CloudWatch agent on Amazon EKS clusters with the EC2 launch type

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster, follow these steps.

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster

1. Enter the following command to check whether the `amazon-cloudwatch` namespace has already been created:

   ```
   kubectl get namespace
   ```

2. If `amazon-cloudwatch` is not displayed in the results, create it by entering the following command:

   ```
   kubectl create namespace amazon-cloudwatch
   ```

3. To deploy the agent with the default configuration and have it send data to the Amazon Region that it is installed in, enter the following command:

   ```
   kubectl apply -f https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
   ```

   To have the agent send data to a different Region instead, follow these steps:

   a. Download the YAML file for the agent by entering the following command:

      ```
      curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
      ```

   b. Open the file with a text editor, and search for the `cwagentconfig.json` block of the file.

   c. Add the highlighted lines, specifying the Region that you want:

      ```
      cwagentconfig.json: |
          {
            "agent": {
              "region": "us-east-2"
            },
      ```

```
    "logs": { ...
```

d. Save the file and deploy the agent using your updated file.

```
kubectl apply -f prometheus-eks.yaml
```

Installing the CloudWatch agent on Amazon EKS clusters with the Fargate launch type

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster with the Fargate launch type, follow these steps.

To install the CloudWatch agent with Prometheus support on an Amazon EKS cluster with the Fargate launch type

1. Enter the following command to create a Fargate profile for the CloudWatch agent so that it can run inside the cluster. Replace *MyCluster* with the name of the cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--name amazon-cloudwatch \
--namespace amazon-cloudwatch
```

2. To install the CloudWatch agent, enter the following command. Replace *MyCluster* with the name of the cluster. This name is used in the log group name that stores the log events collected by the agent, and is also used as a dimension for the metrics collected by the agent.

   Replace *region* with the name of the Region where you want the metrics to be sent. For example, `us-west-1`.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks-fargate.yaml | 
sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" | 
kubectl apply -f -
```

Installing the CloudWatch agent on a Kubernetes cluster

To install the CloudWatch agent with Prometheus support on a cluster running Kubernetes, enter the following command:

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/prometheus-k8s.yaml | 
sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" | 
kubectl apply -f -
```

Replace *MyCluster* with the name of the cluster. This name is used in the log group name that stores the log events collected by the agent, and is also used as a dimension for the metrics collected by the agent.

Replace *region* with the name of the Amazon Region where you want the metrics to be sent. For example, **us-west-1**.

Verify that the agent is running

On both Amazon EKS and Kubernetes clusters, you can enter the following command to confirm that the agent is running.

```
kubectl get pod -l "app=cwagent-prometheus" -n amazon-cloudwatch
```

If the results include a single CloudWatch agent pod in the `Running` state, the agent is running and collecting Prometheus metrics. By default the CloudWatch agent collects metrics for App Mesh, NGINX, Memcached, Java/JMX, and HAProxy every minute. For more information about those metrics, see Prometheus metrics collected by the CloudWatch agent. For instructions on how to see your Prometheus metrics in CloudWatch, see Viewing your Prometheus metrics

You can also configure the CloudWatch agent to collect metrics from other Prometheus exporters. For more information, see Scraping additional Prometheus sources and importing those metrics.

Scraping additional Prometheus sources and importing those metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config> in the Prometheus documentation. The other is for the CloudWatch agent configuration.

For Amazon EKS clusters, the configurations are defined in `prometheus-eks.yaml` (for the EC2 launch type) or `prometheus-eks-fargate.yaml` (for the Fargate launch type) as two config maps:

- The `name: prometheus-config` section contains the settings for Prometheus scraping.
- The `name: prometheus-cwagentconfig` section contains the configuration for the CloudWatch agent. You can use this section to configure how the Prometheus metrics are collected by CloudWatch. For example, you specify which metrics are to be imported into CloudWatch, and define their dimensions.

For Kubernetes clusters running on Amazon EC2 instances, the configurations are defined in the `prometheus-k8s.yaml` YAML file as two config maps:

- The `name: prometheus-config` section contains the settings for Prometheus scraping.
- The `name: prometheus-cwagentconfig` section contains the configuration for the CloudWatch agent.

To scrape additional Prometheus metrics sources and import those metrics to CloudWatch, you modify both the Prometheus scrape configuration and the CloudWatch agent configuration, and then re-deploy the agent with the updated configuration.

VPC security group requirements

The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.

The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. By default, the sample configuration file contains the following global configuration lines:

```
global:
  scrape_interval: 1m
  scrape_timeout: 10s
```

- **scrape_interval**— Defines how frequently to scrape targets.
- **scrape_timeout**— Defines how long to wait before a scrape request times out.

You can also define different values for these settings at the job level, to override the global configurations.

Prometheus scraping jobs

The CloudWatch agent YAML files already have some default scraping jobs configured. For example, in `prometheus-eks.yaml`, the default scraping jobs are configured in the `job_name` lines in the `scrape_configs` section. In this file, the following default `kubernetes-pod-jmx` section scrapes JMX exporter metrics.

```
  - job_name: 'kubernetes-pod-jmx'
     sample_limit: 10000
     metrics_path: /metrics
     kubernetes_sd_configs:
     - role: pod
     relabel_configs:
     - source_labels: [__address__]
       action: keep
       regex: '.*:9404$'
     - action: labelmap
       regex: __meta_kubernetes_pod_label_(.+)
     - action: replace
       source_labels:
       - __meta_kubernetes_namespace
       target_label: Namespace
     - source_labels: [__meta_kubernetes_pod_name]
       action: replace
       target_label: pod_name
     - action: replace
       source_labels:
       - __meta_kubernetes_pod_container_name
       target_label: container_name
     - action: replace
       source_labels:
       - __meta_kubernetes_pod_controller_name
       target_label: pod_controller_name
     - action: replace
       source_labels:
       - __meta_kubernetes_pod_controller_kind
       target_label: pod_controller_kind
     - action: replace
       source_labels:
       - __meta_kubernetes_pod_phase
```

```
        target_label: pod_phase
```

Each of these default targets are scraped, and the metrics are sent to CloudWatch in log events using embedded metric format. For more information, see Embedding metrics within logs.

Log events from Amazon EKS and Kubernetes clusters are stored in the **/aws/containerinsights/*cluster_name*/prometheus** log group in CloudWatch Logs. Log events from Amazon ECS clusters are stored in the **/aws/ecs/containerinsights/*cluster_name*/prometheus** log group.

Each scraping job is contained in a different log stream in this log group. For example, the Prometheus scraping job `kubernetes-pod-appmesh-envoy` is defined for App Mesh. All App Mesh Prometheus metrics from Amazon EKS and Kubernetes clusters are sent to the log stream named **/aws/containerinsights/*cluster_name*>prometheus/kubernetes-pod-appmesh-envoy/**.

To add a new scraping target, you add a new `job_name` section to the `scrape_configs` section of the YAML file, and restart the agent. For an example of this process, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file has a `prometheus` section under `metrics_collected` for the Prometheus scraping configuration. It includes the following configuration options:

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional. If you omit it, the agent can detect the Amazon EKS or Kubernetes cluster name.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics. This field is optional. If you omit it, CloudWatch uses **/aws/containerinsights/*cluster_name*/prometheus** for logs from Amazon EKS and Kubernetes clusters.
- **prometheus_config_path**— specifies the Prometheus scrape configuration file path. If the value of this field starts with `env:` the Prometheus scrape configuration file contents will be retrieved from the container's environment variable. Do not change this field.
- **ecs_service_discovery**— is the section to specify the configuration for Amazon ECS Prometheus service discovery. For more information, see Detailed guide for autodiscovery on Amazon ECS clusters.

  The `ecs_service_discovery` section can contain the following fields:

- `sd_frequency` is the frequency to discover the Prometheus exporters. Specify a number and a unit suffix. For example, `1m` for once per minute or `30s` for once per 30 seconds. Valid unit suffixes are `ns`, `us`, `ms`, `s`, `m`, and `h`.

  This field is optional. The default is 60 seconds (1 minute).
- `sd_target_cluster` is the target Amazon ECS cluster name for auto-discovery. This field is optional. The default is the name of the Amazon ECS cluster where the CloudWatch agent is installed.
- `sd_cluster_region` is the target Amazon ECS cluster's Region. This field is optional. The default is the Region of the Amazon ECS cluster where the CloudWatch agent is installed. .
- `sd_result_file` is the path of the YAML file for the Prometheus target results. The Prometheus scrape configuration will refer to this file.
- `docker_label` is an optional section that you can use to specify the configuration for docker label-based service discovery. If you omit this section, docker label-based discovery is not used. This section can contain the following fields:
  - `sd_port_label` is the container's docker label name that specifies the container port for Prometheus metrics. The default value is `ECS_PROMETHEUS_EXPORTER_PORT`. If the container does not have this docker label, the CloudWatch agent will skip it.
  - `sd_metrics_path_label` is the container's docker label name that specifies the Prometheus metrics path. The default value is `ECS_PROMETHEUS_METRICS_PATH`. If the container does not have this docker label, the agent assumes the default path `/metrics`.
  - `sd_job_name_label` is the container's docker label name that specifies the Prometheus scrape job name. The default value is `job`. If the container does not have this docker label, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- `task_definition_list` is an optional section that you can use to specify the configuration of task definition-based service discovery. If you omit this section, task definition-based discovery is not used. This section can contain the following fields:
  - `sd_task_definition_arn_pattern` is the pattern to use to specify the Amazon ECS task definitions to discover. This is a regular expression.
  - `sd_metrics_ports` lists the containerPort for the Prometheus metrics. Separate the containerPorts with semicolons.
  - `sd_container_name_pattern` specifies the Amazon ECS task container names. This is a regular expression.

  - `sd_metrics_path` specifies the Prometheus metric path. If you omit this, the agent assumes the default path `/metrics`
  - `sd_job_name` specifies the Prometheus scrape job name. If you omit this field, the CloudWatch agent uses the job name in the Prometheus scrape configuration.
- **metric_declaration—** are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
  - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.

    If you have multiple labels specified in `source_labels`, we recommend that you do not use ^ or $ characters in the regular expression for `label_matcher`.
  - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
  - `label_separator` specifies the separator to be used in the `label_matcher` line if multiple `source_labels` are specified. The default is `;`. You can see this default used in the `label_matcher` line in the following example.
  - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
  - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

See the following `metric_declaration` example.

```
"metric_declaration": [
  {
     "source_labels":[ "Service", "Namespace"],
     "label_matcher":"(.*node-exporter.*|.*kube-dns.*);kube-system",
     "dimensions":[
        ["Service", "Namespace"]
     ],
     "metric_selectors":[
        "^coredns_dns_request_type_count_total$"
     ]
  }
```

```
]
```

This example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of `Service` contains either `node-exporter` or `kube-dns`.
- The value of `Namespace` is `kube-system`.
- The Prometheus metric `coredns_dns_request_type_count_total` contains both `Service` and `Namespace` labels.

The log event that is sent includes the following highlighted section:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"coredns_dns_request_type_count_total"
            }
         ],
         "Dimensions":[
            [
               "Namespace",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "Namespace":"kube-system",
   "Service":"kube-dns",
   "coredns_dns_request_type_count_total":2562,
   "eks_amazonaws_com_component":"kube-dns",
   "instance":"192.168.61.254:9153",
   "job":"kubernetes-service-endpoints",
   ...
}
```

Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics

The Kubernetes API Server exposes Prometheus metrics on endpoints by default. The official example for the Kubernetes API Server scraping configuration is available on Github.

The following tutorial shows how to do the following steps to begin importing Kubernetes API Server metrics into CloudWatch:

- Adding the Prometheus scraping configuration for Kubernetes API Server to the CloudWatch agent YAML file.
- Configuring the embedded metric format metrics definitions in the CloudWatch agent YAML file.
- (Optional) Creating a CloudWatch dashboard for the Kubernetes API Server metrics.

> **Note**
>
> The Kubernetes API Server exposes gauge, counter, histogram, and summary metrics. In this release of Prometheus metrics support, CloudWatch imports only the metrics with gauge, counter, and summary types.

To start collecting Kubernetes API Server Prometheus metrics in CloudWatch

1. Download the latest version of the `prometheus-eks.yaml`, `prometheus-eks-fargate.yaml`, or `prometheus-k8s.yaml` file by entering one of the following commands.

   For an Amazon EKS cluster with the EC2 launch type, enter the following command:

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
   ```

   For an Amazon EKS cluster with the Fargate launch type, enter the following command:

   ```
   curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks-fargate.yaml
   ```

   For a Kubernetes cluster running on an Amazon EC2 instance, enter the following command:

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-k8s.yaml
```

2. Open the file with a text editor, find the `prometheus-config` section, and add the following section inside of that section. Then save the changes:

```
    # Scrape config for API servers
    - job_name: 'kubernetes-apiservers'
      kubernetes_sd_configs:
        - role: endpoints
          namespaces:
            names:
              - default
      scheme: https
      tls_config:
        ca_file: /var/run/secrets/kubernetes.io/serviceaccount/ca.crt
        insecure_skip_verify: true
      bearer_token_file: /var/run/secrets/kubernetes.io/serviceaccount/token
      relabel_configs:
      - source_labels: [__meta_kubernetes_service_name, 
 __meta_kubernetes_endpoint_port_name]
        action: keep
        regex: kubernetes;https
      - action: replace
        source_labels:
        - __meta_kubernetes_namespace
        target_label: Namespace
      - action: replace
        source_labels:
        - __meta_kubernetes_service_name
        target_label: Service
```

3. While you still have the YAML file open in the text editor, find the `cwagentconfig.json` section. Add the following subsection and save the changes. This section puts the API server metrics onto the CloudWatch agent allow list. Three types of API Server metrics are added to the allow list:

   - etcd object counts
   - API Server registration controller metrics
   - API Server request metrics

```
{"source_labels": ["job", "resource"],
  "label_matcher": "^kubernetes-apiservers;(services|daemonsets.apps|
deployments.apps|configmaps|endpoints|secrets|serviceaccounts|replicasets.apps)",
  "dimensions": [["ClusterName","Service","resource"]],
  "metric_selectors": [
  "^etcd_object_counts$"
  ]
},
{"source_labels": ["job", "name"],
   "label_matcher": "^kubernetes-apiservers;APIServiceRegistrationController$",
   "dimensions": [["ClusterName","Service","name"]],
   "metric_selectors": [
   "^workqueue_depth$",
   "^workqueue_adds_total$",
   "^workqueue_retries_total$"
  ]
},
{"source_labels": ["job","code"],
  "label_matcher": "^kubernetes-apiservers;2[0-9]{2}$",
  "dimensions": [["ClusterName","Service","code"]],
  "metric_selectors": [
   "^apiserver_request_total$"
  ]
},
{"source_labels": ["job"],
  "label_matcher": "^kubernetes-apiservers",
  "dimensions": [["ClusterName","Service"]],
  "metric_selectors": [
  "^apiserver_request_total$"
  ]
},
```

4. If you already have the CloudWatch agent with Prometheus support deployed in the cluster, you must delete it by entering the following command:

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

5. Deploy the CloudWatch agent with your updated configuration by entering one of the following commands. For an Amazon EKS cluster with the EC2 launch type, enter:

```
kubectl apply -f prometheus-eks.yaml
```

For an Amazon EKS cluster with the Fargate launch type, enter the following command. Replace *MyCluster* and *region* with values to match your deployment.

```
cat prometheus-eks-fargate.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

For a Kubernetes cluster, enter the following command. Replace *MyCluster* and *region* with values to match your deployment.

```
cat prometheus-k8s.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

Once you have done this, you should see a new log stream named **kubernetes-apiservers** in the **/aws/containerinsights/*cluster_name*/prometheus** log group. This log stream should include log events with an embedded metric format definition like the following:

```
{
   "CloudWatchMetrics":[
      {
         "Metrics":[
            {
               "Name":"apiserver_request_total"
            }
         ],
         "Dimensions":[
            [
               "ClusterName",
               "Service"
            ]
         ],
         "Namespace":"ContainerInsights/Prometheus"
      }
   ],
   "ClusterName":"my-cluster-name",
   "Namespace":"default",
```

```
    "Service":"kubernetes",
    "Timestamp":"1592267020339",
    "Version":"0",
    "apiserver_request_count":0,
    "apiserver_request_total":0,
    "code":"0",
    "component":"apiserver",
    "contentType":"application/json",
    "instance":"192.0.2.0:443",
    "job":"kubernetes-apiservers",
    "prom_metric_type":"counter",
    "resource":"pods",
    "scope":"namespace",
    "verb":"WATCH",
    "version":"v1"
}
```

You can view your metrics in the CloudWatch console in the **ContainerInsights/Prometheus** namespace. You can also optionally create a CloudWatch dashboard for your Prometheus Kubernetes API Server metrics.

(Optional) Creating a dashboard for Kubernetes API Server metrics

To see Kubernetes API Server metrics in your dashboard, you must have first completed the steps in the previous sections to start collecting these metrics in CloudWatch.

To create a dashboard for Kubernetes API Server metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Make sure you have the correct Amazon Region selected.
3. In the navigation pane, choose **Dashboards**.
4. Choose **Create Dashboard**. Enter a name for the new dashboard, and choose **Create dashboard**.
5. In **Add to this dashboard**, choose **Cancel**.
6. Choose **Actions**, **View/edit source**.
7. Download the following JSON file: Kubernetes API Dashboard source.
8. Open the JSON file that you downloaded with a text editor, and make the following changes:

   - Replace all the `{{YOUR_CLUSTER_NAME}}` strings with the exact name of your cluster. Make sure not to add whitespaces before or after the text.

- Replace all the `{{YOUR_AWS_REGION}}` strings with the name of the Region where the metrics are collected. For example `us-west-2`. Be sure not to add whitespaces before or after the text.

9. Copy the entire JSON blob and paste it into the text box in the CloudWatch console, replacing what is already in the box.
10. Choose **Update**, **Save dashboard**.

(Optional) Set up sample containerized Amazon EKS workloads for Prometheus metric testing

To test the Prometheus metric support in CloudWatch Container Insights, you can set up one or more of the following containerized workloads. The CloudWatch agent with Prometheus support automatically collects metrics from each of these workloads. To see the metrics that are collected by default, see Prometheus metrics collected by the CloudWatch agent.

Before you can install any of these workloads, you must install Helm 3.x by entering the following commands:

```
brew install helm
```

For more information, see Helm.

Topics

Set up Amazon App Mesh sample workload for Amazon EKS and Kubernetes

Prometheus support in CloudWatch Container Insights supports Amazon App Mesh. The following sections explain how to set up App Mesh.

Topics

- [Set up Amazon App Mesh sample workload on an Amazon EKS cluster with the EC2 launch type or a Kubernetes cluster]
- [Set up Amazon App Mesh sample workload on an Amazon EKS cluster with the Fargate launch type]

Set up Amazon App Mesh sample workload on an Amazon EKS cluster with the EC2 launch type or a Kubernetes cluster

Use these instructions if you are setting up App Mesh on a cluster running Amazon EKS with the EC2 launch type, or a Kubernetes cluster.

Configure IAM permissions

You must add the **AWSAppMeshFullAccess** policy to the IAM role for your Amazon EKS or Kubernetes node group. On Amazon EKS, this node group name looks similar to `eksctl-integ-test-eks-prometheus-NodeInstanceRole-ABCDEFHIJKL`. On Kubernetes, it might look similar to `nodes.integ-test-kops-prometheus.k8s.local`.

Install App Mesh

To install the App Mesh Kubernetes controller, follow the instructions in App Mesh Controller.

Install a sample application

aws-app-mesh-examples contains several Kubernetes App Mesh walkthroughs. For this tutorial, you install a sample color application that shows how http routes can use headers for matching incoming requests.

To use a sample App Mesh application to test Container Insights

1. Install the application using these instructions: https://github.com/aws/aws-app-mesh-examples/tree/main/walkthroughs/howto-k8s-http-headers.
2. Launch a curler pod to generate traffic:

```
kubectl -n default run -it curler --image=tutum/curl /bin/bash
```

3. Curl different endpoints by changing HTTP headers. Run the curl command multiple times, as shown:

```
curl -H "color_header: blue" front.howto-k8s-http-headers.svc.cluster.local:8080/;
 echo;

curl -H "color_header: red" front.howto-k8s-http-headers.svc.cluster.local:8080/;
 echo;

curl -H "color_header: yellow" front.howto-k8s-http-
headers.svc.cluster.local:8080/; echo;
```

4. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
5. In the Amazon Region where your cluster is running, choose **Metrics** in the navigation pane. The metric are in the **ContainerInsights/Prometheus** namespace.
6. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group `/aws/containerinsights/your_cluster_name/prometheus` in the log stream `kubernetes-pod-appmesh-envoy`.

Deleting the App Mesh test environment

When you have finished using App Mesh and the sample application, use the following commands to delete the unnecessary resources. Delete the sample application by entering the following command:

```
cd aws-app-mesh-examples/walkthroughs/howto-k8s-http-headers/
kubectl delete -f _output/manifest.yaml
```

Delete the App Mesh controller by entering the following command:

```
helm delete appmesh-controller -n appmesh-system
```

Set up Amazon App Mesh sample workload on an Amazon EKS cluster with the Fargate launch type

Use these instructions if you are setting up App Mesh on a cluster running Amazon EKS with the Fargate launch type.

Configure IAM permissions

To set up IAM permissions, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create iamserviceaccount --cluster MyCluster \
 --namespace howto-k8s-fargate \
 --name appmesh-pod \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshEnvoyAccess \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapDiscoverInstanceAccess \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess \
 --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshFullAccess \
 --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapFullAccess \
 --override-existing-serviceaccounts \
 --approve
```

Install App Mesh

To install the App Mesh Kubernetes controller, follow the instructions in App Mesh Controller. Be sure to follow the instructions for Amazon EKS with the Fargate launch type.

Install a sample application

aws-app-mesh-examples contains several Kubernetes App Mesh walkthroughs. For this tutorial, you install a sample color application that works for Amazon EKS clusters with the Fargate launch type.

To use a sample App Mesh application to test Container Insights

1. Install the application using these instructions: https://github.com/aws/aws-app-mesh-examples/tree/main/walkthroughs/howto-k8s-fargate.

   Those instructions assume that you are creating a new cluster with the correct Fargate profile. If you want to use an Amazon EKS cluster that you've already set up, you can use the following commands to set up that cluster for this demonstration. Replace *MyCluster* with the name of your cluster.

   ```
   eksctl create iamserviceaccount --cluster MyCluster \
    --namespace howto-k8s-fargate \
    --name appmesh-pod \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshEnvoyAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapDiscoverInstanceAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSXRayDaemonWriteAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSAppMeshFullAccess \
    --attach-policy-arn arn:aws:iam::aws:policy/AWSCloudMapFullAccess \
   ```

```
 --override-existing-serviceaccounts \
 --approve
```

```
eksctl create fargateprofile --cluster MyCluster \
--namespace howto-k8s-fargate --name howto-k8s-fargate
```

2. Port forward the front application deployment:

```
kubectl -n howto-k8s-fargate port-forward deployment/front 8080:8080
```

3. Curl the front app:

```
while true; do  curl -s http://localhost:8080/color; sleep 0.1; echo ; done
```

4. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
5. In the Amazon Region where your cluster is running, choose **Metrics** in the navigation pane. The metric are in the **ContainerInsights/Prometheus** namespace.
6. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group `/aws/containerinsights/your_cluster_name/prometheus` in the log stream `kubernetes-pod-appmesh-envoy`.

Deleting the App Mesh test environment

When you have finished using App Mesh and the sample application, use the following commands to delete the unnecessary resources. Delete the sample application by entering the following command:

```
cd aws-app-mesh-examples/walkthroughs/howto-k8s-fargate/
kubectl delete -f _output/manifest.yaml
```

Delete the App Mesh controller by entering the following command:

```
helm delete appmesh-controller -n appmesh-system
```

Set up NGINX with sample traffic on Amazon EKS and Kubernetes

NGINX is a web server that can also be used as a load balancer and reverse proxy. For more information about how Kubernetes uses NGINX for ingress , see kubernetes/ingress-nginx.

To install Ingress-NGINX with a sample traffic service to test Container Insights Prometheus support

1. Enter the following command to add the Helm ingress-nginx repo:

```
helm repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
```

2. Enter the following commands:

```
kubectl create namespace nginx-ingress-sample

helm install my-nginx ingress-nginx/ingress-nginx \
--namespace nginx-ingress-sample \
--set controller.metrics.enabled=true \
--set-string controller.metrics.service.annotations."prometheus\.io/port"="10254" \
--set-string controller.metrics.service.annotations."prometheus\.io/scrape"="true"
```

3. Check whether the services started correctly by entering the following command:

```
kubectl get service -n nginx-ingress-sample
```

   The output of this command should display several columns, including an `EXTERNAL-IP` column.

4. Set an `EXTERNAL-IP` variable to the value of the `EXTERNAL-IP` column in the row of the NGINX ingress controller.

```
EXTERNAL_IP=your-nginx-controller-external-ip
```

5. Start some sample NGINX traffic by entering the following command.

```
SAMPLE_TRAFFIC_NAMESPACE=nginx-sample-traffic
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_traffic/nginx-traffic/nginx-traffic-sample.yaml |
sed "s/{{external_ip}}/$EXTERNAL_IP/g" |
sed "s/{{namespace}}/$SAMPLE_TRAFFIC_NAMESPACE/g" |
kubectl apply -f -
```

6. Enter the following command to confirm that all three pods are in the `Running` status.

```
kubectl get pod -n $SAMPLE_TRAFFIC_NAMESPACE
```

If they are running, you should soon see metrics in the **ContainerInsights/Prometheus** namespace.

To uninstall NGINX and the sample traffic application

1. Delete the sample traffic service by entering the following command:

```
kubectl delete namespace $SAMPLE_TRAFFIC_NAMESPACE
```

2. Delete the NGINX egress by the Helm release name.

```
helm uninstall my-nginx --namespace nginx-ingress-sample
kubectl delete namespace nginx-ingress-sample
```

Set up memcached with a metric exporter on Amazon EKS and Kubernetes

memcached is an open-source memory object caching system. For more information, see [What is Memcached?](https://aws.amazon.com/memcached/).

If you are running memcached on a cluster with the Fargate launch type, you need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace memcached-sample --name memcached-sample
```

To install memcached with a metric exporter to test Container Insights Prometheus support

1. Enter the following command to add the repo:

```
helm repo add bitnami https://charts.bitnami.com/bitnami
```

2. Enter the following command to create a new namespace:

```
kubectl create namespace memcached-sample
```

3. Enter the following command to install Memcached

```
helm install my-memcached bitnami/memcached --namespace memcached-sample \
--set metrics.enabled=true \
--set-string serviceAnnotations.prometheus\\.io/port="9150" \
--set-string serviceAnnotations.prometheus\\.io/scrape="true"
```

4. Enter the following command to confirm the annotation of the running service:

```
kubectl describe service my-memcached-metrics -n memcached-sample
```

You should see the following two annotations:

```
Annotations:   prometheus.io/port: 9150
               prometheus.io/scrape: true
```

To uninstall memcached

- Enter the following commands:

```
helm uninstall my-memcached --namespace memcached-sample
kubectl delete namespace memcached-sample
```

Set up Java/JMX sample workload on Amazon EKS and Kubernetes

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

Container Insights can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Java, and Tomcat (Catalina) using the JMX Exporter.

Default Prometheus scrape configuration

By default, the CloudWatch agent with Prometheus support scrapes the Java/JMX Prometheus metrics from `http://CLUSTER_IP:9404/metrics` on each pod in an Amazon EKS or Kubernetes cluster. This is done by `role: pod` discovery of Prometheus `kubernetes_sd_config`. 9404 is the default port allocated for JMX Exporter by Prometheus. For more information about `role: pod` discovery, see [pod](). You can configure the JMX Exporter to expose the metrics on a different port or metrics_path. If you do change the port or path, update the default jmx scrape_config in the CloudWatch agent config map. Run the following command to get the current CloudWatch agent Prometheus configuration:

```
kubectl describe cm prometheus-config -n amazon-cloudwatch
```

The fields to change are the `/metrics` and `regex: '.*:9404$'` fields, as highlighted in the following example.

```
job_name: 'kubernetes-jmx-pod'
sample_limit: 10000
metrics_path: /metrics
kubernetes_sd_configs:
- role: pod
relabel_configs:
- source_labels: [__address__]
  action: keep
  regex: '.*:9404$'
- action: replace
  regex: (.+)
  source_labels:
```

Other Prometheus scrape configuration

If you expose your application running on a set of pods with Java/JMX Prometheus exporters by a Kubernetes Service, you can also switch to use `role: service` discovery or `role: endpoint` discovery of Prometheus `kubernetes_sd_config`. For more information about these discovery methods, see [service](), [endpoints](), and [<kubernetes_sd_config>.]().

More meta labels are provided by these two service discovery modes which could be useful for you to build the CloudWatch metrics dimensions. For example, you can relabel `__meta_kubernetes_service_name` to `Service` and include it into your metrics' dimension. For more informatio about customizing your CloudWatch metrics and their dimensions, see [CloudWatch agent configuration for Prometheus]().

Docker image with JMX Exporter

Next, build a Docker image. The following sections provide two example Dockerfiles.

When you have built the image, load it into Amazon EKS or Kubernetes, and then run the following command to verify that Prometheus metrics are exposed by JMX_EXPORTER on port 9404. Replace *$JAR_SAMPLE_TRAFFIC_POD* with the running pod name and replace *$JAR_SAMPLE_TRAFFIC_NAMESPACE* with your application namespace.

If you are running JMX Exporter on a cluster with the Fargate launch type, you also need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace $JAR_SAMPLE_TRAFFIC_NAMESPACE\
 --name $JAR_SAMPLE_TRAFFIC_NAMESPACE
```

```
kubectl exec $JAR_SAMPLE_TRAFFIC_POD -n $JARCAT_SAMPLE_TRAFFIC_NAMESPACE -- curl
 http://localhost:9404
```

Example: Apache Tomcat Docker image with Prometheus metrics

Apache Tomcat server exposes JMX mBeans by default. You can integrate JMX Exporter with Tomcat to expose JMX mBeans as Prometheus metrics. The following example Dockerfile shows the steps to build a testing image:

```
# From Tomcat 9.0 JDK8 OpenJDK
FROM tomcat:9.0-jdk8-openjdk

RUN mkdir -p /opt/jmx_exporter

COPY ./jmx_prometheus_javaagent-0.12.0.jar /opt/jmx_exporter
COPY ./config.yaml /opt/jmx_exporter
COPY ./setenv.sh /usr/local/tomcat/bin
COPY your web application.war /usr/local/tomcat/webapps/

RUN chmod  o+x /usr/local/tomcat/bin/setenv.sh

ENTRYPOINT ["catalina.sh", "run"]
```

The following list explains the four COPY lines in this Dockerfile.

- Download the latest JMX Exporter jar file from https://github.com/prometheus/jmx_exporter.

- `config.yaml` is the JMX Exporter configuration file. For more information, see https://github.com/prometheus/jmx_exporter#Configuration.

  Here is a sample configuration file for Java and Tomcat:

```
lowercaseOutputName: true
lowercaseOutputLabelNames: true

rules:
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|
ProcessCpuLoad|OpenFileDescriptorCount|AvailableProcessors)'
  name: java_lang_OperatingSystem_$1
  type: GAUGE

- pattern: 'java.lang<type=Threading><>(TotalStartedThreadCount|ThreadCount)'
  name: java_lang_threading_$1
  type: GAUGE

- pattern: 'Catalina<type=GlobalRequestProcessor, name=\"(\w+-\w+)-(\d+)\"><>(\w+)'
  name: catalina_globalrequestprocessor_$3_total
  labels:
    port: "$2"
    protocol: "$1"
  help: Catalina global $3
  type: COUNTER

- pattern: 'Catalina<j2eeType=Servlet, WebModule=//([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-
a-zA-Z0-9+&@#/%=~_|]), name=([-a-zA-Z0-9+/$%~_-|!.]*), J2EEApplication=none,
 J2EEServer=none><>(requestCount|maxTime|processingTime|errorCount)'
  name: catalina_servlet_$3_total
  labels:
    module: "$1"
    servlet: "$2"
  help: Catalina servlet $3 total
  type: COUNTER

- pattern: 'Catalina<type=ThreadPool, name="(\w+-\w+)-(\d+)"><>(currentThreadCount|
currentThreadsBusy|keepAliveCount|pollerThreadCount|connectionCount)'
  name: catalina_threadpool_$3
  labels:
    port: "$2"
    protocol: "$1"
```

```
  help: Catalina threadpool $3
  type: GAUGE

- pattern: 'Catalina<type=Manager, host=([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-a-zA-
Z0-9+&@#/%=~_|]), context=([-a-zA-Z0-9+/$%~_-|!.]*)><>(processingTime|sessionCounter|
rejectedSessions|expiredSessions)'
  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

- `setenv.sh` is a Tomcat startup script to start the JMX exporter along with Tomcat and expose Prometheus metrics on port 9404 of the localhost. It also provides the JMX Exporter with the `config.yaml` file path.

```
$ cat setenv.sh
export JAVA_OPTS="-javaagent:/opt/jmx_exporter/
jmx_prometheus_javaagent-0.12.0.jar=9404:/opt/jmx_exporter/config.yaml $JAVA_OPTS"
```

- your web application.war is your web application `war` file to be loaded by Tomcat.

Build a Docker image with this configuration and upload it to an image repository.

Example: Java Jar Application Docker image with Prometheus metrics

The following example Dockerfile shows the steps to build a testing image:

```
# Alpine Linux with OpenJDK JRE
FROM openjdk:8-jre-alpine

RUN mkdir -p /opt/jmx_exporter

COPY ./jmx_prometheus_javaagent-0.12.0.jar /opt/jmx_exporter
COPY ./SampleJavaApplication-1.0-SNAPSHOT.jar /opt/jmx_exporter
COPY ./start_exporter_example.sh /opt/jmx_exporter
COPY ./config.yaml /opt/jmx_exporter

RUN chmod -R o+x /opt/jmx_exporter
```

```
RUN apk add curl

ENTRYPOINT exec /opt/jmx_exporter/start_exporter_example.sh
```

The following list explains the four `COPY` lines in this Dockerfile.

- Download the latest JMX Exporter jar file from https://github.com/prometheus/jmx_exporter.
- `config.yaml` is the JMX Exporter configuration file. For more information, see https://github.com/prometheus/jmx_exporter#Configuration.

  Here is a sample configuration file for Java and Tomcat:

```
lowercaseOutputName: true
lowercaseOutputLabelNames: true

rules:
- pattern: 'java.lang<type=OperatingSystem><>(FreePhysicalMemorySize|
TotalPhysicalMemorySize|FreeSwapSpaceSize|TotalSwapSpaceSize|SystemCpuLoad|
ProcessCpuLoad|OpenFileDescriptorCount|AvailableProcessors)'
  name: java_lang_OperatingSystem_$1
  type: GAUGE

- pattern: 'java.lang<type=Threading><>(TotalStartedThreadCount|ThreadCount)'
  name: java_lang_threading_$1
  type: GAUGE

- pattern: 'Catalina<type=GlobalRequestProcessor, name=\"(\w+-\w+)-(\d+)\"><>(\w+)'
  name: catalina_globalrequestprocessor_$3_total
  labels:
    port: "$2"
    protocol: "$1"
  help: Catalina global $3
  type: COUNTER

- pattern: 'Catalina<j2eeType=Servlet, WebModule=//([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-
a-zA-Z0-9+&@#/%=~_|]), name=([-a-zA-Z0-9+/$%~_-|!.]*), J2EEApplication=none,
 J2EEServer=none><>(requestCount|maxTime|processingTime|errorCount)'
  name: catalina_servlet_$3_total
  labels:
    module: "$1"
    servlet: "$2"
  help: Catalina servlet $3 total
  type: COUNTER
```

```
- pattern: 'Catalina<type=ThreadPool, name="(\w+-\w+)-(\d+)"><>(currentThreadCount|
currentThreadsBusy|keepAliveCount|pollerThreadCount|connectionCount)'
  name: catalina_threadpool_$3
  labels:
    port: "$2"
    protocol: "$1"
  help: Catalina threadpool $3
  type: GAUGE

- pattern: 'Catalina<type=Manager, host=([-a-zA-Z0-9+&@#/%?=~_|!:.,;]*[-a-zA-
Z0-9+&@#/%=~_|]), context=([-a-zA-Z0-9+/$%~_-|!.]*)><>(processingTime|sessionCounter|
rejectedSessions|expiredSessions)'
  name: catalina_session_$3_total
  labels:
    context: "$2"
    host: "$1"
  help: Catalina session $3 total
  type: COUNTER

- pattern: ".*"
```

- `start_exporter_example.sh` is the script to start the JAR application with the Prometheus metrics exported. It also provides the JMX Exporter with the `config.yaml` file path.

```
$ cat start_exporter_example.sh
java -javaagent:/opt/jmx_exporter/jmx_prometheus_javaagent-0.12.0.jar=9404:/
opt/jmx_exporter/config.yaml -cp  /opt/jmx_exporter/SampleJavaApplication-1.0-
SNAPSHOT.jar com.gubupt.sample.app.App
```

- SampleJavaApplication-1.0-SNAPSHOT.jar is the sample Java application jar file. Replace it with the Java application that you want to monitor.

Build a Docker image with this configuration and upload it to an image repository.

Set up HAProxy with a metric exporter on Amazon EKS and Kubernetes

HAProxy is an open-source proxy application. For more information, see [HAProxy](https://www.haproxy.org/).

If you are running HAProxy on a cluster with the Fargate launch type, you need to set up a Fargate profile before doing the steps in this procedure. To set up the profile, enter the following command. Replace *`MyCluster`* with the name of your cluster.

```
eksctl create fargateprofile --cluster MyCluster \
--namespace haproxy-ingress-sample --name haproxy-ingress-sample
```

To install HAProxy with a metric exporter to test Container Insights Prometheus support

1. Enter the following command to add the Helm incubator repo:

```
helm repo add haproxy-ingress https://haproxy-ingress.github.io/charts
```

2. Enter the following command to create a new namespace:

```
kubectl create namespace haproxy-ingress-sample
```

3. Enter the following commands to install HAProxy:

```
helm install haproxy haproxy-ingress/haproxy-ingress \
--namespace haproxy-ingress-sample \
--set defaultBackend.enabled=true \
--set controller.stats.enabled=true \
--set controller.metrics.enabled=true \
--set-string controller.metrics.service.annotations."prometheus\.io/port"="9101" \
--set-string controller.metrics.service.annotations."prometheus\.io/scrape"="true"
```

4. Enter the following command to confirm the annotation of the service:

```
kubectl describe service haproxy-haproxy-ingress-metrics -n haproxy-ingress-sample
```

You should see the following annotations.

```
Annotations:   prometheus.io/port: 9101
               prometheus.io/scrape: true
```

To uninstall HAProxy

- Enter the following commands:

```
helm uninstall haproxy --namespace haproxy-ingress-sample
kubectl delete namespace haproxy-ingress-sample
```

Tutorial for adding a new Prometheus scrape target: Redis OSS on Amazon EKS and Kubernetes clusters

This tutorial provides a hands-on introduction to scrape the Prometheus metrics of a sample Redis OSS application on Amazon EKS and Kubernetes. Redis OSS (https://redis.io/) is an open source (BSD licensed), in-memory data structure store, used as a database, cache and message broker. For more information, see redis.

redis_exporter (MIT License licensed) is used to expose the Redis OSS Prometheus metrics on the specified port (default: 0.0.0.0:9121). For more information, see redis_exporter.

The Docker images in the following two Docker Hub repositories are used in this tutorial:

- redis
- redis_exporter

To install a sample Redis OSS workload which exposes Prometheus metrics

1. Set the namespace for the sample Redis OSS workload.

   ```
   REDIS_NAMESPACE=redis-sample
   ```

2. If you are running Redis OSS on a cluster with the Fargate launch type, you need to set up a Fargate profile. To set up the profile, enter the following command. Replace *MyCluster* with the name of your cluster.

   ```
   eksctl create fargateprofile --cluster MyCluster \
   --namespace $REDIS_NAMESPACE --name $REDIS_NAMESPACE
   ```

3. Enter the following command to install the sample Redis OSS workload.

   ```
   curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
   insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
   prometheus/sample_traffic/redis/redis-traffic-sample.yaml \
   | sed "s/{{namespace}}/$REDIS_NAMESPACE/g" \
   | kubectl apply -f -
   ```

4. The installation includes a service named `my-redis-metrics` which exposes the Redis OSS Prometheus metric on port 9121 Enter the following command to get the details of the service:

```
kubectl describe service/my-redis-metrics  -n $REDIS_NAMESPACE
```

In the `Annotations` section of the results, you'll see two annotations which match the Prometheus scrape configuration of the CloudWatch agent, so that it can auto-discover the workloads:

```
prometheus.io/port: 9121
prometheus.io/scrape: true
```

The related Prometheus scrape configuration can be found in the `- job_name: kubernetes-service-endpoints` section of `kubernetes-eks.yaml` or `kubernetes-k8s.yaml`.

To start collecting Redis OSS Prometheus metrics in CloudWatch

1. Download the latest version of the of `kubernetes-eks.yaml` or `kubernetes-k8s.yaml` file by entering one of the following commands. For an Amazon EKS cluster with the EC2 launch type, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks.yaml
```

For an Amazon EKS cluster with the Fargate launch type, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-eks-fargate.yaml
```

For a Kubernetes cluster running on an Amazon EC2 instance, enter this command.

```
curl -O https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-prometheus/prometheus-k8s.yaml
```

2. Open the file with a text editor, and find the `cwagentconfig.json` section. Add the following subsection and save the changes. Be sure that the indentation follows the existing pattern.

```
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName"]],
  "metric_selectors": [
    "^redis_net_(in|out)put_bytes_total$",
    "^redis_(expired|evicted)_keys_total$",
    "^redis_keyspace_(hits|misses)_total$",
    "^redis_memory_used_bytes$",
    "^redis_connected_clients$"
  ]
},
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName","cmd"]],
  "metric_selectors": [
    "^redis_commands_total$"
  ]
},
{
  "source_labels": ["pod_name"],
  "label_matcher": "^redis-instance$",
  "dimensions": [["Namespace","ClusterName","db"]],
  "metric_selectors": [
    "^redis_db_keys$"
  ]
},
```

   The section you added puts the Redis OSS metrics onto the CloudWatch agent allow list. For a list of these metrics, see the following section.

3. If you already have the CloudWatch agent with Prometheus support deployed in this cluster, you must delete it by entering the following command.

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
```

4. Deploy the CloudWatch agent with your updated configuration by entering one of the following commands. Replace *MyCluster* and *region* to match your settings.

   For an Amazon EKS cluster with the EC2 launch type, enter this command.

```
kubectl apply -f prometheus-eks.yaml
```

   For an Amazon EKS cluster with the Fargate launch type, enter this command.

```
cat prometheus-eks-fargate.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

   For a Kubernetes cluster, enter this command.

```
cat prometheus-k8s.yaml \
| sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/region/" \
| kubectl apply -f -
```

Viewing your Redis OSS Prometheus metrics

This tutorial sends the following metrics to the **ContainerInsights/Prometheus** namespace in CloudWatch. You can use the CloudWatch console to see the metrics in that namespace.

Metric name	Dimensions	
`redis_net_input_bytes_total`	ClusterName, `Namespace`	
`redis_net_output_bytes_total`	ClusterName, `Namespace`	
`redis_expired_keys_total`	ClusterName, `Namespace`	

Metric name	Dimensions	
redis_evicted_keys_total	ClusterName, Namespace	
redis_keyspace_hits_total	ClusterName, Namespace	
redis_keyspace_misses_total	ClusterName, Namespace	
redis_memory_used_bytes	ClusterName, Namespace	
redis_connected_clients	ClusterName, Namespace	
redis_commands_total	ClusterName, Namespace , cmd	
redis_db_keys	ClusterName, Namespace , db	

Note

The value of the **cmd** dimension can be: append, client, command, config, dbsize, flushall, get, incr, info, latency, or slowlog.

The value of the **db** dimension can be db0 to db15.

You can also create a CloudWatch dashboard for your Redis OSS Prometheus metrics.

To create a dashboard for Redis OSS Prometheus metrics

1. Create environment variables, replacing the values below to match your deployment.

```
DASHBOARD_NAME=your_cw_dashboard_name
REGION_NAME=your_metric_region_such_as_us-east-1
CLUSTER_NAME=your_k8s_cluster_name_here
NAMESPACE=your_redis_service_namespace_here
```

2. Enter the following command to create the dashboard.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-
insights/latest/k8s-deployment-manifest-templates/deployment-mode/service/cwagent-
prometheus/sample_cloudwatch_dashboards/redis/cw_dashboard_redis.json \
| sed "s/{{YOUR_AWS_REGION}}/${REGION_NAME}/g" \
| sed "s/{{YOUR_CLUSTER_NAME}}/${CLUSTER_NAME}/g" \
| sed "s/{{YOUR_NAMESPACE}}/${NAMESPACE}/g" \
```

Prometheus metric type conversion by the CloudWatch Agent

The Prometheus client libraries offer four core metric types:

- Counter
- Gauge
- Summary
- Histogram

The CloudWatch agent supports the counter, gauge, and summary metric types.

The Prometheus metrics with the unsupported histogram metric type are dropped by the CloudWatch agent. For more information, see Logging dropped Prometheus metrics.

Gauge metrics

A Prometheus gauge metric is a metric that represents a single numerical value that can arbitrarily go up and down. The CloudWatch agent scrapes gauge metrics and send these values out directly.

Counter metrics

A Prometheus counter metric is a cumulative metric that represents a single monotonically increasing counter whose value can only increase or be reset to zero. The CloudWatch agent calculates a delta from the previous scrape and sends the delta value as the metric value in the log event. So the CloudWatch agent will start to produce one log event from the second scrape and continue with subsequent scrapes, if any.

Summary metrics

A Prometheus summary metric is a complex metric type which is represented by multiple data points. It provides a total count of observations and a sum of all observed values. It calculates configurable quantiles over a sliding time window.

The sum and count of a summary metric are cumulative, but the quantiles are not. The following example shows the variance of quantiles.

```
# TYPE go_gc_duration_seconds summary
go_gc_duration_seconds{quantile="0"} 7.123e-06
go_gc_duration_seconds{quantile="0.25"} 9.204e-06
go_gc_duration_seconds{quantile="0.5"} 1.1065e-05
go_gc_duration_seconds{quantile="0.75"} 2.8731e-05
go_gc_duration_seconds{quantile="1"} 0.003841496
go_gc_duration_seconds_sum 0.37630427
go_gc_duration_seconds_count 9774
```

The CloudWatch agent handles the sum and count of a summary metric in the same way as it handles counter metrics, as described in the previous section. The CloudWatch agent preserves the quantile values as they are originally reported.

Prometheus metrics collected by the CloudWatch agent

The CloudWatch agent with Prometheus support automatically collects metrics from several services and workloads. The metrics that are collected by default are listed in the following sections. You can also configure the agent to collect more metrics from these services, and to collect Prometheus metrics from other applications and services. For more information about collecting additional metrics, see CloudWatch agent configuration for Prometheus.

Prometheus metrics collected from Amazon EKS and Kubernetes clusters are in the **ContainerInsights/Prometheus** namespace. Prometheus metrics collected from Amazon ECS clusters are in the **ECS/ContainerInsights/Prometheus** namespace.

Topics

- Prometheus metrics for App Mesh

- Prometheus metrics for NGINX
- Prometheus metrics for Memcached
- Prometheus metrics for Java/JMX
- Prometheus metrics for HAProxy

Prometheus metrics for App Mesh

The following metrics are automatically collected from App Mesh .

Prometheus metrics for App Mesh on Amazon EKS and Kubernetes clusters

Metric name	Dimensions	
envoy_http_downstream_rq_total	ClusterName, Namespace	
envoy_http_downstream_rq_xx	ClusterName, Namespace ClusterName, Namespace , envoy_http_conn_manager_prefix, envoy_response_code_class

envoy_http_downstream_rq_xx	ClusterName, TaskDefinitionFamily, envoy_http_conn_manager_prefix, envoy_response_code_class ClusterName, TaskDefinitionFamily, envoy_response_code_class	

Note

TaskDefinitionFamily is the Kubernetes namespace of the mesh.
The value of envoy_http_conn_manager_prefix can be ingress, egress, or admin.
The value of envoy_response_code_class can be 1 (stands for 1xx), 2 stands for 2xx), 3 stands for 3xx), 4 stands for 4xx), or 5 stands for 5xx).

Prometheus metrics for NGINX

The following metrics are automatically collected from NGINX on Amazon EKS and Kubernetes clusters.

Metric name	Dimensions	
nginx_ingress_controller_nginx_process_cpu_seconds_total	ClusterName, Namespace , Service	
nginx_ingress_controller_success	ClusterName, Namespace , Service	

Metric name	Dimensions	
nginx_ingress_controller_requests	ClusterName, Namespace , Service	
nginx_ingress_controller_nginx_process_connections	ClusterName, Namespace , Service	
nginx_ingress_controller_nginx_process_connections_total	ClusterName, Namespace , Service	
nginx_ingress_controller_nginx_process_resident_memory_bytes	ClusterName, Namespace , Service	
nginx_ingress_controller_config_last_reload_successful	ClusterName, Namespace , Service	

Metric name	Dimensions	
nginx_ingress_controller_requests	ClusterName, Namespace , Service, status	

Prometheus metrics for Memcached

The following metrics are automatically collected from Memcached on Amazon EKS and Kubernetes clusters.

Metric name	Dimensions	
memcached_current_items	ClusterName, Namespace , Service	
memcached_current_connections	ClusterName, Namespace , Service	
memcached_limit_bytes	ClusterName, Namespace , Service	
memcached_current_bytes	ClusterName, Namespace , Service	
memcached_written_bytes_total	ClusterName, Namespace , Service	
memcached_read_bytes_total	ClusterName, Namespace , Service	
memcached_items_evicted_total	ClusterName, Namespace , Service	

Metric name	Dimensions
memcached_items_reclaimed_total	ClusterName, Namespace , Service
memcached_commands_total	ClusterName, Namespace , Service ClusterName, Namespace , Service, command ClusterName, Namespace , Service, status, command

Prometheus metrics for Java/JMX

Metrics collected on Amazon EKS and Kubernetes clusters

On Amazon EKS and Kubernetes clusters, Container Insights can collect the following predefined Prometheus metrics from the Java Virtual Machine (JVM), Java, and Tomcat (Catalina) using the JMX Exporter. For more information, see [prometheus/jmx_exporter](https://github.com/prometheus/jmx_exporter) on Github.

Java/JMX on Amazon EKS and Kubernetes clusters

Metric name	Dimensions
jvm_classes_loaded	ClusterName , Namespace
jvm_threads_current	ClusterName , Namespace
jvm_threads_daemon	ClusterName , Namespace
java_lang_operatingsystem_totalswapspacesize	ClusterName , Namespace

Metric name	Dimensions	
java_lang_operatingsystem_systemcpuload	ClusterName ,Namespace	
java_lang_operatingsystem_processcpuload	ClusterName ,Namespace	
java_lang_operatingsystem_freeswapspacesize	ClusterName ,Namespace	
java_lang_operatingsystem_totalphysicalmemorysize	ClusterName ,Namespace	
java_lang_operatingsystem_freephysicalmemorysize	ClusterName ,Namespace	
java_lang_operatingsystem_openfiledescriptorcount	ClusterName ,Namespace	

Metric name	Dimensions	
java_lang_operatingsystem_availableprocessors	ClusterName , Namespace	
jvm_memory_bytes_used	ClusterName , Namespace , area	
jvm_memory_pool_bytes_used	ClusterName , Namespace , pool	

Note

The values of the area dimension can be heap or nonheap.

The values of the pool dimension can be Tenured Gen, Compress Class Space, Survivor Space, Eden Space, Code Cache, or Metaspace.

Tomcat/JMX on Amazon EKS and Kubernetes clusters

In addition to the Java/JMX metrics in the previous table, the following metrics are also collected for the Tomcat workload.

Metric name	Dimensions	
catalina_manager_activesessions	ClusterName , Namespace	
catalina_manager_rejectedsessions	ClusterName , Namespace	

Metric name	Dimensions	
catalina_globalrequestprocessor_bytesreceived	ClusterName ,Namespace	
catalina_globalrequestprocessor_bytessent	ClusterName ,Namespace	
catalina_globalrequestprocessor_requestcount	ClusterName ,Namespace	
catalina_globalrequestprocessor_errorcount	ClusterName ,Namespace	
catalina_globalrequestprocessor_processingtime	ClusterName ,Namespace	

Java/JMX on Amazon ECS clusters

Metric name	Dimensions	
jvm_classes_loaded	ClusterName ,TaskDefinitionFamily	
jvm_threads_current	ClusterName ,TaskDefinitionFamily	
jvm_threads_daemon	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_totalswapspacesize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_systemcpuload	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_processcpuload	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_freeswapspacesize	ClusterName ,TaskDefinitionFamily	
java_lang_operatingsystem_totalphysicalmemorysize	ClusterName ,TaskDefinitionFamily	

Metric name	Dimensions	
java_lang_operatingsystem_freephysicalmemorysize	ClusterName , TaskDefinitionFamily	
java_lang_operatingsystem_openfiledescriptorcount	ClusterName , TaskDefinitionFamily	
java_lang_operatingsystem_availableprocessors	ClusterName , TaskDefinitionFamily	
jvm_memory_bytes_used	ClusterName , TaskDefinitionFamily, area	
jvm_memory_pool_bytes_used	ClusterName , TaskDefinitionFamily, pool	

Note

The values of the area dimension can be heap or nonheap.

The values of the pool dimension can be Tenured Gen, Compress Class Space, Survivor Space, Eden Space, Code Cache, or Metaspace.

Tomcat/JMX on Amazon ECS clusters

In addition to the Java/JMX metrics in the previous table, the following metrics are also collected for the Tomcat workload on Amazon ECS clusters.

Metric name	Dimensions	
catalina_manager_activesessions	ClusterName , TaskDefinitionFamily	
catalina_manager_rejectedsessions	ClusterName , TaskDefinitionFamily	
catalina_globalrequestprocessor_bytesreceived	ClusterName , TaskDefinitionFamily	
catalina_globalrequestprocessor_bytessent	ClusterName , TaskDefinitionFamily	
catalina_globalrequestprocessor_requestcount	ClusterName , TaskDefinitionFamily	
catalina_globalrequestprocessor_errorcount	ClusterName , TaskDefinitionFamily	

Metric name	Dimensions	
catalina_globalrequestprocessor_processingtime	ClusterName ,TaskDefinitionFamily	

Prometheus metrics for HAProxy

The following metrics are automatically collected from HAProxy on Amazon EKS and Kubernetes clusters.

The metrics collected depend on which version of HAProxy Ingress that you are using. For more information about HAProxy Ingress and its versions, see haproxy-ingress.

Metric name	Dimensions	Availability
haproxy_backend_bytes_in_total	ClusterName ,Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_bytes_out_total	ClusterName ,Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_connection_errors_total	ClusterName ,Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_connections_total	ClusterName ,Namespace , Service	All versions of HAProxy Ingress

Metric name	Dimensions	Availability
haproxy_backend_current_sessions	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_backend_http_responses_total	ClusterName , Namespace , Service, code, backend	All versions of HAProxy Ingress
haproxy_backend_status	ClusterName , Namespace , Service	Only in versions 0.10 or later of HAProxy Ingress
haproxy_backend_up	ClusterName , Namespace , Service	Only in versions of HAProxy Ingress earlier than 0.10
haproxy_frontend_bytes_in_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_bytes_out_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_connections_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_current_sessions	ClusterName , Namespace , Service	All versions of HAProxy Ingress

Metric name	Dimensions	Availability
haproxy_frontend_http_requests_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_http_responses_total	ClusterName , Namespace , Service, code, frontend	All versions of HAProxy Ingress
haproxy_frontend_request_errors_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress
haproxy_frontend_requests_denied_total	ClusterName , Namespace , Service	All versions of HAProxy Ingress

Note

The values of the code dimension can be 1xx, 2xx, 3xx, 4xx, 5xx, or other.
The values of the backend dimension can be:

- http-default-backend, http-shared-backend, or httpsback-shared-backend for HAProxy Ingress version 0.0.27 or earlier.
- _default_backend for HAProxy Ingress versions later than 0.0.27.

The values of the frontend dimension can be:

- httpfront-default-backend, httpfront-shared-frontend, or httpfronts for HAProxy Ingress version 0.0.27 or earlier.
- _front_http or _front_https for HAProxy Ingress versions later than 0.0.27.

Viewing your Prometheus metrics

You can monitor and alarm on all your Prometheus metrics including the curated pre-aggregated metrics from App Mesh, NGINX, Java/JMX, Memcached, and HAProxy, and any other manually configured Prometheus exporter you may have added. For more information about collecting metrics from other Prometheus exporters, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

In the CloudWatch console, Container Insights provides the following pre-built reports:

- For Amazon EKS and Kubernetes clusters, there are pre-built reports for App Mesh, NGINX, HAPROXY, Memcached, and Java/JMX.
- For Amazon ECS clusters, there are pre-built reports for App Mesh and Java/JMX.

Container Insights also provides custom dashboards for each of the workloads that Container Insights collects curated metrics from. You can download these dashboards from GitHub

To see all your Prometheus metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. In the list of namespaces, choose **ContainerInsights/Prometheus** or **ECS/ContainerInsights/Prometheus**.
4. Choose one of the sets of dimensions in the following list. Then select the checkbox next to the metrics that you want to see.

To see pre-built reports on your Prometheus metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Performance Monitoring**.
3. In the drop-down box near the top of the page, choose any of the Prometheus options.

   In the other drop-down box, choose a cluster to view

We have also provided custom dashboards for NGINX, App Mesh, Memcached, HAProxy, and Java/JMX.

To use a custom dashboard that Amazon has provided

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Dashboards**.
3. Choose **Create Dashboard**. Enter a name for the new dashboard, and choose **Create dashboard**.
4. In **Add to this dashboard**, choose **Cancel**.
5. Choose **Actions**, **View/edit source**.
6. Download one of the following JSON files:
   - NGINX custom dashboard source on Github.
   - App Mesh custom dashboard source on Github.
   - Memcached custom dashboard source on Github
   - HAProxy-Ingress custom dashboard source on Github
   - Java/JMX custom dashboard source on Github.
7. Open the JSON file that you downloaded with a text editor, and make the following changes:
   - Replace all the `{{YOUR_CLUSTER_NAME}}` strings with the exact name of your cluster. Make sure not to add whitespaces before or after the text.
   - Replace all the `{{YOUR_REGION}}` strings with the Amazon Region where your cluster is running. For example, **`us-west-1`** Make sure not to add whitespaces before or after the text.
   - Replace all the `{{YOUR_NAMESPACE}}` strings with the exact namespace of your workload.
   - Replace all the `{{YOUR_SERVICE_NAME}}` strings with the exact service name of your workload. For example, **`haproxy-haproxy-ingress-controller-metrics`**
8. Copy the entire JSON blob and paste it into the text box in the CloudWatch console, replacing what is already in the box.
9. Choose **Update**, **Save dashboard**.

Prometheus metrics troubleshooting

This section provides help for troubleshooting your Prometheus metrics setup.

- [Prometheus metrics troubleshooting on Amazon EKS and Kubernetes clusters]

Prometheus metrics troubleshooting on Amazon ECS

This section provides help for troubleshooting your Prometheus metrics setup on Amazon ECS clusters.

I don't see Prometheus metrics sent to CloudWatch Logs

The Prometheus metrics should be ingested as log events in the log group **/aws/ecs/containerinsights/cluster-name/Prometheus**. If the log group is not created or the Prometheus metrics are not sent to the log group, you will need to first check whether the Prometheus targets have been successfully discovered by the CloudWatch agent. And next check the security group and permission settings of the CloudWatch agent. The following steps guide you to do the debugging.

Step 1: Enable the CloudWatch agent debugging mode

First, change the CloudWatch agent to debug mode by adding the following bold lines to your Amazon CloudFormation template file, `cwagent-ecs-prometheus-metric-for-bridge-host.yaml` or `cwagent-ecs-prometheus-metric-for-awsvpc.yaml`. Then save the file.

```
cwagentconfig.json: |
    {
      "agent": {
        "debug": true
      },
      "logs": {
        "metrics_collected": {
```

Create a new Amazon CloudFormation changeset against the existing stack. Set other parameters in the changeset to the same values as in your existing Amazon CloudFormation stack. The following example is for a CloudWatch agent installed in an Amazon ECS cluster using the EC2 launch type and the bridge network mode.

```
ECS_NETWORK_MODE=bridge
 CREATE_IAM_ROLES=True
ECS_TASK_ROLE_NAME=your_selected_ecs_task_role_name
ECS_EXECUTION_ROLE_NAME=your_selected_ecs_execution_role_name
NEW_CHANGESET_NAME=your_selected_ecs_execution_role_name
```

```
aws cloudformation create-change-set --stack-name CWAgent-Prometheus-ECS-${ECS_CLUSTER_NAME}-EC2-${ECS_NETWORK_MODE} \
    --template-body file://cwagent-ecs-prometheus-metric-for-bridge-host.yaml \
    --parameters ParameterKey=ECSClusterName,ParameterValue=$ECS_CLUSTER_NAME \
                 ParameterKey=CreateIAMRoles,ParameterValue=$CREATE_IAM_ROLES \
                 ParameterKey=ECSNetworkMode,ParameterValue=$ECS_NETWORK_MODE \
                 ParameterKey=TaskRoleName,ParameterValue=$ECS_TASK_ROLE_NAME \
                 ParameterKey=ExecutionRoleName,ParameterValue=$ECS_EXECUTION_ROLE_NAME \
    --capabilities CAPABILITY_NAMED_IAM \
    --region $AWS_REGION \
    --change-set-name $NEW_CHANGESET_NAME
```

Go to the Amazon CloudFormation console to review the new changeset, `$NEW_CHANGESET_NAME`. There should be one change applied to the **CWAgentConfigSSMParameter** resource. Execute the changeset and restart the CloudWatch agent task by entering the following commands.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 0 \
--service your_service_name_here \
--region $AWS_REGION
```

Wait about 10 seconds and then enter the following command.

```
aws ecs update-service --cluster $ECS_CLUSTER_NAME \
--desired-count 1 \
--service your_service_name_here \
--region $AWS_REGION
```

Step 2: Check the ECS service discovery logs

The ECS task definition of the CloudWatch agent enables the logs by default in the section below. The logs are sent to CloudWatch Logs in the log group **/ecs/ecs-cwagent-prometheus**.

```
LogConfiguration:
  LogDriver: awslogs
    Options:
      awslogs-create-group: 'True'
      awslogs-group: "/ecs/ecs-cwagent-prometheus"
      awslogs-region: !Ref AWS::Region
      awslogs-stream-prefix: !Sub 'ecs-${ECSLaunchType}-awsvpc'
```

Filter the logs by the string `ECS_SD_Stats` to get the metrics related to the ECS service discovery, as shown in the following example.

```
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeContainerInstances: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeInstancesRequest: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeTaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_DescribeTasks: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: AWSCLI_ListTasks: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: Exporter_DiscoveredTargetCount: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Get_EC2MetaData: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Get_TaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Size_ContainerInstance: 1
2020-09-1T01:53:14Z D! ECS_SD_Stats: LRUCache_Size_TaskDefinition: 2
2020-09-1T01:53:14Z D! ECS_SD_Stats: Latency: 43.399783ms
```

The meaning of each metric for a particular ECS service discovery cycle is as follows:

- **AWSCLI_DescribeContainerInstances** – the number of `ECS::DescribeContainerInstances` API calls made.
- **AWSCLI_DescribeInstancesRequest** – the number of `ECS::DescribeInstancesRequest` API calls made.
- **AWSCLI_DescribeTaskDefinition** – the number of `ECS::DescribeTaskDefinition` API calls made.
- **AWSCLI_DescribeTasks** – the number of `ECS::DescribeTasks` API calls made.
- **AWSCLI_ListTasks** – the number of `ECS::ListTasks` API calls made.
- **ExporterDiscoveredTargetCount** – the number of Prometheus targets that were discovered and successfully exported into the target result file within the container.
- **LRUCache_Get_EC2MetaData** – the number of times that container instances metadata was retrieved from the cache.
- **LRUCache_Get_TaskDefinition** – the number of times that ECS task definition metadata was retrieved from the cache.
- **LRUCache_Size_ContainerInstance** – the number of unique container instance's metadata cached in memory.
- **LRUCache_Size_TaskDefinition** – the number of unique ECS task definitions cached in memory.
- **Latency** – how long the service discovery cycle takes.

Check the value of `ExporterDiscoveredTargetCount` to see whether the discovered Prometheus targets match your expectations. If not, the possible reasons are as follows:

- The configuration of ECS service discovery might not match your application's setting. For the docker label-based service discovery, your target containers may not have the necessary docker label configured in the CloudWatch agent to auto discover them. For the ECS task definition ARN regular expression-based service discovery, the regex setting in the CloudWatch agent may not match your application's task definition.
- The CloudWatch agent's ECS task role might not have permission to retrieve the metadata of ECS tasks. Check that the CloudWatch agent has been granted the following read-only permissions:
  - `ec2:DescribeInstances`
  - `ecs:ListTasks`
  - `ecs:DescribeContainerInstances`
  - `ecs:DescribeTasks`
  - `ecs:DescribeTaskDefinition`

Step 3: Check the network connection and the ECS task role policy

If there are still no log events sent to the target CloudWatch Logs log group even though the value of `Exporter_DiscoveredTargetCount` indicates that there are discovered Prometheus targets, this could be caused by one of the following:

- The CloudWatch agent might not be able to connect to the Prometheus target ports. Check the security group setting behind the CloudWatch agent. The private IP should alow the CloudWatch agent to connect to the Prometheus exporter ports.
- The CloudWatch agent's ECS task role might not have the **CloudWatchAgentServerPolicy** managed policy. The CloudWatch agent's ECS task role needs to have this policy to be able to send the Prometheus metrics as log events. If you used the sample Amazon CloudFormation template to create the IAM roles automatically, both the ECS task role and the ECS execution role are granted with the least privilege to perform the Prometheus monitoring.

Prometheus metrics troubleshooting on Amazon EKS and Kubernetes clusters

This section provides help for troubleshooting your Prometheus metrics setup on Amazon EKS and Kubernetes clusters.

General troubleshooting steps on Amazon EKS

To confirm that the CloudWatch agent is running, enter the following command.

```
kubectl get pod -n amazon-cloudwatch
```

The output should include a row with `cwagent-prometheus-*id*` in the `NAME` column and `Running` in the `STATUS column.`

To display details about the running pod, enter the following command. Replace *pod-name* with the complete name of your pod that has a name that starts with `cw-agent-prometheus`.

```
kubectl describe pod pod-name -n amazon-cloudwatch
```

If you have CloudWatch Container Insights installed, you can use CloudWatch Logs Insights to query the logs from the CloudWatch agent collecting the Prometheus metrics.

To query the application logs

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **CloudWatch Logs Insights**.
3. Select the log group for the application logs, **/aws/containerinsights/*cluster-name*/application**
4. Replace the search query expression with the following query, and choose **Run query**

```
fields ispresent(kubernetes.pod_name) as haskubernetes_pod_name, stream,
 kubernetes.pod_name, log |
filter haskubernetes_pod_name and kubernetes.pod_name like /cwagent-prometheus
```

You can also confirm that Prometheus metrics and metadata are being ingested as CloudWatch Logs events.

To confirm that Prometheus data is being ingested

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **CloudWatch Logs Insights**.
3. Select the **/aws/containerinsights/*cluster-name*/prometheus**
4. Replace the search query expression with the following query, and choose **Run query**

```
fields @timestamp, @message | sort @timestamp desc | limit 20
```

Logging dropped Prometheus metrics

This release does not collect Prometheus metrics of the histogram type. You can use the CloudWatch agent to check whether any Prometheus metrics are being dropped because they are histogram metrics. You can also log a list of the first 500 Prometheus metrics that are dropped and not sent to CloudWatch because they are histogram metrics.

To see whether any metrics are being dropped, enter the following command:

```
kubectl logs -l "app=cwagent-prometheus" -n amazon-cloudwatch --tail=-1
```

If any metrics are being dropped, you will see the following lines in the `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` file.

```
I! Drop Prometheus metrics with unsupported types. Only Gauge, Counter and Summary are
 supported.
I! Please enable CWAgent debug mode to view the first 500 dropped metrics
```

If you see those lines and want to know what metrics are being dropped, use the following steps.

To log a list of dropped Prometheus metrics

1. Change the CloudWatch agent to debug mode by adding the following bold lines to your `prometheus-eks.yaml` or `prometheus-k8s.yaml`file, and save the file.

   ```
   {
         "agent": {
           "debug": true
         },
   ```

   This section of the file should then look like this:

   ```
   cwagentconfig.json: |
       {
         "agent": {
           "debug": true
   ```

```
    },
    "logs": {
      "metrics_collected": {
```

2. Reinstall the CloudWatch agent to enable debug mode by entering the following commands:

```
kubectl delete deployment cwagent-prometheus -n amazon-cloudwatch
kubectl apply -f prometheus.yaml
```

   The dropped metrics are logged in the CloudWatch agent pod.

3. To retrieve the logs from the CloudWatch agent pod, enter the following command:

```
kubectl logs -l "app=cwagent-prometheus" -n amazon-cloudwatch --tail=-1
```

   Or, if you have Container Insights Fluentd logging installed, the logs are also saved in the CloudWatch Logs log group **/aws/containerinsights/*cluster_name*/application**.

   To query these logs, you can follow the steps for querying the application logs in [General troubleshooting steps on Amazon EKS](#).

Where are the Prometheus metrics ingested as CloudWatch Logs log events?

The CloudWatch agent creates a log stream for each Prometheus scrape job configuration. For example, in the `prometheus-eks.yaml` and `prometheus-k8s.yaml` files, the line `job_name: 'kubernetes-pod-appmesh-envoy'` scrapes App Mesh metrics. The Prometheus target is defined as `kubernetes-pod-appmesh-envoy`. So all App Mesh Prometheus metrics are ingested as CloudWatch Logs events in the log stream **kubernetes-pod-appmesh-envoy** under the log group named **/aws/containerinsights/cluster-name/Prometheus**.

I don't see Amazon EKS or Kubernetes Prometheus metrics in CloudWatch metrics

First, make sure that the Prometheus metrics are ingested as log events in the log group **/aws/containerinsights/cluster-name/Prometheus**. Use the information in [Where are the Prometheus metrics ingested as CloudWatch Logs log events?](#) to help you check the target log stream. If the log stream is not created or there are no new log events in the log stream, check the following:

- Check that the Prometheus metrics exporter endpoints are set up correctly
- Check that the Prometheus scraping configurations in the `config map: cwagent-prometheus` section of the CloudWatch agent YAML file is correct. The configuration should

be the same as it would be in a Prometheus configuration file. For more information, see <scrape_config> in the Prometheus documentation.

If the Prometheus metrics are ingested as log events correctly, check that the embedded metric format settings are added into the log events to generate the CloudWatch metrics.

```
"CloudWatchMetrics":[
   {
      "Metrics":[
         {
            "Name":"envoy_http_downstream_cx_destroy_remote_active_rq"
         }
      ],
      "Dimensions":[
         [
            "ClusterName",
            "Namespace"
         ]
      ],
      "Namespace":"ContainerInsights/Prometheus"
   }
],
```

For more information about embedded metric format, see Specification: Embedded metric format.

If there is no embedded metric format in the log events, check that the `metric_declaration` section is configured correctly in the `config map: prometheus-cwagentconfig` section of the CloudWatch agent installation YAML file. For more information, see Tutorial for adding a new Prometheus scrape target: Prometheus API Server metrics.

Integration with Application Insights

Amazon CloudWatch Application Insights helps you monitor your applications and identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. For more information, see Detect common application problems with CloudWatch Application Insights.

You can enable Application Insights to gather additional data from your containerized applications and microservices. If you haven't done this already, you can enable it by choosing **Auto-configure Application Insights** below the performance view in the Container Insights dashboard.

If you have already set up CloudWatch Application Insights to monitor your containerized applications, the Application Insights dashboard appears below the Container Insights dashboard.

For more information about Application Insights and containerized applications, see Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring.

Viewing Amazon ECS lifecycle events within Container Insights

You can view Amazon ECS lifecycle events within the Container Insights console. This helps you correlate your container metrics, logs, and events in a single view to give you a more complete operational visibility.

The events include container instance state change events, task state change events, and service action events. They are automatically sent by Amazon ECS to Amazon EventBridge and are also collected in CloudWatch in event log format. For more information about these events, see Amazon ECS events.

Standard Container Insights pricing applies for Amazon ECS Lifecycle events. For more information, see Amazon CloudWatch Pricing.

To configure the table of lifecycle events and create rules for a cluster, you must have the `events:PutRule`, `events:PutTargets`, and `logs:CreateLogGroup` permissions. You must also make sure that there is a resource policy that enables EventBridge to create the log stream and send logs to CloudWatch Logs. If this resource policy doesn't exist, you can enter the following command to create it:

```
aws --region region logs put-resource-policy --policy-name 'EventBridgeCloudWatchLogs'
 --policy-document '{
    "Statement": [
        {
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Effect": "Allow",
            "Principal": {
                "Service": ["events.amazonaws.com", "delivery.logs.amazonaws.com"]
            },
            "Resource": "arn:aws:logs:region:account-id:log-group:/aws/events/ecs/
containerinsights/*:*",
            "Sid": "TrustEventBridgeToStoreECSLifecycleLogEvents"
        }
```

```
    ],
    "Version": "2012-10-17"
}'
```

You can use the following command to check whether you already have this policy, and to confirm that attaching it worked correctly.

```
aws logs describe-resource-policies --region region --output json
```

To view the table of lifecycle events, you must have the `events:DescribeRule`, `events:ListTargetsByRule`, and `logs:DescribeLogGroups` permissions.

To view Amazon ECS lifecycle events in the CloudWatch Container Insights console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**, **Container Insights**.
3. Choose **View performance dashboards**.
4. In the next drop-down, choose either **ECS Clusters**, **ECS Services**, or **ECS Tasks**.
5. If you chose **ECS Services** or **ECS Tasks** in the previous step, choose the **Lifecycle events** tab.
6. At the bottom of the page, if you see **Configure lifecycle events**, choose it to create EventBridge rules for your cluster.

   The events are displayed below the container insights panes and above the Application Insights section. To run extra analytics and create additional visualizations on these events, choose **View in Logs Insights** in the Lifecycle Events table.

Troubleshooting Container Insights

The following sections can help if you're having trouble issues with Container Insights.

Failed deployment on Amazon EKS or Kubernetes

If the agent doesn't deploy correctly on a Kubernetes cluster, try the following:

- Run the following command to get the list of pods.

  ```
  kubectl get pods -n amazon-cloudwatch
  ```

- Run the following command and check the events at the bottom of the output.

```
kubectl describe pod pod-name -n amazon-cloudwatch
```

- Run the following command to check the logs.

```
kubectl logs pod-name -n amazon-cloudwatch
```

Unauthorized panic: Cannot retrieve cadvisor data from kubelet

If your deployment fails with the error `Unauthorized panic: Cannot retrieve cadvisor data from kubelet`, your kubelet might not have Webhook authorization mode enabled. This mode is required for Container Insights. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

Deploying Container Insights on a deleted and re-created cluster on Amazon ECS

If you delete an existing Amazon ECS cluster that does not have Container Insights enabled, and you re-create it with the same name, you can't enable Container Insights on this new cluster at the time you re-create it. You can enable it by re-creating it, and then entering the following command:

```
aws ecs update-cluster-settings --cluster myCICluster --settings name=container
 Insights,value=enabled
```

Invalid endpoint error

If you see an error message similar to the following, check to make sure that you replaced all the placeholders such as *cluster-name* and *region-name* in the commands that you are using with the correct information for your deployment.

```
"log": "2020-04-02T08:36:16Z E! cloudwatchlogs: code: InvalidEndpointURL, message:
 invalid endpoint uri, original error: &url.Error{Op:\"parse\", URL:\"https://
logs.{{region_name}}.amazonaws.com/\", Err:\"{\"}, &awserr.baseError{code:
\"InvalidEndpointURL\", message:\"invalid endpoint uri\", errs:[]error{(*url.Error)
(0xc0008723c0)}}\n",
```

Metrics don't appear in the console

If you don't see any Container Insights metrics in the Amazon Web Services Management Console, be sure that you have completed the setup of Container Insights. Metrics don't appear before

Container Insights has been set up completely. For more information, see [Setting up Container Insights](#).

Pod metrics missing on Amazon EKS or Kubernetes after upgrading cluster

This section might be useful if all or some pod metrics are missing after you deploy the CloudWatch agent as a daemonset on a new or upgraded cluster, or you see an error log with the message `W! No pod metric collected`.

These errors can be caused by changes in the container runtime, such as containerd or the docker systemd cgroup driver. You can usually solve this by updating your deployment manifest so that the containerd socket from the host is mounted into the container. See the following example:

```
# For full example see https://github.com/aws-samples/amazon-cloudwatch-container-
insights/blob/latest/k8s-deployment-manifest-templates/deployment-mode/daemonset/
container-insights-monitoring/cwagent/cwagent-daemonset.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  name: cloudwatch-agent
  namespace: amazon-cloudwatch
spec:
  template:
    spec:
      containers:
        - name: cloudwatch-agent
# ...
          # Don't change the mountPath
          volumeMounts:
# ...
            - name: dockersock
              mountPath: /var/run/docker.sock
              readOnly: true
            - name: varlibdocker
              mountPath: /var/lib/docker
              readOnly: true
            - name: containerdsock # NEW mount
              mountPath: /run/containerd/containerd.sock
              readOnly: true
# ...
      volumes:
# ...
        - name: dockersock
```

```
          hostPath:
            path: /var/run/docker.sock
        - name: varlibdocker
          hostPath:
            path: /var/lib/docker
        - name: containerdsock # NEW volume
          hostPath:
            path: /run/containerd/containerd.sock
```

No pod metrics when using Bottlerocket for Amazon EKS

Bottlerocket is a Linux-based open source operating system that is purpose-built by Amazon for running containers.

Bottlerocket uses a different `containerd` path on the host, so you need to change the volumes to its location. If you don't, you see an error in the logs that includes `W! No pod metric collected`. See the following example.

```
volumes:
  # ...
    - name: containerdsock
      hostPath:
        # path: /run/containerd/containerd.sock
        # bottlerocket does not mount containerd sock at normal place
        # https://github.com/bottlerocket-os/bottlerocket/
commit/91810c85b83ff4c3660b496e243ef8b55df0973b
        path: /run/dockershim.sock
```

No container filesystem metrics when using the containerd runtime for Amazon EKS or Kubernetes

This is a known issue and is being worked on by community contributors. For more information, see [Disk usage metric for containerd] and [container file system metrics is not supported by cadvisor for containerd] on GitHub.

Unexpected log volume increase from CloudWatch agent when collecting Prometheus metrics

This was a regression introduced in version 1.247347.6b250880 of the CloudWatch agent. This regression has already been fixed in more recent versions of the agent. It's impact was limited to scenarios where customers collected the logs of the CloudWatch agent itself and were also using Prometheus. For more information, see [prometheus] agent is printing all the scraped metrics in log on GitHub.

Latest docker image mentioned in release notes not found from Dockerhub

We update the release note and tag on Github before we start the actual release internally. It usually takes 1-2 weeks to see the latest docker image on registries after we bump the version number on Github. There is no nightly release for the CloudWatch agent container image. You can build the image directly from source at the following location: https://github.com/aws/amazon-cloudwatch-agent/tree/main/amazon-cloudwatch-container-insights/cloudwatch-agent-dockerfile

CrashLoopBackoff error on the CloudWatch agent

If you see a `CrashLoopBackOff` error for the CloudWatch agent, make sure that your IAM permissions are set correctly. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

CloudWatch agent or Fluentd pod stuck in pending

If you have a CloudWatch agent or Fluentd pod stuck in `Pending` or with a `FailedScheduling` error, determine if your nodes have enough compute resources based on the number of cores and amount of RAM required by the agents. Enter the following command to describe the pod:

```
kubectl describe pod cloudwatch-agent-85ppg -n amazon-cloudwatch
```

Building your own CloudWatch agent Docker image

You can build your own CloudWatch agent Docker image by referring to the Dockerfile located at https://github.com/aws-samples/amazon-cloudwatch-container-insights/blob/latest/cloudwatch-agent-dockerfile/Dockerfile.

The Dockerfile supports building multi-architecture images directly using `docker buildx`.

Deploying other CloudWatch agent features in your containers

You can deploy additional monitoring features in your containers using the CloudWatch agent. These features include the following:

- **Embedded Metric Format**— For more information, see Embedding metrics within logs.
- **StatsD**— For more information, see Retrieve custom metrics with StatsD.

Instructions and necessary files are located on GitHub at the following locations:

- For Amazon ECS containers, see Example Amazon ECS task definitions based on deployment modes.
- For Amazon EKS and Kubernetes containers, see Example Kubernetes YAML files based on deployment modes.

CloudWatch Database Insights

Use CloudWatch Database Insights to monitor and troubleshoot Amazon Aurora MySQL, Amazon Aurora PostgreSQL, Amazon RDS for SQL Server, RDS for MySQL, RDS for PostgreSQL, RDS for Oracle, and RDS for MariaDB databases at scale.

With Database Insights, you can monitor your database fleet with pre-built, opinionated dashboards. To help you analyze the performance of your fleet, the Database Insights dashboards display curated metrics and visualizations, and you can customize these dashboards. By presenting metrics in a single dashboard for all databases in your fleet, Database Insights allows you to monitor your databases simultaneously.

For example, you can use Database Insights to find a database that is performing poorly within a fleet of hundreds of database instances. You can then choose that instance and use Database Insights to troubleshoot issues.

For information about engine, Amazon Web Services Region, and instance class support, see Aurora DB engine, Region, and instance class support for Database Insights and Amazon RDS DB engine, Region, and instance class support for Database Insights.

Database Insights supports monitoring workloads only within the same Amazon account.

To get started with Database Insights, see the following topics.

Topics

Modes for Database Insights

Database Insights has an Advanced mode and a Standard mode. Standard mode is the default for Database Insights, and you can turn on the Advanced mode for your database.

The following table shows which features CloudWatch supports for the Advanced mode and Standard mode of Database Insights.

Feature	Standard mode	Advanced mode
Analyze the top contributors to DB Load by dimension	Supported	Supported
Query, graph, and set alarms on database metrics with up to 7 days of retention	Supported	Supported
Define fine-grained access control policies to restrict access to potentially sensitive dimensions such as SQL text	Supported	Supported
Analyze operating system processes happening in your databases with detailed metrics per running process You must have Amazon RDS Enhanced Monitoring enabled to use this feature.	Not supported	Supported
Create and save fleet-wide monitoring views to assess health across hundreds of databases	Not supported	Supported
Analyze SQL locks with 15 months of retention and a guided UX	Not supported	Supported only for Aurora PostgreSQL
Analyze SQL execution plans with 15 months of retention and guided UX	Not supported	Supported only for Aurora PostgreSQL, RDS for Oracle, and RDS for SQL Server
Visualize per-query statistics	Not supported	Supported
Analyze slow SQL queries	Not supported	Supported
View calling services with CloudWatch Application Signals	Not supported	Supported

Feature	Standard mode	Advanced mode
View a consolidated dashboard for all database telemetry, including metrics, logs, events, and applications	Not supported	Supported
Import Performance Insights counter metrics into CloudWatch automatically	Not supported	Supported
View Amazon RDS events in CloudWatch	Not supported	Supported
Analyze database performance for a time period of your choice with on-demand analysis	Not supported	Supported only for Aurora PostgreSQL, Aurora MySQL, RDS for PostgreSQL, RDS for MySQL, and RDS for MariaDB

Note

Database Insights feature availability differs in different Amazon Regions, because not all Advanced Mode features are available in all Regions.

Data retention

The Advanced mode of Database Insights retains 15 months of metrics collected by Performance Insights.

If Performance Insights is enabled for the Standard mode, Amazon RDS retains 7 days of Performance Insights counter metrics.

For information about counter metrics for Performance Insights, see Performance Insights counter metrics.

For information about the retention period for CloudWatch metrics collected by Database Insights, see the following topics.

- Amazon CloudWatch metrics for Amazon Aurora in the *Amazon Aurora User Guide*

- Amazon CloudWatch metrics for Amazon Relational Database Service in the *Amazon RDS User Guide*
- Amazon CloudWatch metrics for Amazon RDS Performance Insights in the *Amazon Aurora User Guide*
- Amazon CloudWatch metrics for Amazon RDS Performance Insights in the *Amazon Aurora User Guide*

How Database Insights integrates with Performance Insights

Performance Insights is a database performance monitoring service.

Database Insights builds upon and extends the capabilities of Performance Insights. Database Insights adds monitoring, analysis, and optimization features.

To enable the Advanced mode of Database Insights, you must enable Performance Insights.

Database Insights imports Performance Insights counter metrics into CloudWatch automatically. The Advanced mode of Database Insights automatically retains 15 months of all metrics collected by Database Insights, including Performance Insights metrics and CloudWatch metrics. This automatically happens for you when you enable Advanced mode in an instance, with no further configuration needed. For information about Performance Insights counter metrics, see Performance Insights counter metrics in the *Amazon Aurora User Guide*.

Pricing

For information about pricing, see Amazon CloudWatch Pricing.

Get started with CloudWatch Database Insights

The Standard mode of Database Insights is enabled by default for your Amazon RDS and Aurora databases. To get started with the Advanced mode of Database Insights, you can create a new database or modify a database.

For information about enabling the Advanced mode or the Standard mode of Database Insights for an Amazon RDS database, see the following topics.

- Turning on the Advanced mode of Database Insights for Amazon RDS in the *Amazon RDS User Guide*

- Turning on the Standard mode of Database Insights for Amazon RDS in the *Amazon RDS User Guide*
- Turning CloudWatch Database Insights on or off when creating a DB instance or Multi-AZ DB cluster for Amazon RDS in the *Amazon RDS User Guide*

For information about enabling the Advanced mode or the Standard mode of Database Insights for an Amazon Aurora database, see the following topics.

- Turning on the Advanced mode of Database Insights for Amazon Aurora in the *Amazon Aurora User Guide*
- Turning on the Standard mode of Database Insights for Amazon Aurora in the *Amazon Aurora User Guide*

Required permissions for Database Insights

Certain IAM permissions are required to use Database Insights. Database Insights requires permissions for CloudWatch, CloudWatch Logs, Amazon RDS, and Amazon RDS Performance Insights. You might not need to provide these permissions to your user or role if you have broader permissions.

The following CloudWatch permissions are required to use Database Insights.

- `cloudwatch:BatchGetServiceLevelIndicatorReport`
- `cloudwatch:DescribeAlarms`
- `cloudwatch:GetDashboard`
- `cloudwatch:GetMetricData`
- `cloudwatch:ListMetrics`
- `cloudwatch:PutDashboard`

The following CloudWatch Logs permissions are required to use Database Insights.

- `logs:DescribeLogGroups`
- `logs:GetQueryResults`
- `logs:StartQuery`
- `logs:StopQuery`

The following Amazon RDS permissions are required to use Database Insights.

- `rds:DescribeDBClusters`
- `rds:DescribeDBInstances`
- `rds:DescribeEvents`

The following Performance Insights permissions are required to use Database Insights.

- `pi:ListAvailableResourceMetrics`
- `pi:ListAvailableResourceDimensions`
- `pi:DescribeDimensionKeys`
- `pi:GetDimensionKeyDetails`
- `pi:GetResourceMetrics`
- `pi:ListPerformanceAnalysisReports`
- `pi:GetResourceMetadata`
- `pi:GetPerformanceAnalysisReport`
- `pi:CreatePerformanceAnalysisReport`
- `pi:DeletePerformanceAnalysisReport`
- `pi:ListTagsForResource`
- `pi:TagResource`
- `pi:UntagResource`

The following sample policy contains the permissions required for full access to Database Insights.

Sample policy for full access

```
{
    "Version": "2012-10-17",
    "Statement": [{
    "Effect" : "Allow",
      "Action" : [
        "cloudwatch:BatchGetServiceLevelIndicatorReport",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:GetMetricData",
        "cloudwatch:ListMetrics",
```

```
        "cloudwatch:PutDashboard"
      ],
      "Resource" : "*"
    },
    {
    "Effect" : "Allow",
      "Action" : [
        "logs:DescribeLogGroups",
        "logs:GetQueryResults",
        "logs:StartQuery",
        "logs:StopQuery"
      ],
      "Resource" : "*"
    },
    {
    "Effect" : "Allow",
      "Action" : [
        "pi:DescribeDimensionKeys",
        "pi:GetDimensionKeyDetails",
        "pi:GetResourceMetadata",
        "pi:GetResourceMetrics",
        "pi:ListAvailableResourceDimensions",
        "pi:ListAvailableResourceMetrics",
        "pi:CreatePerformanceAnalysisReport",
        "pi:GetPerformanceAnalysisReport",
        "pi:ListPerformanceAnalysisReports",
        "pi:DeletePerformanceAnalysisReport",
        "pi:TagResource",
        "pi:UntagResource",
        "pi:ListTagsForResource"
      ],
      "Resource" : "arn:aws:pi:*:*:*/rds/*"
    },
    {
    "Effect" : "Allow",
      "Action" : [
        "rds:DescribeDBInstances",
        "rds:DescribeDBClusters",
        "rds:DescribeEvents"
      ],
      "Resource" : "*"
    }
  ]
```

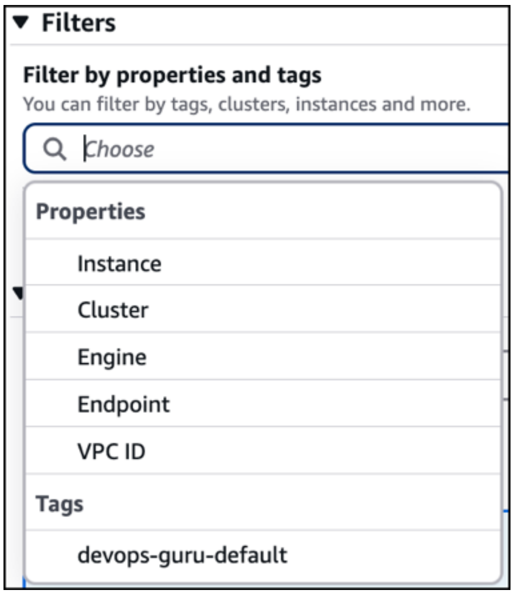
```
}
```

Viewing the Fleet Health Dashboard for CloudWatch Database Insights

You can use the Fleet Health Dashboard to view a snapshot of the health of your database fleet.

Fleet health views

A *database fleet* in Database Insights is a group of databases that you want to monitor. You can create a monitoring view for a database fleet by choosing filters in the **Filters** component. This component allows you to apply filters on properties, such as cluster or instance names and tags. In the Fleet Health Dashboard, CloudWatch shows databases that match at least one of the filter conditions for the fleet health view.

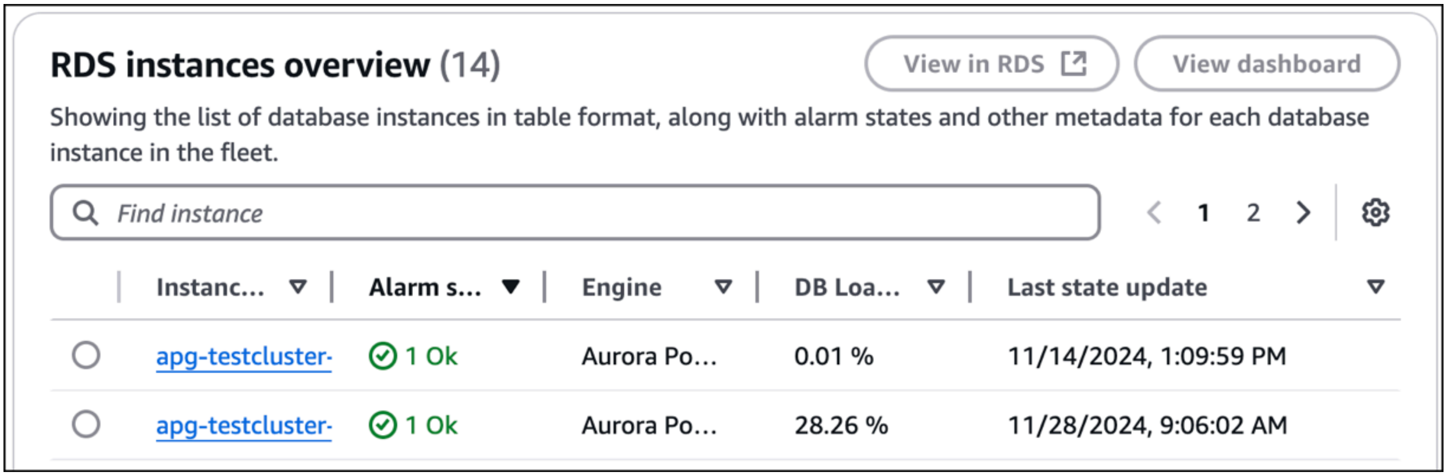


To create, modify, or delete views for database fleets, use the procedures in the following topics.

- Create a fleet health view for CloudWatch Database Insights
- Edit a fleet health view for CloudWatch Database Insights
- Delete a fleet health view for CloudWatch Database Insights

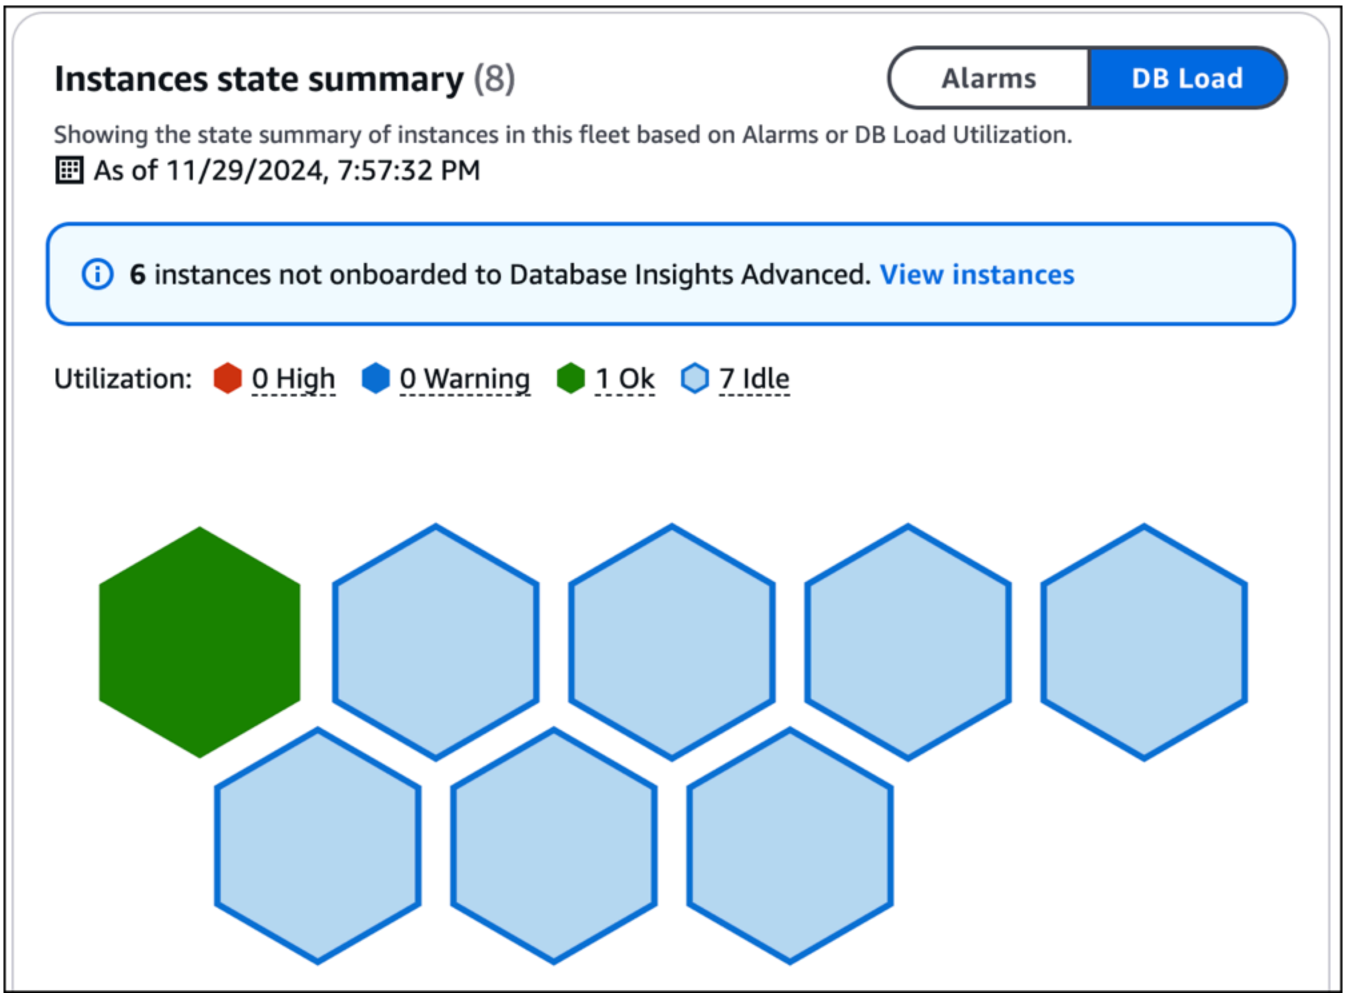
RDS instances overview table

Use the **RDS instances overview** table to view the alarm state, max DB Load percentage, and the time of the last state update for each instance in your fleet.

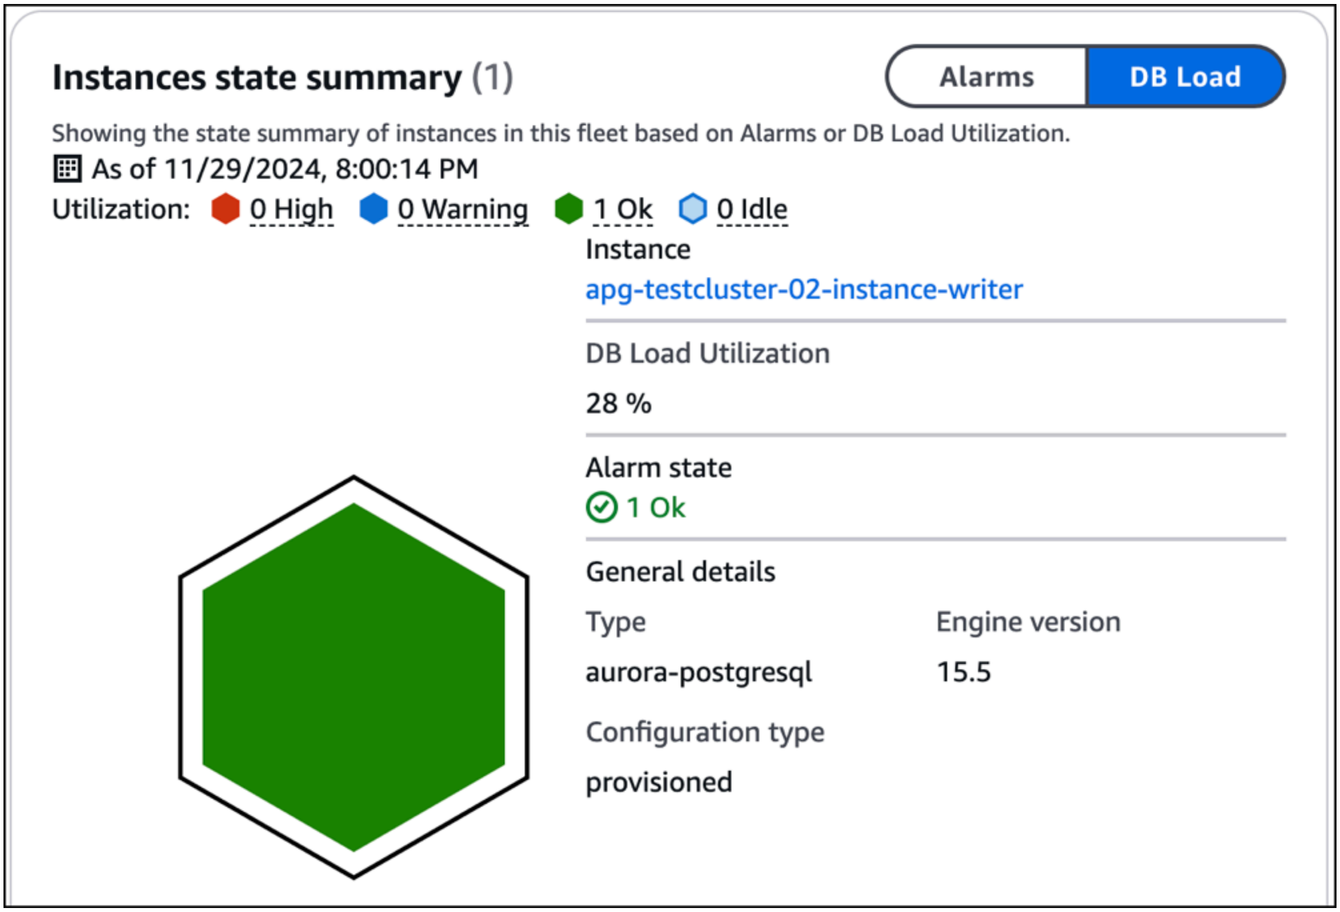


Instances state summary

Use the **Instances state summary** to view the health of all instances in your fleet. The Instances state summary provides two views based on **Alarms** and the DB Load metric. By default, CloudWatch displays the **Alarms** view.



Each node in the honeycomb represents an instance. For more information about an instance, you can choose the corresponding node and choose **Filter view by this instance**.



The honeycomb component summarizes the alarm state for instances in your fleet with the number of nodes in each state at the top of the honeycomb. CloudWatch displays the time of the last refresh of the data shown in the honeycomb.

When you switch to the **DB Load** view, you can see the overall health of the fleet from the point of view of the DB Load metric. Database load (DB Load) measures the number of active sessions in your database. DB Load is the key metric in Database Insights and is collected every second. CloudWatch categorizes DB instances into the following states based on thresholds for DB Load.

- High
- Warning
- Ok
- Idle

You can see the thresholds for DB Load by choosing the corresponding state icons.

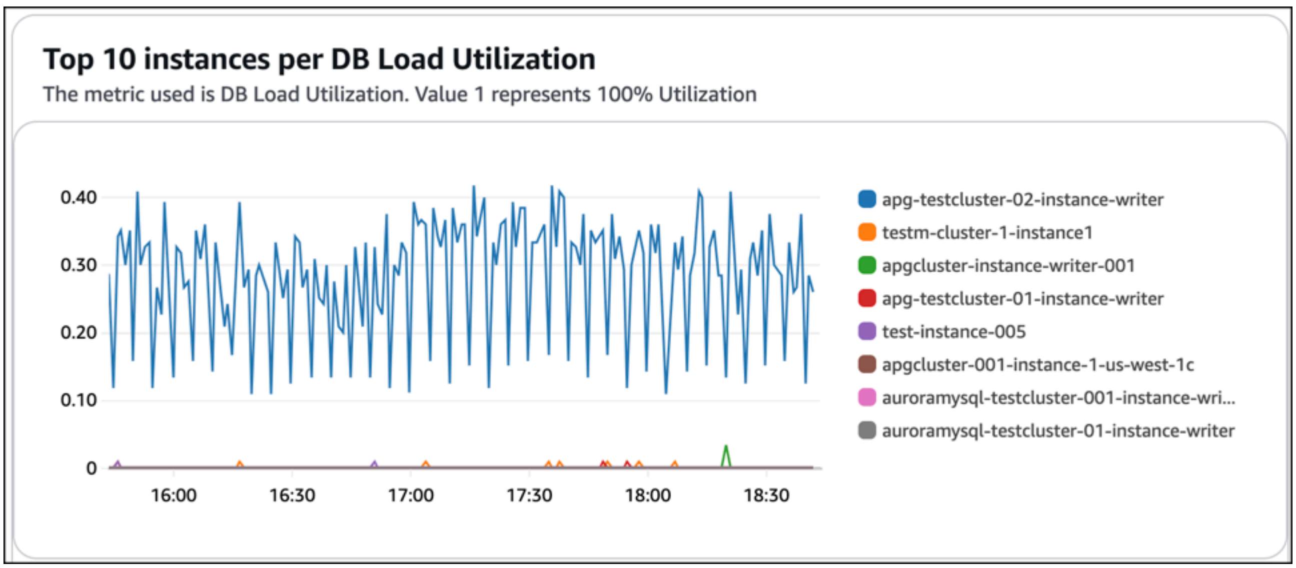
For information about DB Load for Amazon RDS, see Database load in the *Amazon RDS User Guide*. For information about DB Load for Amazon Aurora, see Database load in the *Amazon Aurora User Guide*.

By default, CloudWatch displays the average DB Load. Choose **Max** to monitor the maximum DB Load for each instance.

Choose a node from the Instances state summary to display alarms and DB Load for the instance.

Top 10 charts

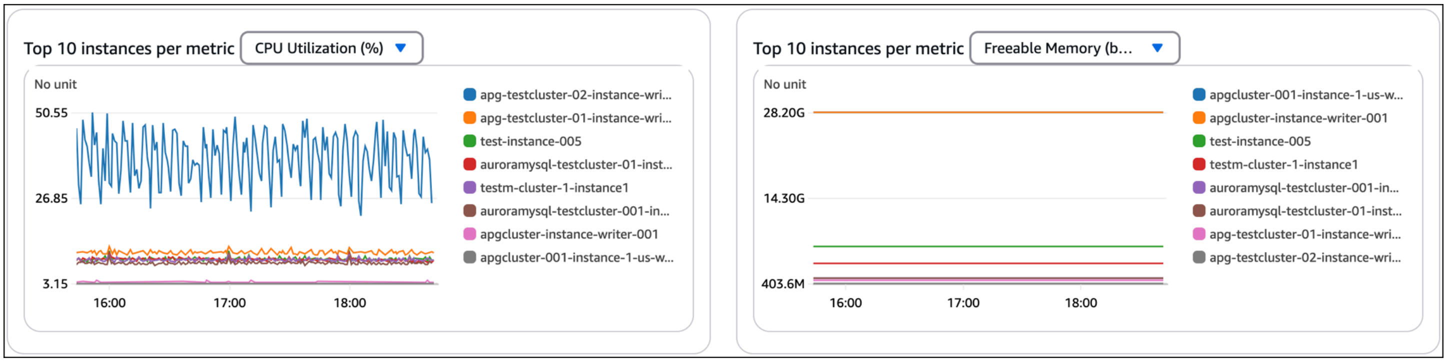
Use the **Top 10 instances per relative DB Load** chart to view the DB Load trend over time for the 10 instances with the highest DB Load. The chart also provides the top queries and top wait events for the instance with the highest DB Load.



Use the **Top 10 instances per metric** charts to compare two key metrics for the top 10 instances in your fleet. You can select the following metrics.

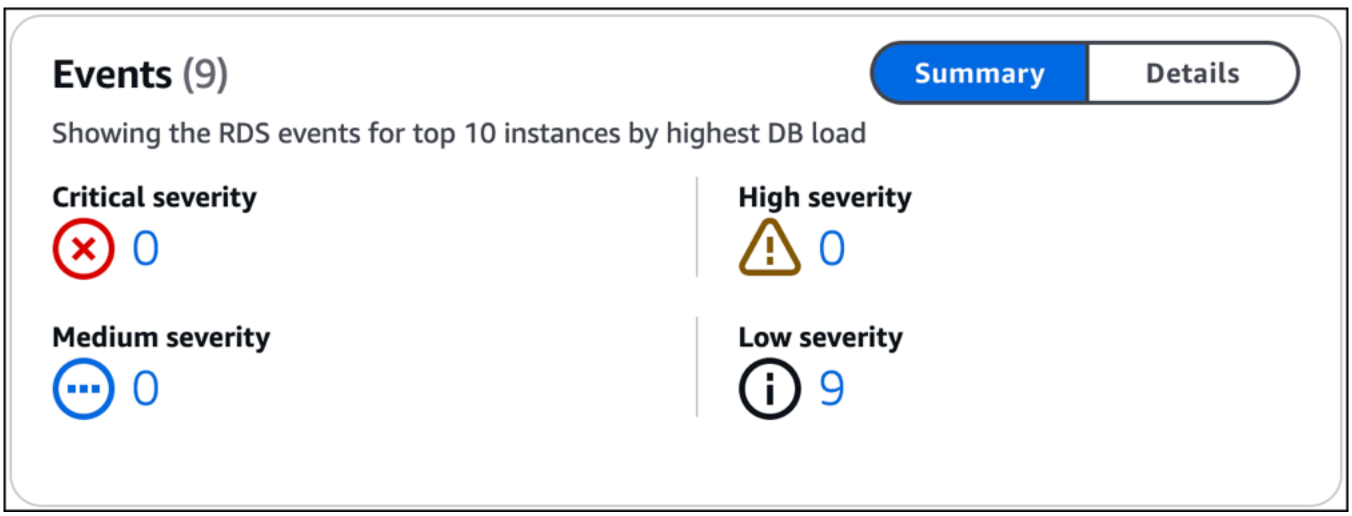
- CPU Utilization (%)
- Freeable Memory (%)
- DB Connections (%)
- Network throughput
- Read IOPS
- Write IOPS

- Read Latency
- Write Latency

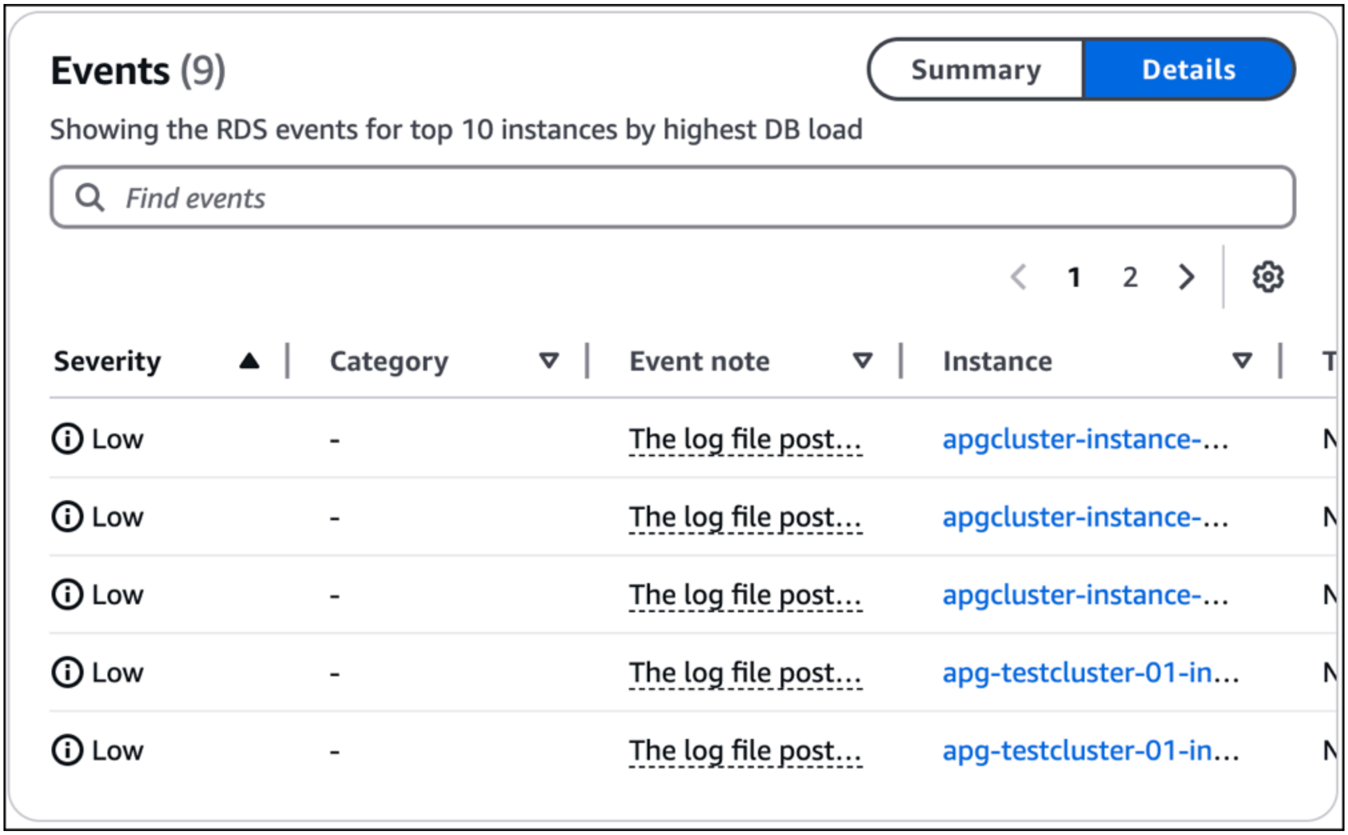


Amazon RDS events

Use the **Events** summary and table to view RDS events for instances in your fleet.



To view the **Events** table, choose **Details**.

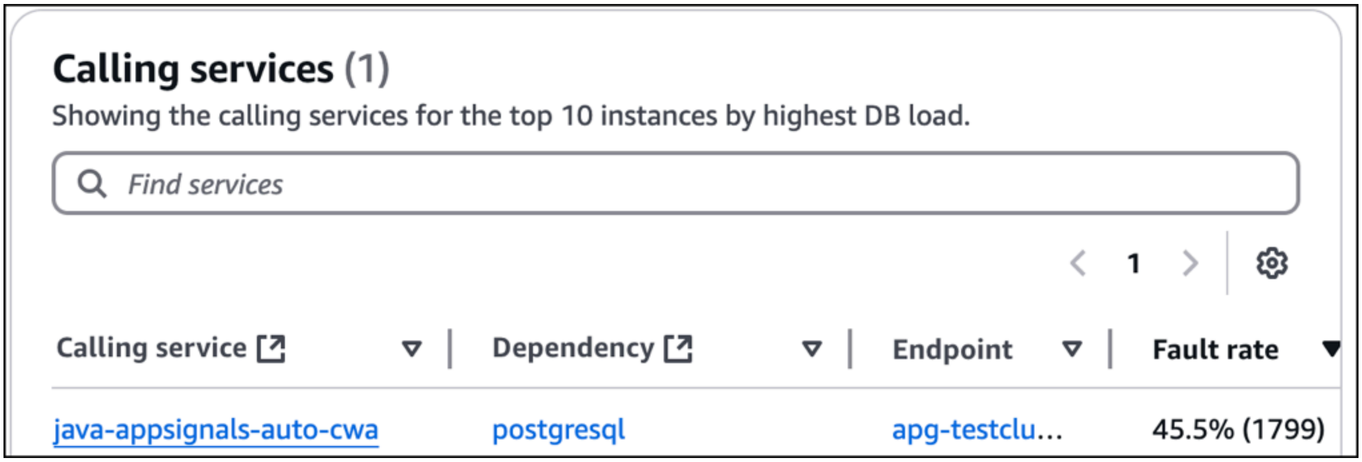


For a list of events for Amazon RDS and Amazon Aurora, see the following topics.

- Amazon RDS event categories and event messages for Aurora in the *Amazon Aurora User Guide*
- Amazon RDS event categories and event messages in the *Amazon RDS User Guide*

Calling services table

Use the **Calling services** table to view CloudWatch Application Signals services that are calling your database endpoints and related application-level metrics such as latency or errors.



Database Insights shows the services that are calling your top 10 instances by DB Load. To view calling services for another instance, choose the instance in the database instance dashboard.

When the endpoint called by the application is an Aurora cluster, Database Insights will display either the writer or the reader endpoint for the Aurora cluster in the **Calling services** table, not the individual database instance. However, when the endpoint called by the application is an Amazon RDS cluster, Database Insights shows the specific database instance the application is calling within the Amazon RDS cluster.

For more information about CloudWatch Application Signals, see [Application Signals](#).

Create a fleet health view for CloudWatch Database Insights

To create a fleet health view, use the following procedure.

To create a fleet health view

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose filters for the fleet of databases you want to monitor.
5. Choose **Save filter as fleet**.
6. In the **Save filter set (fleet)** window, enter a name for your fleet.
7. Choose the **Save** button.

To access the saved fleet, choose the **Saved fleets** dropdown. Then, choose a fleet.

Edit a fleet health view for CloudWatch Database Insights

To edit a fleet health view, use the following procedure.

To edit a fleet health view

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose the **Saved fleets** dropdown.
5. Choose the vertical ellipsis for a fleet health view you want to edit.
6. In the **Edit filter set (fleet)** window, you can edit the name of the fleet and the filters for the fleet.
7. Choose the **Save** button.

Delete a fleet health view for CloudWatch Database Insights

To delete a fleet health view, use the following procedure.

To delete a fleet health view

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose the **Saved fleets** dropdown.
5. Choose the vertical ellipsis for a fleet health view you want to delete.
6. In the **Delete filter set (fleet)** window, choose the **Delete** button.

Viewing the Database Instance Dashboard for CloudWatch Database Insights

Use the Database Instance Dashboard to view a snapshot of the health of a DB instance.

To analyze lock trees and execution plans for Amazon Aurora PostgreSQL, see the following topics.

Topics

- Analyzing lock trees for Amazon Aurora PostgreSQL with CloudWatch Database Insights
- Analyzing execution plans with CloudWatch Database Insights

Database load chart

Database load (DB Load) measures the level of session activity in your database. DB Load is the key metric in Database Insights, and Database Insights collects DB Load every second.

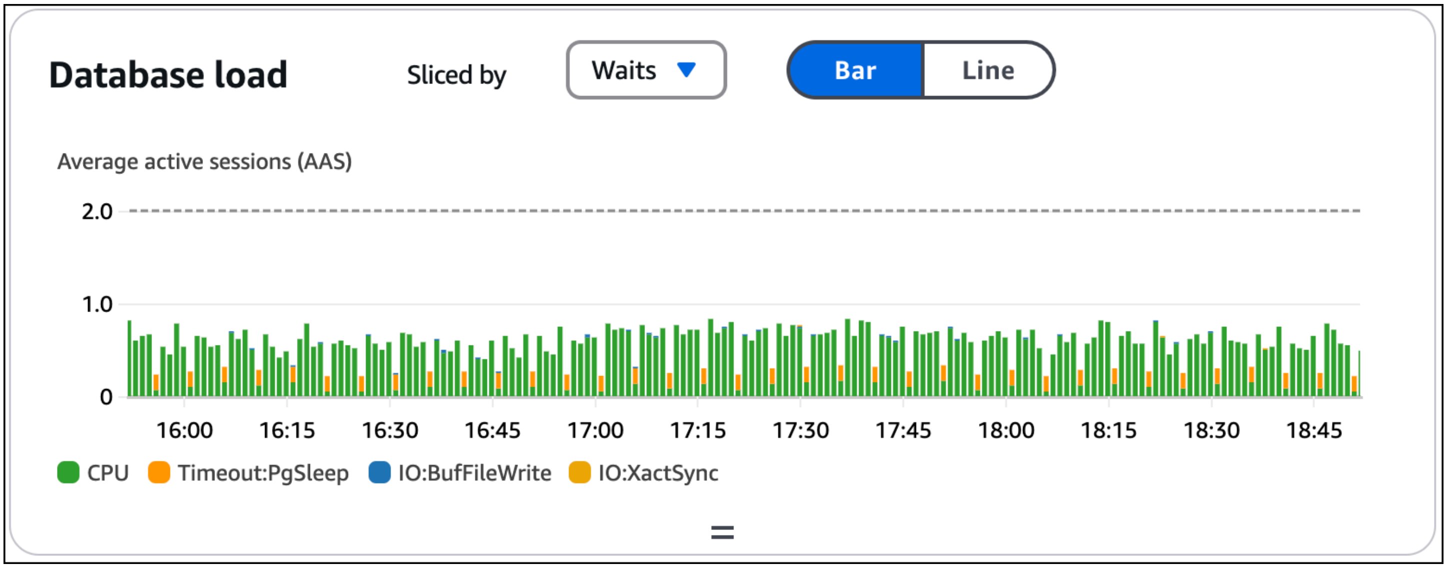
For more information about DB Load, see Database load in the *Amazon RDS User Guide* or Database load in the *Amazon Aurora User Guide*.

Use the **Database load** chart to view DB Load sliced (grouped) by the following dimensions for all supported database engines.

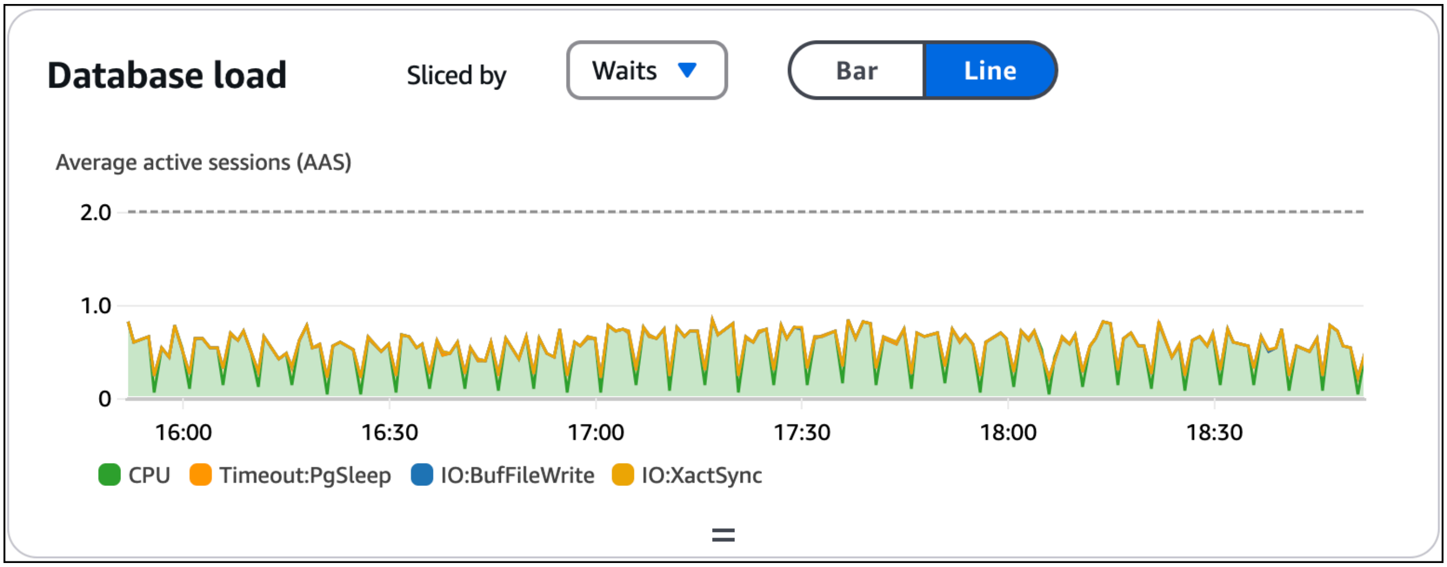
- Blocking object (only for database engines that support locking analysis)
- Blocking session (only for database engines that support locking analysis)
- Blocking SQL (only for database engines that support locking analysis)
- Database
- Host
- SQL
- User
- Waits
- Application (only for Amazon Aurora PostgreSQL)
- Plans (only for database engines that support execution plan capture)
- Session type (only for Amazon Aurora PostgreSQL)

Note

For information about analyzing Oracle PDB load in Amazon RDS, see Analyzing top Oracle PDB load in the *Amazon RDS User Guide*.



By default, CloudWatch displays DB Load with a bar chart. Choose **Line** to display DB Load with a stacked line chart.



DB Load analysis tab

Use the **DB Load analysis** tab to monitor the top contributors to DB Load for each of the following dimensions.

- Database
- Host
- SQL
- User

- Waits
- Lock analysis (only for database engines that support locking analysis)
- Application (only for Amazon Aurora PostgreSQL)
- Session type (only for Amazon Aurora PostgreSQL)

Analyze statistics for a query

You might want to analyze statistics for a query with a high DB Load. To analyze statistics for a query, use the following procedure.

To analyze statistics for queries

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose the **Database Instance** view.
5. Choose a DB instance.
6. Choose the **Top SQL** tab.
7. To view statistics for a query, choose a query.

Database telemetry tab

Use the **Database telemetry** tab to view metrics, logs, events, and slow queries for the selected instance.

Metrics section for database telemetry

The **Metrics** section displays a default metrics dashboard customized for each engine type.

You can customize this dashboard by adding OS metrics, database counter metrics, and CloudWatch metrics to it. You can also remove metrics from the dashboard. You can customize one dashboard for each engine type in a Region in your account. This means that all instances for a specific engine type in that Region in the same account will have the same metrics dashboard.

Users who have edit permissions for your dashboards in your account can edit any dashboard for any engine.

Changes you make to a dashboard are saved automatically, and apply to every instance of the database engine in that Region and account.

To customize the dashboard in the Database telemetry tab for an engine type

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**, **Database Insights**.
3. For **Database Views**, choose **Database Instance**.
4. In the **Filters** section, find and choose the database instance that you want to view metrics for.
5. Choose the **Database Telemetry** tab, then choose the **Metrics** tab.

   The default database instance dashboard appears.
6. To add a widget to the dashboard, do the following:

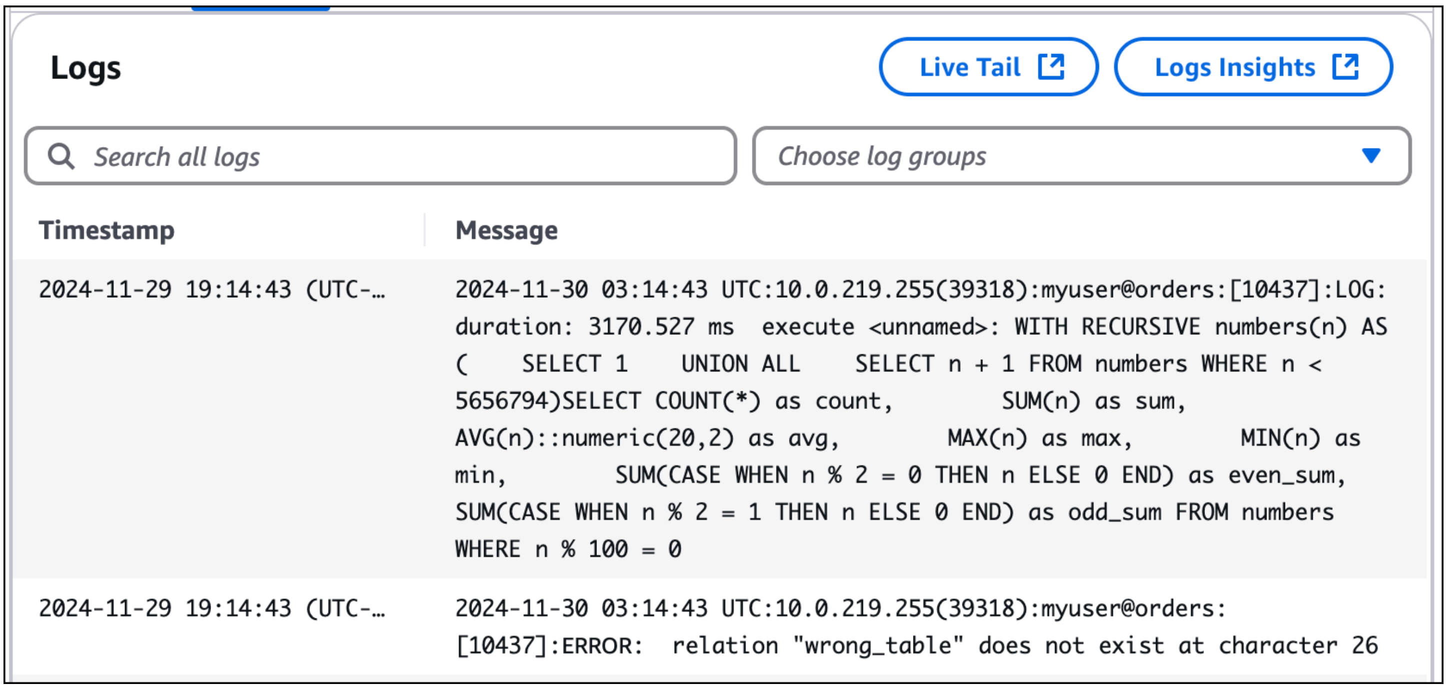
   a. Choose **Add Create widget**.
   b. In the **Create widget** popup, find the metric or metrics that you want to add, and select the checkbox for each one. If you select multiple metrics in this step, they will all appear in the same new widget on the dashboard. Then choose **Create widget**.

      Remember that any changes you make to this dashboard will apply to all Database Insights dashboards for this engine type in this Region in the account.

7. To delete a graph from the dashboard, choose the vertical ellipsis in the widget, then choose **Delete**.
8. To add more metrics to an existing widget in the dashboard, or change its title, choose the vertical ellipsis in the widget, and choose **Edit**. Then in the **Update widget** popup, find the metric or metrics that you want to add, select their checkboxes, and choose **Update Widget**. You can also change the widget title.
9. After customizing a dashboard, you can reset it to its original default state by choosing **Reset Dashboard**.

Logs section for database telemetry

The **Logs** section provides a view of database logs exported to CloudWatch Logs for the selected DB instance.



For information about publishing logs to CloudWatch Logs for Amazon RDS, see Publishing database logs to Amazon CloudWatch Logs in the *Amazon RDS User Guide*. For information about publishing logs to CloudWatch Logs for Amazon Aurora, see Publishing database logs to Amazon CloudWatch Logs in the *Amazon Aurora User Guide*.

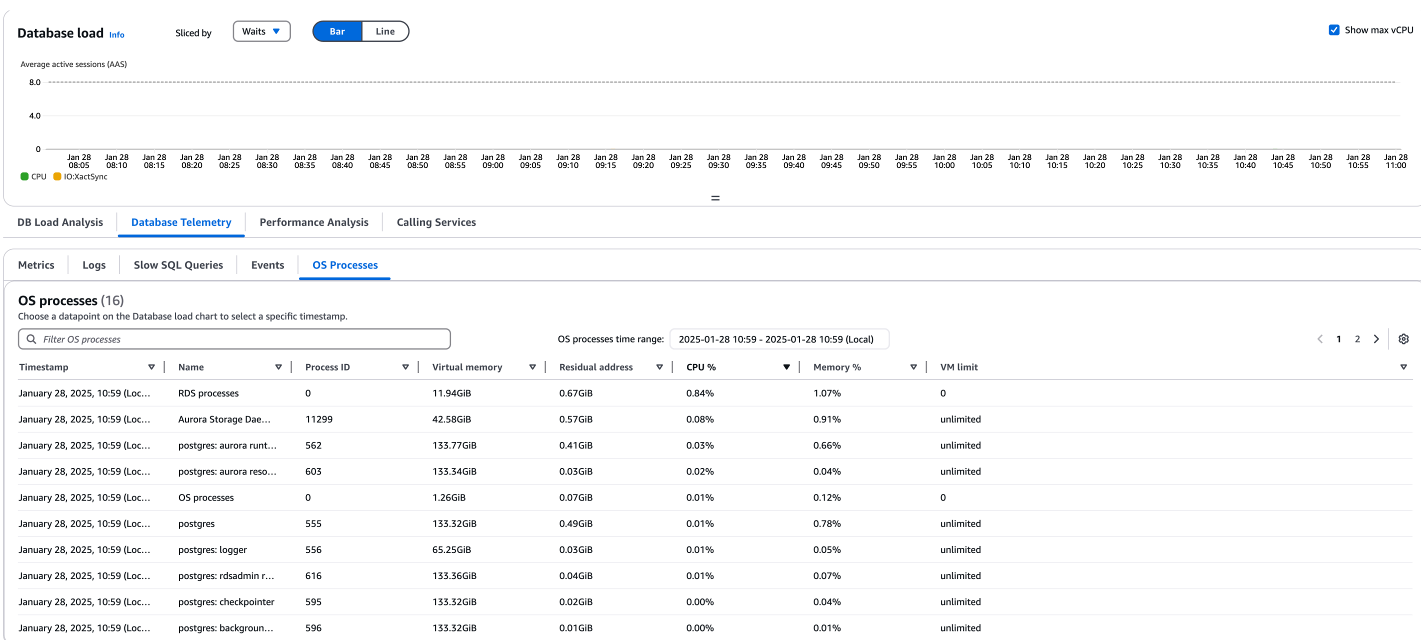
Amazon RDS and OS processes data for database telemetry

You can use the **OS Processes** tab within the **Database telemetry** tab to view metrics for the operating system (OS) that your DB instance runs on. The metrics provide a snapshot of OS processes running on your databases for a given timestamp, as well as key metrics such as memory and CPU utilization for each running process. Database Insights correlates these metrics with the metrics in your database load chart, so if you choose a data point in the database load chart, the OS processes data is updated to display telemetry from the same time stamp.

When you choose a data point, Database Insights automatically select the period to display, depending on the time range you have chosen for the overall page. The farthest back that you can go depends on the retention time that you have configured for the `RDSOSMetrics` log group.

If you haven't chosen a time stamp, by default the table is populated with telemetry for the latest timestamp.

> **Note**
>
> OS process information is available only if you have [Amazon RDS Enhanced Monitoring](#) enabled. Enhanced Monitoring incurs additional charges. For more information, see [Cost of Enhanced Monitoring](#).



In the **OS processes** view, the following data is displayed for each process:

- **Process ID** –The ID of this process.
- **Virtual memory** –The amount of virtual memory allocated to the process, in Kibibytes.

- **Residual address –** The actual physical memory being used by the process.
- **CPU % –** The percentage of the total CPU bandwidth being used by the process.
- **Memory % –** The percentage of the total memory being used by the process.
- **VM limit –** The maximum amount of virtual memory that can be allocated to the process.

  If the value in this column is 0, then VM limits are not applicable to that process.

The monitoring data that is displayed is retrieved from Amazon CloudWatch Logs. You can also retrieve these metrics directly from the log stream in CloudWatch Logs. For more information, see Viewing OS metrics using CloudWatch Logs.

OS processes metrics are not returned during the following:

- A failover of the database instance.
- Changing the instance class of the database instance (scale compute).

OS processes metrics are returned during a reboot of a database instance because only the database engine is rebooted. Metrics for the operating system are still reported.

Slow SQL Queries section for database telemetry

To view slow SQL queries and query patterns, you must enable log exports to CloudWatch Logs and configure DB parameters for your database.

For information about publishing Amazon RDS logs to CloudWatch Logs, see Publishing database logs to Amazon CloudWatch Logs in the *Amazon RDS User Guide*.

For information about publishing Aurora logs to CloudWatch Logs, see Publishing database logs to Amazon CloudWatch Logs in the *Amazon Aurora User Guide*.

For information about configuring DB parameters for your database in Amazon RDS, see Configuring your database to monitor slow SQL queries with Database Insights for Amazon RDS in the *Amazon RDS User Guide*.

For information about configuring DB parameters for your database in Amazon Aurora, see Configuring your database to monitor slow SQL queries with Database Insights for Amazon Aurora in the *Amazon Aurora User Guide*.

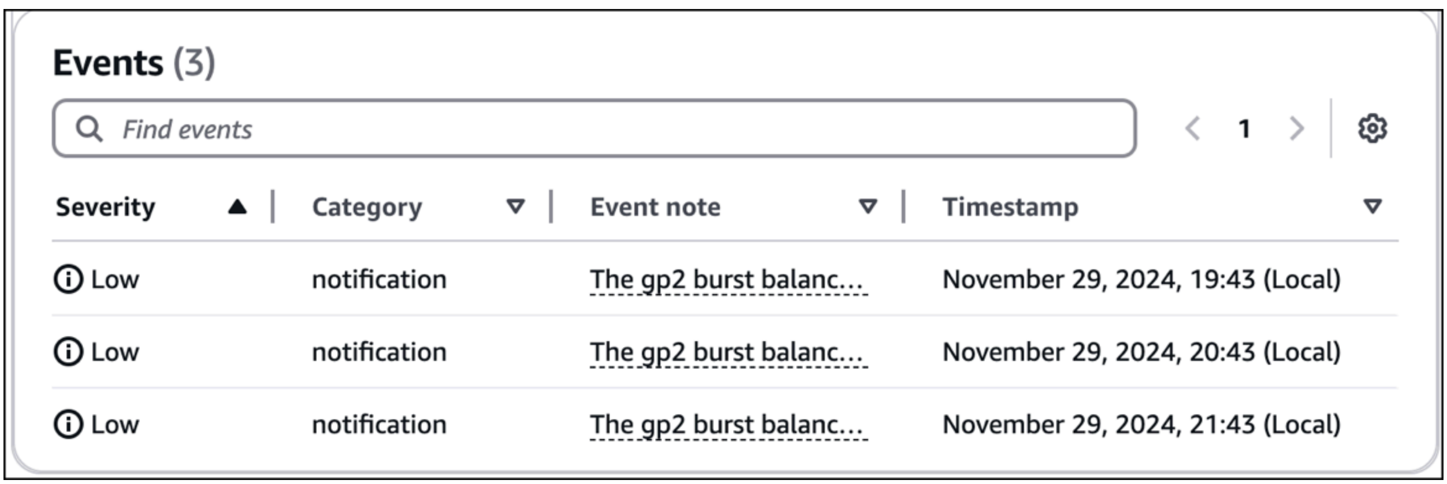
The **Slow SQL Queries** section provides a list of slow query patterns sorted by frequency. By selecting a pattern, you can view a list of slow queries that match the selected pattern. You can use the slow query list to identify slow queries affecting your DB instance.

Database Insights displays statistics for slow queries. The statistics represent only queries that exceed the configured slow query duration threshold.

> **Important**
>
> Slow queries may contain sensitive data. Mask your sensitive data with CloudWatch Logs. For more information about masking log data, see Help protect sensitive log data with masking in the *Amazon CloudWatch Logs User Guide*.

Events table

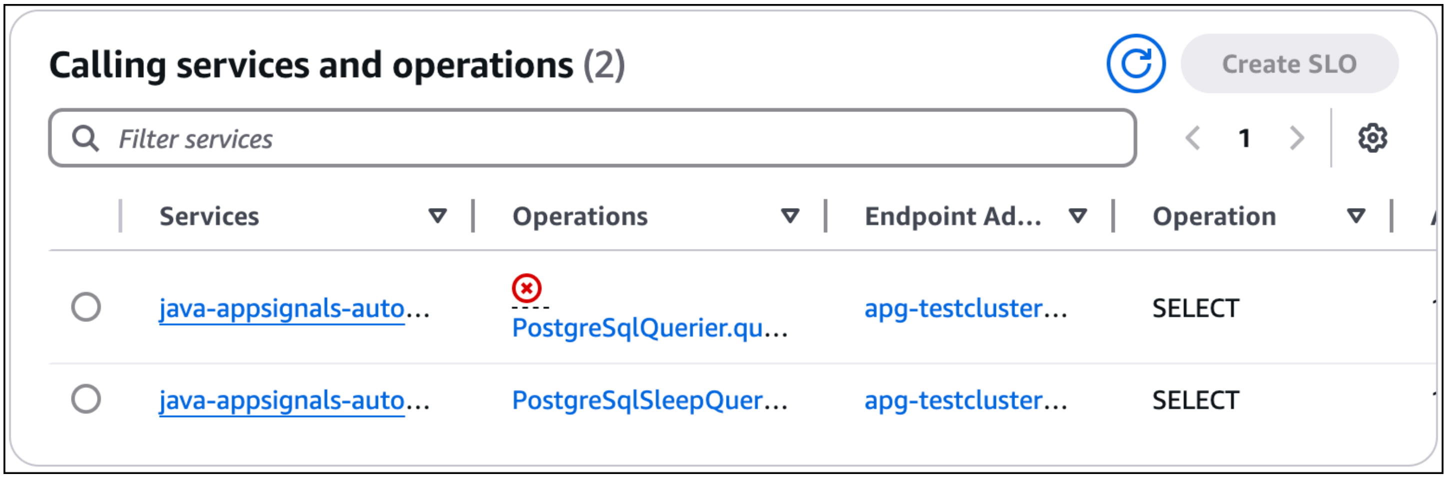
Use the **Events** table to view RDS events for your DB instance. For a list of events for Amazon Aurora, see Amazon RDS event categories and event messages for Aurora in the *Amazon Aurora User Guide*. For a list of events for Amazon Relational Database Service, see Amazon RDS event categories and event messages for Aurora in the *Amazon RDS User Guide*.



Calling services tab

Database Insights shows the services and operations that are calling your instance. Database Insights integrates with CloudWatch Application Signals to provide metrics for each service and operation, including availability, latency, errors, and volume.

When the endpoint called by the application is an Aurora cluster, Database Insights will show either the writer or the reader endpoint for the Aurora cluster in the **Calling services** table, not the individual database instance. However, when the endpoint called by the application is an Amazon RDS cluster, Database Insights shows the specific database instance the application is calling within the Amazon RDS cluster."



Analyze database performance on demand with CloudWatch Database Insights

Analyze database performance with on-demand analyses for your Amazon RDS databases with CloudWatch Database Insights.

Use the **Performance analysis** tab to view performance analysis reports for databases in your fleet.

For information about performance analysis reports for Amazon Aurora, see Analyzing database performance for a period of time in the *Amazon Aurora User Guide*.

> **Note**
>
> You must create performance analysis reports using the Amazon RDS console, Amazon CLI, or API. For information about creating a performance analysis report for Amazon Aurora, see Creating a performance analysis report in Performance Insights in the *Amazon Aurora User Guide*.

Integrating CloudWatch Database Insights with CloudWatch Application Signals

Integrate CloudWatch Database Insights with CloudWatch Application Signals.

Use the **Calling services** tab to view the CloudWatch Application Signals services and operations that called an endpoint of the selected instance. By default, CloudWatch sorts the table by fault rate. Choose values in the **Services**, **Operations**, or **Endpoint address** columns to view the corresponding resource in the CloudWatch Application Signals console.

For more information about supported systems for CloudWatch Application Signals, see Supported systems.

Analyzing lock trees for Amazon Aurora PostgreSQL with CloudWatch Database Insights

To troubleshoot performance issues caused by locks, you can analyze lock trees for Amazon Aurora PostgreSQL databases with CloudWatch Database Insights using the following.

- **Sliced by** dropdown – Choose the **Blocking object**, **Blocking session**, or **Blocking SQL** dimensions in the **Database load** chart to view how distinct top blockers contribute to DB Load over time. With the DB load chart, you can analyze if top blockers are constant or change often. Then, you can troubleshoot the blockers.

- **Lock analysis** tab – Choose **DB Load Analysis**, then choose the **Lock analysis** tab to view information about lock contention in your database.

> **Note**
>
> CloudWatch Database Insights supports lock analysis for all Aurora PostgreSQL versions. To analyze lock trees, you must have Database Insights Advance Mode enabled. For information on how to turn on Advanced mode, see Turning on the Advanced mode of Database Insights for Amazon Aurora and Turning on the Advanced mode of Database Insights for Amazon Relational Database Service

The lock analysis tab provides information about lock contention for your database. The lock tree visualization shows the relationships and dependencies between lock requests from different sessions.

Database Insights captures snapshots every 15 seconds. Snapshots show the lock data for your database at a point in time.

> **Note**
>
> When CloudWatch detects high locking, CloudWatch displays the **High locking detected** banner for the **Lock analysis** tab. CloudWatch detects high locking if CloudWatch takes a lock snapshot for each 15 second interval for 15 consecutive minutes.

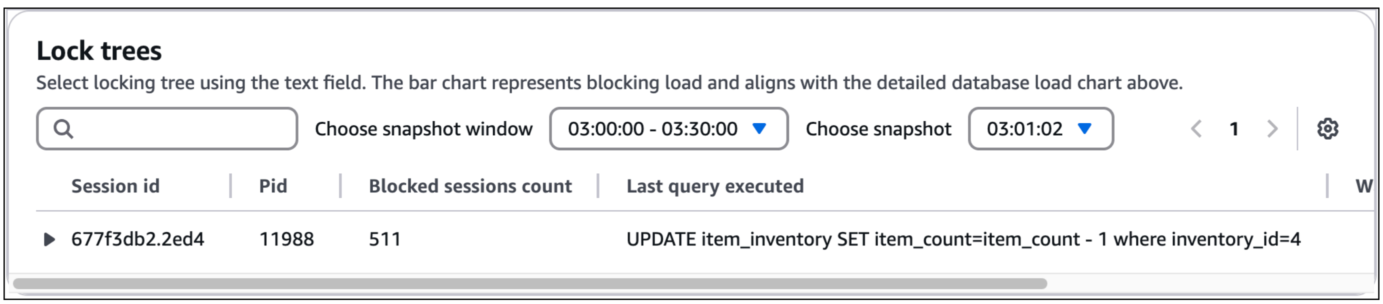
Each node in the tree represents a specific session. The parent node is a session that is blocking its child nodes.

To analyze lock trees, use the following procedure.

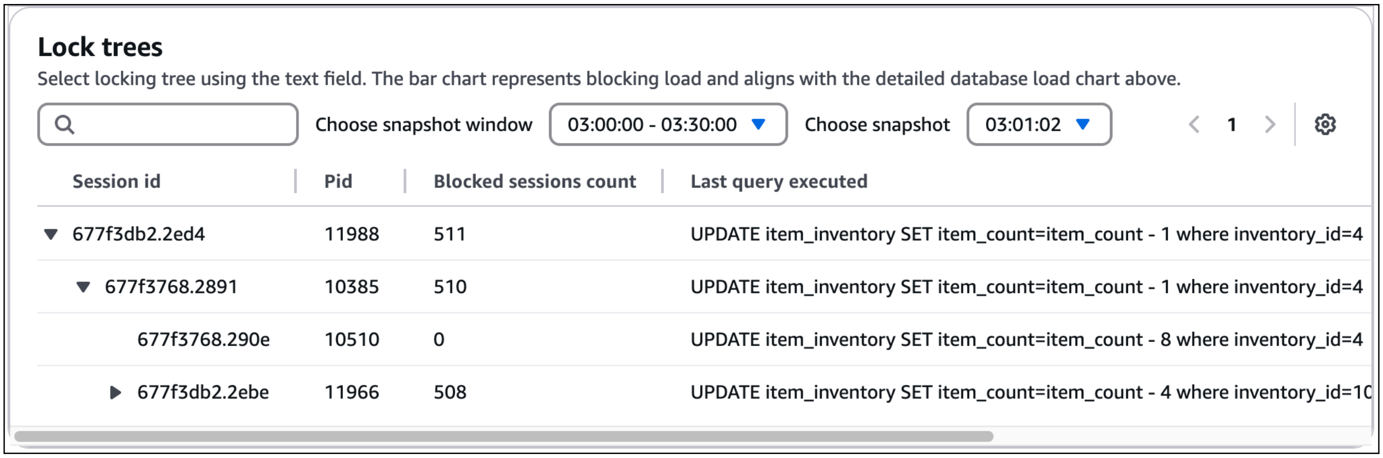
To analyze lock trees

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose the **Database Instance** view.
5. Choose a DB instance.
6. Choose the **DB load analysis** tab.
7. Choose the **Lock analysis** tab.

   To view lock data for a DB instance, choose a period of 1 day or less.
8. Choose a snapshot window. By default, Database Insights chooses the snapshot window with the most blocked sessions.

9. To view lock data for a snapshot, choose the time Database Insights took the snapshot.
10. To expand a lock tree, choose the arrow next to the session ID.



Lock snapshot data

Database Insights provides the following information for each lock request. To view columns that aren't enabled by default, choose the **Settings** icon for the **Lock trees** table and enable other columns.

Column name	Definition	Default column	Notes
`session_id`	The unique session identifier.	Yes	The `session_id` is derived from `HEX(pg_stat_activity.backend_start).HEX(pg_locks.pid)`.
`pid`	The PID of this backend.	Yes	`pg_locks.pid`
`blocked_sessions_count`	The number of sessions blocked by this lock.	Yes	The `blocked_sessions_count` is derived from the number of session IDs blocked by this lock.

Column name	Definition	Default column	Notes
`last_query_executed`	The last query executed by this session. For blockers, it may not be the query that holds the blocking lock.	Yes	`pg_stat_activity.query`
`wait_event`	The wait event name if the backend is currently waiting, otherwise the value is NULL.	Yes	`pg_stat_activity.wait_event`
`blocking_time_(In Seconds)`	The time (in seconds) since the start of this lock.	Yes	The `blocking_time_(In Seconds)` is derived from the start time of the waiting transaction (`pg_locks.waitstart`) for the first waiter.
`blocking_mode`	The lock mode held by the blocking session.	No	`pg_locks.mode`
`waiting_mode`	The lock mode requested by the waiting session.	No	`pg_locks.mode`
`application`	The name of the application that is connected to this backend.	No	`pg_stat_activity.application_name`
`blocking_txn_start_time`	The start time of the blocking transaction or null if no transaction is active.	No	`pg_stat_activity.xact_start`
`waiting_start_time`	The time when a waiting user session started waiting for this lock, or null if the lock is held.	No	`pg_locks.waitstart`

Column name	Definition	Default column	Notes
session_start_time	The time when a user session was started.	No	pg_stat_activity.backend_start
state	The state of a backend.	No	pg_stat_activity.state
wait_event_type	The type of wait event for which this session is waiting.	No	pg_stat_activity.wait_event_type
last_query_exec_time	The time when the last query was started.	No	pg_stat_activity.query_start
user	The name of the user logged into this backend.	No	pg_stat_activity.usename
host	The host name of the connected client, as reported by a reverse DNS lookup of `client_addr` . This field will only be non-null for IP connections, and only when [log_hostname](#) is enabled.	No	pg_stat_activity.client_hostname
port	The TCP port number that the client is using for communication with this backend, or `-1` if a Unix socket is used. If this field is null, it indicates that this is an internal server process.	No	pg_stat_activity.client_port

Column name	Definition	Default column	Notes
client_address	The IP address of the client connected to this backend. If this field is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum.	No	pg_stat_activity.client_addr
granted	The value is true if lock is held and false if lock is awaited.	No	pg_locks.granted
waiting_tuple	The tuple number targeted by the lock within the page, or null if the target is not a tuple.	No	pg_locks.tuple
waiting_page	The page number targeted by the lock within the relation, or null if the target is not a relation page or tuple.	No	pg_locks.page
waiting_transaction_id	The ID of the transaction targeted by the lock, or null if the target is not a transaction ID.	No	pg_locks.transactionid
waiting_relation	The OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation.	No	pg_locks.relation
waiting_object_id	The OID of the lock target within its system catalog, or null if the target is not a general database object.	No	pg_locks.objid
waiting_database_id	The OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID.	No	pg_locks.database

Column name	Definition	Default column	Notes
waiting_database_name	The name of the database in which the lock target exists.	No	pg_stat_activity.datname
waiting_locktype	The type of the lockable object: relation, extend, frozenid, page, tuple, transactionid, virtualxid, spectoken, object, userlock, advisory, or applytransaction.	No	pg_locks.locktype
is_fastpath	The value is true if the lock was taken with the fast path and false if taken from the main lock table.	No	pg_locks.fastpath

For more information about the values in the `pg_stat_activity` and `pg_locks` views, see the following topics in the PostgreSQL documentation.

- pg_locks
- pg_stat_activity

Analyzing execution plans with CloudWatch Database Insights

You can analyze execution plans for the Amazon Aurora PostgreSQL, RDS for Microsoft SQL Server and RDS for Oracle databases by using the following methods.

- **Sliced by** dropdown – Choose the **Plans** dimension in the **Database load** chart to view how different plans contribute to DB Load over time.
- **Top SQL** tab – Choose **DB Load Analysis**, then choose the **Top SQL** tab to view the number of plans for each digest query.

  To analyze execution plans for a digest query, choose the query and then choose the **Plans** tab. For more information, see the following procedure.

Prerequisites

To analyze execution plans, you must be using the Advanced mode of Database Insights. For information on how to turn on Advanced mode, see Turning on the Advanced mode of Database Insights for Amazon Aurora and Turning on the Advanced mode of Database Insights for Amazon Relational Database Service.

If you are using Aurora PostgreSQL, you also have the following prerequisites:

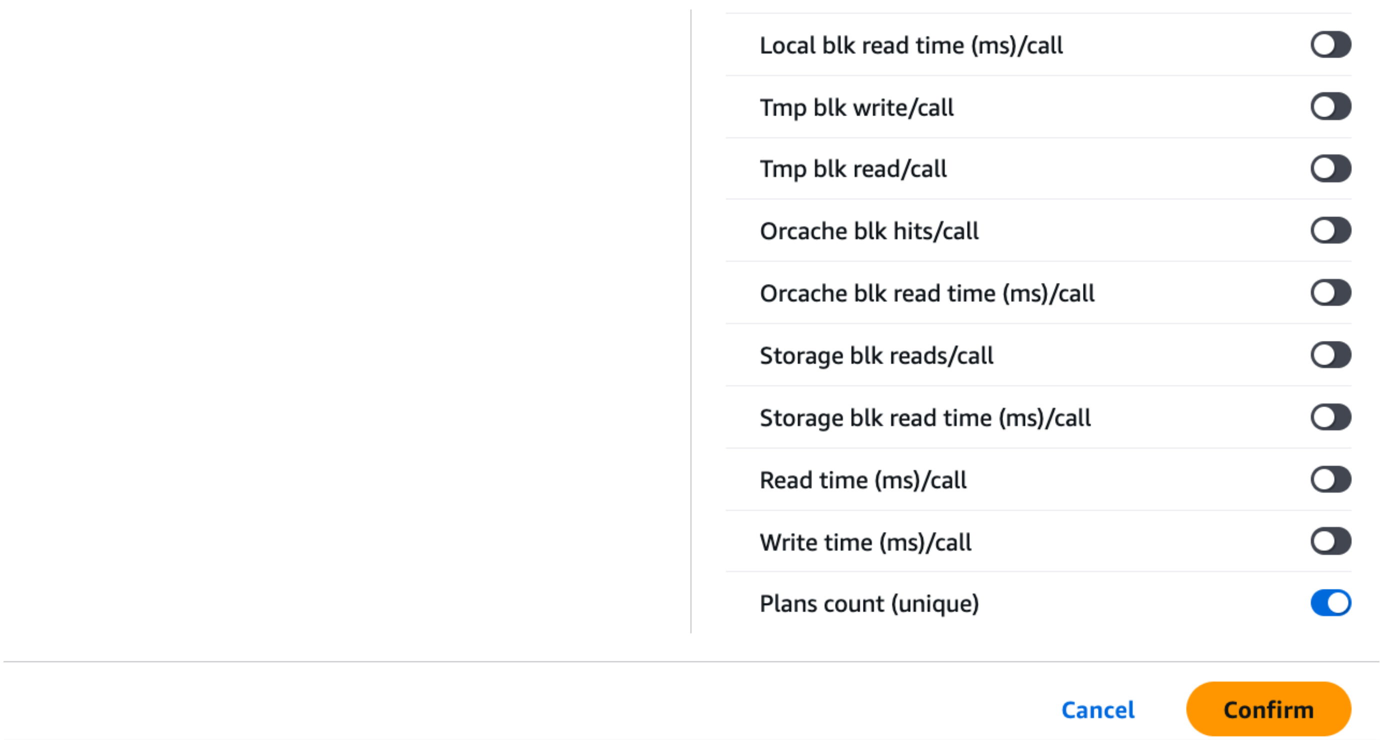
- Your DB instance must use Aurora PostgreSQL version 14.10, 15.5, or later. For information about upgrading your Aurora PostgreSQL DB cluster, see Upgrading Amazon Aurora PostgreSQL DB clusters in the *Amazon Aurora User Guide*.
- You must configure your DB cluster to analyze execution plans by setting the parameter `aurora_compute_plan_id` to on with one of the following options.
  - Creating a DB cluster parameter group in Amazon Aurora in the *Amazon Aurora User Guide*
  - Modifying parameters in a DB cluster parameter group in Amazon Aurora in the *Amazon Aurora User Guide*

Analyze execution plans

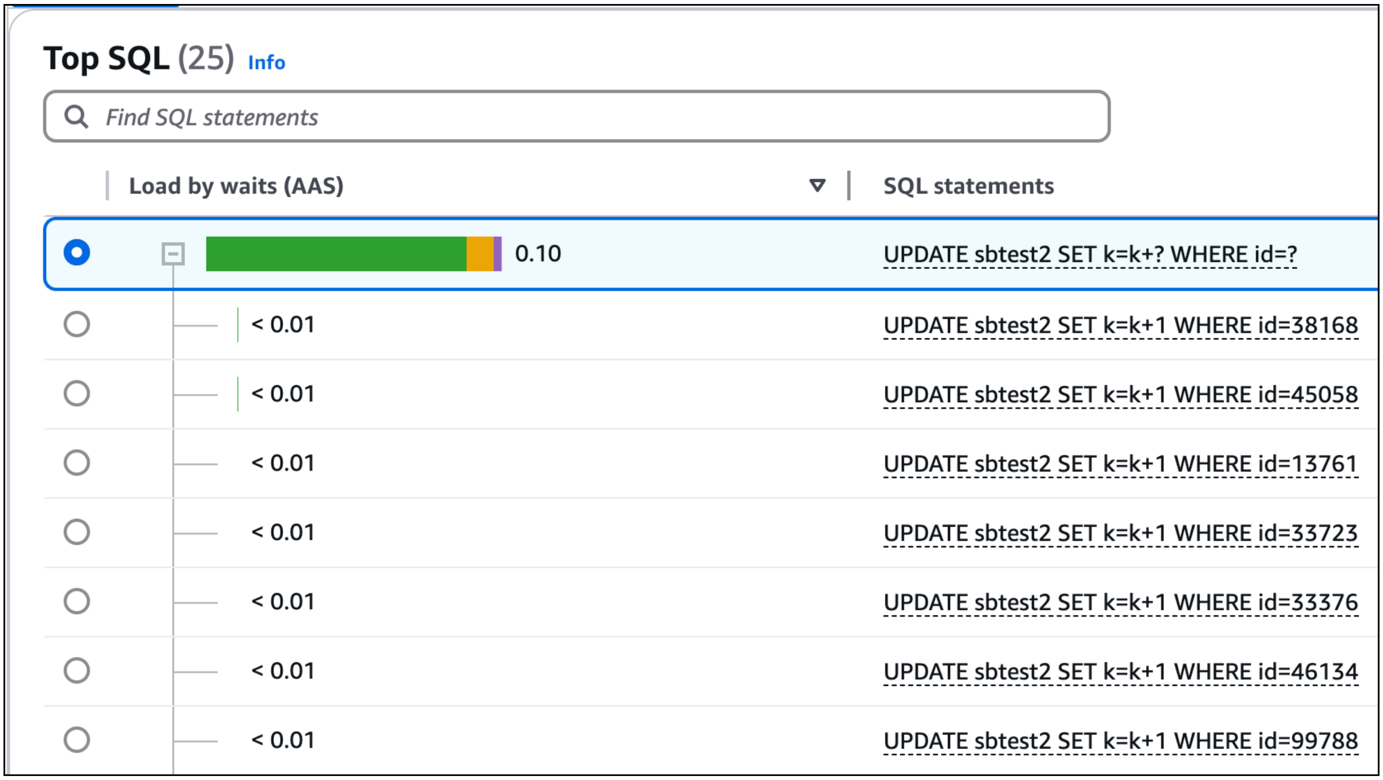
To analyze execution plans, use the following procedure.

To analyze execution plans

1. Sign in to the Amazon Web Services Management Console and open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Insights**.
3. Choose **Database Insights**.
4. Choose the **Database Instance** view.
5. Choose a DB instance.
6. Choose the **Top SQL** tab. The **Plans Count** column shows the number of plans collected for each digest query.
7. (Optional) If the **Plans Count** column doesn't appear, choose the **Settings** icon on the **Top SQL** table to customize the visibility and order of columns.



8. Choose a digest query to expand it into its component statements.

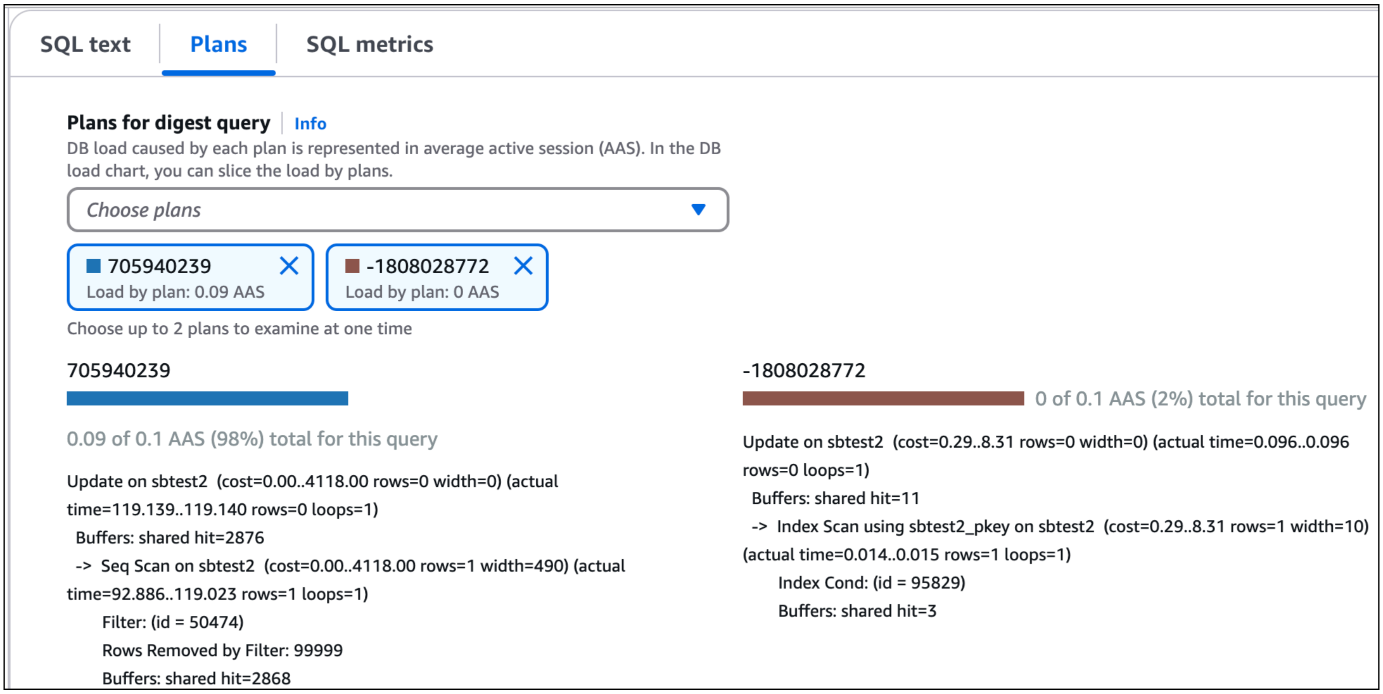


9. Scroll down and view the SQL text. Then, choose the **Plans** tab.

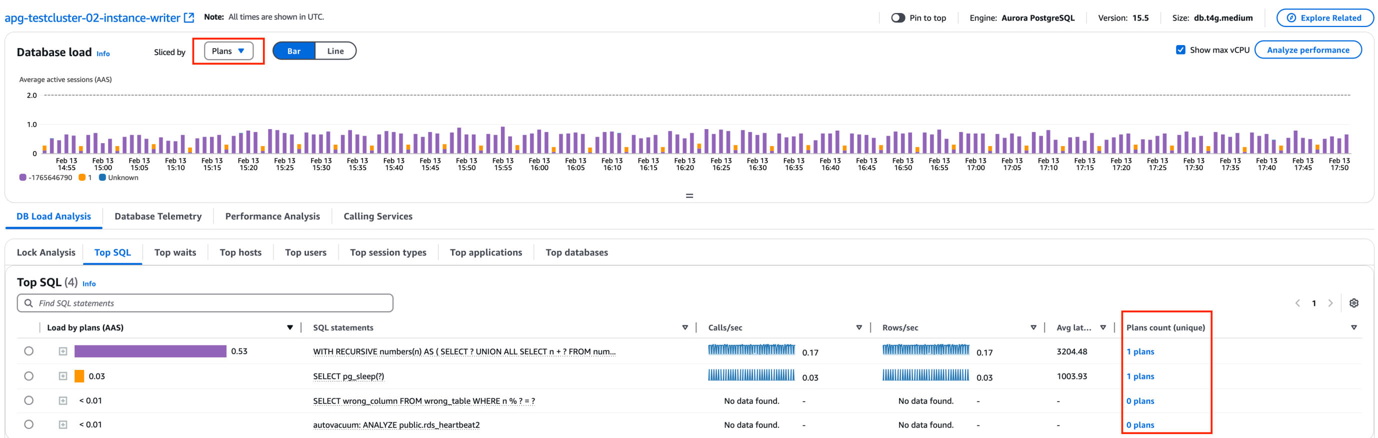
   By default, CloudWatch displays the estimated execution plan. For Aurora PostgreSQL, to view actual execution plans, enable the `aurora_stat_plans.with_analyze` parameter for your DB instance. For more information about the parameter `aurora_stat_plans.with_analyze`, see [Monitoring query execution plans and peak memory for Aurora PostgreSQL](#) in the *Amazon Aurora User Guide*.

10. To compare plans from the same digest query, choose two **Plans** from the **Plans for digest query** list.

    You can view either one or two plans for a query at a time. In the following example screenshot, both plans are for Aurora PostgreSQL.



11. You can also view how each plan contributes to DBLoad over time by choosing **Plans** in the **Slice by** drop-down in the DBLoad chart.



Troubleshooting for CloudWatch Database Insights

Use the following information to troubleshoot issues for CloudWatch Database Insights.

Applying tags to Amazon RDS resources

To apply tags to your databases, use the Amazon RDS API, Amazon CLI, or Amazon RDS console. For more information, see the following topics.

- AddTagsToResource in the *Amazon RDS API Reference*
- add-tags-to-resource in the *Amazon RDS Command Line Reference*
- Tagging Amazon Aurora and Amazon RDS resources in the *Amazon Aurora User Guide*

Maximum DB instances for fleets

You can't monitor more than 500 DB instances in a database fleet. You can use filters to create a fleet health view with less than 500 DB instances.

Use Contributor Insights to analyze high-cardinality data

You can use Contributor Insights to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. This helps you find top talkers and understand who or what is impacting system performance. For example, you can find bad hosts, identify the heaviest network users, or find the URLs that generate the most errors.

You can build your rules from scratch, and when you use the Amazon Web Services Management Console you can also use sample rules that Amazon has created. Rules define the log fields that you want to use to define contributors, such as `IpAddress`. You can also filter the log data to find and analyze the behavior of individual contributors.

CloudWatch also provides built-in rules that you can use to analyze metrics from other Amazon services.

All rules analyze incoming data in real time.

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can create Contributor Insights rules in that monitoring account that analyze log groups in source accounts and in the monitoring account. You can also create a single rule that analyzes log groups in multiple accounts. For more information, see [CloudWatch cross-account observability](#).

> **Important**
>
> If you are using a log transformer on the log group, then when you create a Contributor Insights rule, you must specify the original field key of the logs instead of the transformed field key.

With Contributor Insights, you are charged for each occurrence of a log event that matches a rule. For more information, see [Amazon CloudWatch Pricing](#).

> **Note**
>
> Contributor Insights can only match log entries when the numeric values that the rule references are between -1e9 and 1e9. If a value in a log entry is outside of this range, Contributor Insights skips that log entry.

Topics

Create a Contributor Insights rule in CloudWatch

You can create rules to analyze log data. Any logs in JSON or Common Log Format (CLF) can be evaluated. This includes your custom logs that follow one of these formats and logs from Amazon services such as Amazon VPC flow logs, Amazon Route 53 DNS query logs, Amazon ECS container logs, and logs from Amazon CloudTrail, Amazon SageMaker AI, Amazon RDS, Amazon AppSync and API Gateway.

In a rule, when you specify field names or values, all matching is case sensitive.

You can use built-in sample rules when you create a rule or you can create your own rule from scratch. Contributor Insights includes sample rules for the following types of logs:

- Amazon API Gateway logs
- Amazon Route 53 public DNS query logs
- Amazon Route 53 resolver query logs
- CloudWatch Container Insights logs
- VPC flow logs

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can create Contributor Insights rules for log groups in the source accounts linked to this monitoring account, in addition to creating rules for log groups in the monitoring account. You can also set up a single rule that monitors log groups in different accounts. For more information, see CloudWatch cross-account observability.

> **Important**
>
> When you grant a user the `cloudwatch:PutInsightRule` permission, by default that user can create a rule that evaluates any log group in CloudWatch Logs. You can add IAM policy conditions that limit these permissions for a user to include and exclude specific log groups. For more information, see Using condition keys to limit Contributor Insights users' access to log groups.

To create a rule using a built-in sample rule

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Logs**, **Contributor Insights**.
3. Choose **Create rule**.
4. For **Select log group(s)**, select the log group(s) that you want your rule to monitor. You can select as many as 20 log groups. If you are signed in to a monitoring account that is set up for CloudWatch cross-account observability, you can select log groups in source accounts, and you can also set up a single rule to analyze log groups in different accounts.

   - (Optional) To select all log groups that have names beginning with a specific string, choose the **Select by prefix match** dropdown, and then enter the prefix. If this is a monitoring account, you can optionally select the accounts to search in, otherwise all accounts are selected.

   > **Note**
   >
   > You incur charges for each log event that matches your rule. If you choose the **Select by prefix match** dropdown, be aware of how many log groups the prefix can match. If you search more log groups than you want, you might incur unexpected charges. For more information, see Amazon CloudWatch Pricing.

5. For **Rule type**, choose **Sample rule**. Then choose **Select sample rule** and select the rule.
6. The sample rule has filled out the **Log format**, **Contribution**, **Filters**, and **Aggregate on** fields. You can adjust those values, if you like.
7. Choose **Next**.

8. For **Rule name**, enter a name. Valid characters are A-Z, a-z, 0-9, (hyphen), (underscore), and (period).
9. Choose whether to create the rule in a disabled or enabled state. If you choose to enable it, the rule immediately starts analyzing your data. You incur costs when you run enabled rules. For more information, see [Amazon CloudWatch Pricing](#).

   Contributor Insights analyzes only new log events after a rule is created. A rule cannot process logs events that were previously processed by CloudWatch Logs.
10. (Optional) For **Tags**, add one or more key-value pairs as tags for this rule. Tags can help you identify and organize your Amazon resources and track your Amazon costs. For more information, see [Tagging your Amazon CloudWatch resources](#).
11. Choose **Create**.

To create a rule from scratch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Logs**, **Contributor Insights**.
3. Choose **Create rule**.
4. For **Select log group(s)**, select the log group(s) that you want your rule to monitor. You can select as many as 20 log groups. If you are signed in to a monitoring account that is set up for CloudWatch cross-account observability, you can select log groups in source accounts, and you can also set up a single rule to analyze log groups in different accounts.

   - (Optional) To select all log groups that have names beginning with a specific string, choose the **Select by prefix match** dropdown, and then enter the prefix.

   > **Note**
   >
   > You incur charges for each log event that matches your rule. If you choose the **Select by prefix match** dropdown, be aware of how many log groups the prefix can match. If you search more log groups than you want, you might incur unexpected charges. For more information, see [Amazon CloudWatch Pricing](#).
5. For **Rule type**, choose **Custom rule**.
6. For **Log format**, choose **JSON** or **CLF**.

7. You can finish creating the rule by using the wizard or by choosing the **Syntax** tab and specifying your rule syntax manually.

   To continue using the wizard, do the following:

   a. For **Contribution**, **Key**, enter a contributor type that you want to report on. The report displays the top-N values for this contributor type.

      Valid entries are any log field that has values. Examples include **`requestId`**, **`sourceIPaddress`**, and **`containerID`**.

      For information about finding the log field names for the logs in a certain log group, see [Finding Log Fields](#).

      Keys larger than 1 KB are truncated to 1KB.

   b. (Optional) Choose **Add new key** to add more keys. You can include as many as four keys in a rule. If you enter more than one key, the contributors in the report are defined by unique value combinations of the keys. For example, if you specify three keys, each unique combination of values for the three keys is counted as a unique contributor.

   c. (Optional) If you want to add a filter that narrows the scope of your results, choose **Add filter**. For **Match**, enter the name of the log field that you want to filter on. For **Condition**, choose a comparison operator, and enter a value that you want to filter for.

      You can add as many as four filters in a rule. Multiple filters are joined by AND logic, so only log events that match all filters are evaluated.

      > **Note**
      >
      > Arrays that follow comparison operators, such as `In`, `NotIn`, or `StartsWith`, can include as many as 10 string values. For more information about the Contributor Insights rules syntax, see [Contributor Insights rule syntax in CloudWatch](#).

   d. For **Aggregate on**, choose **Count** or **Sum**. Choosing **Count** causes the contributor ranking to be based on the number of occurrences. Choosing **Sum** causes the ranking to be based on the aggregated sum of the values of the field that you specify for **Contribution**, **Value**.

8. To enter your rule as a JSON object instead of using the wizard, do the following:

   a. Choose the **Syntax** tab.

   b. In **Rule body**, enter the JSON object for your rule. For information about rule syntax, see [Contributor Insights rule syntax in CloudWatch](#).

9. Choose **Next**.
10. For **Rule name**, enter a name. Valid characters are A-Z, a-z, 0-9, "-", "_", and ".".
11. Choose whether to create the rule in a disabled or enabled state. If you choose to enable it, the rule immediately starts analyzing your data. You incur costs when you run enabled rules. For more information, see [Amazon CloudWatch Pricing](#).

    Contributor Insights analyzes only new log events after a rule is created. A rule cannot process logs events that were previously processed by CloudWatch Logs.
12. (Optional) For **Tags**, add one or more key-value pairs as tags for this rule. Tags can help you identify and organize your Amazon resources and track your Amazon costs. For more information, see [Tagging your Amazon CloudWatch resources](#).
13. Choose **Next**.
14. Confirm the settings that you entered, and choose **Create rule**.

You can disable, enable, or delete rules that you have created.

To enable, disable, or delete a rule in Contributor Insights

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Logs**, **Contributor Insights**.
3. In the list of rules, select the check box next to a single rule.

   Built-in rules are created by Amazon services and can't be edited, disabled, or deleted.
4. Choose **Actions**, and then choose the option you want.

Finding log fields

When you create a rule, you need to know the names of fields in the log entries in a log group.

To find the log fields in a log group

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, under **Logs**, choose **Insights**.

3. Above the query editor, select one or more log groups to query.

   When you select a log group, CloudWatch Logs Insights automatically detects fields in the data in the log group and displays them in the right pane in **Discovered fields**.

Contributor Insights rule syntax in CloudWatch

This section explains the syntax for Contributor Insights rules. Use this syntax only when you are creating a rule by entering a JSON block. If you use the wizard to create a rule, you don't need to know the syntax. For more information about creating rules using the wizard, see [Create a Contributor Insights rule in CloudWatch](#).

All matching of rules to log event field names and values is case sensitive.

The following example illustrates the syntax for JSON logs.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "API-Gateway-Access-Logs*",
        "Log-group-name2"
    ],
    "LogFormat": "JSON",
    "Contribution": {
        "Keys": [
            "$.ip"
        ],
        "ValueOf": "$.requestBytes",
        "Filters": [
            {
                "Match": "$.httpMethod",
                "In": [
                    "PUT"
                ]
            }
        ]
    },
    "AggregateOn": "Sum"
}
```

Fields in Contributor Insights rules

Schema

The value of `Schema` for a rule that analyzes CloudWatch Logs data must always be `{"Name": "CloudWatchLogRule", "Version": 1}`

LogGroupNames

An array of strings. For each element in the array, you can optionally use `*` at the end of a string to include all log groups with names that start with that prefix.

Be careful about using wildcards with log group names. You incur charges for each log event that matches a rule. If you accidentally search more log groups than you intend, you might incur unexpected charges. For more information, see Amazon CloudWatch Pricing.

LogGroupARNs

If you are creating this rule in a CloudWatch cross-account observability monitoring account, you can use `LogGroupARNs` to specify log groups in source accounts that are linked to the monitoring account, and to specify log groups in the monitoring account itself. You must specify either `LogGroupNames` or `LogGroupARNs` in your rule, but not both.

`LogGroupARNs` is an array of strings. For each element in the array, you can optionally use `*` as a wildcard in certain situations. For example you can specify `arn:aws:logs:us-west-1:*:log-group/MyLogGroupName2` to specify log groups named `MyLogGroupName2` in all source accounts and in the monitoring account, in the US West (N. California) Region. You can also specify `arn:aws:logs:us-west-1:111122223333:log-group/GroupNamePrefix*` to specify all log groups in US West (N. California) in 111122223333 that have names starting with `GroupNamePrefix`.

You can't specify a partial Amazon account ID as a prefix with a wild card.

Be careful about using wildcards with log group ARNs. You incur charges for each log event that matches a rule. If you accidentally search more log groups than you intend, you might incur unexpected charges. For more information, see Amazon CloudWatch Pricing.

LogFormat

Valid values are `JSON` and `CLF`.

Contribution

This object includes a `Keys` array with as many as four members, optionally a single `ValueOf`, and optionally an array of as many as four `Filters`.

Keys

An array of up to four log fields that are used as dimensions to classify contributors. If you enter more than one key, each unique combination of values for the keys is counted as a unique contributor. The fields must be specified using JSON property format notation.

ValueOf

(Optional) Specify this only when you are specifying `Sum` as the value of `AggregateOn`. `ValueOf` specifies a log field with numerical values. In this type of rule, the contributors are ranked by their sum of the value of this field, instead of their number of occurrences in the log entries. For example, if you want to sort contributors by their total `BytesSent` over a period, you would set `ValueOf` to `BytesSent` and specify `Sum` for `AggregateOn`.

Filters

Specifies an array of as many as four filters to narrow the log events that are included in the report. If you specify multiple filters, Contributor Insights evaluates them with a logical AND operator. You can use this to filter out irrelevant log events in your search or you can use it to select a single contributor to analyze their behavior.

Each member in the array must include a `Match` field and a field indicating the type of matching operator to use.

The `Match` field specifies a log field to evaluate in the filter. The log field is specified using JSON property format notation.

The matching operator field must be one of the following: `In`, `NotIn`, `StartsWith`, `GreaterThan`, `LessThan`, `EqualTo`, `NotEqualTo`, or `IsPresent`. If the operator field is `In`, `NotIn`, or `StartsWith`, it is followed by an array of string values to check for. Contributor Insights evaluates the array of string values with an OR operator. The array can include as many as 10 string values.

If the operator field is `GreaterThan`, `LessThan`, `EqualTo`, or `NotEqualTo`, it is followed by a single numerical value to compare with.

If the operator field is `IsPresent`, it is followed by either `true` or `false`. This operator matches log events based on whether the specified log field is present in the log event. The `isPresent` works only with values in the leaf node of JSON properties. For example, a filter that looks for matches to `c-count` does not evaluate a log event with a value of `details.c-count.c1`.

See the following four filter examples:

```
{"Match": "$.httpMethod", "In": [ "PUT", ] }
{"Match": "$.StatusCode", "EqualTo": 200 }
{"Match": "$.BytesReceived", "GreaterThan": 10000}
{"Match": "$.eventSource", "StartsWith": [ "ec2", "ecs" ] }
```

AggregateOn

Valid values are `Count` and `Sum`. Specifies whether to aggregate the report based on a count of occurrences or a sum of the values of the field that is specified in the `ValueOf` field.

JSON property format notation

The `Keys`, `ValueOf`, and `Match` fields follow JSON property format with dot notation, where $ represents the root of the JSON object. This is followed by a period and then an alphanumeric string with the name of the subproperty. Multiple property levels are supported.

The first character of the string can only be A-Z or a-z. The following characters of the string can be A-Z, a-z, or 0-9.

The following list illustrates valid examples of JSON property format:

```
$.userAgent
$.endpoints[0]
$.users[1].name
$.requestParameters.instanceId
```

Additional field in rules for CLF logs

Common Log Format (CLF) log events do not have names for the fields like JSON does. To provide the fields to use for Contributor Insights rules, a CLF log event can be treated as array with an index starting from 1. You can specify the first field as **"1"**, the second field as **"2"**, and so on.

To make a rule for a CLF log easier to read, you can use `Fields`. This enables you to provide a naming alias for CLF field locations. For example, you can specify that the location "4" is an IP address. Once specified, `IpAddress` can be used as property in the `Keys`, `ValueOf`, and `Filters` in the rule.

The following is an example of a rule for a CLF log that uses the `Fields` field.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "API-Gateway-Access-Logs*"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "4": "IpAddress",
        "7": "StatusCode"
    },
    "Contribution": {
        "Keys": [
            "IpAddress"
        ],
        "Filters": [
            {
                "Match": "StatusCode",
                "EqualTo": 200
            }
        ]
    },
    "AggregateOn": "Count"
}
```

CloudWatch Contributor Insights rule examples

This section contains examples that illustrate use cases for Contributor Insights rules.

VPC Flow Logs: Byte transfers by source and destination IP address

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
```

```
    "LogGroupNames": [
        "/aws/containerinsights/sample-cluster-name/flowlogs"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "4": "srcaddr",
        "5": "dstaddr",
        "10": "bytes"
    },
    "Contribution": {
        "Keys": [
            "srcaddr",
            "dstaddr"
        ],
        "ValueOf": "bytes",
        "Filters": []
    },
    "AggregateOn": "Sum"
}
```

VPC Flow Logs: Highest number of HTTPS requests

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "/aws/containerinsights/sample-cluster-name/flowlogs"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "5": "destination address",
        "7": "destination port",
        "9": "packet count"
    },
    "Contribution": {
        "Keys": [
            "destination address"
        ],
        "ValueOf": "packet count",
        "Filters": [
            {
```

```
                "Match": "destination port",
                "EqualTo": 443
            }
        ]
    },
    "AggregateOn": "Sum"
}
```

VPC Flow Logs: Rejected TCP connections

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "/aws/containerinsights/sample-cluster-name/flowlogs"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "3": "interfaceID",
        "4": "sourceAddress",
        "8": "protocol",
        "13": "action"
    },
    "Contribution": {
        "Keys": [
            "interfaceID",
            "sourceAddress"
        ],
        "Filters": [
            {
                "Match": "protocol",
                "EqualTo": 6
            },
            {
                "Match": "action",
                "In": [
                    "REJECT"
                ]
            }
        ]
    },
```

```
    "AggregateOn": "Sum"
}
```

Route 53 NXDomain responses by source address

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Count",
    "Contribution": {
        "Filters": [
            {
                "Match": "$.rcode",
                "StartsWith": [
                    "NXDOMAIN"
                ]
            }
        ],
        "Keys": [
            "$.srcaddr"
        ]
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "<loggroupname>"
    ]
}
```

Route 53 resolver queries by domain name

```
{

        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Count",
    "Contribution": {
        "Filters": [],
        "Keys": [
            "$.query_name"
        ]
```

```
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "<loggroupname>"
    ]
}
```

Route 53 resolver queries by query type and source address

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Count",
    "Contribution": {
        "Filters": [],
        "Keys": [
            "$.query_type",
            "$.srcaddr"
        ]
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "<loggroupname>"
    ]
}
```

Viewing Contributor Insights reports in CloudWatch

To view graphs of report data and a ranked list of contributors found by your rules, follow these steps.

To view your rule reports

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Logs**, **Contributor Insights**.
3. In the list of rules, choose the name of a rule.

   The graph displays the results of the rule over the last three hours. The table under the graph shows the top 10 contributors.

4. To change the number of contributors shown in the table, choose **Top 10 contributors** at the top of the graph.
5. To filter the graph to show only the results from a single contributor, choose that contributor in the table legend. To again show all contributors, choose that same contributor again in the legend.
6. To change the time range shown in the report, choose **15m**, **30m**, **1h**, **2h**, **3h**, or **custom** at the top of the graph.

   The maximum time range for the report is 24 hours, but you can choose a 24-hour window that occurred up to 15 days ago. To choose a time window in the past, choose **custom**, **absolute**, and then specify your time window.
7. To change the length of the time period used for the aggregation and ranking of contributors, choose **period** at the top of the graph. Viewing a longer time period generally shows a smoother report with few spikes. Choosing a shorter time period is more likely to display spikes.
8. To add this graph to a CloudWatch dashboard, choose **Add to dashboard**.
9. To open the CloudWatch Logs Insights query window, with the log groups in this report already loaded in the query box, choose **View logs**.
10. To export the report data to your clipboard or a CSV file, choose **Export**.

Graphing metrics generated by rules in CloudWatch

Contributor Insights provides a metric math function, `INSIGHT_RULE_METRIC`. You can use this function to add data from a Contributor Insights report to a graph in the **Metrics** tab of the CloudWatch console. You can also set an alarm based on this math function. For more information about metric math functions, see [Using math expressions with CloudWatch metrics](#).

To use this metric math function, you must be signed in to an account that has both the `cloudwatch:GetMetricData` and `cloudwatch:GetInsightRuleReport` permissions.

The syntax is `INSIGHT_RULE_METRIC(ruleName, metricName)`. *`ruleName`* is the name of a Contributor Insights rule. *`metricName`* is one of the values in the following list. The value of *`metricName`* determines which type of data the math function returns.

- `UniqueContributors` — the number of unique contributors for each data point.

- MaxContributorValue — the value of the top contributor for each data point. The identity of the contributor might change for each data point in the graph.

  If this rule aggregates by Count, the top contributor for each data point is the contributor with the most occurrences in that period. If the rule aggregates by Sum, the top contributor is the contributor with the greatest sum in the log field specified by the rule's Value during that period.
- SampleCount — the number of data points matched by the rule.
- Sum — the sum of the values from all contributors during the time period represented by that data point.
- Minimum — the minimum value from a single observation during the time period represented by that data point.
- Maximum — the maximum value from a single observation during the time period represented by that data point.
- Average — the average value from all contributors during the time period represented by that data point.

Setting an alarm on Contributor Insights metric data

Using the function INSIGHT_RULE_METRIC, you can set alarms on metrics that Contributor Insights generates. For example, you can create an alarm that's based on the percentage of rejected transmission control protocol (TCP) connections. To get started with this type of alarm, you can create rules like the ones shown in the following two examples:

Example rule: "RejectedConnectionsRule"

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "/aws/containerinsights/sample-cluster-name/flowlogs"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "3": "interfaceID",
        "4": "sourceAddress",
```

```
        "8": "protocol",
        "13": "action"
    },
    "Contribution": {
        "Keys": [
            "interfaceID",
            "sourceAddress"
        ],
        "Filters": [
            {
                "Match": "protocol",
                "EqualTo": 6
            },
            {
                "Match": "action",
                "In": [
                    "REJECT"
                ]
            }
        ]
    },
    "AggregateOn": "Sum"
}
```

Example rule: "TotalConnectionsRule"

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "LogGroupNames": [
        "/aws/containerinsights/sample-cluster-name/flowlogs"
    ],
    "LogFormat": "CLF",
    "Fields": {
        "3": "interfaceID",
        "4": "sourceAddress",
        "8": "protocol",
        "13": "action"
    },
    "Contribution": {
        "Keys": [
```

```
            "interfaceID",
            "sourceAddress"
        ],
        "Filters": [{
            "Match": "protocol",
            "EqualTo": 6
        }],
        "AggregateOn": "Sum"
    }
}
```

After you create your rules, you can select the **Metrics** tab in the CloudWatch Console, where you can use the following example metric math expressions to graph the data that Contributor Insights reports:

Example: Metric math expressions

```
e1 INSIGHT_RULE_METRIC("RejectedConnectionsRule", "Sum")
e2 INSIGHT_RULE_METRIC("TotalConnectionsRule", "Sum")
e3 (e1/e2)*100
```

In the example, the metric math expression `e3` returns all of the rejected TCP connections. If you want to be notified when 20 percent of the TCP connections are rejected, you can modify the expression by changing the threshold from `100` to `20`.

> **Note**
>
> You can set an alarm on a metric that you're monitoring from the **Metrics** section. While on the **Graphed metrics** tab, you can select the **Create alarm** icon under the **Actions** column. The **Create alarm** icon looks like a bell.

For more information about graphing metrics and using metric math functions, see the following section: [Add a math expression to a CloudWatch graph](#).

Using Contributor Insights built-in rules in CloudWatch

You can use Contributor Insights built-in rules to analyze metrics from other Amazon services. The following services support built-in rules:

- [Contributor Insights for Amazon DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

- Use built-in Contributor Insights rules in the *Amazon PrivateLink Guide*.

Detect common application problems with CloudWatch Application Insights

You can use Amazon CloudWatch Application Insights to detect problems with your applications. CloudWatch Application Insights facilitates observability for your applications and underlying Amazon resources. It helps you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications. Application Insights, which is powered by SageMaker and other Amazon technologies, provides automated dashboards that show potential problems with monitored applications, which help you to quickly isolate ongoing issues with your applications and infrastructure. The enhanced visibility into the health of your applications that Application Insights provides helps reduce mean time to repair (MTTR) to troubleshoot your application issues.

When you add your applications to Amazon CloudWatch Application Insights, it scans the resources in the applications and recommends and configures metrics and logs on CloudWatch for application components. Example application components include SQL Server backend databases and Microsoft IIS/Web tiers. Application Insights analyzes metric patterns using historical data to detect anomalies, and continuously detects errors and exceptions from your application, operating system, and infrastructure logs. It correlates these observations using a combination of classification algorithms and built-in rules. Then, it automatically creates dashboards that show the relevant observations and problem severity information to help you prioritize your actions. For common problems in .NET and SQL application stacks, such as application latency, SQL Server failed backups, memory leaks, large HTTP requests, and canceled I/O operations, it provides additional insights that point to a possible root cause and steps for resolution. Built-in integration with Amazon SSM OpsCenter allows you to resolve issues by running the relevant Systems Manager Automation document.

What is Amazon CloudWatch Application Insights?

CloudWatch Application Insights helps you monitor your applications that use Amazon EC2 instances along with other application resources. It identifies and sets up key metrics, logs, and alarms across your application resources and technology stack (for example, your Microsoft SQL Server database, web (IIS) and application servers, OS, load balancers, and queues). It continuously monitors metrics and logs to detect and correlate anomalies and errors. When errors and anomalies are detected, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. To assist with troubleshooting, it creates automated dashboards for detected problems, which include correlated metric anomalies and log errors, along with additional insights to point you to a potential root cause. The automated dashboards help you to take remedial actions to keep your applications healthy and to prevent impact to the end-users of your application. It also creates OpsItems so that you can resolve problems using Amazon SSM OpsCenter.

You can configure important counters, such as Mirrored Write Transaction/sec, Recovery Queue Length, and Transaction Delay, as well as Windows Event Logs on CloudWatch. When a failover event or problem occurs with your SQL HA workload, such as a restricted access to query a target database, CloudWatch Application Insights provides automated insights .

CloudWatch Application Insights integrates with Amazon Launch Wizard to provide a one-click monitoring setup experience for deploying SQL Server HA workloads on Amazon. When you select the option to set up monitoring and insights with Application Insights on the Launch Wizard console, CloudWatch Application Insights automatically sets up relevant metrics, logs, and alarms on CloudWatch, and starts monitoring newly deployed workloads. You can view automated insights and detected problems, along with the health of your SQL Server HA workloads, on the CloudWatch console.

Contents

Features

Application Insights provides the following features.

Automatic set up of monitors for application resources

CloudWatch Application Insights reduces the time it takes to set up monitoring for your applications. It does this by scanning your application resources, providing a customizable list of recommended metrics and logs, and setting them up on CloudWatch to provide necessary visibility into your application resources, such as Amazon EC2 and Elastic Load Balancers (ELB). It also sets up dynamic alarms on monitored metrics. The alarms are automatically updated based on anomalies detected in the previous two weeks.

Problem detection and notification

CloudWatch Application Insights detects signs of potential problems with your application, such as metric anomalies and log errors. It correlates these observations to surface potential problems with your application. It then generates CloudWatch Events, which can be configured to receive notifications or take actions. This eliminates the need for you to create individual alarms on metrics or log errors. Additionally, you can Configure Amazon SNS notifications to receive alerts for detected problems.

Troubleshooting

CloudWatch Application Insights creates CloudWatch automatic dashboards for problems that are detected. The dashboards show details about the problem, including the associated metric anomalies and log errors to help you with troubleshooting. They also provide additional insights that point to potential root causes of the anomalies and errors.

Concepts

The following concepts are important for understanding how Application Insights monitors your application.

Component

An auto-grouped, standalone, or custom grouping of similar resources that make up an application. We recommend grouping similar resources into custom components for better monitoring.

Observation

An individual event (metric anomaly, log error, or exception) that is detected with an application or application resource.

Problem

Problems are detected by correlating, classifying, and grouping related observations.

For definitions of other key concepts for CloudWatch Application Insights, see [Amazon CloudWatch Concepts](#).

Pricing

CloudWatch Application Insights sets up recommended metrics and logs for selected application resources using CloudWatch metrics, Logs, and Events for notifications on detected problems. These features are charged to your Amazon account according to CloudWatch pricing. For detected problems, SSM OpsItems are also created by Application Insights to notify you about problems. Additionally, Application Insights creates SSM Parameter Store parameters to configure the CloudWatch agents on your instances. The Amazon EC2 Systems Manager features are charged according to SSM pricing. You are not charged for setup assistance, monitoring, data analysis, or problem detection.

Costs for CloudWatch Application Insights

Costs for Amazon EC2 include usage of the following features:

- CloudWatch Agent
  - CloudWatch Agent log groups
  - CloudWatch Agent metrics

- Prometheus log groups (for JMX workloads)

Costs for all resources include usage of the following features:

- CloudWatch alarms (majority of cost)
- SSM OpsItems (minimal cost)

Example cost calculation

The costs in this example are considered according to the following scenario.

You created a resource group that includes the following:

- An Amazon EC2 instance with SQL Server installed.
- An attached Amazon EBS volume.

When you onboard this resource group with CloudWatch Application Insights, the SQL Server workload installed on the Amazon EC2 instance is detected. CloudWatch Application Insights starts monitoring the following metrics.

The following metrics are monitored for the SQL Server instance:

- CPUUtilization
- StatusCheckFailed
- Memory % Committed Bytes in Use
- Memory Available Mbytes
- Network Interface Bytes Total/sec
- Paging File % Usage
- Physical Disk % Disk Time
- Processor % Processor Time
- SQLServer:Buffer Manager cache hit ratio
- SQLServer:Buffer Manager life expectancy
- SQLServer:General Statistics Processes blocked
- SQLServer:General Statistics User Connections
- SQLServer:Locks Number of Deadlocks/sec

- SQLServer:SQL Statistics Batch Requests/sec
- System Processor Queue Length

The following metrics are monitored for the volumes attached to the SQL Server instance:

- VolumeReadBytes
- VolumeWriteBytes
- VolumeReadOps
- VolumeWriteOps
- VolumeTotalReadTime
- VolumeTotalWriteTime
- VolumeIdleTime
- VolumeQueueLength
- VolumeThroughputPercentage
- VolumeConsumedReadWriteOps
- BurstBalance

For this scenario, the costs are calculated according to the CloudWatch pricing page and the SSM pricing page:

- **Custom metrics**

  For this scenario, 13 of the above metrics are emitted to CloudWatch using the CloudWatch agent. These metrics are treated as custom metrics. The cost for each custom metric is $.3/month. The total cost for these custom metrics is 13 * $.3 = $3.90/month.
- **Alarms**

  For this scenario, CloudWatch Application Insights monitors 26 metrics in total, which creates 26 alarms. The cost for each alarm is $.1/month. The total cost for alarms is 26 * $.1 = $2.60/month.
- **Data ingestion and error logs**

  The cost of data ingestion is $.05/GB and storage for the SQL Server error log is $.03/GB. The total cost for data ingestion and the error log is $.05/GB + $.03/GB= $.08/GB.
- **Amazon EC2 Systems Manager OpsItems**

An SSM OpsItem is created for each problem detected by CloudWatch Application Insights. For *n* number of problems in your application, the total cost is $.00267 * *n*/month.

Related services

The following services are used along with CloudWatch Application Insights:

Related Amazon services

- **Amazon CloudWatch** provides system-wide visibility into resource utilization, application performance, and operational health. It collects and tracks metrics, sends alarm notifications, automatically updates resources that you are monitoring based on the rules that you define, and allows you to monitor your own custom metrics. CloudWatch Application Insights is initiated through CloudWatch—specifically, within the CloudWatch default operational dashboards. For more information, see the *Amazon CloudWatch User Guide*.
- **CloudWatch Container Insights** collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. You can use Container Insights to monitor Amazon ECS, Amazon Elastic Kubernetes Service, and Kubernetes platforms on Amazon EC2. When Application Insights is enabled on the Container Insights or Application Insights consoles, Application Insights displays detected problems on your Container Insights dashboard. For more information, see Container Insights .
- **Amazon DynamoDB** is a fully managed NoSQL database service that lets you offload the administrative burdens of operating and scaling a distributed database so that you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling. DynamoDB also offers encryption at rest, which eliminates the operational burden and complexity involved in protecting sensitive data.
- **Amazon EC2** provides scalable computing capacity in the Amazon Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, to configure security and networking, and to manage storage. You can scale up or down to handle changes in requirements or spikes in popularity, which reduces your need to forecast traffic. For more information, see the *Amazon EC2 User Guide for Linux Instances* or *Amazon EC2 Guide for Windows Instances*.
- **Amazon Elastic Block Store (Amazon EBS)** provides block-level storage volumes for use with Amazon EC2 instances. Amazon EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances. Amazon EBS volumes that are attached to an instance are exposed as storage volumes that persist independently from the life of the

instance. You can create a file system on top of these volumes, or use them in any way you would use a block device (such as a hard drive). You can dynamically change the configuration of a volume attached to an instance. For more information, see the Amazon EBS User Guide.

- **Amazon EC2 Auto Scaling** helps ensure that you have the correct number of EC2 instances available to handle the load for your application. For more information, see the *Amazon EC2 Auto Scaling User Guide*.
- **Elastic Load Balancing** distributes incoming applications or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones. For more information, see the *Elastic Load Balancing User Guide*.
- **IAM** is a web service that helps you to securely control access to Amazon resources for your users. Use IAM to control who can use your Amazon resources (authentication), and to control the resources they can use and how they can use them (authorization). For more information, see Authentication and Access Control for Amazon CloudWatch.
- **Amazon Lambda** lets you build serverless applications composed of functions that are triggered by events and automatically deploy them using CodePipeline and Amazon CodeBuild. For more information, see Amazon Lambda Applications.
- **Amazon Launch Wizard for SQL Server** reduces the time it takes to deploy SQL Server high availability solution to the cloud. You input your application requirements, including performance, number of nodes, and connectivity on the service console, and Amazon Launch Wizard identifies the right Amazon resources to deploy and run your SQL Server Always On application.
- **Amazon Resource Groups** help you to organize the resources that make up your application. With Resource Groups, you can manage and automate tasks on a large number of resources at one time. Only one Resource Group can be registered for a single application. For more information, see the *Amazon Resource Groups User Guide*.
- **Amazon SQS** offers a secure, durable, and available hosted queue that allows you to integrate and decouple distributed software systems and components. For more information, see the *Amazon SQS User Guide*.
- **Amazon Step Functions** is a serverless function composer that allows you to sequence a variety of Amazon services and resources, including Amazon Lambda functions, into structured, visual workflows. For more information, see the Amazon Step Functions User Guide.
- **Amazon SSM OpsCenter** aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation documents (runbooks) that you can use to quickly resolve issues. You can specify searchable, custom data for each OpsItem. You can also

view automatically-generated summary reports about OpsItems by status and source. For more information, see the *Amazon Systems Manager User Guide*.

- **Amazon API Gateway** is an Amazon service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale. API developers can create APIs that access Amazon or other web services, as well as data stored in the Amazon Cloud. For more information, see the Amazon API Gateway User Guide.

> **Note**
>
> Application Insights supports only REST API protocols (v1 of the API Gateway service).

- **Amazon Elastic Container Service (Amazon ECS)** is a fully managed container orchestration service. You can use Amazon ECS to run your most sensitive and mission-critical applications. For more information, see the Amazon Elastic Container Service Developer Guide.
- **Amazon Elastic Kubernetes Service (Amazon EKS)** is a managed service that you can use to run Kubernetes on Amazon without having to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications. For more information, see the Amazon EKS User Guide.
- **Kubernetes on Amazon EC2**. Kubernetes is open-source software that helps you deploy and manage containerized applications at scale. Kubernetes manages clusters of Amazon EC2 compute instances and runs containers on those instances with processes for deployment, maintenance, and scaling. With Kubernetes, you can run any type of containerized application with the same toolset on-premises and in the cloud. For more information, see Kubernetes Documentation: Getting started.
- **Amazon FSx** helps you to launch and run popular file systems that are fully managed by Amazon. With Amazon FSx, you can leverage the feature sets and performance of common open source and commercially-licensed file systems to avoid time-consuming administrative tasks. For more information, see the Amazon FSx Documentation.
- **Amazon Simple Notification Service (SNS)** is a fully-managed messaging service for both application-to-application and application-to-person communication. You can configure Amazon SNS for monitoring by Application Insights. When Amazon SNS is configured as a resource for monitoring, Application Insights tracks SNS metrics to help determine why SNS messages may encounter issues or fail.
- **Amazon Elastic File System (Amazon EFS)** is a fully-managed elastic NFS file system for use with Amazon Web Services Cloud services and on-premises resources. It is built to scale to

petabytes on demand without disrupting applications. It grows and shrinks automatically as you add and remove files, which eliminates the need to provision and manage capacity to accommodate growth. For more information, see the Amazon Elastic File System documentation.

Related third-party services

- For some workloads and applications monitored in Application Insights, **Prometheus JMX exporter** is installed using Amazon Systems Manager Distributor so that CloudWatch Application Insights can retrieve Java-specific metrics. When you choose to monitor a Java application, Application Insights automatically installs the Prometheus JMX exporter for you.

Supported application components

CloudWatch Application Insights scans your resource group to identify application components. Components can be standalone, auto-grouped (such as instances in an Auto Scaling group or behind a load balancer), or custom (by grouping together individual Amazon EC2 instances).

The following components are supported by CloudWatch Application Insights:

Amazon components

- Amazon EC2
- Amazon EBS
- Amazon RDS
- Elastic Load Balancing: Application Load Balancer and Classic Load Balancer (all target instances of these load balancers are identified and configured).
- Amazon EC2 Auto Scaling groups: Amazon Auto Scaling (Auto Scaling groups are dynamically configured for all target instances; if your application scales up, CloudWatch Application Insights automatically configures the new instances). Auto Scaling groups are not supported for CloudFormation stack-based resource groups.
- Amazon Lambda
- Amazon Simple Queue Service (Amazon SQS)
- Amazon DynamoDB table
- Amazon S3 bucket metrics
- Amazon Step Functions

- Amazon API Gateway REST API stages
- Amazon Elastic Container Service (Amazon ECS): cluster, service, and task
- Amazon Elastic Kubernetes Service (Amazon EKS): cluster
- Kubernetes on Amazon EC2: Kubernetes cluster running on EC2
- Amazon SNS topic

Any other component type resources are not currently tracked by CloudWatch Application Insights. If a component type that is supported does not appear in your Application Insights application, the component may already be registered and managed by another application you own that is monitored by Application Insights.

Supported technology stacks

You can use CloudWatch Application Insights to monitor your applications running on Windows Server and Linux operating systems by selecting the application tier dropdown menu option for one of the following technologies:

- Front-end: Microsoft Internet Information Services (IIS) Web Server
- Worker-tier:
  - .NET Framework
  - .NET Core
- Applications:
  - Java
  - SAP NetWeaver standard, distributed, and high availability deployments
- Active Directory
- SharePoint
- Databases:
  - Microsoft SQL Server running on Amazon RDS or Amazon EC2 (including SQL Server High Availability configurations. See, Component configuration examples).
  - MySQL running on Amazon RDS, Amazon Aurora, or Amazon EC2
  - PostgreSQL running on Amazon RDS or Amazon EC2
  - Amazon DynamoDB table
  - Oracle running on Amazon RDS or Amazon EC2

- SAP HANA database on a single Amazon EC2 instance and multiple EC2 instances
- Cross-AZ SAP HANA database high availability setup
- SAP Sybase ASE database on a single Amazon EC2 instance
- Cross-AZ SAP Sybase ASE database high availability setup

If none of the technology stacks listed above apply to your application resources, you can monitor your application stack by choosing **Custom** from the application tier dropdown menu on the **Manage monitoring** page.

How Amazon CloudWatch Application Insights works

CloudWatch Application Insights provides monitoring of your application resources. The following information describes how Application Insights works.

Topics

How Application Insights monitors applications

The following information describes how Application Insights monitors applications.

Application discovery and configuration

The first time an application is added to CloudWatch Application Insights it scans the application components to recommend key metrics, logs, and other data sources to monitor for your application. You can then configure your application based on these recommendations.

Data preprocessing

CloudWatch Application Insights continuously analyzes the data sources being monitored across the application resources to discover metric anomalies and log errors (observations).

Intelligent problem detection

The CloudWatch Application Insights engine detects problems in your application by correlating observations using classification algorithms and built-in rules. To assist in troubleshooting, it creates automated CloudWatch dashboards, which include contextual information about the problems.

Alert and action

When CloudWatch Application Insights detects a problem with your application, it generates CloudWatch Events to notify you of the problem. See [Application Insights CloudWatch Events for detected problems] for more information about how to set up these Events. Additionally, you can [configure Amazon SNS notifications] to receive alerts for detected problems.

Example scenario

You have an ASP .NET application that is backed by a SQL Server database. Suddenly, your database begins to malfunction because of high memory pressure. This leads to application performance degradation and possibly HTTP 500 errors in your web servers and load balancer.

With CloudWatch Application Insights and its intelligent analytics, you can identify the application layer that is causing the problem by checking the dynamically created dashboard that shows the related metrics and log file snippets. In this case, the problem might be at the SQL database layer.

Data retention

CloudWatch Application Insights retains problems for 55 days and observations for 60 days.

Quotas

For default quotas for CloudWatch Application Insights, see [Amazon CloudWatch Application Insights endpoints and quotas]. Unless otherwise noted, each quota is per Amazon Region. Contact [Amazon Support] to request an increase in your service quota. Many services contain quotas that cannot be changed. For more information about the quotas for a specific service, see the documentation for that service.

Amazon Systems Manager (SSM) packages used by CloudWatch Application Insights

The packages listed in this section are used by Application Insights, and can be independently managed and deployed with Amazon Systems Manager Distributor. For more information about SSM Distributor, see [Amazon Systems Manager Distributor] in the *Amazon Systems Manager User Guide*.

Packages:

- AWSObservabilityExporter-JMXExporterInstallAndConfigure
- AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure
- AWSObservabilityExporter-HAClusterExporterInstallAndConfigure
- AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure
- AWSObservabilityExporter-SQLExporterInstallAndConfigure

`AWSObservabilityExporter-JMXExporterInstallAndConfigure`

You can retrieve workload-specific Java metrics from Prometheus JMX exporter for Application Insights to configure and monitor alarms. In the Application Insights console, on the **Manage monitoring** page, select **JAVA application** from the **Application tier** dropdown. Then under **JAVA Prometheus exporter configuration**, select your **Collection method** and **JMX port number**.

To use Amazon Systems Manager Distributor to package, install, and configure the Amazon-provided Prometheus JMX exporter package independently of Application Insights, complete the following steps.

Prerequisites for using the Prometheus JMX exporter SSM package

- SSM agent version 2.3.1550.0 or later installed
- The JAVA_HOME environment variable is set

Install and configure the `AWSObservabilityExporter-JMXExporterInstallAndConfigure` package

The `AWSObservabilityExporter-JMXExporterInstallAndConfigure` package is an SSM Distributor package that you can use to install and configure Prometheus JMX Exporter. When Java metrics are sent by the Prometheus JMX exporter, the CloudWatch agent can be configured to retrieve the metrics for the CloudWatch service.

1. Based on your preferences, prepare the Prometheus JMX exporter YAML configuration file located in the Prometheus GitHub repository. Use the example configuration and option descriptions to guide you.
2. Copy the Prometheus JMX exporter YAML configuration file encoded as Base64 to a new SSM parameter in SSM Parameter Store.

3. Navigate to the SSM Distributor console and open the **Owned by Amazon** tab. Select **AWSObservabilityExporter-JMXExporterInstallAndConfigure** and choose **Install one time**.

4. Update the SSM parameter you created in the first step by replacing "Additional Arguments" with the following:

```
{
  "SSM_EXPORTER_CONFIGURATION": "{{ssm:<SSM_PARAMETER_STORE_NAME>}}",
  "SSM_EXPOSITION_PORT": "9404"
}
```

> **Note**
>
> Port 9404 is the default port used to send Prometheus JMX metrics. You can update this port.

Example: Configure CloudWatch agent to retrieve Java metrics

1. Install the Prometheus JMX exporter, as described in the previous procedure. Then verify that it is correctly installed on your instance by checking the port status.

   Successful installation on Windows instance example

```
PS C:\> curl http://localhost:9404 (http://localhost:9404/)
StatusCode : 200
StatusDescription : OK
Content : # HELP jvm_info JVM version info
```

   Successful installation on Linux instance example

```
$ curl localhost:9404
# HELP jmx_config_reload_failure_total Number of times configuration have failed to
 be reloaded.
# TYPE jmx_config_reload_failure_total counter
jmx_config_reload_failure_total 0.0
```

2. Create the Prometheus service discovery YAML file. The following example service discovery file performs the following:

- Specifies the Prometheus JMX exporter host port as `localhost: 9404`.
- Attaches labels (`Application`, `ComponentName`, and `InstanceId`) to the metrics, which can be set as CloudWatch metric dimensions.

```
$ cat prometheus_sd_jmx.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    Application: myApp
    ComponentName: arn-cn:aws:elasticloadbalancing:cn-
north-1:123456789012:loadbalancer/app/sampl-Appli-MMZW8E3GH4H2/aac36d7fea2a6e5b
    InstanceId: i-12345678901234567
```

3. Create the Prometheus JMX exporter configuration YAML file. The following example configuration file specifies the following:

   - The metrics retrieval job interval and timeout period.
   - The metrics retrieval jobs (`jmx` and `sap`), also known as scraping, which include the job name, maximum time series returned at a time, and service discovery file path.

```
$ cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    file_sd_configs:
      - files: ["/tmp/prometheus_sd_jmx.yaml"]
  - job_name: sap
    sample_limit: 10000
    file_sd_configs:
      - files: ["/tmp/prometheus_sd_sap.yaml"]
```

4. Verify that the CloudWatch agent is installed on your Amazon EC2 instance and that the version is 1.247346.1b249759 or later. To install the CloudWatch agent on your EC2 instance, see Installing the CloudWatch Agent. To verify the version, see Finding information about CloudWatch agent versions.

5. Configure the CloudWatch agent. For more information about how to configure the CloudWatch agent configuration file, see [Manually create or edit the CloudWatch agent configuration file](). The following example CloudWatch agent configuration file performs the following:

   - Specifies the Prometheus JMX exporter configuration file path.
   - Specifies the target log group to which to publish EMF metric logs.
   - Specifies two sets of dimensions for each metric name.
   - Sends 8 (4 metric names * 2 sets of dimensions per metric name) CloudWatch metrics.

```
{
   "logs":{
      "logs_collected":{
         ....
      },
      "metrics_collected":{
         "prometheus":{
            "cluster_name":"prometheus-test-cluster",
            "log_group_name":"prometheus-test",
            "prometheus_config_path":"/tmp/prometheus.yaml",
            "emf_processor":{
               "metric_declaration_dedup":true,
               "metric_namespace":"CWAgent",
               "metric_unit":{
                  "jvm_threads_current":"Count",
                  "jvm_gc_collection_seconds_sum":"Second",
                  "jvm_memory_bytes_used":"Bytes"
               },
               "metric_declaration":[
                  {
                     "source_labels":[
                        "job"
                     ],
                     "label_matcher":"^jmx$",
                     "dimensions":[
                        [
                           "InstanceId",
                           "ComponentName"
                        ],
                        [
                           "ComponentName"
```

```
                        ]
                    ],
                    "metric_selectors":[
                        "^java_lang_threading_threadcount$",
                        "^java_lang_memory_heapmemoryusage_used$",
                        "^java_lang_memory_heapmemoryusage_committed$"
                    ]
                }
            ]
        }
      }
    }
  },
  "metrics":{
    ....
  }
}
```

AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure

You can retrieve workload-specific SAP HANA metrics from Prometheus HANA database exporter for Application Insights to configure and monitor alarms. For more information, see Set up your SAP HANA database for monitoring in this guide.

To use Amazon Systems Manager Distributor to package, install, and configure the Amazon-provided Prometheus HANA database exporter package independently of Application Insights, complete the following steps.

Prerequisites for using the Prometheus HANA database exporter SSM package

- SSM agent version 2.3.1550.0 or later installed
- SAP HANA database
- Linux operating system (SUSE Linux, RedHat Linux)
- A secret with SAP HANA database monitoring credentials, using Amazon Secrets Manager. Create a secret using the key/value pairs format, specify the key username, and enter the database user for the value. Add a second key password, and then enter the password for the value. For more information about how to create secrets, see Create a secret in the *Amazon Secrets Manager User Guide*. The secret must be formatted as follows:

```
{
```

```
  "username": "<database_user>",
  "password": "<database_password>"
}
```

Install and configure the `AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure` package

The `AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure` package is an SSM Distributor package that you can use to install and configure Prometheus HANA database Exporter. When HANA database metrics are sent by the Prometheus HANA database exporter, the CloudWatch agent can be configured to retrieve the metrics for the CloudWatch service.

1. Create an SSM parameter in SSM Parameter Store to store the Exporter configurations. The following is an example parameter value.

```
{\"exposition_port\":9668,\"multi_tenant\":true,\"timeout\":600,\"hana\":{\"host\":
\"localhost\",\"port\":30013,\"aws_secret_name\":\"HANA_DB_CREDS\",\"scale_out_mode
\":true}}
```

> **Note**
>
> In this example, the export runs only on the Amazon EC2 instance with the active SYSTEM database, and it will remain idle on the other EC2 instances in order to avoid duplicate metrics. The exporter can retrieve all of the database tenant information from the SYSTEM database.

2. Create an SSM parameter in SSM Parameter Store to store the Exporter metrics queries. The package can accept more than one metrics parameter. Each parameter must have a valid JSON object format. The following is an example parameter value:

```
{\"SELECT MAX(TIMESTAMP) TIMESTAMP, HOST, MEASURED_ELEMENT_NAME CORE,
 SUM(MAP(CAPTION, 'User Time', TO_NUMBER(VALUE), 0)) USER_PCT, SUM(MAP(CAPTION,
 'System Time', TO_NUMBER(VALUE), 0)) SYSTEM_PCT, SUM(MAP(CAPTION, 'Wait
 Time', TO_NUMBER(VALUE), 0)) WAITIO_PCT, SUM(MAP(CAPTION, 'Idle Time', 0,
 TO_NUMBER(VALUE))) BUSY_PCT, SUM(MAP(CAPTION, 'Idle Time', TO_NUMBER(VALUE), 0))
 IDLE_PCT FROM sys.M_HOST_AGENT_METRICS WHERE MEASURED_ELEMENT_TYPE = 'Processor'
 GROUP BY HOST, MEASURED_ELEMENT_NAME;\":{\"enabled\":true,\"metrics\":[{\"name\":
\"hanadb_cpu_user\",\"description\":\"Percentage of CPU time spent by HANA DB in user
 space, over the last minute (in seconds)\",\"labels\":[\"HOST\",\"CORE\"],\"value\":
```

```
\"USER_PCT\",\"unit\":\"percent\",\"type\":\"gauge\"},{\"name\":\"hanadb_cpu_system
\",\"description\":\"Percentage of CPU time spent by HANA DB in Kernel space,
 over the last minute (in seconds)\",\"labels\":[\"HOST\",\"CORE\"],\"value\":
\"SYSTEM_PCT\",\"unit\":\"percent\",\"type\":\"gauge\"},{\"name\":\"hanadb_cpu_waitio
\",\"description\":\"Percentage of CPU time spent by HANA DB in IO mode, over the
 last minute (in seconds)\",\"labels\":[\"HOST\",\"CORE\"],\"value\":\"WAITIO_PCT\",
\"unit\":\"percent\",\"type\":\"gauge\"},{\"name\":\"hanadb_cpu_busy\",\"description
\":\"Percentage of CPU time spent by HANA DB, over the last minute (in seconds)\",
\"labels\":[\"HOST\",\"CORE\"],\"value\":\"BUSY_PCT\",\"unit\":\"percent\",\"type\":
\"gauge\"},{\"name\":\"hanadb_cpu_idle\",\"description\":\"Percentage of CPU time not
 spent by HANA DB, over the last minute (in seconds)\",\"labels\":[\"HOST\",\"CORE
\"],\"value\":\"IDLE_PCT\",\"unit\":\"percent\",\"type\":\"gauge\"}]}}
```

For more information about metrics queries, see the `SUSE / hanadb_exporter` repo on GitHub.

3. Navigate to the SSM Distributor console and open the **Owned by Amazon** tab. Select **AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure*** and choose **Install one time**.
4. Update the SSM parameter you created in the first step by replacing "Additional Arguments" with the following:

```
{
  "SSM_EXPORTER_CONFIG": "{{ssm:<*SSM_CONFIGURATIONS_PARAMETER_STORE_NAME>*}}",
  "SSM_SID": "<SAP_DATABASE_SID>",
  "SSM_EXPORTER_METRICS_1": "{{ssm:<SSM_FIRST_METRICS_PARAMETER_STORE_NAME>}}",
  "SSM_EXPORTER_METRICS_2": "{{ssm:<SSM_SECOND_METRICS_PARAMETER_STORE_NAME>}}"
}
```

5. Select the Amazon EC2 instances with SAP HANA database, and choose **Run**.

`AWSObservabilityExporter-HAClusterExporterInstallAndConfigure`

You can retrieve workload-specific High Availability (HA) cluster metrics from Prometheus HANA cluster exporter for Application Insights to configure and monitor alarms for an SAP HANA database High Availability setup. For more information, see Set up your SAP HANA database for monitoring in this guide.

To use Amazon Systems Manager Distributor to package, install, and configure the Amazon-provided Prometheus HA cluster exporter package independently of Application Insights, complete the following steps.

Prerequisites for using the Prometheus HA cluster exporter SSM package

- SSM agent version 2.3.1550.0 or later installed
- HA cluster for Pacemaker, Corosync, SBD, and DRBD
- Linux operating system (SUSE Linux, RedHat Linux)

Install and configure the `AWSObservabilityExporter-HAClusterExporterInstallAndConfigure` package

The `AWSObservabilityExporter-HAClusterExporterInstallAndConfigure` package is an SSM Distributor package that you can use to install and configure Prometheus HA Cluster Exporter. When cluster metrics are sent by the Prometheus HANA database exporter, the CloudWatch agent can be configured to retrieve the metrics for the CloudWatch service.

1. Create an SSM parameter in SSM Parameter Store to store the Exporter configurations in JSON format. The following is an example parameter value.

   ```
   {\"port\":\"9664\",\"address\":\"0.0.0.0\",\"log-level\":\"info\",\"crm-mon-path
   \":\"/usr/sbin/crm_mon\",\"cibadmin-path\":\"/usr/sbin/cibadmin\",\"corosync-
   cfgtoolpath-path\":\"/usr/sbin/corosync-cfgtool\",\"corosync-quorumtool-path\":\"/
   usr/sbin/corosync-quorumtool\",\"sbd-path\":\"/usr/sbin/sbd\",\"sbd-config-path\":
   \"/etc/sysconfig/sbd\",\"drbdsetup-path\":\"/sbin/drbdsetup\",\"enable-timestamps
   \":false}
   ```

   For more information about the exporter configurations, see the `ClusterLabs / ha_cluster_exporter` repo on GitHub.
2. Navigate to the SSM Distributor console and open the **Owned by Amazon** tab. Select **AWSObservabilityExporter-HAClusterExporterInstallAndConfigure*** and choose **Install one time**.
3. Update the SSM parameter you created in the first step by replacing "Additional Arguments" with the following:

   ```
   {
     "SSM_EXPORTER_CONFIG": "{{ssm:<*SSM_CONFIGURATIONS_PARAMETER_STORE_NAME>*}}"
   }
   ```
4. Select the Amazon EC2 instances with SAP HANA database, and choose **Run**.

`AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure`

You can retrieve workload-specific SAP NetWeaver metrics from Prometheus SAP host exporter for Application Insights to configure and monitor alarms for SAP NetWeaver Distributed and High Availability deployments.

To use Amazon Systems Manager Distributor to package, install, and configure the SAP host exporter package independently of Application Insights, complete the following steps.

Prerequisites for using the Prometheus SAP host exporter SSM package

- SSM agent version 2.3.1550.0 or later installed
- SAP NetWeaver application servers
- Linux operating system (SUSE Linux, RedHat Linux)

Install and configure the `AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure` package

The `AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure` package is an SSM Distributor package that you can use to install and configure SAP NetWeaver Prometheus metrics exporter. When SAP NetWeaver metrics are sent by the Prometheus exporter, the CloudWatch agent can be configured to retrieve the metrics for the CloudWatch service.

1. Create an SSM parameter in SSM Parameter Store to store the Exporter configurations in JSON format. The following is an example parameter value.

   ```
   {\"address\":\"0.0.0.0\",\"port\":\"9680\",\"log-level\":\"info\",\"is-HA\":false}
   ```

   - **address**

     The target address to which to send the Prometheus metrics. The default value is `localhost`.

   - **port**

     The target port to which to send the Prometheus metrics. The default value is `9680`.

   - **is-HA**

     `true` for SAP NetWeaver High Availability deployments. For all other deployments the value is `false`.

2. Navigate to the SSM Distributor console and open the **Owned by Amazon** tab. Select **AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure** and choose **Install one time**.

3. Update the SSM parameter you created in the first step by replacing "Additional Arguments" with the following:

```
{
  "SSM_EXPORTER_CONFIG": "{{ssm:<SSM_CONFIGURATIONS_PARAMETER_STORE_NAME>}}",
  "SSM_SID": "<SAP_DATABASE_SID>",
  "SSM_INSTANCES_NUM": "<instances_number seperated by comma>"
}
```

Example

```
{
  "SSM_EXPORTER_CONFIG": "{{ssm:exporter_config_paramter}}",
  "SSM_INSTANCES_NUM": "11,12,10",
  "SSM_SID": "PR1"
}
```

4. Select the Amazon EC2 instances with SAP NetWeaver applications, and choose **Run**.

> **Note**
>
> The Prometheus exporter services the SAP NetWeaver metrics on a local endpoint. The local endpoint can be accessed by only the operating system users on the Amazon EC2 instance. Therefore, after the exporter package is installed, the metrics are available to all of the operating system users. The default local endpoint is `localhost:9680/metrics`.

`AWSObservabilityExporter-SQLExporterInstallAndConfigure`

You can retrieve workload-specific SQL Server metrics from Prometheus SQL exporter for Application Insights to monitor key metrics.

To use Amazon Systems Manager Distributor to package, install, and configure the SQL exporter package independently of Application Insights, complete the following steps.

Prerequisites for using the Prometheus SQL exporter SSM package

- SSM agent version 2.3.1550.0 or later installed
- Amazon EC2 instance running SQL Server on Windows with SQL Server user authentication enabled.
- A SQL Server user with the following permissions:

```
GRANT VIEW ANY DEFINITION TO
```

```
GRANT VIEW SERVER STATE TO
```

- A secret containing the database connection string using Amazon Secrets Manager. For more information about how to create secrets, see Create a secret in the *Amazon Secrets Manager User Guide*. The secret must be formatted as follows:

```
{
  "data_source_name":"sqlserver://<username>:<password>@localhost:1433"
}
```

> **Note**
>
> If the password or username contains special characters, you must percent encode the special characters to ensure a successful connection to the database.

Install and configure the `AWSObservabilityExporter-SQLExporterInstallAndConfigure` package

The `AWSObservabilityExporter-SQLExporterInstallAndConfigure` package is an SSM Distributor package that you can use to install and configure SQL Prometheus metrics exporter. When metrics are sent by the Prometheus exporter, the CloudWatch agent can be configured to retrieve the metrics for the CloudWatch service.

1. Based on your preferences, prepare the SQL Exporter YAML configuration. The following sample configuration has a single metric configured. Use the example configuration to update the configuration with additional metrics or create your own configuration.

```
---
```

```
global:
  scrape_timeout_offset: 500ms
  min_interval: 0s
  max_connections: 3
  max_idle_connections: 3
target:
  aws_secret_name: <SECRET_NAME>
  collectors:
    - mssql_standard
collectors:
  - collector_name: mssql_standard
    metrics:
    - metric_name: mssql_batch_requests
      type: counter
      help: 'Number of command batches received.'
      values: [cntr_value]
      query: |
        SELECT cntr_value
        FROM sys.dm_os_performance_counters WITH (NOLOCK)
        WHERE counter_name = 'Batch Requests/sec'
```

2. Copy the Prometheus SQL exporter YAML configuration file encoded as Base64 to a new SSM parameter in SSM Parameter Store.
3. Navigate to the SSM Distributor console and open the **Owned by Amazon** tab. Select **AWSObservabilityExporter-SQLExporterInstallAndConfigure** and choose **Install one time**.
4. Replace the "Additional Arguments" with the following information. The `SSM_PARAMETER_NAME` is the name of the parameter you created in Step 2.

```
{
  "SSM_EXPORTER_CONFIGURATION":
    "{{ssm:<SSM_PARAMETER_STORE_NAME>}}",
    "SSM_PROMETHEUS_PORT": "9399",
    "SSM_WORKLOAD_NAME": "SQL"
}
```

5. Select the Amazon EC2 instance with the SQL Server database, then choose run.

Amazon Systems Manager (SSM) Documents used by CloudWatch Application Insights

Application Insights uses the SSM Documents listed in this section to define the actions that Amazon Systems Manager performs on your managed instances. These documents use the `Run Command` capability of Systems Manager to automate the tasks necessary for carrying out Application Insights monitoring capabilities. The run schedules for these documents are maintained by Application Insights and can't be altered.

For more information about SSM Documents, see [Amazon Systems Manager Documents] in the *Amazon Systems Manager User Guide*.

Documents managed by CloudWatch Application Insights

The following table lists the SSM documents that are managed by Application Insights.

Document name	Description	Run schedule
`AWSEC2-DetectWorkload`	Auto detects applications running in your application environment that can be set up to be monitored by Application Insights.	This document runs hourly in your application environment to get up-to-date application details.
`AWSEC2-CheckPerformanceCounterSets`	Checks whether Performance Counter namespaces are enabled on your Amazon EC2 Windows instances.	This document runs hourly in your application environment and only monitors Performance Counter metrics if the corresponding namespaces are enabled.
`AWSEC2-ApplicationInsightsCloudwatchAgentInstallAndConfigure`	Installs and configures CloudWatch Agent based on the monitoring configuration of your application components.	This document runs every 30 minutes to ensure that the CloudWatch Agent configuration is always accurate and up-to-date. The document also runs immediately after a change is made to your application monitoring setup

Document name	Description	Run schedule
		such as adding or removing metrics or updating log configurations.

Documents managed by Amazon Systems Manager

The following documents are used by CloudWatch Application Insights and managed by Systems Manager.

`AWS-ConfigureAWSPackage`

Application Insights uses this document to install and uninstall Prometheus exporter distributor packages, to collect workload specific metrics, and to enable comprehensive monitoring of workloads on customer Amazon EC2 instances. CloudWatch Application Insights installs the Prometheus exporter distributor packages only if the correlated target workload is running on your instance.

The following table lists the Prometheus exporter distributor packages and the correlated target workloads.

Prometheus exporter distributor package name	Target workload
`AWSObservabilityExporter-HAClusterExporterInstallAndConfigure`	SAP HANA HA
`AWSObservabilityExporter-JMXExporterInstallAndConfigure`	Java/JMX
`AWSObservabilityExporter-SAP-HANADBExporterInstallAndConfigure`	SAP HANA
`AWSObservabilityExporter-SAP-SAPHostExporterInstallAndConfigure`	NetWeaver

Prometheus exporter distributor package name	Target workload
`AWSObservabilityExporter-SQLExporterInstallAndConfigure`	SQL Server (Windows) and SAP ASE (Linux)

`AmazonCloudWatch-ManageAgent`

Application Insights uses this document to manage the status and configuration of CloudWatch Agent on your instances and to collect internal system level metrics and logs from Amazon EC2 instances across operating systems.

Prerequisites, IAM policies, and permissions needed to access CloudWatch Application Insights

To get started with CloudWatch Application Insights, verify that you have met the following prerequisites, have created an IAM policy, and have attached permissions if needed.

Topics

Prerequisites to configure an application for monitoring

You must complete the following prerequisites to configure an application with CloudWatch Application Insights:

- **Amazon Systems Manager enablement** – Install Systems Manager Agent (SSM Agent) on your Amazon EC2 instances, and enable the instances for SSM. For information about how to install the SSM Agent, see Setting up Amazon Systems Manager in the *Amazon Systems Manager User Guide*.
- **EC2 instance role** – You must attach the following Amazon EC2 instance roles to enable Systems Manager
  - You must attach the `AmazonSSMManagedInstanceCore` role to enable Systems Manager. For more information, see Amazon Systems Manager identity-based policy examples.

  - You must attach the `CloudWatchAgentServerPolicy` policy to enable instance metrics and logs to be emitted through CloudWatch. For more information, see [Create IAM roles and users for use with CloudWatch agent](#).

- **Amazon resource groups –** To onboard your applications to CloudWatch Application Insights, create a resource group that includes all of the associated Amazon resources used by your application stack. This includes application load balancers, Amazon EC2 instances running IIS and web front-end, .NET worker tiers, and SQL Server databases. For more information about application components and technology stacks supported by Application Insights, see Supported application components. CloudWatch Application Insights automatically includes Auto Scaling groups using the same tags or CloudFormation stacks as your resource group, because Auto Scaling groups are not supported by CloudFormation resource groups. For more information, see Getting Started with Amazon Resource Groups.
- **IAM permissions –** For users who don't have administrative access, you must create an Amazon Identity and Access Management (IAM) policy that allows Application Insights to create a service-linked role and attach it to the user's identity. For more information about how to create the IAM policy, see IAM policy for CloudWatch Application Insights.
- **Service-linked role –** Application Insights uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is created for you when you create your first Application Insights application in the Application Insights console. For more information, see Using service-linked roles for CloudWatch Application Insights.
- **Performance Counter metrics support for EC2 Windows instances –** To monitor Performance Counter metrics on your Amazon EC2 Windows instances, Performance Counters must be installed on the instances. For Performance Counter metrics and corresponding Performance Counter set names, see Performance Counter metrics. For more information about Performance Counters, see Performance Counters.
- **Amazon CloudWatch agent –** Application Insights installs and configures the CloudWatch agent. If you have CloudWatch agent installed, Application Insights retains your configuration. To avoid a merge conflict, remove the configuration of resources that you want to use in Application Insights from the existing CloudWatch agent configuration file. For more information, see Manually create or edit the CloudWatch agent configuration file.

IAM policy for CloudWatch Application Insights

To use CloudWatch Application Insights, you must create an Amazon Identity and Access Management (IAM) policy and attach it to your user, group, or role. For more information about users, groups, and roles, see IAM Identities (users, user groups, and roles). The IAM policy defines the user permissions.

To create an IAM policy using the console

To create an IAM policy using the IAM console, perform the following steps.

1. Go to the IAM console. In the left navigation pane, select **Policies**.
2. At the top of the page, select **Create policy**.
3. Select the **JSON** tab.
4. Copy and paste the following JSON document under the **JSON** tab.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "applicationinsights:*",
                "iam:CreateServiceLinkedRole",
                "iam:ListRoles",
                "resource-groups:ListGroups"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

5. Select **Review Policy**.
6. Enter a **Name** for the policy, for example, “AppInsightsPolicy.” Optionally, enter a **Description**.
7. Select **Create Policy**.
8. In the left navigation pane, select **User groups**, **Users**, or **Roles**.
9. Select the name of the user group, user, or role to which you would like to attach the policy.
10. Select **Add permissions**.
11. Select **Attach existing policies directly**.
12. Search for the policy that you just created, and select the check box to the left of the policy name.
13. Select **Next: Review**.

14. Make sure that the correct policy is listed, and select **Add permissions**.
15. Make sure that you log in with the user associated with the policy that you just created when you use CloudWatch Application Insights.

To create an IAM policy using the Amazon CLI

To create an IAM policy using the Amazon CLI, run the [create-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/create-policy.html) operation from the command line using the JSON document above as a file in your current folder.

To create an IAM policy using Amazon Tools for Windows PowerShell

To create an IAM policy using the Amazon Tools for Windows PowerShell, run the [New-IAMPolicy](https://docs.aws.amazon.com/powershell/latest/reference/items/New-IAMPolicy.html) cmdlt using the JSON document above as a file in your current folder.

IAM role permissions for account-based application onboarding

If you want to onboard all of the resources in your account, and you choose not to use the [Application Insights managed policy](#) for full access to Application Insights functionality, you must attach the following permissions to your IAM role so that Application Insights can discover all of the resources in your account:

```
"ec2:DescribeInstances"
"ec2:DescribeNatGateways"
"ec2:DescribeVolumes"
"ec2:DescribeVPCs"
"rds:DescribeDBInstances"
"rds:DescribeDBClusters"
"sqs:ListQueues"
"elasticloadbalancing:DescribeLoadBalancers"
"autoscaling:DescribeAutoScalingGroups"
"lambda:ListFunctions"
"dynamodb:ListTables"
"s3:ListAllMyBuckets"
"sns:ListTopics"
"states:ListStateMachines"
"apigateway:GET"
"ecs:ListClusters"
"ecs:DescribeTaskDefinition"
"ecs:ListServices"
"ecs:ListTasks"
"eks:ListClusters"
```

```
"eks:ListNodegroups"
"fsx:DescribeFileSystems"
"route53:ListHealthChecks"
"route53:ListHostedZones"
"route53:ListQueryLoggingConfigs"
"route53resolver:ListFirewallRuleGroups"
"route53resolver:ListFirewallRuleGroupAssociations"
"route53resolver:ListResolverEndpoints"
"route53resolver:ListResolverQueryLogConfigs"
"route53resolver:ListResolverQueryLogConfigAssociations"
"logs:DescribeLogGroups"
"resource-explorer:ListResources"
```

Set up application for monitoring using the Amazon Web Services Management Console

This section provides steps to set up, configure, and manage your CloudWatch Application Insights application using the console, the Amazon CLI, and Amazon Tools for Windows PowerShell.

Topics

- Set up, configure, and manage your application for monitoring from the CloudWatch console
- Set up, configure, and manage your application for monitoring using the command line
- Application Insights CloudWatch Events for detected problems
- Receive notifications for detected problems

Set up, configure, and manage your application for monitoring from the CloudWatch console

This section provides steps to set up, configure, and manage your application for monitoring from the CloudWatch console.

Console procedures

- Add and configure an application
- Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring
- Disable monitoring for an application component
- Delete an application

Add and configure an application

Add and configure an application from the CloudWatch console

To get started with CloudWatch Application Insights from the CloudWatch console, perform the following steps.

1. **Start.** Open the CloudWatch console landing page. From the left navigation pane, under **Insights**, choose **Application Insights**. The page that opens shows the list of applications that are monitored with CloudWatch Application Insights, along with their monitoring status.
2. **Add an application.** To set up monitoring for your application, choose **Add an application**. When you choose **Add an application**, you are prompted to **Choose Application Type**.

    - **Resource group-based application**. When you select this option, you can choose which resource groups in this account to monitor. To use multiple applications on a component, you must use resource group-based monitoring.
    - **Account-based application**. When you select this option, you can monitor all of the resources in this account. If you want to monitor all of the resources in an account, we recommend this option over the resource group-based option because the application onboarding process is faster.

    > **Note**
    >
    > You can't combine resource group-based monitoring with account-based monitoring using Application Insights. In order to change the application type, you must delete all of the applications that are being monitored, and **Choose Application Type**.

    When you add your first application for monitoring, CloudWatch Application Insights creates a service-linked role in your account, which gives Application Insights permissions to call other Amazon services on your behalf. For more information about the service-linked role created in your account by Application Insights, see Using service-linked roles for CloudWatch Application Insights.
3. Resource-based application monitoring

    1. **Select an application or resource group.** On the **Specify application details** page, select the Amazon resource group that contains your application resources from the

dropdown list. These resources include front-end servers, load balancers, auto scaling groups, and database servers.

If you have not created a resource group for your application, you can create one by choosing **Create new resource group**. For more information about creating resource groups, see the *Amazon Resource Groups User Guide*.

2. **Notifications for problem insights.** To view and get notified when problems are detected for selected applications, choose Amazon SNS notifications or Systems Manager OpsCenter Opsitems.

   a. **Set up Amazon SNS notification (Recommended).** Choose **Select existing topic** or **Create new topic**.

   b. **Integrate with Amazon Systems Manager OpsCenter.** Under **Advanced Settings**, select the **Generate Systems Manager OpsCenter OpsItems for remedial actions** check box. To track the operations that are taken to resolve operational work items (OpsItems) that are related to your Amazon resources, provide the Amazon SNS topic ARN.

3. **Monitor CloudWatch Events**. Select the check box to integrate Application Insights monitoring with CloudWatch Events to get insights from Amazon EBS, Amazon EC2, Amazon CodeDeploy, Amazon ECS, Amazon Health APIs And Notifications, Amazon RDS, Amazon S3, and Amazon Step Functions.

4. **Tags — optional**. CloudWatch Application Insights supports both tag-based and CloudFormation-based resource groups (with the exception of Auto Scaling groups). For more information, see Working with Tag Editor.

5. Choose **Next**.

   An ARN is generated for the application in the following format.

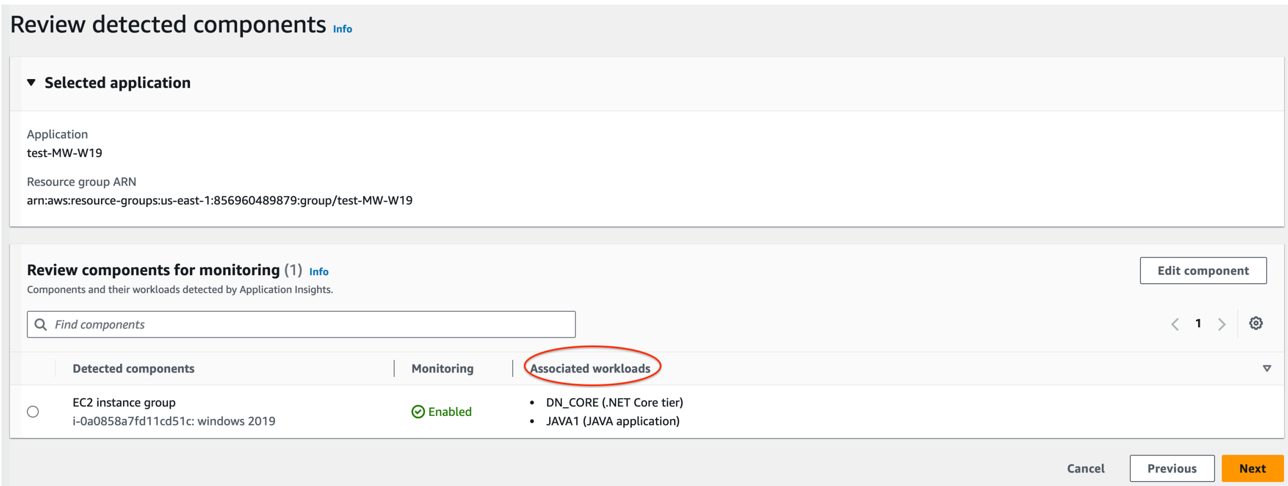
```
arn:partition:applicationinsights:region:account-id:application/resource-group/resource-group-name
```

   Example

```
arn-cn:aws:applicationinsights:cn-north-1:123456789012:application/resource-group/my-resource-group
```

6. On the **Review detected components** page, under **Review components for monitoring**, the table lists the detected components and their associated detected workloads.

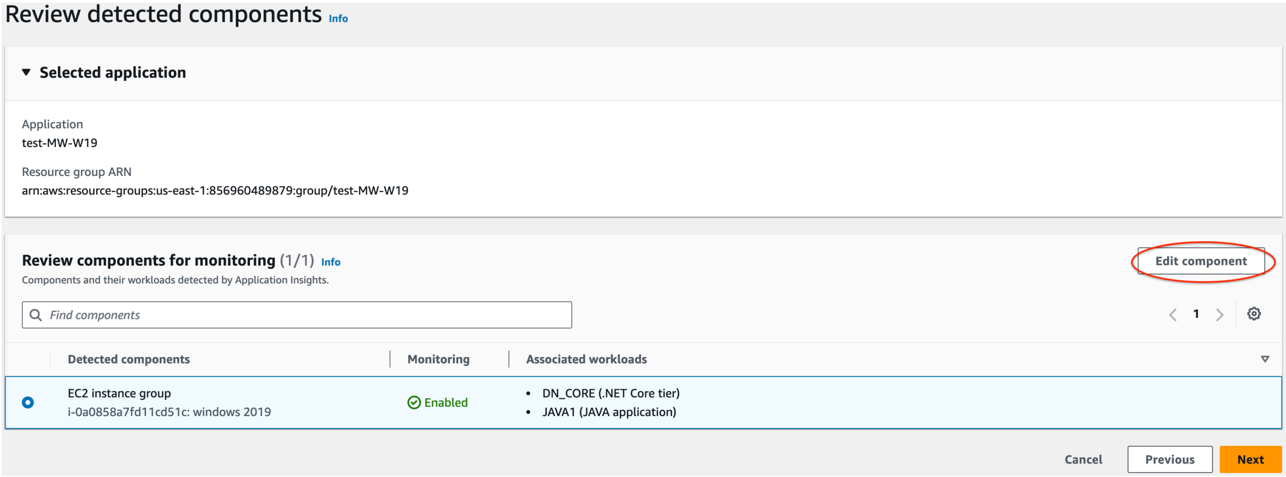
> **Note**
>
> For components that support multiple customized workloads, you can monitor up to five workloads for each component. These workloads will be monitored separately from the component.



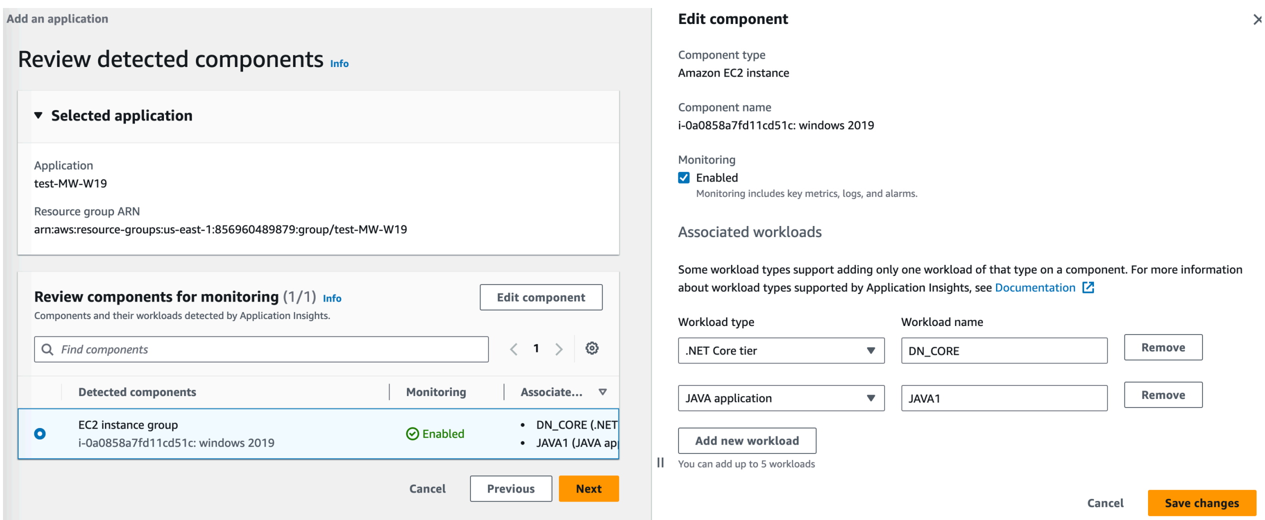
Under **Associated workloads**, there are several possible messages that appear if a workload is not listed.

- **Couldn't detect workloads** – An issue occurred when trying to detect workloads. Make sure that you have completed the Prerequisites to configure an application for monitoring. If you need to add workloads, choose **Edit component**.
- **No workloads detected** – We didn't detect any workloads. You may need to add workloads. To do so, choose **Edit component**.
- **Not applicable** – The component doesn't support customized workloads and will be monitored with default metrics, alarms, and logs. You can't add workloads to these components.

7. To edit a component, select a component, and then choose **Edit component**. A side panel opens with workloads detected on the component. In this panel, you can edit the component details and add new workloads.

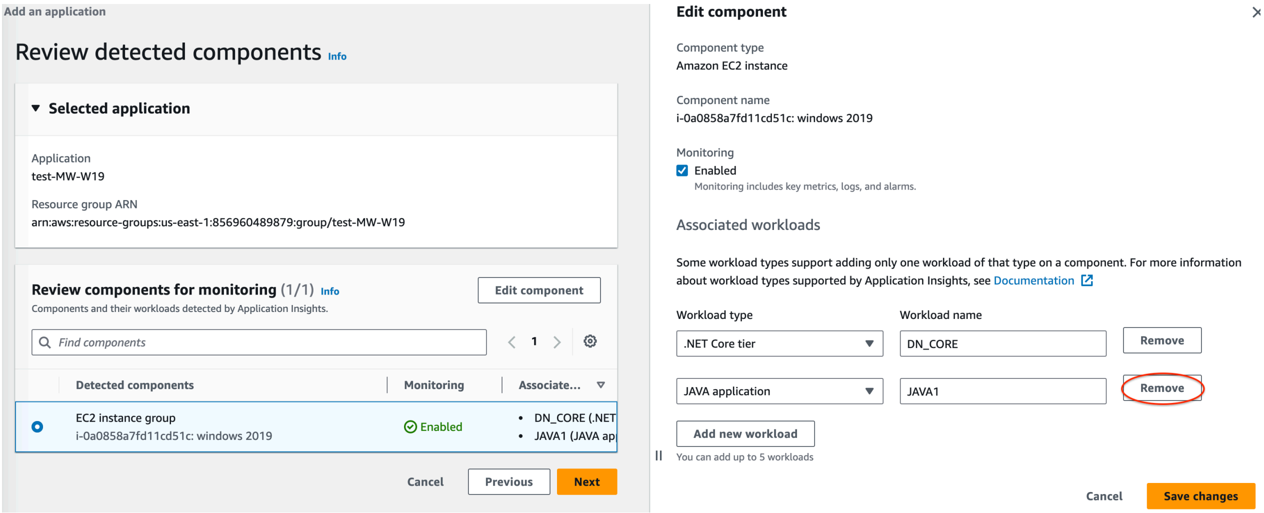


- To edit the workload type or name, use the dropdown list.

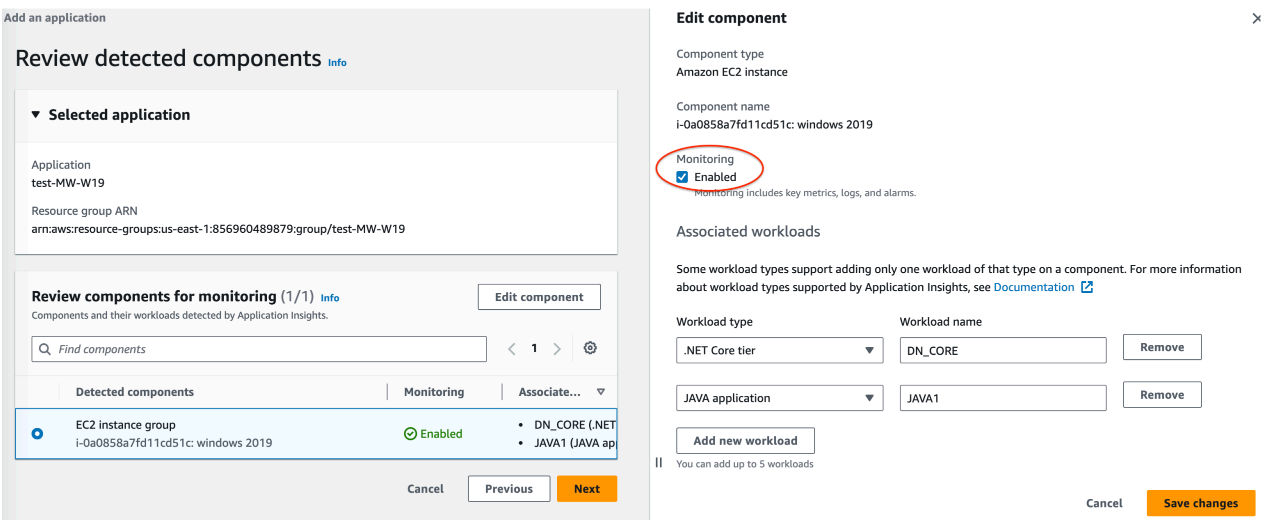


- To add a workload to the component, choose **Add new workload**.

  - If **Add new workload** doesn't appear, this component doesn't support multiple workloads.
  - If the **Associated workloads** heading doesn't appear, this component doesn't support customized workloads.
- To remove a workload, choose **Remove** next to the workload that you want to remove from monitoring.



- To disable monitoring for the entire component, clear the **Monitoring** check box.



- When you are done editing the component, choose **Save changes** in the lower right corner. Any changes to workloads for a component are visible on the **Review components for monitoring** table under **Associated workloads**.

8. On the **Review detected components** page, choose **Next**.
9. The **Specify component details** page includes all components with customizable associated workloads from the previous step.

> **Note**
>
> If a component header has an *optional* tag, additional details for the workloads in that component are optional.

If a component doesn't appear on this page, the component doesn't have any additional details that can be specified in this step.

10. Choose **Next**.

11. On the **Review and submit** page, review all monitored component and workload details.

12. Choose **Submit**.

Account-based application monitoring

1. **Application name**. Enter a name for your account-based application.
2. **Automated monitoring of new resources**. By default, Application Insights uses recommended settings to configure monitoring for resource components that are added to your account after you onboard the application. You can exclude monitoring for resources added after onboarding your application by clearing the check box.
3. **Monitor CloudWatch Events**. Select the check box to integrate Application Insights monitoring with CloudWatch Events to get insights from Amazon EBS, Amazon EC2, Amazon CodeDeploy, Amazon ECS, Amazon Health APIs And Notifications, Amazon RDS, Amazon S3, and Amazon Step Functions.
4. **Integrate with Amazon Systems Manager OpsCenter.** To view and get notified when problems are detected for selected applications, select the **Generate Systems Manager OpsCenter OpsItems for remedial actions** check box. To track the operations that are taken to resolve operational work items (OpsItems) that are related to your Amazon resources, provide the SNS topic ARN.
5. **Tags — optional**. CloudWatch Application Insights supports both tag-based and CloudFormation-based resource groups (with the exception of Auto Scaling groups). For more information, see [Working with Tag Editor](#).
6. **Discovered resources**. All of the resources discovered in your account are added to this list. If Application Insights is unable to discover all of the resources in your account,

an error message appears at the top of the page. This message includes a link to the documentation for how to add the required permissions.

7. Choose **Next**.

   An ARN is generated for the application in the following format.

   ```
   arn:partition:applicationinsights:region:account-id:application/
   TBD/application-name
   ```

   Example

   ```
   arn-cn:aws:applicationinsights:cn-north-1:123456789012:application/TBD/my-
   application
   ```

4. After you submit your application monitoring configuration, you will be taken to the details page for the application, where you can view the **Application summary**, the list of **Monitored components** and **Unmonitored components**, and, by selecting the tabs next to **Components**, the **Configuration history**, **Log patterns**, and any **Tags** that you have applied.

   To view insights for the application, choose **View Insights**.

   You can update your selections for CloudWatch Events monitoring and integration with Amazon Systems Manager OpsCenter by choosing **Edit**.

   Under **Components**, you can select the **Actions** menu to Create, Modify, or Ungroup an instance group.

   You can manage monitoring for components, including application tier, log groups, event logs, metrics, and custom alarms, by selecting the bullet next to a component and choosing **Manage monitoring**.

Enable Application Insights for Amazon ECS and Amazon EKS resource monitoring

You can enable Application Insights to monitor containerized applications and microservices from the Container Insights console. Application Insights supports monitoring for the following resources:

- Amazon ECS clusters
- Amazon ECS services

- Amazon ECS tasks
- Amazon EKS clusters

When Application Insights is enabled, it provides recommended metrics and logs, detects potential problems, generates CloudWatch Events, and creates automatic dashboards for your containerized applications and microservices.

You can enable Application Insights for containerized resources from the Container Insights or Application Insights consoles.

Enable Application Insights from the Container Insights console

From the Container Insights console, on the Container Insights **Performance monitoring** dashboard, choose **Auto-configure Application Insights**. When Application Insights is enabled, it displays details about detected problems.

Enable Application Insights from the Application Insights console

When ECS clusters appear in the component list, Application Insights automatically enables additional container monitoring with Container Insights.

For EKS clusters, you can enable additional monitoring with Container Insights to provide diagnostics information, such as container restart failures, to help you isolate and resolve problems. Additional steps are required to set up Container Insights for EKS. For information, see Setting up Container Insights on Amazon EKS and Kubernetes for steps to set up Container Insights on EKS.

Additional monitoring for EKS with Container Insights is supported on Linux instances with EKS.

For more information about Container Insights support for ECS and EKS clusters, see Container Insights.

Disable monitoring for an application component

To disable monitoring for an application component, from the application details page, select the component for which you want to disable monitoring. Choose **Actions**, and then **Remove from monitoring**.

Delete an application

To delete an application, from the CloudWatch dashboard, on the left navigation pane, choose **Application Insights** under **Insights**. Select the application that you want to delete. Under **Actions**, choose **Delete application**. This deletes monitoring and deletes all of the saved monitors for application components. The application resources are not deleted.

Set up, configure, and manage your application for monitoring using the command line

This section provides steps for setting up, configuring, and managing your application for monitoring using the Amazon CLI and Amazon Tools for Windows PowerShell.

Command line procedures

- Add and manage an application
- Manage and update monitoring
- Configure monitoring for SQL Always On Availability Groups
- Configure monitoring for MySQL RDS
- Configure monitoring for MySQL EC2
- Configure monitoring for PostgreSQL RDS
- Configure monitoring for PostgreSQL EC2
- Configure monitoring for Oracle RDS
- Configure monitoring for Oracle EC2

Add and manage an application

You can add, get information about, manage, and configure your Application Insights application using the command line.

Topics

- Add an application
- Describe an application
- List components in an application
- Describe a component
- Group similar resources into a custom component
- Ungroup a custom component
- Update an application

- Update a custom component

Add an application

Add an application using the Amazon CLI

To use the Amazon CLI to add an application for your resource group called `my-resource-group`, with OpsCenter enabled to deliver the created opsItem to the SNS topic ARN `arn-cn:aws:sns:cn-north-1:123456789012:MyTopic`, use the following command.

```
aws application-insights create-application --resource-group-name my-resource-group --ops-center-enabled --ops-item-sns-topic-arn arn-cn:aws:sns:cn-north-1:123456789012:MyTopic
```

Add an application using Amazon Tools for Windows PowerShell

To use Amazon Tools for Windows PowerShell to add an application for your resource group called `my-resource-group` with OpsCenter enabled to deliver the created opsItem to the SNS topic ARN `arn:aws:sns:cn-north-1:123456789012:MyTopic`, use the following command.

```
New-CWAIApplication -ResourceGroupName my-resource-group -OpsCenterEnabled true -OpsItemSNSTopicArn arn-cn:aws:sns:cn-north-1:123456789012:MyTopic
```

Describe an application

Describe an application using the Amazon CLI

To use the Amazon CLI to describe an application created on a resource group called `my-resource-group`, use the following command.

```
aws application-insights describe-application --resource-group-name my-resource-group
```

Describe an application using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to describe an application created on a resource group called `my-resource-group`, use the following command.

```
Get-CWAIApplication -ResourceGroupName my-resource-group
```

List components in an application

List components in an application using the Amazon CLI

To use the Amazon CLI to list the components created on a resource group called `my-resource-group`, use the following command.

```
aws application-insights list-components --resource-group-name my-resource-group
```

List components in an application using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to list the components created on a resource group called `my-resource-group`, use the following command.

```
Get-CWAIComponentList -ResourceGroupName my-resource-group
```

Describe a component

Describe a component using the Amazon CLI

You can use the following Amazon CLI command to describe a component called `my-component` that belongs to an application created on a resource group called `my-resource-group`.

```
aws application-insights describe-component --resource-group-name my-resource-group --
component-name my-component
```

Describe a component using Amazon Tools for Windows PowerShell

You can use the following Amazon Tools for Windows PowerShell command to describe a component called `my-component` that belongs to an application created on a resource group called `my-resource-group`.

```
Get-CWAIComponent -ComponentName my-component -ResourceGroupName my-resource-group
```

Group similar resources into a custom component

We recommend grouping similar resources, such as .NET web server instances, into custom components for easier onboarding and better monitoring and insights. Currently, CloudWatch Application Insights supports custom groups for EC2 instances.

To group resources into a custom component using the Amazon CLI

To use the Amazon CLI to group three instances (`arn-cn:aws:ec2:cn-north-1:123456789012:instance/i-11111`, `arn-cn:aws:ec2:cn-north-1:123456789012:instance/i-22222`, and `arn-cn:aws:ec2:cn-north-1:123456789012:instance/i-33333`) together into a custom component called `my-component` for an application created for the resource group called `my-resource-group`, use the following command.

```
aws application-insights create-component --resource-group-name my-resource-group --component-name my-component --resource-list arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-11111 arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-22222 arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-33333
```

To group resources into a custom component using Amazon Tools for Windows PowerShell

To use Amazon Tools for Windows PowerShell to group three instances (`arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-11111`, `arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-22222`, and `arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-33333`) together into a custom component called `my-component`, for an application created for the resource group called `my-resource-group`, use the following command.

```
New-CWAIComponent -ResourceGroupName my-resource-group -ComponentName my-component -ResourceList arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-11111,arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-22222,arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-33333
```

Ungroup a custom component

To ungroup a custom component using the Amazon CLI

To use the Amazon CLI to ungroup a custom component named `my-component` in an application created on the resource group, `my-resource-group`, use the following command.

```
aws application-insights delete-component --resource-group-name my-resource-group --component-name my-new-component
```

To ungroup a custom component using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to ungroup a custom component named `my-component` in an application created on the resource group, `my-resource-group`, use the following command.

```
Remove-CWAIComponent -ComponentName my-component -ResourceGroupName my-resource-group
```

Update an application

Update an application using the Amazon CLI

You can use the Amazon CLI to update an application to generate Amazon Systems Manager OpsCenter OpsItems for problems detected with the application, and to associate the created OpsItems to the SNS topic `arn:aws-cn:sns:cn-north-1:123456789012:MyTopic`, using the following command.

```
aws application-insights update-application --resource-group-name my-resource-group --ops-center-enabled --ops-item-sns-topic-arn arn:aws-cn:sns:cn-north-1:123456789012:MyTopic
```

Update an application using Amazon Tools for Windows PowerShell

You can use the Amazon Tools for Windows PowerShell to update an application to generate Amazon SSM OpsCenter OpsItems for problems detected with the application, and to associate the created OpsItems to the SNS topic , using the following command.

```
Update-CWAIApplication -ResourceGroupName my-resource-group -OpsCenterEnabled true -OpsItemSNSTopicArn arn:aws-cn:sns:cn-north-1:123456789012:MyTopic
```

Update a custom component

Update a custom component using the Amazon CLI

You can use the Amazon CLI to update a custom component called `my-component` with a new component name, `my-new-component`, and an updated group of instances, by using the following command.

```
aws application-insights update-component --resource-group-name my-resource-group
 --component-name my-component --new-component-name my-new-component --resource-list arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-44444 arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-55555
```

Update a custom component using Amazon Tools for Windows PowerShell

You can use the Amazon Tools for Windows PowerShell to update a custom component called `my-component` with a new component name, `my-new-component`, and an updated group of instances, by using the following command.

```
Update-CWAIComponent -ComponentName my-component -NewComponentName my-new-component -ResourceGroupName my-resource-group -ResourceList arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-44444,arn:aws-cn:ec2:cn-north-1:123456789012:instance/i-55555
```

Manage and update monitoring

You can manage and update monitoring for your Application Insights application using the command line.

Topics

- List problems with your application
- Describe an application problem
- Describe the anomalies or errors associated with a problem
- Describe an anomaly or error with the application
- Describe the monitoring configurations of a component
- Describe the recommended monitoring configuration of a component
- Update the monitoring configurations for a component
- Remove a specified resource group from Application Insights monitoring

List problems with your application

List problems with your application using the Amazon CLI

To use the Amazon CLI to list problems with your application detected between 1,000 and 10,000 milliseconds since Unix Epoch for an application created on a resource group called `my-resource-group`, use the following command.

```
aws application-insights list-problems --resource-group-name my-resource-group --start-time 1000 --end-time 10000
```

List problems with your application using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to list problems with your application detected between 1,000 and 10,000 milliseconds since Unix Epoch for an application created on a resource group called `my-resource-group`, use the following command.

```
$startDate = "8/6/2019 3:33:00"
$endDate = "8/6/2019 3:34:00"
Get-CWAIProblemList -ResourceGroupName my-resource-group -StartTime $startDate -
EndTime $endDate
```

Describe an application problem

Describe an application problem using the Amazon CLI

To use the Amazon CLI to describe a problem with problem id `p-1234567890`, use the following command.

```
aws application-insights describe-problem —problem-id p-1234567890
```

Describe an application problem using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to describe a problem with problem id `p-1234567890`, use the following command.

```
Get-CWAIProblem -ProblemId p-1234567890
```

Describe the anomalies or errors associated with a problem

Describe the anomalies or errors associated with a problem using the Amazon CLI

To use the Amazon CLI to describe the anomalies or errors associated with a problem with problem id `p-1234567890`, use the following command.

```
aws application-insights describe-problem-observations --problem-id -1234567890
```

Describe the anomalies or errors associated with a problem using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to describe the anomalies or errors associated with a problem with problem id `p-1234567890`, use the following command.

```
Get-CWAIProblemObservation -ProblemId p-1234567890
```

Describe an anomaly or error with the application

Describe an anomaly or error with the application using the Amazon CLI

To use the Amazon CLI to describe an anomaly or error with the application with the observation id `o-1234567890`, use the following command.

```
aws application-insights describe-observation —observation-id o-1234567890
```

Describe an anomaly or error with the application using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to describe an anomaly or error with the application with the observation id `o-1234567890`, use the following command.

```
Get-CWAIObservation -ObservationId o-1234567890
```

Describe the monitoring configurations of a component

Describe the monitoring configurations of a component using the Amazon CLI

To use the Amazon CLI to describe the monitoring configuration of a component called `my-component` in an application created on the resource group `my-resource-group`, use the following command.

```
aws application-insights describe-component-configuration —resource-group-name my-resource-group —component-name my-component
```

Describe the monitoring configurations of a component using Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to describe the monitoring configuration of a component called `my-component`, in an application created on the resource group `my-resource-group`, use the following command.

```
Get-CWAIComponentConfiguration -ComponentName my-component -ResourceGroupName my-resource-group
```

For more information about component configuration and for example JSON files, see Work with component configurations.

Describe the recommended monitoring configuration of a component

Describe the recommended monitoring configuration of a component using the Amazon CLI

When the component is part of a .NET Worker application, you can use the Amazon CLI to describe the recommended monitoring configuration of a component called `my-component` in an application created on the resource group `my-resource-group`, by using the following command.

```
aws application-insights describe-component-configuration-recommendation --resource-group-name my-resource-group --component-name my-component --tier DOT_NET_WORKER
```

Describe the recommended monitoring configuration of a component using Amazon Tools for Windows PowerShell

When the component is part of a .NET Worker application, you can use the Amazon Tools for Windows PowerShell to describe the recommended monitoring configuration of a component called `my-component` in an application created on the resource group `my-resource-group`, by using the following command.

```
Get-CWAIComponentConfigurationRecommendation -ComponentName my-component -ResourceGroupName my-resource-group -Tier DOT_NET_WORKER
```

For more information about component configuration and for example JSON files, see Work with component configurations.

Update the monitoring configurations for a component

Update the monitoring configurations for a component using the Amazon CLI

To use the Amazon CLI to update the component called `my-component` in an application created on the resource group called `my-resource-group`, use the following command. The command includes these actions:

1. Enable monitoring for the component.
2. Set the tier of the component to `.NET Worker`.
3. Update the JSON configuration of the component to read from the local file `configuration.txt`.

```
aws application-insights update-component-configuration --resource-group-name my-
resource-group --component-name my-component --tier DOT_NET_WORKER --monitor --
component-configuration "file://configuration.txt"
```

Update the monitoring configurations for a component using the Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to update the component called `my-component` in an application created on the resource group called `my-resource-group`, use the following command. The command includes these actions:

1. Enable monitoring for the component.
2. Set the tier of the component to `.NET Worker`.
3. Update the JSON configuration of the component to read from the local file `configuration.txt`.

```
[string]$config = Get-Content -Path configuration.txt
Update-CWAIComponentConfiguration -ComponentName my-component -ResourceGroupName my-
resource-group -Tier DOT_NET_WORKER -Monitor 1 -ComponentConfiguration $config
```

For more information about component configuration and for example JSON files, see Work with component configurations.

Remove a specified resource group from Application Insights monitoring

Remove a specified resource group from Application Insights monitoring using the Amazon CLI

To use the Amazon CLI to remove an application created on the resource group called `my-resource-group` from monitoring, use the following command.

```
aws application-insights delete-application --resource-group-name my-resource-group
```

Remove a specified resource group from Application Insights monitoring using the Amazon Tools for Windows PowerShell

To use the Amazon Tools for Windows PowerShell to remove an application created on the resource group called `my-resource-group` from monitoring, use the following command.

```
Remove-CWAIApplication -ResourceGroupName my-resource-group
```

Configure monitoring for SQL Always On Availability Groups

1. Create an application for the resource group with the SQL HA EC2 instances.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. Define the EC2 instances that represent the SQL HA cluster by creating a new application component.

```
aws application-insights create-component --resource-group-name
 "<RESOURCE_GROUP_NAME>" --component-name SQL_HA_CLUSTER --resource-list
 "arn:aws-cn:ec2:<REGION>:<ACCOUNT_ID>:instance/<CLUSTER_INSTANCE_1_ID>" "arn:aws-
cn:ec2:<REGION>:<ACCOUNT_ID>:instance/<CLUSTER_INSTANCE_2_ID>
```

3. Configure the SQL HA component.

```
aws application-insights  update-component-configuration --resource-group-name
 "<RESOURCE_GROUP_NAME>" --region <REGION> --component-name "SQL_HA_CLUSTER" --
monitor --tier SQL_SERVER_ALWAYSON_AVAILABILITY_GROUP --monitor  --component-
configuration '{
  "subComponents" : [ {
    "subComponentType" : "AWS::EC2::Instance",
    "alarmMetrics" : [ {
      "alarmMetricName" : "CPUUtilization",
      "monitor" : true
    }, {

        "monitor" : true
      } ]
    } ]
}'
```

> **Note**
>
> Application Insights must ingest Application Event logs (information level) to detect cluster activities such as failover.

Configure monitoring for MySQL RDS

1. Create an application for the resource group with the RDS MySQL database instance.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. The error log is enabled by default. The slow query log can be enabled using data parameter groups. For more information, see Accessing the MySQL Slow Query and General Logs.

   • `set slow_query_log = 1`

- set log_output = FILE

3. Export the logs to be monitored to CloudWatch logs. For more information, see Publishing MySQL Logs to CloudWatch Logs.
4. Configure the MySQL RDS component.

```
aws application-insights  update-component-configuration --resource-group-name
 "<RESOURCE_GROUP_NAME>" --region <REGION> --component-name "<DB_COMPONENT_NAME>"
 --monitor --tier DEFAULT --monitor  --component-configuration "{\"alarmMetrics\":
[{\"alarmMetricName\":\"CPUUtilization\",\"monitor\":true}],\"logs\":[{\"logType\":
\"MYSQL\",\"monitor\":true},{\"logType\": \"MYSQL_SLOW_QUERY\",\"monitor\":false}]}"
```

Configure monitoring for MySQL EC2

1. Create an application for the resource group with the SQL HA EC2 instances.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. The error log is enabled by default. The slow query log can be enabled using data parameter groups. For more information, see Accessing the MySQL Slow Query and General Logs.
   - set slow_query_log = 1
   - set log_output = FILE
3. Configure the MySQL EC2 component.

```
aws application-insights  update-component-configuration --resource-group-name
 "<RESOURCE_GROUP_NAME>" --region <REGION> --component-name "<DB_COMPONENT_NAME>"
 --monitor --tier MYSQL --monitor  --component-configuration "{\"alarmMetrics\":
[{\"alarmMetricName\":\"CPUUtilization\",\"monitor\":true}],\"logs\":[{\"logGroupName
\":\"<UNIQUE_LOG_GROUP_NAME>\",\"logPath\":\"C:\\\\ProgramData\\\\MySQL\\\\MySQL
 Server **\\\\Data\\\\<FILE_NAME>.err\",\"logType\":\"MYSQL\",\"monitor\":true,
\"encoding\":\"utf-8\"}]}"
```

Configure monitoring for PostgreSQL RDS

1. Create an application for the resource group with the PostgreSQL RDS database instance.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. Publishing PostgreSQL logs to CloudWatch is not enabled by default. To enable monitoring, open the RDS console and select the database to monitor. Choose **Modify** in the upper right corner, and select the check box labeled **PostgreSQL** log. Choose **Continue** to save this setting.
3. Your PostgreSQL logs are exported to CloudWatch.
4. Configure the PostgreSQL RDS component.

```
aws application-insights update-component-configuration --region <REGION> --resource-
group-name <RESOURCE_GROUP_NAME> --component-name <DB_COMPONENT_NAME> --monitor --
tier DEFAULT --component-configuration
"{
   \"alarmMetrics\":[
      {
         \"alarmMetricName\": \"CPUUtilization\",
         \"monitor\": true
      }
   ],
   \"logs\":[
      {
         \"logType\": \"POSTGRESQL\",
         \"monitor\": true
      }
   ]
}"
```

Configure monitoring for PostgreSQL EC2

1. Create an application for the resource group with the PostgreSQL EC2 instance.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. Configure the PostgreSQL EC2 component.

```
aws application-insights update-component-configuration --region <REGION> --resource-
group-name <RESOURCE_GROUP_NAME> --component-name <DB_COMPONENT_NAME> --monitor --
tier POSTGRESQL --component-configuration
```

```
"{
   \"alarmMetrics\":[
      {
         \"alarmMetricName\":\"CPUUtilization\",
         \"monitor\":true
      }
   ],
   \"logs\":[
      {
         \"logGroupName\":\"<UNIQUE_LOG_GROUP_NAME>\",
         \"logPath\":\"/var/lib/pgsql/data/log/\",
         \"logType\":\"POSTGRESQL\",
         \"monitor\":true,
         \"encoding\":\"utf-8\"
      }
   ]
}"
```

Configure monitoring for Oracle RDS

1. Create an application for the resource group with the Oracle RDS database instance.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. Publishing Oracle logs to CloudWatch is not enabled by default. To enable monitoring, open the RDS console and select the database to monitor. Choose **Modify** in the upper right corner, and select the check boxes labeled **Alert** log and **Listener** log. Choose **Continue** to save this setting.
3. Your Oracle logs are exported to CloudWatch.
4. Configure the Oracle RDS component.

```
aws application-insights update-component-configuration --region <REGION> --resource-
group-name <RESOURCE_GROUP_NAME> --component-name <DB_COMPONENT_NAME> --monitor --
tier DEFAULT --component-configuration
"{
   \"alarmMetrics\":[
      {
         \"alarmMetricName\": \"CPUUtilization\",
         \"monitor\": true
      }
   ],
```

```
   \"logs\":[
      {
         \"logType\": \"ORACLE_ALERT\",
         \"monitor\": true
      },
      {
         \"logType\": \"ORACLE_LISTENER\",
         \"monitor\": true
      }
   ]
}"
```

Configure monitoring for Oracle EC2

1. Create an application for the resource group with the Oracle EC2 instance.

```
aws application-insights create-application --region <REGION> --resource-group-name
  <RESOURCE_GROUP_NAME>
```

2. Configure the Oracle EC2 component.

```
aws application-insights update-component-configuration --region <REGION> --resource-
group-name <RESOURCE_GROUP_NAME> --component-name <DB_COMPONENT_NAME> --monitor --
tier ORACLE --component-configuration
"{
   \"alarmMetrics\":[
      {
         \"alarmMetricName\":\"CPUUtilization\",
         \"monitor\":true
      }
   ],
   \"logs\":[
      {
         \"logGroupName\":\"<UNIQUE_LOG_GROUP_NAME>\",
         \"logPath\":\"/opt/oracle/diag/rdbms/*/*/trace\",
         \"logType\":\"ORACLE_ALERT\",
         \"monitor\":true,
      },
      {
         \"logGroupName\":\"<UNIQUE_LOG_GROUP_NAME>\",
         \"logPath\":\"/opt/oracle/diag/tnslsnr/$HOSTNAME/listener/trace/\",
         \"logType\":\"ORACLE_ALERT\",
```

```
            \"monitor\":true,
        }
    ]
}"
```

Application Insights CloudWatch Events for detected problems

For each application that is added to CloudWatch Application Insights, a CloudWatch event is published for the following events on a best effort basis:

- **Problem creation.** Emitted when CloudWatch Application Insights detects a new problem.
  - Detail Type: **"Application Insights Problem Detected"**
  - Detail:
    - `problemId`: The detected problem ID.
    - `region`: The Amazon Region where the problem was created.
    - `resourceGroupName`: The Resource Group for the registered application for which the problem was detected.
    - `status`: The status of the problem. Possible status and definitions are as follows:
      - `In progress`: A new problem has been identified. The problem is still receiving observations.
      - `Recovering`: The problem is stabilizing. You can manually resolve the problem when it is in this state.
      - `Resolved`: The problem is resolved. There are no new observations about this problem.
      - `Recurring`: The problem was resolved within the past 24 hours. It has reopened as a result of additional observations.
    - `severity`: The severity of the problem.
    - `problemUrl`: The console URL for the problem.

- **Problem update.** Emitted when the problem is updated with a new observation or when an existing observation is updated and the problem is subsequently updated; updates include a resolution or closure of the problem.
  - Detail Type: **"Application Insights Problem Updated"**
  - Detail:
    - `problemId`: The created problem ID.

- `region`: The Amazon Region where the problem was created.
- `resourceGroupName`: The Resource Group for the registered application for which the problem was detected.
- `status`: The status of the problem.
- `severity`: The severity of the problem.
- `problemUrl`: The console URL for the problem.

Receive notifications for detected problems

You can use Amazon SNS notifications, Systems Manager OpsCenter, or CloudWatch Events to receive notifications about problems that are detected in your applications.

CloudWatch Application Insights Amazon SNS notifications for detected problems

You can configure Amazon SNS notifications using the Amazon Web Services Management Console or the Amazon CLI. To set up notifications using the Amazon Web Services Management Console, you must have the necessary Amazon SNS permissions as shown in the following example.

```
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "sns:ListTopics",
          "sns:Subscribe",
          "sns:CreateTopic"
        ],
        "Resource": [
          "*"
        ]
      }
    ]
}
```

After you set up Amazon SNS notifications, you receive email notifications when a problem is created or resolved. You also receive notifications when a new observation is added to an existing problem.

The following example shows the content of an email notification.

```
    You are receiving this email because Problem "p-1234567" has been CREATED by Amazon
 CloudWatch Application Insights

    Problem Details:
    Problem URL: https:////console.aws.amazon.com/cloudwatch/home?region=us-
east-1#settings:AppInsightsSettings/problemDetails?problemId=p-1234567
    Problem Summary: Title of the problem
    Severity: HIGH
    Insights: Something specific is broken
    Status : RESOLVED
    AffectedResource: arn:aws:ec2:us-east-1:555555555555:host/testResource
    Region: us-east-1
    RecurringCount: 0

      StopTime: 2024-08-15T22:12:46.007Z
```

How to receive problem notifications using Systems Manager

Actions through Amazon Systems Manager. CloudWatch Application Insights provides built-in integration with Systems Manager OpsCenter. If you choose to use this integration for your application, an OpsItem is created on the OpsCenter console for every problem detected with the application. From the OpsCenter console, you can view summarized information about the problem detected by CloudWatch Application Insights and pick a Systems Manager Automation runbook to take remedial actions or further identify Windows processes that are causing resource issues in your application.

How to receive problem notifications using CloudWatch Events

From the CloudWatch console, select **Rules** under **Events** in the left navigation pane. From the **Rules** page, select **Create rule**. Choose **Amazon CloudWatch Application Insights** from the

Service Name dropdown list and choose the **Event Type**. Then, choose **Add target** and select the target and parameters, for example, an **SNS topic** or **Lambda function**.

Application Insights cross-account observability

With CloudWatch Application Insights cross-account observability, you can monitor and troubleshoot your applications that span multiple Amazon accounts within a single Region.

You can use Amazon CloudWatch Observability Access Manager to set up one or more of your Amazon accounts as a monitoring account. You'll provide the monitoring account with the ability to view data in your source account by creating a sink in your monitoring account. You use the sink to create a link from your source account to your monitoring account. For more information, see CloudWatch cross-account observability.

Required resources

For proper functionality of CloudWatch Application Insights cross-account observability, ensure that the following telemetry types are shared through the CloudWatch Observability Access Manager.

- Applications in CloudWatch Application Insights
- Metrics in Amazon CloudWatch
- Log groups in Amazon CloudWatch Logs
- Traces in Amazon X-Ray

Work with component configurations

A component configuration is a text file in JSON format that describes the configuration settings of the component. This section provides an example template fragment, descriptions of component configuration sections, and example component configurations.

Topics

Component configuration template fragment

The following example shows a template fragment in JSON format.

```
{
  "alarmMetrics" : [
    list of alarm metrics
  ],
  "logs" : [
    list of logs
  ],
  "processes" : [
   list of processes
  ],
  "windowsEvents" : [
    list of windows events channels configurations
  ],
  "alarms" : [
    list of CloudWatch alarms
  ],
  "jmxPrometheusExporter": {
    JMX Prometheus Exporter configuration
  },
  "hanaPrometheusExporter": {
      SAP HANA Prometheus Exporter configuration
  },
  "haClusterPrometheusExporter": {
      HA Cluster Prometheus Exporter configuration
  },
  "netWeaverPrometheusExporter": {
      SAP NetWeaver Prometheus Exporter configuration
  },
  "subComponents" : [
    {
      "subComponentType" : "AWS::EC2::Instance" ...
      component nested instances configuration
    },
    {
      "subComponentType" : "AWS::EC2::Volume" ...
      component nested volumes configuration
    }
  ]
}
```

Component configuration sections

A component configuration includes several major sections. Sections in a component configuration can be listed in any order.

- **alarmMetrics (optional)**

  A list of metrics to monitor for the component. All component types can have an alarmMetrics section.
- **logs (optional)**

  A list of logs to monitor for the component. Only EC2 instances can have a logs section.
- **processes (optional)**

  A list of processes to monitor for the component. Only EC2 instances can have a processes section.
- **subComponents (optional)**

  Nested instance and volume subComponent configuration for the component. The following types of components can have nested instances and a subComponents section: ELB, ASG, custom-grouped EC2 instances , and EC2 instances.
- **alarms (optional)**

  A list of alarms to monitor for the component. All component types can have an alarm section.
- **windowsEvents (optional)**

  A list of windows events to monitor for the component. Only Windows on EC2 instances have a `windowsEvents` section.
- **JMXPrometheusExporter (optional)**

  JMXPrometheus Exporter configuration.
- **hanaPrometheusExporter (optional)**

  SAP HANA Prometheus Exporter configuration.
- **haClusterPrometheusExporter (optional)**

  HA Cluster Prometheus Exporter configuration.
- **netWeaverPrometheusExporter (optional)**

SAP NetWeaver Prometheus Exporter configuration.

- **sapAsePrometheusExporter (optional)**

  SAP ASE Prometheus Exporter configuration.

The following example shows the syntax for the **subComponents section fragment** in JSON format.

```
[
  {
    "subComponentType" : "AWS::EC2::Instance",
    "alarmMetrics" : [
      list of alarm metrics
    ],
    "logs" : [
      list of logs
    ],
    "processes": [
      list of processes
    ],
    "windowsEvents" : [
      list of windows events channels configurations
    ]
  },
  {
    "subComponentType" : "AWS::EC2::Volume",
    "alarmMetrics" : [
      list of alarm metrics
    ]
  }
]
```

Component configuration section properties

This section describes the properties of each component configuration section.

Sections

- Metric
- Log
- Process

- JMX Prometheus Exporter
- HANA Prometheus Exporter
- HA Cluster Prometheus Exporter
- NetWeaver Prometheus Exporter
- SAP ASE Prometheus Exporter
- Windows Events
- Alarm

Metric

Defines a metric to be monitored for the component.

JSON

```
{
  "alarmMetricName" : "monitoredMetricName",
  "monitor" : true/false
}
```

Properties

- **alarmMetricName (required)**

  The name of the metric to be monitored for the component. For metrics supported by Application Insights, see Logs and metrics supported by Amazon CloudWatch Application Insights.
- **monitor (optional)**

  Boolean to indicate whether to monitor the metric. The default value is `true`.

Log

Defines a log to be monitored for the component.

JSON

```
{
  "logGroupName" : "logGroupName",
  "logPath" : "logPath",
```

```
  "logType" : "logType",
  "encoding" : "encodingType",
  "monitor" : true/false
}
```

Properties

- **logGroupName (required)**

  The CloudWatch log group name to be associated to the monitored log. For the log group name constraints, see CreateLogGroup.

- **logPath (required for EC2 instance components; not required for components that do not use CloudWatch Agent, such as Amazon Lambda)**

  The path of the logs to be monitored. The log path must be an absolute Windows system file path. For more information, see CloudWatch Agent Configuration File: Logs Section.

- **logType (required)**

  The log type decides the log patterns against which Application Insights analyzes the log. The log type is selected from the following:

  - SQL_SERVER
  - MYSQL
  - MYSQL_SLOW_QUERY
  - POSTGRESQL
  - ORACLE_ALERT
  - ORACLE_LISTENER
  - IIS
  - APPLICATION
  - WINDOWS_EVENTS
  - WINDOWS_EVENTS_ACTIVE_DIRECTORY
  - WINDOWS_EVENTS_DNS
  - WINDOWS_EVENTS_IIS
  - WINDOWS_EVENTS_SHAREPOINT
  - SQL_SERVER_ALWAYSON_AVAILABILITY_GROUP
  - SQL_SERVER_FAILOVER_CLUSTER_INSTANCE

  - DEFAULT
  - CUSTOM
  - STEP_FUNCTION
  - API_GATEWAY_ACCESS
  - API_GATEWAY_EXECUTION
  - SAP_HANA_LOGS
  - SAP_HANA_TRACE
  - SAP_HANA_HIGH_AVAILABILITY
  - SAP_NETWEAVER_DEV_TRACE_LOGS
  - PACEMAKER_HIGH_AVAILABILITY
- **encoding (optional)**

  The type of encoding of the logs to be monitored. The specified encoding should be included in the list of CloudWatch agent supported encodings. If not provided, CloudWatch Application Insights uses the default encoding of type utf-8, except for:

  - SQL_SERVER: utf-16 encoding
  - IIS: ascii encoding
- **monitor (optional)**

  Boolean that indicates whether to monitor the logs. The default value is `true`.

Process

Defines a process to be monitored for the component.

JSON

```
{
  "processName" : "monitoredProcessName",
  "alarmMetrics" : [
      list of alarm metrics
  ]
}
```

Properties

- **processName (required)**

  The name of the process to be monitored for the component. The process name must not contain a process stem, such as `sqlservr` or `sqlservr.exe`.

- **alarmMetrics (required)**

  A list of metrics to monitor for this process. To view process metrics supported by CloudWatch Application Insights, see Amazon Elastic Compute Cloud (EC2).

JMX Prometheus Exporter

Defines the JMX Prometheus Exporter settings.

JSON

```
"JMXPrometheusExporter": {
  "jmxURL" : "JMX URL",
  "hostPort" : "The host and port",
  "prometheusPort" : "Target port to emit Prometheus metrics"
}
```

Properties

- **jmxURL (optional)**

  A complete JMX URL to connect to.

- **hostPort (optional)**

  The host and port to connect to through remote JMX. Only one of `jmxURL` and `hostPort` can be specified.

- **prometheusPort (optional)**

  The target port to send Prometheus metrics to. If not specified, the default port 9404 is used.

HANA Prometheus Exporter

Defines the HANA Prometheus Exporter settings.

JSON

```
"hanaPrometheusExporter": {
    "hanaSid": "SAP HANA  SID",
    "hanaPort": "HANA database port",
    "hanaSecretName": "HANA secret name",
    "prometheusPort": "Target port to emit Prometheus metrics"
}
```

Properties

- **hanaSid**

  The three-character SAP system ID (SID) of the SAP HANA system.

- **hanaPort**

  The HANA database port by which the exporter will query HANA metrics.

- **hanaSecretName**

  The Amazon Secrets Manager secret that stores HANA monitoring user credentials. The HANA Prometheus exporter uses these credentials to connect to the database and query HANA metrics.

- **prometheusPort (optional)**

  The target port to which Prometheus sends metrics. If not specified, the default port 9668 is used.

HA Cluster Prometheus Exporter

Defines the HA Cluster Prometheus Exporter settings.

JSON

```
"haClusterPrometheusExporter": {
    "prometheusPort": "Target port to emit Prometheus metrics"
}
```

Properties

- **prometheusPort (optional)**

  The target port to which Prometheus sends metrics. If not specified, the default port 9664 is used.

NetWeaver Prometheus Exporter

Defines the NetWeaver Prometheus Exporter settings.

JSON

```
"netWeaverPrometheusExporter": {
    "sapSid": "SAP NetWeaver  SID",
    "instanceNumbers": [ "Array of instance Numbers of SAP NetWeaver system "],
"prometheusPort": "Target port to emit Prometheus metrics"
}
```

Properties

- **sapSid**

  The 3 character SAP system ID (SID) of the SAP NetWeaver system.

- **instanceNumbers**

  Array of the instance Numbers of SAP NetWeaver system.

  Example: `"instanceNumbers": [ "00", "01"]`

- **prometheusPort (optional)**

  The target port to which to send Prometheus metrics. If not specified, the default port `9680` is used.

SAP ASE Prometheus Exporter

Defines the SAP ASE Prometheus Exporter settings.

JSON

```
"sapASEPrometheusExporter": {
    "sapAseSid": "SAP ASE SID",
    "sapAsePort": "SAP ASE database port",
    "sapAseSecretName": "SAP ASE secret name",
    "prometheusPort": "Target port to emit Prometheus metrics",
    "agreeToEnableASEMonitoring": true
}
```

Properties

- **sapAseSid**

  The three-character SAP system ID (SID) of the SAP ASE system.
- **sapAsePort**

  The SAP ASE database port by which the exporter will query ASE metrics.
- **sapAseSecretName**

  The Amazon Secrets Manager secret that stores ASE monitoring user credentials. The SAP ASE Prometheus exporter uses these credentials to connect to the database and query ASE metrics.
- **prometheusPort (optional)**

  The target port to which Prometheus sends metrics. If not specified, the default port 9399 is used. If there is another ASE DB that is using the default port, then we use 9499.

Windows Events

Defines Windows Events to log.

JSON

```
{
  "logGroupName" : "logGroupName",
  "eventName" : "eventName",
  "eventLevels" : ["ERROR","WARNING","CRITICAL","INFORMATION","VERBOSE"],
  "monitor" : true/false
}
```

Properties

- **logGroupName (required)**

  The CloudWatch log group name to be associated to the monitored log. For the log group name constraints, see CreateLogGroup.
- **eventName (required)**

The type of Windows Events to log. It is equivalent to the Windows Event log channel name. For example, System, Security, CustomEventName, etc. This field is required for each type of Windows event to log.

- **eventLevels (required)**

  The levels of event to log. You must specify each level to log. Possible values include `INFORMATION`, `WARNING`, `ERROR`, `CRITICAL`, and `VERBOSE`. This field is required for each type of Windows Event to log.

- **monitor (optional)**

  Boolean that indicates whether to monitor the logs. The default value is `true`.

Alarm

Defines a CloudWatch alarm to be monitored for the component.

JSON

```
{
  "alarmName" : "monitoredAlarmName",
  "severity" : HIGH/MEDIUM/LOW
}
```

Properties

- **alarmName (required)**

  The name of the CloudWatch alarm to be monitored for the component.

- **severity (optional)**

  Indicates the degree of outage when the alarm goes off.

Component configuration examples

The following examples show component configurations in JSON format for relevant services.

Example component configurations

- Amazon DynamoDB table

- Amazon EC2 Auto Scaling (ASG)
- Amazon EKS cluster
- Amazon Elastic Compute Cloud (EC2) instance
- Amazon Elastic Container Service (Amazon ECS)
- Amazon ECS services
- Amazon ECS tasks
- Amazon Elastic File System (Amazon EFS)
- Amazon FSx
- Amazon Relational Database Service (RDS) Aurora MySQL
- Amazon Relational Database Service (RDS) instance
- Amazon Route 53 health check
- Amazon Route 53 hosted zone
- Amazon Route 53 Resolver endpoint
- Amazon Route 53 Resolver query logging configuration
- Amazon S3 bucket
- Amazon Simple Queue Service (SQS)
- Amazon SNS topic
- Amazon Virtual Private Cloud (Amazon VPC)
- Amazon VPC Network Address Translation (NAT) gateways
- API Gateway REST API stages
- Application Elastic Load Balancing
- Amazon Lambda Function
- Amazon Network Firewall rule group
- Amazon Network Firewall rule group association
- Amazon Step Functions
- Customer-grouped Amazon EC2 instances
- Elastic Load Balancing
- Java
- Kubernetes on Amazon EC2
- RDS MariaDB and RDS MySQL

- RDS Oracle
- RDS PostgreSQL
- SAP ASE on Amazon EC2
- SAP ASE High Availability on Amazon EC2
- SAP HANA on Amazon EC2
- SAP HANA High Availability on Amazon EC2
- SAP NetWeaver on Amazon EC2
- SAP NetWeaver High Availability on Amazon EC2
- SQL Always On Availability Group
- SQL failover cluster instance

Amazon DynamoDB table

The following example shows a component configuration in JSON format for Amazon DynamoDB table.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "SystemErrors",
      "monitor": false
    },
    {
      "alarmMetricName": "UserErrors",
      "monitor": false
    },
    {
      "alarmMetricName": "ConsumedReadCapacityUnits",
      "monitor": false
    },
    {
      "alarmMetricName": "ConsumedWriteCapacityUnits",
      "monitor": false
    },
    {
      "alarmMetricName": "ReadThrottleEvents",
      "monitor": false
    },
    {
```

```
      "alarmMetricName": "WriteThrottleEvents",
      "monitor": false
    },
    {
      "alarmMetricName": "ConditionalCheckFailedRequests",
      "monitor": false
    },
    {
      "alarmMetricName": "TransactionConflict",
      "monitor": false
    }
  ],
  "logs": []
}
```

Amazon EC2 Auto Scaling (ASG)

The following example shows a component configuration in JSON format for Amazon EC2 Auto Scaling (ASG).

```
{
    "alarmMetrics" : [
      {
        "alarmMetricName" : "CPUCreditBalance"
      }, {
        "alarmMetricName" : "EBSIOBalance%"
      }
    ],
    "subComponents" : [
      {
        "subComponentType" : "AWS::EC2::Instance",
        "alarmMetrics" : [
          {
            "alarmMetricName" : "CPUUtilization"
          }, {
            "alarmMetricName" : "StatusCheckFailed"
          }
        ],
        "logs" : [
          {
            "logGroupName" : "my_log_group",
            "logPath" : "C:\\LogFolder\\*",
            "logType" : "APPLICATION"
```

```
          }
        ],
        "processes" : [
          {
            "processName" : "my_process",
            "alarmMetrics" : [
              {
                  "alarmMetricName" : "procstat cpu_usage",
                  "monitor" : true
              }, {
                  "alarmMetricName" : "procstat memory_rss",
                  "monitor" : true
              }
          ]
      }
  ],
        "windowsEvents" : [
          {
            "logGroupName" : "my_log_group_2",
            "eventName" : "Application",
            "eventLevels" : [ "ERROR", "WARNING", "CRITICAL" ]
          }
        ]
      }, {
        "subComponentType" : "AWS::EC2::Volume",
        "alarmMetrics" : [
          {
            "alarmMetricName" : "VolumeQueueLength"
          }, {
            "alarmMetricName" : "BurstBalance"
          }
        ]
      }
    ],
    "alarms" : [
      {
        "alarmName" : "my_asg_alarm",
        "severity" : "LOW"
      }
    ]
  }
```

Amazon EKS cluster

The following example shows a component configuration in JSON format for Amazon EKS cluster.

```
{
    "alarmMetrics":[
       {
          "alarmMetricName": "cluster_failed_node_count",
          "monitor":true
       },
       {
          "alarmMetricName": "node_cpu_reserved_capacity",
          "monitor":true
       },
       {
          "alarmMetricName": "node_cpu_utilization",
          "monitor":true
       },
       {
          "alarmMetricName": "node_filesystem_utilization",
          "monitor":true
       },
       {
          "alarmMetricName": "node_memory_reserved_capacity",
          "monitor":true
       },
       {
          "alarmMetricName": "node_memory_utilization",
          "monitor":true
       },
       {
          "alarmMetricName": "node_network_total_bytes",
          "monitor":true
       },
       {
          "alarmMetricName": "pod_cpu_reserved_capacity",
          "monitor":true
       },
       {
          "alarmMetricName": "pod_cpu_utilization",
          "monitor":true
       },
       {
          "alarmMetricName": "pod_cpu_utilization_over_pod_limit",
```

```
            "monitor":true
        },
        {
            "alarmMetricName": "pod_memory_reserved_capacity",
            "monitor":true
        },
        {
            "alarmMetricName": "pod_memory_utilization",
            "monitor":true
        },
        {
            "alarmMetricName": "pod_memory_utilization_over_pod_limit",
            "monitor":true
        },
        {
            "alarmMetricName": "pod_network_rx_bytes",
            "monitor":true
        },
        {
            "alarmMetricName": "pod_network_tx_bytes",
            "monitor":true
        }
    ],
    "logs":[
        {
            "logGroupName": "/aws/containerinsights/kubernetes/application",
            "logType":"APPLICATION",
            "monitor":true,
            "encoding":"utf-8"
        }
    ],
    "subComponents":[
        {
            "subComponentType":"AWS::EC2::Instance",
            "alarmMetrics":[
                {
                    "alarmMetricName":"CPUUtilization",
                    "monitor":true
                },
                {
                    "alarmMetricName":"StatusCheckFailed",
                    "monitor":true
                },
                {
```

```
                "alarmMetricName":"disk_used_percent",
                "monitor":true
             },
             {
                "alarmMetricName":"mem_used_percent",
                "monitor":true
             }
          ],
          "logs":[
             {

                        "monitor" : true
                    }, {
                        "alarmMetricName" : "procstat memory_rss",
                        "monitor" : true
                    }
                ]
            }
        ],
          "windowsEvents":[
             {
                "logGroupName":"my_log_group_2",
                "eventName":"Application",
                "eventLevels":[
                   "ERROR",
                   "WARNING",
                   "CRITICAL"
                ],
                "monitor":true
             }
          ]
       },
```

```
      {
         "subComponentType":"AWS::AutoScaling::AutoScalingGroup",
         "alarmMetrics":[
            {
               "alarmMetricName":"CPUCreditBalance",
               "monitor":true
            },
            {
               "alarmMetricName":"EBSIOBalance%",
               "monitor":true
            }
         ]
      },
      {
         "subComponentType":"AWS::EC2::Volume",
         "alarmMetrics":[
            {
               "alarmMetricName":"VolumeReadBytes",
               "monitor":true
            },
            {
               "alarmMetricName":"VolumeWriteBytes",
               "monitor":true
            },
            {
               "alarmMetricName":"VolumeReadOps",
               "monitor":true
            },
            {
               "alarmMetricName":"VolumeWriteOps",
               "monitor":true
            },
            {
               "alarmMetricName":"VolumeQueueLength",
               "monitor":true
            },
            {
               "alarmMetricName":"BurstBalance",
               "monitor":true
            }
         ]
      }
   ]
```

```
}
```

Note

- The `subComponents` section of `AWS::EC2::Instance`, `AWS::EC2::Volume`, and `AWS::AutoScaling::AutoScalingGroup` applies only to Amazon EKS cluster running on the EC2 launch type.
- The `windowsEvents` section of `AWS::EC2::Instance` in `subComponents` applies only to Windows running on Amazon EC2 instances.

Amazon Elastic Compute Cloud (EC2) instance

The following example shows a component configuration in JSON format for an Amazon EC2 instance.

Important

When an Amazon EC2 instance enters a `stopped` state, it is removed from monitoring. When it returns to a `running` state, it is added to the list of **Unmonitored components** on the **Application details** page of the CloudWatch Application Insights console. If automatic monitoring of new resources is enabled for the application, the instance is added to the list of **Monitored components**. However, the logs and metrics are set to the default for the workload. The previous log and metrics configuration is not saved.

```
{
    "alarmMetrics" : [
      {
        "alarmMetricName" : "CPUUtilization",
        "monitor" : true
      }, {
        "alarmMetricName" : "StatusCheckFailed"
      }
    ],
    "logs" : [
      {
        "logGroupName" : "my_log_group",
        "logPath" : "C:\\LogFolder\\*",
```

```
        "logType" : "APPLICATION",
        "monitor" : true
      },
      {
        "logGroupName" : "my_log_group_2",
        "logPath" : "C:\\LogFolder2\\*",
        "logType" : "IIS",
        "encoding" : "utf-8"
      }
    ],
    "processes" : [
        {
            "processName" : "my_process",
            "alarmMetrics" : [
                {

Amazon Elastic Container Service (Amazon ECS)

The following example shows a component configuration in JSON format for Amazon Elastic Container Service (Amazon ECS).

```
{
    "alarmMetrics":[
       {
          "alarmMetricName":"CpuUtilized",
          "monitor":true
       },
       {
          "alarmMetricName":"MemoryUtilized",
          "monitor":true
       },
       {
          "alarmMetricName":"NetworkRxBytes",
          "monitor":true
       },
       {
          "alarmMetricName":"NetworkTxBytes",
          "monitor":true
```

```
      },
      {
         "alarmMetricName":"RunningTaskCount",
         "monitor":true
      },
      {
         "alarmMetricName":"PendingTaskCount",
         "monitor":true
      },
      {
         "alarmMetricName":"StorageReadBytes",
         "monitor":true
      },

             }
          ]
       }
    ]
 }
```

> **Note**
>
> - The `subComponents` section of `AWS::EC2::Instance` and `AWS::EC2::Volume` applies only to Amazon ECS clusters with ECS service or ECS task running on the EC2 launch type.
> - The `windowsEvents` section of `AWS::EC2::Instance` in `subComponents` applies only to Windows running on Amazon EC2 instances.

Amazon ECS services

The following example shows a component configuration in JSON format for an Amazon ECS service.

```
{
    "alarmMetrics":[
       {
          "alarmMetricName":"CPUUtilization",
          "monitor":true
       },
       {
          "alarmMetricName":"MemoryUtilization",
          "monitor":true
       },
       {
          "alarmMetricName":"CpuUtilized",
```

```
            "monitor":true
         },
         {
            "alarmMetricName":"MemoryUtilized",
            "monitor":true
         },
         {
            "alarmMetricName":"NetworkRxBytes",
            "monitor":true
         },
         {
            "alarmMetricName":"NetworkTxBytes",
            "monitor":true
         },
         {
            "alarmMetricName":"RunningTaskCount",
            "monitor":true
         },
         {
            "alarmMetricName":"PendingTaskCount",
            "monitor":true
         },

              },
              {
                 "alarmMetricName":"BurstBalance",
                 "monitor":"true"
              }
           ]
        }
     ]
  }
```

Note

- The `subComponents` section of `AWS::EC2::Instance` and `AWS::EC2::Volume` applies only to Amazon ECS running on the EC2 launch type.
- The `windowsEvents` section of `AWS::EC2::Instance` in `subComponents` applies only to Windows running on Amazon EC2 instances.

Amazon ECS tasks

The following example shows a component configuration in JSON format for an Amazon ECS task.

```
{
```

```
    "logs":[
       {
          "logGroupName":"/ecs/my-task-definition",
          "logType":"APPLICATION",
          "monitor":true
       }
    ],
    "processes" : [
        {
            "processName" : "my_process",
            "alarmMetrics" : [
                {
                    "alarmMetricName" : "procstat cpu_usage",
                    "monitor" : true
                }, {
                    "alarmMetricName" : "procstat memory_rss",
                    "monitor" : true
                }
            ]
        }
    ]
 }
```

Amazon Elastic File System (Amazon EFS)

The following example shows a component configuration in JSON format for Amazon EFS.

```
{
   "alarmMetrics": [
     {
       "alarmMetricName": "BurstCreditBalance",
       "monitor": true
     },
     {
       "alarmMetricName": "PercentIOLimit",
       "monitor": true
     },
     {
       "alarmMetricName": "PermittedThroughput",
       "monitor": true
     },
     {
       "alarmMetricName": "MeteredIOBytes",
       "monitor": true
```

```
    },
    {
      "alarmMetricName": "TotalIOBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "DataWriteIOBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "DataReadIOBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "MetadataIOBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "ClientConnections",
      "monitor": true
    },
    {
      "alarmMetricName": "TimeSinceLastSync",
      "monitor": true
    },
    {
      "alarmMetricName": "Throughput",
      "monitor": true
    },
    {
      "alarmMetricName": "PercentageOfPermittedThroughputUtilization",
      "monitor": true
    },
    {
      "alarmMetricName": "ThroughputIOPS",
      "monitor": true
    },
    {
      "alarmMetricName": "PercentThroughputDataReadIOBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "PercentThroughputDataWriteIOBytes",
      "monitor": true
```

```
      },
      {
        "alarmMetricName": "PercentageOfIOPSDataReadIOBytes",
        "monitor": true
      },
      {
        "alarmMetricName": "PercentageOfIOPSDataWriteIOBytes",
        "monitor": true
      },
      {
        "alarmMetricName": "AverageDataReadIOBytesSize",
        "monitor": true
      },
      {
        "alarmMetricName": "AverageDataWriteIOBytesSize",
        "monitor": true
      }
    ],
    "logs": [
     {
     "logGroupName": "/aws/efs/utils",
     "logType": "EFS_MOUNT_STATUS",
     "monitor": true,
     }
    ]
  }
```

Amazon FSx

The following example shows a component configuration in JSON format for Amazon FSx.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "DataReadBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "DataWriteBytes",
      "monitor": true
    },
    {
      "alarmMetricName": "DataReadOperations",
      "monitor": true
```

```
    },
    {
      "alarmMetricName": "DataWriteOperations",
      "monitor": true
    },
    {
      "alarmMetricName": "MetadataOperations",
      "monitor": true
    },
    {
      "alarmMetricName": "FreeStorageCapacity",
      "monitor": true
    }
  ]
}
```

Amazon Relational Database Service (RDS) Aurora MySQL

The following example shows a component configuration in JSON format for Amazon RDS Aurora MySQL.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "CPUUtilization",
      "monitor": true
    },
    {
      "alarmMetricName": "CommitLatency",
      "monitor": true
    }
  ],
  "logs": [
    {
      "logType": "MYSQL",
      "monitor": true,
    },
    {
      "logType": "MYSQL_SLOW_QUERY",
      "monitor": false
    }
  ]
}
```

Amazon Relational Database Service (RDS) instance

The following example shows a component configuration in JSON format for an Amazon RDS instance.

```
{
  "alarmMetrics" : [
    {
      "alarmMetricName" : "BurstBalance",
      "monitor" : true
    }, {
      "alarmMetricName" : "WriteThroughput",
      "monitor" : false
    }
  ],

  "alarms" : [
    {
      "alarmName" : "my_rds_instance_alarm",
      "severity" : "MEDIUM"
    }
  ]
}
```

Amazon Route 53 health check

The following example shows a component configuration in JSON format for Amazon Route 53 health check.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "ChildHealthCheckHealthyCount",
      "monitor": true
    },
    {
      "alarmMetricName": "ConnectionTime",
      "monitor": true
    },
    {
      "alarmMetricName": "HealthCheckPercentageHealthy",
      "monitor": true
    },
```

```
    {
      "alarmMetricName": "HealthCheckStatus",
      "monitor": true
    },
    {
      "alarmMetricName": "SSLHandshakeTime",
      "monitor": true
    },
    {
      "alarmMetricName": "TimeToFirstByte",
      "monitor": true
    }
  ]
}
```

Amazon Route 53 hosted zone

The following example shows a component configuration in JSON format for Amazon Route 53 hosted zone.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "DNSQueries",
      "monitor": true
    },
    {
      "alarmMetricName": "DNSSECInternalFailure",
      "monitor": true
    },
    {
      "alarmMetricName": "DNSSECKeySigningKeysNeedingAction",
      "monitor": true
    },
    {
      "alarmMetricName": "DNSSECKeySigningKeyMaxNeedingActionAge",
      "monitor": true
    },
    {
      "alarmMetricName": "DNSSECKeySigningKeyAge",
      "monitor": true
    }
  ],
```

```
  "logs": [
    {
      "logGroupName":"/hosted-zone/logs",
      "logType": "ROUTE53_DNS_PUBLIC_QUERY_LOGS",
      "monitor": true
    }
  ]
}
```

Amazon Route 53 Resolver endpoint

The following example shows a component configuration in JSON format for Amazon Route 53 Resolver endpoint.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "EndpointHealthyENICount",
      "monitor": true
    },
    {
      "alarmMetricName": "EndpointUnHealthyENICount",
      "monitor": true
    },
    {
      "alarmMetricName": "InboundQueryVolume",
      "monitor": true
    },
    {
      "alarmMetricName": "OutboundQueryVolume",
      "monitor": true
    },
    {
      "alarmMetricName": "OutboundQueryAggregateVolume",
      "monitor": true
    }
  ]
}
```

Amazon Route 53 Resolver query logging configuration

The following example shows a component configuration in JSON format for Amazon Route 53 Resolver query logging configuration.

```
{
  "logs": [
    {
      "logGroupName": "/resolver-query-log-config/logs",
      "logType": "ROUTE53_RESOLVER_QUERY_LOGS",
      "monitor": true
    }
  ]
}
```

Amazon S3 bucket

The following example shows a component configurations in JSON format for Amazon S3 bucket.

```
{
    "alarmMetrics" : [
        {
            "alarmMetricName" : "ReplicationLatency",
            "monitor" : true
        }, {
            "alarmMetricName" : "5xxErrors",
            "monitor" : true
        }, {
            "alarmMetricName" : "BytesDownloaded"
            "monitor" : true
        }
    ]
}
```

Amazon Simple Queue Service (SQS)

The following example shows a component configuration in JSON format for Amazon Simple Queue Service.

```
{
  "alarmMetrics" : [
    {
      "alarmMetricName" : "ApproximateAgeOfOldestMessage"
    }, {
      "alarmMetricName" : "NumberOfEmptyReceives"
    }
  ],
```

```
  "alarms" : [
    {
      "alarmName" : "my_sqs_alarm",
      "severity" : "MEDIUM"
    }
  ]
}
```

Amazon SNS topic

The following example shows a component configuration in JSON format for Amazon SNS topic.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "NumberOfNotificationsFailed",
      "monitor": true
    },
    {
      "alarmMetricName": "NumberOfNotificationsFilteredOut-InvalidAttributes",
      "monitor": true
    },
    {
      "alarmMetricName": "NumberOfNotificationsFilteredOut-NoMessageAttributes",
      "monitor": true
    },
    {
      "alarmMetricName": "NumberOfNotificationsFailedToRedriveToDlq",
      "monitor": true
    }
  ]
}
```

Amazon Virtual Private Cloud (Amazon VPC)

The following example shows a component configuration in JSON format for Amazon VPC.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "NetworkAddressUsage",
      "monitor": true
    },
```

```
    {
      "alarmMetricName": "NetworkAddressUsagePeered",
      "monitor": true
    },
    {
      "alarmMetricName": "VPCFirewallQueryVolume",
      "monitor": true
    }
  ]
}
```

Amazon VPC Network Address Translation (NAT) gateways

The following example shows a component configuration in JSON format for NAT gateways.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "ErrorPortAllocation",
      "monitor": true
    },
    {
      "alarmMetricName": "IdleTimeoutCount",
      "monitor": true
    }
  ]
}
```

API Gateway REST API stages

The following example shows a component configuration in JSON format for API Gateway REST API stages.

```
{
     "alarmMetrics" : [
         {
             "alarmMetricName" : "4XXError",
             "monitor" : true
         },
         {
             "alarmMetricName" : "5XXError",
             "monitor" : true
         }
```

```
    ],
    "logs" : [
        {
            "logType" : "API_GATEWAY_EXECUTION",
            "monitor" : true
        },
        {
            "logType" : "API_GATEWAY_ACCESS",
            "monitor" : true
        }
    ]
}
```

Application Elastic Load Balancing

The following example shows a component configuration in JSON format for Application Elastic Load Balancing.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "ActiveConnectionCount",
    }, {
      "alarmMetricName": "TargetResponseTime"
    }
  ],
  "subComponents": [
    {
      "subComponentType": "AWS::EC2::Instance",
      "alarmMetrics": [
        {
          "alarmMetricName": "CPUUtilization",
        }, {
          "alarmMetricName": "StatusCheckFailed"
        }
      ],
      "logs": [
        {
          "logGroupName": "my_log_group",
          "logPath": "C:\\LogFolder\\*",
          "logType": "APPLICATION",
        }
      ],
```

```
      "windowsEvents": [
        {
          "logGroupName": "my_log_group_2",
          "eventName": "Application",
          "eventLevels": [ "ERROR", "WARNING", "CRITICAL" ]
        }
      ]
    }, {
      "subComponentType": "AWS::EC2::Volume",
      "alarmMetrics": [
        {
          "alarmMetricName": "VolumeQueueLength",
        }, {
          "alarmMetricName": "BurstBalance"
        }
      ]
    }
  ],

  "alarms": [
    {
      "alarmName": "my_alb_alarm",
      "severity": "LOW"
    }
  ]
}
```

Amazon Lambda Function

The following example shows a component configuration in JSON format for Amazon Lambda Function.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "Errors",
      "monitor": true
    },
    {
      "alarmMetricName": "Throttles",
      "monitor": true
    },
    {
```

```
      "alarmMetricName": "IteratorAge",
      "monitor": true
    },
    {
      "alarmMetricName": "Duration",
      "monitor": true
    }
  ],
  "logs": [
    {
      "logType": "DEFAULT",
      "monitor": true
    }
  ]
}
```

Amazon Network Firewall rule group

The following example shows a component configuration in JSON format for Amazon Network Firewall rule group.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "FirewallRuleGroupQueryVolume",
      "monitor": true
    }
  ]
}
```

Amazon Network Firewall rule group association

The following example shows a component configuration in JSON format for Amazon Network Firewall rule group association.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "FirewallRuleGroupQueryVolume",
      "monitor": true
    }
  ]
```

```
}
```

Amazon Step Functions

The following example shows a component configurations in JSON format for Amazon Step Functions.

```
{
  "alarmMetrics": [
    {
      "alarmMetricName": "ExecutionsFailed",
      "monitor": true
    },
    {
      "alarmMetricName": "LambdaFunctionsFailed",
      "monitor": true
    },
    {
      "alarmMetricName": "ProvisionedRefillRate",
      "monitor": true
    }
  ],
  "logs": [
    {
     "logGroupName": "/aws/states/HelloWorld-Logs",
      "logType": "STEP_FUNCTION",
      "monitor": true,
    }
  ]
}
```

Customer-grouped Amazon EC2 instances

The following example shows a component configuration in JSON format for customer-grouped Amazon EC2 instances.

```
{
    "subComponents": [
      {
        "subComponentType": "AWS::EC2::Instance",
        "alarmMetrics": [
          {
            "alarmMetricName": "CPUUtilization",
```

```
        },
        {
          "alarmMetricName": "StatusCheckFailed"
        }
      ],
      "logs": [
        {
          "logGroupName": "my_log_group",
          "logPath": "C:\\LogFolder\\*",
          "logType": "APPLICATION",
        }
      ],
      "processes": [
          {
              "processName": "my_process",
              "alarmMetrics": [
                  {
                      "alarmMetricName": "procstat cpu_usage",
                      "monitor": true
                  }, {
                      "alarmMetricName": "procstat memory_rss",
                      "monitor": true
                  }
              ]
          }
      ],
      "windowsEvents": [
        {
          "logGroupName": "my_log_group_2",
          "eventName": "Application",
          "eventLevels": [ "ERROR", "WARNING", "CRITICAL" ]
        }
      ]
    }, {
      "subComponentType": "AWS::EC2::Volume",
      "alarmMetrics": [
        {
          "alarmMetricName": "VolumeQueueLength",
        }, {
          "alarmMetricName": "BurstBalance"
        }
      ]
    }
  ],
```

```
    "alarms": [
      {
        "alarmName": "my_alarm",
        "severity": "MEDIUM"
      }
    ]
  }
```

Elastic Load Balancing

The following example shows a component configuration in JSON format for Elastic Load Balancing.

```
{
    "alarmMetrics": [
      {
        "alarmMetricName": "EstimatedALBActiveConnectionCount"
      }, {
        "alarmMetricName": "HTTPCode_Backend_5XX"
      }
    ],
    "subComponents": [
      {
        "subComponentType": "AWS::EC2::Instance",
        "alarmMetrics": [
          {
            "alarmMetricName": "CPUUtilization"
          }, {
            "alarmMetricName": "StatusCheckFailed"
          }
        ],
        "logs": [
          {
            "logGroupName": "my_log_group",
            "logPath": "C:\\LogFolder\\*",
            "logType": "APPLICATION"
          }
        ],
        "processes": [
          {
            "processName": "my_process",
            "alarmMetrics": [
                {
```

```
                "alarmMetricName": "procstat cpu_usage",
                "monitor": true
              }, {
                "alarmMetricName": "procstat memory_rss",
                "monitor": true
              }
            ]
        }
      ],
      "windowsEvents": [
        {
          "logGroupName": "my_log_group_2",
          "eventName": "Application",
          "eventLevels": [ "ERROR", "WARNING", "CRITICAL" ],
          "monitor": true
        }
      ]
    }, {
      "subComponentType": "AWS::EC2::Volume",
      "alarmMetrics": [
        {
          "alarmMetricName": "VolumeQueueLength"
        }, {
          "alarmMetricName": "BurstBalance"
        }
      ]
    }
  ],

  "alarms": [
    {
      "alarmName": "my_elb_alarm",
      "severity": "HIGH"
    }
  ]
}
```

Java

The following example shows a component configuration in JSON format for Java.

```
{
  "alarmMetrics": [ {
    "alarmMetricName": "java_lang_threading_threadcount",
```

```
      "monitor": true
    },
    {
      "alarmMetricName": "java_lang_memory_heapmemoryusage_used",
      "monitor": true
    },
    {
      "alarmMetricName": "java_lang_memory_heapmemoryusage_committed",
      "monitor": true
    }],
    "logs": [ ],
    "JMXPrometheusExporter": {
        "hostPort": "8686",
        "prometheusPort": "9404"
    }
}
```

Note

Application Insights does not support configuring authentication for Prometheus JMX exporter. For information about how to set up authentication, see the Prometheus JMX exporter example configuration.

Kubernetes on Amazon EC2

The following example shows a component configuration in JSON format for Kubernetes on Amazon EC2.

```
{
    "alarmMetrics":[
       {
          "alarmMetricName":"cluster_failed_node_count",
          "monitor":true
       },
       {
          "alarmMetricName":"node_cpu_reserved_capacity",
          "monitor":true
       },
       {
          "alarmMetricName":"node_cpu_utilization",
          "monitor":true
```

```
        },
        {
           "alarmMetricName":"node_filesystem_utilization",
           "monitor":true
        },
        {
           "alarmMetricName":"node_memory_reserved_capacity",
           "monitor":true
        },
        {
           "alarmMetricName":"node_memory_utilization",
           "monitor":true
        },
        {
           "alarmMetricName":"node_network_total_bytes",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_cpu_reserved_capacity",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_cpu_utilization",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_cpu_utilization_over_pod_limit",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_memory_reserved_capacity",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_memory_utilization",
           "monitor":true
        },
        {
           "alarmMetricName":"pod_memory_utilization_over_pod_limit",

      "monitor" : true
    } ]
  } ]
}
```

Create and configure CloudWatch Application Insights monitoring using CloudFormation templates

You can add Application Insights monitoring, including key metrics and telemetry, to your application, database, and web server, directly from Amazon CloudFormation templates.

This section provides sample Amazon CloudFormation templates in both JSON and YAML formats to help you create and configure Application Insights monitoring.

To view the Application Insights resource and property reference in the *Amazon CloudFormation User Guide*, see ApplicationInsights resource type reference.

Sample templates

- Create an Application Insights application for the entire Amazon CloudFormation stack
- Create an Application Insights application with detailed settings
- Create an Application Insights application with CUSTOM mode component configuration
- Create an Application Insights application with DEFAULT mode component configuration
- Create an Application Insights application with DEFAULT_WITH_OVERWRITE mode component configuration

Create an Application Insights application for the entire Amazon CloudFormation stack

To apply the following template, you must create Amazon resources and one or more resource groups from which to create Application Insights applications to monitor those resources. For more information, see Getting started with Amazon Resource Groups.

The first two parts of the following template specify a resource and a resource group. The last part of the template creates an Application Insights application for the resource group, but does not configure the application or apply monitoring. For more information, see the CreateApplication command details in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "Test Resource Group stack",
    "Resources": {
        "EC2Instance": {
            "Type": "AWS::EC2::Instance",
            "Properties": {
                "ImageId" : "ami-abcd1234efgh5678i",
                "SecurityGroupIds" : ["sg-abcd1234"]
            }
        },
        ...
        "ResourceGroup": {
            "Type": "AWS::ResourceGroups::Group",
            "Properties": {
                "Name": "my_resource_group"
            }
        },
        "AppInsightsApp": {
            "Type": "AWS::ApplicationInsights::Application",
            "Properties": {
                "ResourceGroupName": "my_resource_group"
            },
            "DependsOn" : "ResourceGroup"
        }
    }
}
```

Template in YAML format

```
---
AWSTemplateFormatVersion: '2010-09-09'
Description: Test Resource Group stack
Resources:
  EC2Instance:
    Type: AWS::EC2::Instance
    Properties:
      ImageId: ami-abcd1234efgh5678i
      SecurityGroupIds:
      - sg-abcd1234
  ...
  ResourceGroup:
    Type: AWS::ResourceGroups::Group
    Properties:
      Name: my_resource_group
  AppInsightsApp:
    Type: AWS::ApplicationInsights::Application
    Properties:
      ResourceGroupName: my_resource_group
    DependsOn: ResourceGroup
```

The following template section applies the default monitoring configuration to the Application Insights application. For more information, see the CreateApplication command details in the *Amazon CloudWatch Application Insights API Reference*.

When `AutoConfigurationEnabled` is set to `true`, all components of the application are configured with the recommended monitoring settings for the `DEFAULT` application tier. For more information about these settings and tiers, see DescribeComponentConfigurationRecommendation and UpdateComponentConfiguration in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "Test Application Insights Application stack",
    "Resources": {
        "AppInsightsApp": {
            "Type": "AWS::ApplicationInsights::Application",
            "Properties": {
                "ResourceGroupName": "my_resource_group",
```

```
                "AutoConfigurationEnabled": true
            }
        }
    }
}
```

Template in YAML format

```
---
AWSTemplateFormatVersion: '2010-09-09'
Description: Test Application Insights Application stack
Resources:
  AppInsightsApp:
    Type: AWS::ApplicationInsights::Application
    Properties:
      ResourceGroupName: my_resource_group
      AutoConfigurationEnabled: true
```

Create an Application Insights application with detailed settings

The following template performs these actions:

- Creates an Application Insights application with CloudWatch Events notification and OpsCenter enabled. For more information, see the CreateApplication command details in the *Amazon CloudWatch Application Insights API Reference*.
- Tags the application with two tags, one of which has no tag values. For more information, see TagResource in the *Amazon CloudWatch Application Insights API Reference*.
- Creates two custom instance group components. For more information, see CreateComponent in the *Amazon CloudWatch Application Insights API Reference*.
- Creates two log pattern sets. For more information, see CreateLogPattern in the *Amazon CloudWatch Application Insights API Reference*.
- Sets `AutoConfigurationEnabled` to `true`, which configures all components of the application with the recommended monitoring settings for the `DEFAULT` tier. For more information, see DescribeComponentConfigurationRecommendation in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
```

```
    "Type": "AWS::ApplicationInsights::Application",
    "Properties": {
        "ResourceGroupName": "my_resource_group",

Create an Application Insights application with CUSTOM mode component configuration

The following template performs these actions:

- Creates an Application Insights application. For more information, see CreateApplication in the *Amazon CloudWatch Application Insights API Reference*.
- Component `my_component` sets `ComponentConfigurationMode` to `CUSTOM`, which causes this component to be configured with the configuration specified in `CustomComponentConfiguration`. For more information, see UpdateComponentConfiguration in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
    "Type": "AWS::ApplicationInsights::Application",
    "Properties": {
        "ResourceGroupName": "my_resource_group,
        "ComponentMonitoringSettings": [
            {
                "ComponentARN": "my_component",
                "Tier": "SQL_SERVER",
                "ComponentConfigurationMode": "CUSTOM",
                "CustomComponentConfiguration": {
                    "ConfigurationDetails": {
```

```
                    "AlarmMetrics": [

          ...
          Encoding: utf-8
          PatternSet: my_pattern_set_4
        ...
```

Create an Application Insights application with DEFAULT mode component configuration

The following template performs these actions:

- Creates an Application Insights application. For more information, see CreateApplication in the *Amazon CloudWatch Application Insights API Reference*.
- Component my_component sets ComponentConfigurationMode to DEFAULT and Tier to SQL_SERVER, which causes this component to be configured with the configuration settings that Application Insights recommends for the SQL_Server tier. For more information, see DescribeComponentConfiguration and UpdateComponentConfiguration in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
    "Type": "AWS::ApplicationInsights::Application",
    "Properties": {
        "ResourceGroupName": "my_resource_group",
        "ComponentMonitoringSettings": [
            {
                "ComponentARN": "my_component",
                "Tier": "SQL_SERVER",
                "ComponentConfigurationMode": "DEFAULT"
            }
        ]
    }
}
```

Template in YAML format

```
---
Type: AWS::ApplicationInsights::Application
Properties:
  ResourceGroupName: my_resource_group
  ComponentMonitoringSettings:
  - ComponentARN: my_component
    Tier: SQL_SERVER
    ComponentConfigurationMode: DEFAULT
```

Create an Application Insights application with `DEFAULT_WITH_OVERWRITE` mode component configuration

The following template performs these actions:

- Creates an Application Insights application. For more information, see [CreateApplication](#) in the *Amazon CloudWatch Application Insights API Reference*.
- Component `my_component` sets `ComponentConfigurationMode` to `DEFAULT_WITH_OVERWRITE` and `tier` to `DOT_NET_CORE`, which causes this component to be configured with the configuration settings that Application Insights recommends for the `DOT_NET_CORE` tier. Overwritten configuration settings are specified in the `DefaultOverwriteComponentConfiguration`:
  - At the component level `AlarmMetrics` settings are overwritten.

- At the sub-component level, for the EC2_Instance type sub-components, Logs settings are overwritten.

For more information, see UpdateComponentConfiguration in the *Amazon CloudWatch Application Insights API Reference*.

Template in JSON format

```
{
    "Type": "AWS::ApplicationInsights::Application",
    "Properties": {
        "ResourceGroupName": "my_resource_group",
        "ComponentMonitoringSettings": [
            {
                "ComponentName": "my_component",
                "Tier": "DOT_NET_CORE",
                "ComponentConfigurationMode": "DEFAULT_WITH_OVERWRITE",
                "DefaultOverwriteComponentConfiguration": {
                    "ConfigurationDetails": {
                        "AlarmMetrics": [
                            {
                                "AlarmMetricName": "StatusCheckFailed"
                            }
                        ]
                    },
                    "SubComponentTypeConfigurations": [
                        {
                            "SubComponentType": "EC2_INSTANCE",
                            "SubComponentConfigurationDetails": {
                                "Logs": [
                                    {
                                        "LogGroupName": "my_log_group",
                                        "LogPath": "C:\\LogFolder\\*",
                                        "LogType": "IIS",
                                        "Encoding": "utf-8",

```

Tutorial: Set up monitoring for SAP ASE

This tutorial demonstrates how to configure CloudWatch Application Insights to set up monitoring for your SAP ASE databases. You can use CloudWatch Application Insights automatic dashboards to visualize problem details, accelerate troubleshooting, and facilitate mean time to resolution (MTTR) for your SAP ASE databases.

Application Insights for SAP ASE topics

- Supported environments
- Supported operating systems
- Features

- Prerequisites
- Set up monitoring on your SAP ASE database
- Manage monitoring of your SAP ASE database
- Configure the alarm threshold
- View and troubleshoot SAP ASE problems detected by Application Insights
- Troubleshooting Application Insights for SAP ASE

Supported environments

CloudWatch Application Insights supports the deployment of Amazon resources for the following systems and patterns. You provide and install SAP ASE database software and supported SAP application software.

- **One or more SAP ASE databases on a single Amazon EC2 instance** – SAP ASE in a single-node, scale-up architecture.
- **Cross-AZ SAP ASE database high availability setup** – SAP ASE with high availability configured across two Availability Zones using SUSE/RHEL clustering.

> **Note**
>
> CloudWatch Application Insights supports only single SAP system ID (SID) ASE HA environments. If multiple ASE HA SIDs are attached, monitoring will be set up for only the first detected SID.

Supported operating systems

CloudWatch Application Insights for SAP ASE supports x86-64 architecture on the following operating systems:

- SuSE Linux 12 SP4
- SuSE Linux 12 SP5
- SuSE Linux 15
- SuSE Linux 15 SP1

- SuSE Linux 15 SP2
- SuSE Linux 15 SP3
- SuSE Linux 15 SP4
- SuSE Linux 15 SP1 For SAP
- SuSE Linux 15 SP2 For SAP
- SuSE Linux 15 SP3 For SAP
- SuSE Linux 15 SP4 For SAP
- SuSE Linux 12 SP4 For SAP
- SuSE Linux 12 SP5 For SAP
- RedHat Linux 7.6
- RedHat Linux 7.7
- RedHat Linux 7.9
- RedHat Linux 8.1
- RedHat Linux 8.4
- RedHat Linux 8.6

Features

CloudWatch Application Insights for SAP ASE provides the following features:

- Automatic SAP ASE workload detection
- Automatic SAP ASE alarm creation based on static threshold
- Automatic SAP ASE alarm creation based on anomaly detection
- Automatic SAP ASE log pattern recognition
- Health dashboard for SAP ASE
- Problem dashboard for SAP ASE

Prerequisites

You must perform the following prerequisites to configure an SAP ASE database with CloudWatch Application Insights:

- **SAP ASE configuration parameters** – The following configuration parameters must be enabled on your ASE DB: `"enable monitoring"`, `"sql text pipe max messages"`, `"sql text pipe active"`. This allows CloudWatch Application Insights to provide full monitoring capabilities for your DB. If these settings aren't enabled on your ASE database, Application Insights will automatically enable them to collect the necessary metrics to allow monitoring.
- **SAP ASE database user** – The database user provided during Application Insights onboarding must have permission to access the following:
  - System tables in the master database and user (tenant) databases
  - Monitoring tables
- **SAPHostCtrl** – Install and set up SAPHostCtrl on your Amazon EC2 instance.
- **Amazon CloudWatch agent** – Make sure that you are not running a preexisting CloudWatch agent on your Amazon EC2 instance. If you have CloudWatch agent installed, make sure to remove the configuration of the resources you are using in CloudWatch Application Insights from the existing CloudWatch agent configuration file to avoid a merge conflict. For more information, see Manually create or edit the CloudWatch agent configuration file.
- **Amazon Systems Manager enablement** – Install SSM Agent on your instances, and enable the instances enabled for SSM. For information about how to install the SSM agent, see Working with SSM Agent in the *Amazon Systems Manager User Guide*.
- **Amazon EC2 instance roles** – You must attach the following Amazon EC2 instance roles to configure your database.
  - You must attach the `AmazonSSMManagedInstanceCore` role to enable Systems Manager. For more information, see Amazon Systems Manager identity-based policy examples.
  - You must attach the `CloudWatchAgentServerPolicy` to enable instance metrics and logs to be emitted through CloudWatch. For more information, see Create IAM roles and users for use with Amazon CloudWatch agent.
  - You must attach the following IAM inline policy to the Amazon EC2 instance role to read the password stored in Amazon Secrets Manager. For more information about inline policies, see Inline policies in the *Amazon Identity and Access Management User Guide*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
```

```
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:*:*:secret:ApplicationInsights-*"
        }
    ]
}
```

- **Amazon Resource Groups** – You must create a resource group that includes all of the associated Amazon resources used by your application stack to onboard your applications to CloudWatch Application Insights. This includes Amazon EC2 instances and Amazon EBS volumes running your SAP ASE database. If there are multiple databases per account, we recommend that you create one resource group that includes the Amazon resources for each SAP ASE database system.
- **IAM permissions** – For non-admin users:
  - You must create an Amazon Identity and Access Management (IAM) policy that allows Application Insights to create a service-linked role, and attach it to your user identity. For steps to attach the policy, see IAM policy for CloudWatch Application Insights.
  - The user must have permission to create a secret in Amazon Secrets Manager to store the database user credentials. For more information, see Example: Permission to create secrets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:CreateSecret"
      ],
      "Resource": "arn:aws:secretsmanager:*:*:secret:ApplicationInsights-*"
    }
  ]
}
```

- **Service-linked role** – Application Insights uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is created for you when you create your first Application Insights application in the Application Insights console. For more information, see Using service-linked roles for CloudWatch Application Insights.

Set up monitoring on your SAP ASE database

Use the following steps to set up monitoring for your SAP ASE database

1. Open the CloudWatch console.
2. From the left navigation pane, under **Insights**, choose **Application Insights**.
3. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application. In the upper right-hand corner, choose **Add an application**.
4. On the **Specify application details** page, from the dropdown list under **Resource group**, select the Amazon resource group that contains your SAP ASE database resources. If you haven't created a resource group for your application, you can create one by choosing **Create new resource group** under the **Resource group** dropdown. For more information about creating resource groups, see the *Amazon Resource Groups User Guide.*
5. Under **Monitor CloudWatch Events**, select the check box to integrate Application Insights monitoring with CloudWatch Events to get insights from Amazon EBS, Amazon EC2, Amazon CodeDeploy, Amazon ECS, Amazon Health APIs and notifications, Amazon RDS, Amazon S3, and Amazon Step Functions.
6. Under **Integrate with Amazon Systems Manager OpsCenter**, select the check box next to **Generate Amazon Systems Manager OpsCenter OpsItems for remedial actions** to view and get notifications when problems are detected for the selected applications. To track the operations that are performed to resolve operational work items, called OpsItems, that are related to your Amazon resources, provide an SNS topic ARN.
7. You can optionally enter tags to help you identify and organize your resources. CloudWatch Application Insights supports both tag-based and Amazon CloudFormation stack-based resource groups, with the exception of Application Auto Scaling groups. For more information, see Tag Editor in the *Amazon Resource Groups and Tags User Guide*.
8. Choose **Next** to continue to set up monitoring.
9. On the **Review detected components** page, the monitored components and their workloads automatically detected by CloudWatch Application Insights are listed.

   > **Note**
   >
   > Components that contain a detected SAP ASE High Availability workload support only one workload on a component. Components that contain a detected SAP ASE single node workload support multiple workloads, but you can't add or remove workloads. All automatically detected workloads will be monitored.

10. Choose **Next**.

11. On the **Specify component details** page, enter the username and password of your SAP ASE databases.
12. Review your application monitoring configuration, and choose **Submit**.
13. The application details page opens, where you can view the **Application summary**, the list of **Monitored components and workloads**, and **Unmonitored components and workloads**. If you select the radio button next to a component or workload, you can also view the **Configuration history**, **Log patterns**, and any **Tags** that you have created. When you submit your configuration, your account deploys all of the metrics and alarms for your SAP ASE system, which can take up to 2 hours.

Manage monitoring of your SAP ASE database

You can manage user credentials, metrics, and log paths for your SAP ASE database by performing the following steps:

1. Open the CloudWatch console.
2. From the left navigation pane, under **Insights**, choose **Application Insights**.
3. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application.
4. Under **Monitored components**, select the radio button next to the component name. Then, choose **Manage monitoring**.
5. Under **EC2 instance group logs**, you can update the existing log path, log pattern set, and log group name. In addition, you can add up to three additional **Application logs**.
6. Under **Metrics**, you can choose the SAP ASE metrics according to your requirements. SAP ASE metric names are prefixed with `asedb`. You can add up to 60 metrics per component.
7. Under **ASE configuration**, enter the username and password for the SAP ASE database. This is the username and password that Amazon CloudWatch agent uses to connect to the SAP ASE database.
8. Under **Custom alarms**, you can add additional alarms to be monitored by CloudWatch Application Insights.
9. Review your application monitoring configuration and choose **Submit**. When you submit your configuration, your account updates all of the metrics and alarms for your SAP HANA system, which can take up to 2 hours.

Configure the alarm threshold

CloudWatch Application Insights automatically creates a Amazon CloudWatch metric for the alarm to watch, along with the threshold for that metric. The alarm changes to the `ALARM` state when the metric surpasses the threshold for a specified number of evaluation periods. Note that these settings are not retained by Application Insights.

To edit an alarm for a single metric, perform the following steps:

1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/).
2. In the left navigation pane, choose **Alarms**>**All alarms**.
3. Select the radio button next to the alarm that was automatically created by CloudWatch Application Insights. Then choose **Actions**, and select **Edit** from the dropdown menu.
4. Edit the following parameters under **Metric**.

    a. Under **Statistic**, choose one of the statistics or predefined percentiles, or specify a custom percentile. For example, `p95.45`.

    b. Under **Period**, choose the evaluations period for the alarm. When you evaluate the alarm, each period is aggregated into one data point.
5. Edit the following parameters under **Conditions**.

    a. Choose whether the metric must be greater than, less than, or equal to the threshold.

    b. Specify the threshold value.
6. Under **Additional configuration** edit the following parameters.

    a. Under **Datapoints to alarm**, specify the number of data points, or evaluation periods, that must be in the `ALARM` state to initiate the alarm. When the two values match, an alarm is created that enters `ALARM` state if the designated number of consecutive periods are exceeded. To create an `m` out of `n` alarm, specify a lower value for the first data point than for the second. For more information about evaluating alarms, see Evaluating an alarm.

    b. Under **Missing data treatment**, choose the behavior of the alarm when some data points are missing. For more information about missing data treatment, see Configuring how CloudWatch alarms treat missing data.

    c. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information about percentiles with low samples, see Percentile-based CloudWatch alarms and low data samples.

7. Choose **Next**.
8. Under **Notification**, select an SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state.
9. Choose **Update alarm**.

View and troubleshoot SAP ASE problems detected by Application Insights

This section helps you resolve common troubleshooting problems that occur when you configure monitoring for SAP ASE on Application Insights.

SAP ASE Backup Server errors

You can identify the error message by checking the dynamically created dashboard. The dashboard shows the error message reported in the SAP ASE Backup Server. For more details about SAP ASE Backup Server logs, see SAP Documentation Backup Server Error Logging.

SAP ASE long running transactions

Identify the long running transaction and confirm whether it can be stopped or if the running time is intentional. For more details, see 2180410 — How to display transaction log records for long running transactions? — SAP ASE.

SAP ASE User connections

Review whether your SAP ASE database is sized accordingly for the workload you intend to run on the database. For more details, see Configuring User Connections in the SAP documentation.

SAP ASE disk space

You can identify the database layer that is causing the problem by checking the dynamically created dashboard. The dashboard shows the related metrics and log file snippets. It is important to understand the cause of the disk growth and when applicable, increase the physical disk size, the allocated disk space, or both. For more details, see SAP Documentation disk resize in the SAP documentation.

Troubleshooting Application Insights for SAP ASE

This section provides steps to help you resolve common errors returned by the Application Insights dashboard.

Error	Error returned	Root cause	Resolution
Unable to add more than 60 monitor metrics.	`Component cannot have more than 60 monitored metric`	The current metric limit is 60 monitored metrics per component.	Remove unnecessary metrics to adhere to the limit.
No SAP metrics or alarms appear after the onboarding process	The `run` command on the `AWS-ConfigureAWSPackage` failed in Amazon Systems Manager. The output shows the error: `CT-LIBRARY error:ct_connect(): protocol specific layer: external error: The attempt to connect to the server failed`	The username and password might be incorrect.	Verify that the username and password are valid, then rerun the onboarding process.

Tutorial: Set up monitoring for SAP HANA

This tutorial demonstrates how to configure CloudWatch Application Insights to set up monitoring for your SAP HANA databases. You can use CloudWatch Application Insights automatic dashboards to visualize problem details, accelerate troubleshooting, and facilitate mean time to resolution (MTTR) for your SAP HANA databases.

Application Insights for SAP HANA topics

- Supported environments

Supported environments

CloudWatch Application Insights supports the deployment of Amazon resources for the following systems and patterns. You provide and install SAP HANA database software and supported SAP application software.

- **SAP HANA database on a single Amazon EC2 instance** — SAP HANA in a single-node, scale-up architecture, with up to 24TB of memory.
- **SAP HANA database on multiple Amazon EC2 instances** — SAP HANA in a multi-node, scale-out architecture.
- **Cross-AZ SAP HANA database high availability setup** — SAP HANA with high availability configured across two Availability Zones using SUSE/RHEL clustering.

> **Note**
>
> CloudWatch Application Insights supports only single SID HANA environments. If multiple HANA SIDs are attached, monitoring will be set up for only the first detected SID.

Supported operating systems

CloudWatch Application Insights for SAP HANA supports x86-64 architecture on the following operating systems:

- SuSE Linux 12 SP4 For SAP
- SuSE Linux 12 SP5 For SAP

- SuSE Linux 15
- SuSE Linux 15 SP1
- SuSE Linux 15 SP2
- SuSE Linux 15 For SAP
- SuSE Linux 15 SP1 For SAP
- SuSE Linux 15 SP2 For SAP
- SuSE Linux 15 SP3 For SAP
- SuSE Linux 15 SP4 For SAP
- SuSE Linux 15 SP5 For SAP
- RedHat Linux 8.6 For SAP With High Availability and Update Services
- RedHat Linux 8.5 For SAP With High Availability and Update Services
- RedHat Linux 8.4 For SAP With High Availability and Update Services
- RedHat Linux 8.3 For SAP With High Availability and Update Services
- RedHat Linux 8.2 For SAP With High Availability and Update Services
- RedHat Linux 8.1 For SAP With High Availability and Update Services
- RedHat Linux 7.9 For SAP With High Availability and Update Services

Features

CloudWatch Application Insights for SAP HANA provides the following features:

- Automatic SAP HANA workload detection
- Automatic SAP HANA alarm creation based on static threshold
- Automatic SAP HANA alarm creation based on anomaly detection
- Automatic SAP HANA log pattern recognition
- Health dashboard for SAP HANA
- Problem dashboard for SAP HANA

Prerequisites

You must perform the following prerequisites to configure an SAP HANA database with CloudWatch Application Insights:

- **SAP HANA** – Install a running and reachable SAP HANA database 2.0 SPS05 on an Amazon EC2 instance.
- **SAP HANA database user** – A database user with monitoring roles must be created in the SYSTEM database and all tenants.

  Example

  The following SQL commands create a user with monitoring roles.

```
su - <sid>adm
hdbsql -u SYSTEM -p <SYSTEMDB password> -d SYSTEMDB
CREATE USER CW_HANADB_EXPORTER_USER PASSWORD <Monitoring user password> NO
 FORCE_FIRST_PASSWORD_CHANGE;
CREATE ROLE CW_HANADB_EXPORTER_ROLE;
GRANT MONITORING TO CW_HANADB_EXPORTER_ROLE;
GRANT CW_HANADB_EXPORTER_ROLE TO CW_HANADB_EXPORTER_USER;
```

- **Python 3.8** – Install Python 3.8 or later versions on your operating system. Use the latest release of Python. If Python3 is not detected on your operating system, Python 3.6 will be installed.

  For more information, see the installation example.

> **Note**
>
> Manual installation of Python 3.8 or higher is required for SuSE Linux 15 SP4, RedHat Linux 8.6, and later operating systems.

- **Pip3** – Install the installer program, pip3, on your operating system. If pip3 is not detected on your operating system, it will be installed.
- **hdbclient** – CloudWatch Application Insights uses the python driver to connect to the SAP HANA database. If the client is not installed under python3, ensure that you have hdbclient tar file version `2.10 or later` under `/hana/shared/SID/hdbclient/`.
- **Amazon CloudWatch agent** – Make sure that you are not running a preexisting CloudWatch agent on your Amazon EC2 instance. If you have CloudWatch agent installed, make sure to remove the configuration of the resources you are using in CloudWatch Application Insights from the existing CloudWatch agent configuration file to avoid a merge conflict. For more information, see Manually create or edit the CloudWatch agent configuration file.

- **Amazon Systems Manager enablement –** Install SSM Agent on your instances, and the instances must be enabled for SSM. For information about how to install the SSM Agent, see Working with SSM Agent in the *Amazon Systems Manager User Guide*.
- **Amazon EC2 instance roles –** You must attach the following Amazon EC2 instance roles to configure your database.
  - You must attach the `AmazonSSMManagedInstanceCore` role to enable Systems Manager. For more information, see Amazon Systems Manager identity-based policy examples.
  - You must attach the `CloudWatchAgentServerPolicy` to enable instance metrics and logs to be emitted through CloudWatch. For more information, see Create IAM roles and users for use with CloudWatch agent.
  - You must attach the following IAM inline policy to the Amazon EC2 instance role to read the password stored in Amazon Secrets Manager. For more information about inline policies, see Inline policies in the *Amazon Identity and Access Management User Guide*.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:*:*:secret:ApplicationInsights-*"
        }
    ]
}
```

- **Amazon resource groups –** You must create a resource group that includes all of the associated Amazon resources used by your application stack to onboard your applications to CloudWatch Application Insights. This includes Amazon EC2 instances and Amazon EBS volumes running your SAP HANA database. If there are multiple databases per account, we recommend that you create one resource group that includes the Amazon resources for each SAP HANA database system.
- **IAM permissions –** For non-admin users:
  - You must create an Amazon Identity and Access Management (IAM) policy that allows Application Insights to create a service-linked role, and attach it to your user identity. For steps to attach the policy, see IAM policy for CloudWatch Application Insights.

- The user must have permission to create a secret in Amazon Secrets Manager to store the database user credentials. For more information, see Example: Permission to create secrets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:CreateSecret"
      ],
      "Resource": "arn:aws:secretsmanager:*:*:secret:ApplicationInsights-*"
    }
  ]
}
```

- **Service-linked role** – Application Insights uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is created for you when you create your first Application Insights application in the Application Insights console. For more information, see Using service-linked roles for CloudWatch Application Insights.

Set up your SAP HANA database for monitoring

Use the following steps to set up monitoring for your SAP HANA database

1. Open the CloudWatch console.
2. From the left navigation pane, under **Insights**, choose **Application Insights**.
3. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application. In the upper right-hand corner, choose **Add an application**.
4. On the **Specify application details** page, from the dropdown list under **Resource group**, select the Amazon resource group that contains your SAP HANA database resources. If you haven't created a resource group for your application, you can create one by choosing **Create new resource group** under the **Resource group** dropdown. For more information about creating resource groups, see the *Amazon Resource Groups User Guide.*
5. Under **Monitor CloudWatch Events**, select the check box to integrate Application Insights monitoring with CloudWatch Events to get insights from Amazon EBS, Amazon EC2, Amazon

CodeDeploy, Amazon ECS, Amazon Health APIs and notifications, Amazon RDS, Amazon S3, and Amazon Step Functions.

6. Under **Integrate with Amazon Systems Manager OpsCenter**, select the check box next to **Generate Amazon Systems Manager OpsCenter OpsItems for remedial actions** to view and get notifications when problems are detected for the selected applications. To track the operations that are performed to resolve operational work items, called OpsItems, that are related to your Amazon resources, provide an SNS topic ARN.

7. You can optionally enter tags to help you identify and organize your resources. CloudWatch Application Insights supports both tag-based and Amazon CloudFormation stack-based resource groups, with the exception of Application Auto Scaling groups. For more information, see Tag Editor in the *Amazon Resource Groups and Tags User Guide*.

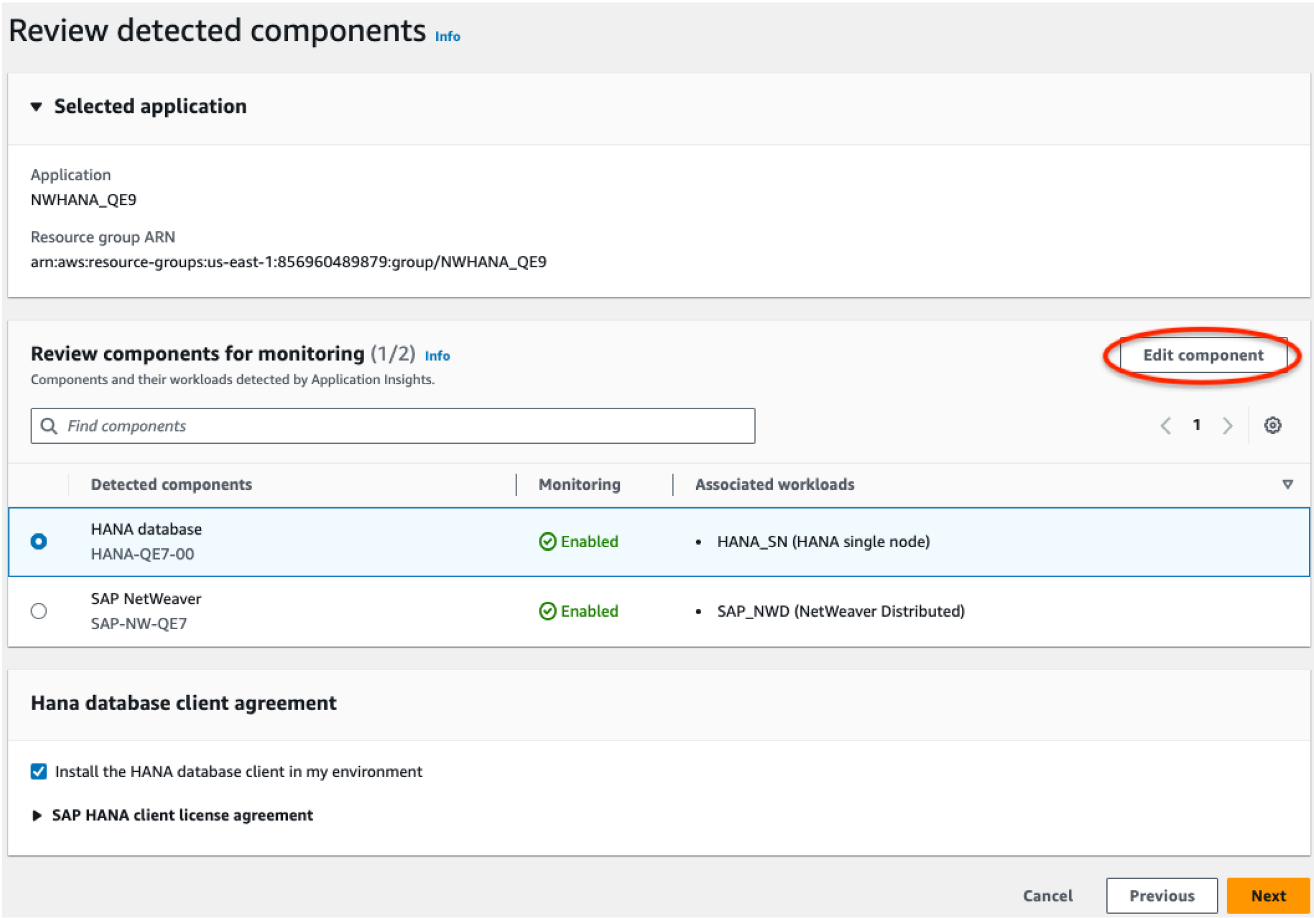
8. Choose **Next** to continue to set up monitoring.

9. On the **Review detected components** page, the monitored components and their workloads automatically detected by CloudWatch Application Insights are listed.

   a. To add workloads to a component that contains a detected SAP HANA single node workload, select the component, then choose **Edit component**.

      Note

      Components that contain a detected SAP HANA multi node or HANA High Availability workload support only one workload on a component.



b. To add a new workload, choose **Add new workload**.

   c. When you are finished editing workloads, choose **Save changes**.

10. Choose **Next**.
11. On the **Specify component details** page, enter the username and password.
12. Review your application monitoring configuration, and choose **Submit**.
13. The application details page opens, where you can view the **Application summary**, the list of **Monitored components and workloads**, and **Unmonitored components and workloads**. If you select the radio button next to a component or workload, you can also view the **Configuration history**, **Log patterns**, and any **Tags** that you have created. When you submit your configuration, your account deploys all of the metrics and alarms for your SAP HANA system, which can take up to 2 hours.

Manage monitoring of your SAP HANA database

You can manage user credentials, metrics, and log paths for your SAP HANA database by performing the following steps:

1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/).
2. From the left navigation pane, under **Insights**, choose **Application Insights**.
3. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application.
4. Under **Monitored components**, select the radio button next to the component name. Then, choose **Manage monitoring**.
5. Under **EC2 instance group logs**, you can update the existing log path, log pattern set, and log group name. In addition, you can add up to three additional **Application logs**.
6. Under **Metrics**, you can choose the SAP HANA metrics according to your requirements. SAP HANA metric names are prefixed with `hanadb`. You can add up to 40 metrics per component.
7. Under **HANA configuration**, enter the password and user name for the SAP HANA database. This is the username and password that Amazon CloudWatch agent uses to connect to the SAP HANA database.
8. Under **Custom alarms**, you can add additional alarms to be monitored by CloudWatch Application Insights.
9. Review your application monitoring configuration and choose **Submit**. When you submit your configuration, your account updates all of the metrics and alarms for your SAP HANA system, which can take up to 2 hours.

View and troubleshoot SAP HANA problems detected by CloudWatch Application Insights

The following sections provide steps to help you resolve common troubleshooting scenarios that occur when you configure monitoring for SAP HANA on Application Insights.

Troubleshooting topics

SAP HANA database reaches memory allocation limit

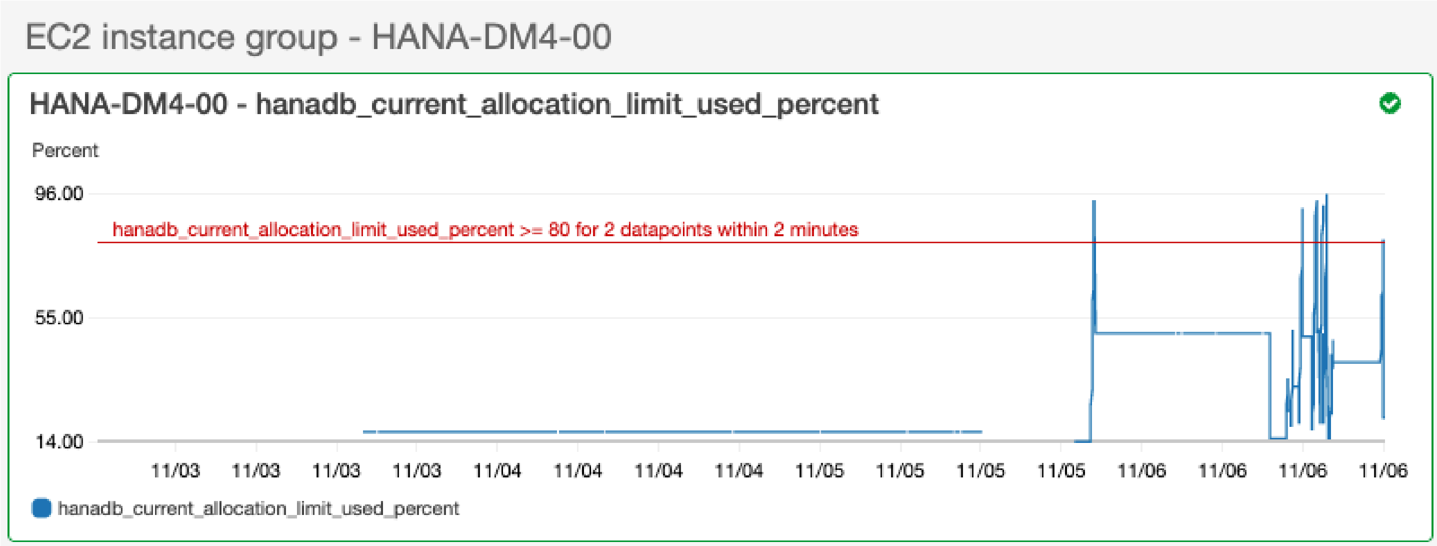
Description

Your SAP application that is backed by an SAP HANA database malfunctions because of high memory pressure, leading to application performance degradation.

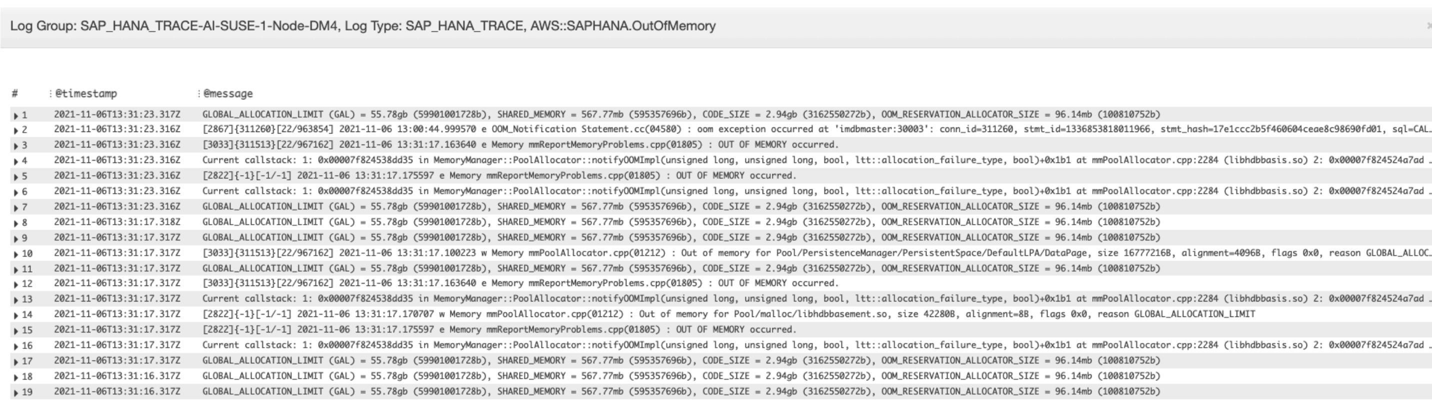
Resolution

You can identify the application layer that is causing the problem by checking the dynamically created dashboard, which shows the related metrics and log file snippets. In the following example, the problem may be because of a large data load in the SAP HANA system.

The used memory allocation exceeds the threshold of 80 percent of the total memory allocation limit.



The log group shows the scheme BNR-DATA and table IMDBMASTER_30003 ran out of memory. In addition, the log group shows the exact time of the issue, current global location limit, shared memory, code size, and OOM reservation allocation size.



Log Group: SAP_HANA_TRACE-AI-SUSE-1-Node-DM4, Log Type: SAP_HANA_TRACE, AWS::SAPHANA.OutOfMemory

#	@timestamp	@message

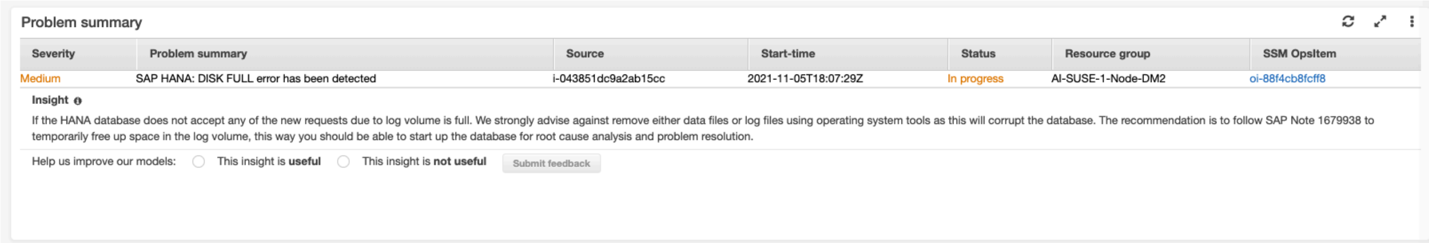
Disk full event

Description

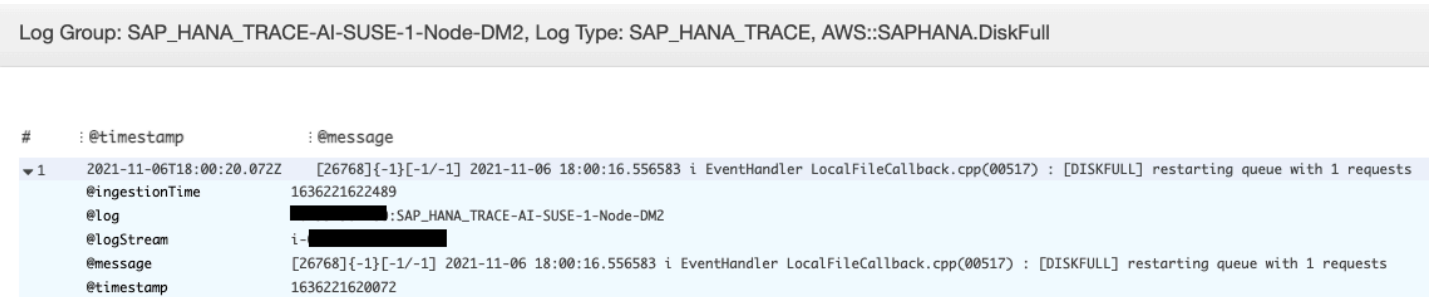
Your SAP application that is backed by an SAP HANA database stops responding, which leads to an inability to access the database.

Resolution

You can identify the database layer that is causing the problem by checking the dynamically created dashboard, which shows the related metrics and log file snippets. In the following example, the problem may be that the administrator failed to enable automatic log backup, which caused the sap/hana/log directory to fill up.



The log group widget in the problem dashboard shows the `DISKFULL` event.



SAP HANA backup stopped running

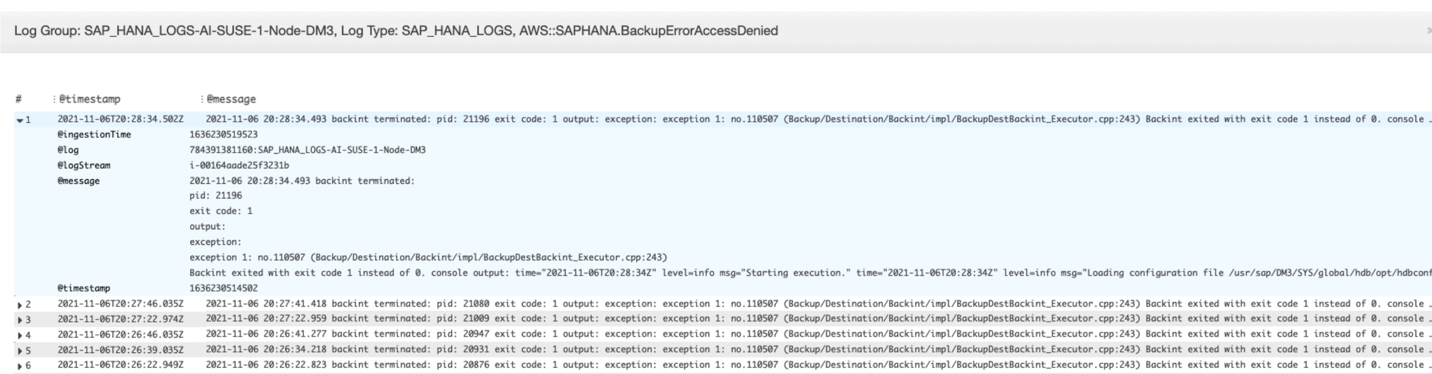
Description

Your SAP application that is backed by an SAP HANA database has stopped working.

Resolution

You can identify the database layer that is causing the problem by checking the dynamically created dashboard, which shows the related metrics and log file snippets.

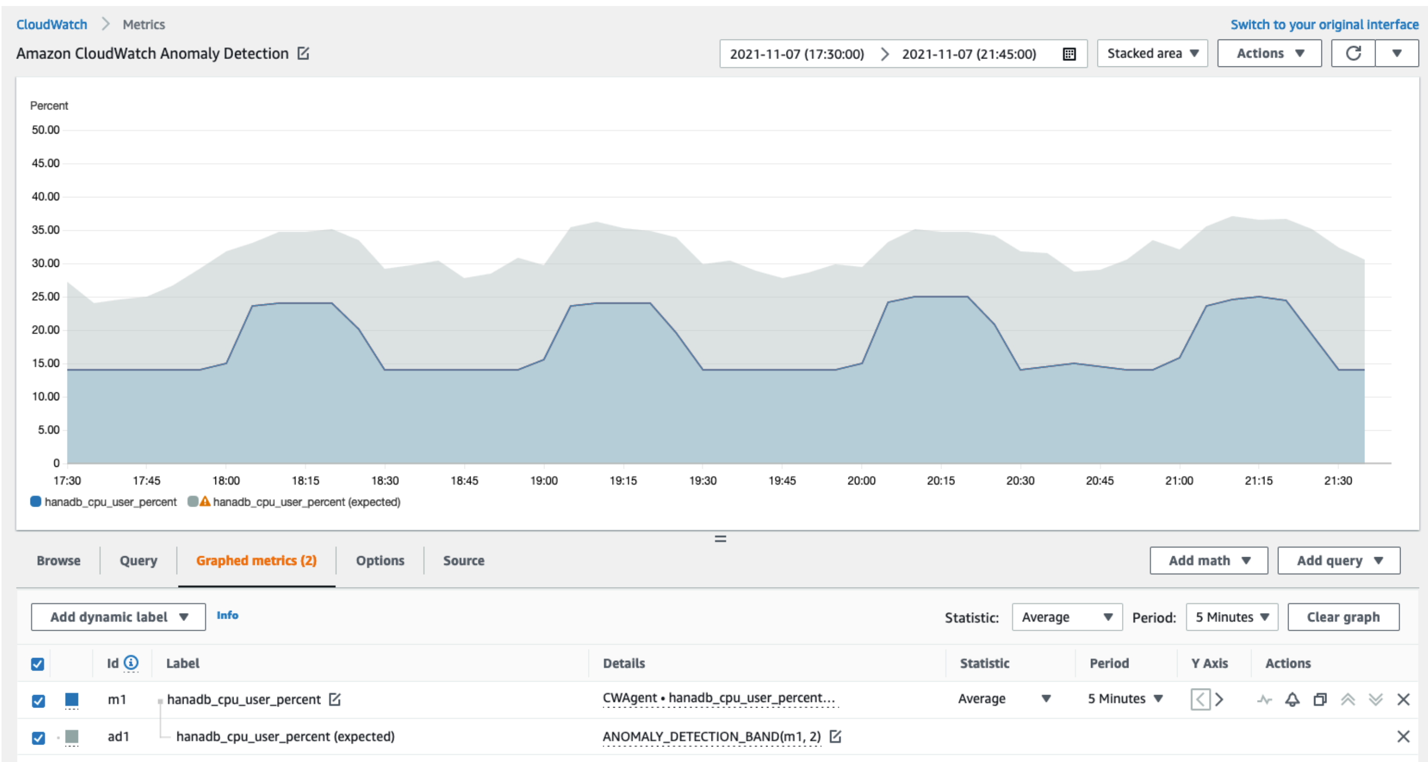
The log group widget in the problem dashboard shows the `ACCESS DENIED` event. This includes additional information, such as the S3 bucket, the S3 bucket folder, and the S3 bucket Region.



Anomaly detection for SAP HANA

For specific SAP HANA metrics, such as the number of thread count, CloudWatch applies statistical and machine learning algorithms to define the threshold. These algorithms continuously analyze the metrics of the SAP HANA database, determine normal baselines, and surface anomalies with minimal user intervention. The algorithms generate an anomaly detection model, which generates a range of expected values that represent normal metric behavior.

Anomaly detection algorithms account for the seasonality and trend changes of metrics. The seasonality changes can be hourly, daily, or weekly, as shown in the following examples of the SAP HANA CPU usage.



After you create a model, CloudWatch anomaly detection continuously evaluates the model and makes adjustments to it to ensure that is it as accurate as possible. This includes retraining the model to adjust if the metric values evolve over time or experience sudden changes. It also includes predictors to improve the models for metrics that are seasonal, spiky, or sparse.

Troubleshooting Application Insights for SAP HANA

This section provides steps to help you resolve common errors returned by the Application Insights dashboard.

Unable to add more than 60 monitored metrics

The output shows the following error.

```
Component cannot have more than 60 monitored metrics
```

Root cause – The current metric limit is 60 monitored metrics per component.

Resolution – To stay under the limit, remove metrics that are not necessary.

No SAP metrics appear after the onboarding process

Use the following information to find out why SAP metrics don't appear on the dashboard after the onboarding process. The first step is to troubleshoot why the SAP metrics don't appear using the Amazon Web Services Management Console or Exporter logs from an Amazon EC2 instance. Next, review the error output to find a resolution.

Troubleshoot why SAP metrics don't appear after onboarding

You can use the Amazon Web Services Management Console or exporter logs from an Amazon EC2 instance for troubleshooting.

Amazon Web Services Management Console

Troubleshoot no SAP metrics appear after onboarding using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the left navigation pane, choose **State Manager**.
3. Under **Associations**, check the status of the document `AWSEC2-ApplicationInsightsCloudwatchAgentInstallAndConfigure`. If the status is `Failed`, under **Execution id**, select the failed id and view the output.
4. Under **Associations**, check the status of the document `AWS-ConfigureAWSPackage`. If the status is `Failed`, under **Execution id**, select the failed id and view the output.

Exporter logs from Amazon EC2 instance

Troubleshoot no SAP metrics appear after onboarding using exporter logs

1. Connect to the Amazon EC2 instance where your SAP HANA database is running.

2. Find the correct naming convention for WORKLOAD_SHORT_NAME using the following command. You will use this short name in the following two steps.

```
sudo systemctl | grep exporter
```

> **Note**
>
> Application Insights adds a suffix, WORKLOAD_SHORT_NAME to the service name depending on the workload that is running. The short names for SAP HANA single node, multiple nodes, and high availability deployments are HANA_SN, HANA_MN, and HANA_HA.

3. To check for errors in the exporter manager service logs, run the following command replacing WORKLOAD_SHORT_NAME with the short name you found in Step 2.

```
sudo journalctl -e --unit=prometheus-
hanadb_exporter_manager_WORKLOAD_SHORT_NAME.service
```

4. If the exporter manager service logs do not show an error, check for errors in the exporter service logs by running the following command.

```
sudo journalctl -e --unit=prometheus-hanadb_exporter_WORKLOAD_SHORT_NAME.service
```

Resolving the common root causes for SAP metrics not appearing after onboarding

The following examples describe how to resolve the common root causes of SAP metrics not appearing after onboarding.

- The output shows the following error.

```
Reading json config file path: /opt/aws/amazon-cloudwatch-agent/etc/amazon-
cloudwatch-agent.d/default ...
Reading json config file path: /opt/aws/amazon-cloudwatch-agent/etc/
amazon-cloudwatch-agent.d/ssm_AmazonCloudWatch-ApplicationInsights-
SSMParameterForTESTCWEC2INSTANCEi0d88867f1f3e36285.tmp ...
2023/11/30 22:25:17 Failed to merge multiple json config files.
2023/11/30 22:25:17 Failed to merge multiple json config files.
2023/11/30 22:25:17 Under path : /metrics/append_dimensions | Error : Different
 values are specified for append_dimensions
```

```
2023/11/30 22:25:17 Under path : /metrics/metrics_collected/disk | Error : Different
 values are specified for disk
2023/11/30 22:25:17 Under path : /metrics/metrics_collected/mem | Error : Different
 values are specified for mem
2023/11/30 22:25:17 Configuration validation first phase failed. Agent version: 1.0.
 Verify the JSON input is only using features supported by this version.
```

Resolution – Application Insights is trying to configure the same metrics that are pre-configured as part of the existing CloudWatch agent configuration file. Remove the existing files under `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.d/` or remove the metrics that are causing the conflict from the existing CloudWatch agent configuration file.

- The output shows the following error.

```
Unable to find a host with system database, for more info rerun using -v
```

  Resolution – The username, password, or database port may be incorrect. Verify that the username, password, and port are valid, then re-run the onboarding process.

- The output shows the following error.

```
This hdbcli installer is not compatible with your Python interpreter
```

  Resolution – Upgrade pip3 and wheel as shown in the following example for Python 3.6.

```
python3.6 -m pip install --upgrade pip setuptools wheel
```

- The output shows the following error.

```
Unable to install hdbcli using pip3. Please try to install it
```

  Resolution – Ensure that you have followed the `hdbclient` prerequisites or install `hdbclient` manually under pip3.

- The output shows the following error.

```
Package 'boto3' requires a different Python: 3.6.15 not in '>= 3.7'
```

  Resolution – Python 3.8 or higher is required for this operating system version. Check the Python 3.8 prerequisites and install it.

- The output shows one of the following installation errors.

```
Can not execute `setup.py` since setuptools is not available in the build environment
```

or

```
[SSL: CERTIFICATE_VERIFY_FAILED]
```

Resolution – Install Python using SUSE Linux commands as shown in the following example. The following example installs the latest version of Python 3.8.

```
wget https://www.python.org/ftp/python/3.8.<LATEST_RELEASE>/
Python-3.8.<LATEST_RELEASE>.tgz
tar xf Python-3.*
cd Python-3.*/
sudo zypper install make gcc-c++ gcc automake autoconf libtool
sudo zypper install zlib-devel
sudo zypper install libopenssl-devel libffi-devel
./configure --with-ensurepip=install
sudo make
sudo make install
sudo su
python3.8 -m pip install --upgrade pip setuptools wheel
```

Tutorial: Set up monitoring for SAP NetWeaver

This tutorial demonstrates how to configure Amazon CloudWatch Application Insights to set up monitoring for SAP NetWeaver. You can use CloudWatch Application Insights automatic dashboards to visualize problem details, accelerate troubleshooting, and reduce mean time to resolution (MTTR) for your SAP NetWeaver application servers.

CloudWatch Application Insights for SAP NetWeaver topics

- Supported environments
- Supported operating systems
- Features
- Prerequisites

- Set up your SAP NetWeaver application servers for monitoring
- Manage monitoring of your SAP NetWeaver application servers
- View and troubleshoot SAP NetWeaver problems detected by CloudWatch Application Insights
- Troubleshooting Application Insights for SAP NetWeaver

Supported environments

CloudWatch Application Insights supports the deployment of Amazon resources for the following systems and patterns.

- **SAP NetWeaver Standard System Deployment.**
- **SAP NetWeaver Distributed deployments on multiple Amazon EC2 instances.**
- **Cross-AZ SAP NetWeaver high availability setup** – SAP NetWeaver with high availability configured across two Availability Zones using SUSE/RHEL clustering.

Supported operating systems

CloudWatch Application Insights for SAP NetWeaver is supported on the following operating systems:

- Oracle Linux 8
- Red Hat Enterprise Linux 7.6
- Red Hat Enterprise Linux 7.7
- Red Hat Enterprise Linux 7.9
- Red Hat Enterprise Linux 8.1
- Red Hat Enterprise Linux 8.2
- Red Hat Enterprise Linux 8.4
- Red Hat Enterprise Linux 8.6
- SUSE Linux Enterprise Server 15 for SAP
- SUSE Linux Enterprise Server 15 SP1 for SAP
- SUSE Linux Enterprise Server 15 SP2 for SAP
- SUSE Linux Enterprise Server 15 SP3 for SAP
- SUSE Linux Enterprise Server 15 SP4 for SAP

- SUSE Linux Enterprise Server 12 SP4 for SAP
- SUSE Linux Enterprise Server 12 SP5 for SAP
- SUSE Linux Enterprise Server 15 except High Availability patterns
- SUSE Linux Enterprise Server 15 SP1 except High Availability patterns
- SUSE Linux Enterprise Server 15 SP2 except High Availability patterns
- SUSE Linux Enterprise Server 15 SP3 except High Availability patterns
- SUSE Linux Enterprise Server 15 SP4 except High Availability patterns
- SUSE Linux Enterprise Server 12 SP4 except High Availability patterns
- SUSE Linux Enterprise Server 12 SP5 except High Availability patterns

Features

CloudWatch Application Insights for SAP NetWeaver 7.0x–7.5x (including ABAP Platform) provides the following features:

- Automatic SAP NetWeaver workload detection
- Automatic SAP NetWeaver alarm creation based on static thresholds
- Automatic SAP NetWeaver log pattern recognition
- Health dashboard for SAP NetWeaver
- Problem dashboard for SAP NetWeaver

Prerequisites

You must perform the following prerequisites to configure SAP NetWeaver with CloudWatch Application Insights:

- **Amazon Systems Manager enablement** – Install SSM Agent on your Amazon EC2 instances, and enable the instances for SSM. For information about how to install the SSM Agent, see [Setting up Amazon Systems Manager](#) in the *Amazon Systems Manager User Guide*.
- **Amazon EC2 instance roles** – You must attach the following Amazon EC2 instance roles to configure your SAP NetWeaver monitoring.
  - You must attach the `AmazonSSMManagedInstanceCore` role to enable Systems Manager. For more information, see [Amazon Systems Manager identity-based policy examples](#).

  - You must attach the `CloudWatchAgentServerPolicy` policy to enable instance metrics and logs to be emitted through CloudWatch. For more information, see Create IAM roles and users for use with CloudWatch agent.

- **Amazon resource groups –** You must create a resource group that includes all of the associated Amazon resources used by your application stack to onboard your applications to CloudWatch Application Insights. This includes Amazon EC2 instances, Amazon EFS, and Amazon EBS volumes running your SAP NetWeaver application servers. If there are multiple SAP NetWeaver systems per account, we recommend that you create one resource group that includes the Amazon resources for each SAP NetWeaver system. For more information about creating resource groups, see the *Amazon Resource Groups and Tags User Guide*.
- **IAM permissions –** For users who don't have administrative access, you must create an Amazon Identity and Access Management (IAM) policy that allows Application Insights to create a service-linked role and attach it to the user's identity. For more information about how to create the IAM policy, see IAM policy.
- **Service-linked role –** Application Insights uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is created for you when you create your first Application Insights application in the Application Insights console. For more information, see Using service-linked roles for CloudWatch Application Insights.
- **Amazon CloudWatch agent –** Application Insights installs and configures the CloudWatch agent. If you have CloudWatch agent installed, Application Insights retains your configuration. To avoid a merge conflict, remove the configuration of resources that you want to use in Application Insights from the existing CloudWatch agent configuration file. For more information, see Manually create or edit the CloudWatch agent configuration file.

Set up your SAP NetWeaver application servers for monitoring

Use the following steps to set up monitoring for your SAP NetWeaver application servers.

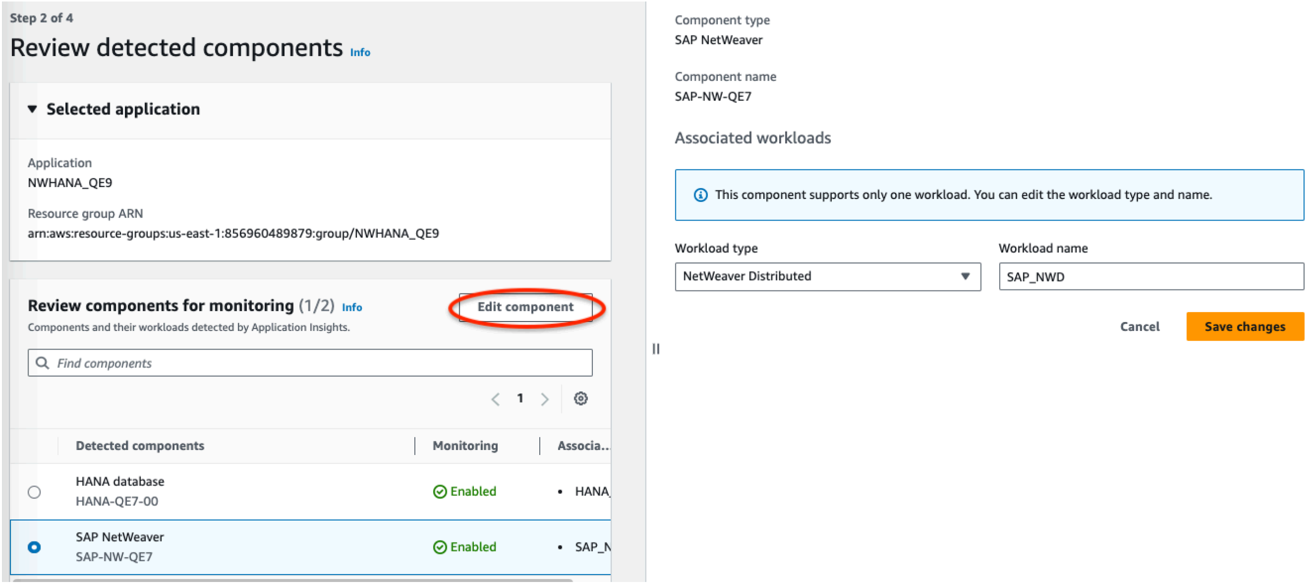
To set up monitoring

1. Open the CloudWatch console.
2. From the left navigation pane, under **Insights**, select **Application Insights**.
3. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application. In the upper right-hand corner, select **Add an application**.

4. On the **Specify application details** page, from the dropdown list under **Resource group**, select the Amazon resource group you created that contains your SAP NetWeaver resources. If you haven't created a resource group for your application, you can create one by choosing **Create new resource group** under the **Resource group** dropdown list.
5. Under **Automatic monitoring of new resources**, select the check box to allow Application Insights to automatically monitor the resources that are added to the application's resource group after onboarding.
6. Under **Monitor EventBridge events**, select the check box to integrate Application Insights monitoring with CloudWatch Events to get insights from Amazon EBS, Amazon EC2, Amazon CodeDeploy, Amazon ECS, Amazon Health APIs and notifications, Amazon RDS, Amazon S3, and Amazon Step Functions.
7. Under **Integrate with Amazon Systems Manager OpsCenter**, select the check box next to **Generate Amazon Systems Manager OpsCenter OpsItems for remedial actions** to view and get notifications when problems are detected for the selected applications. To track the operations that are performed to resolve operational work items, called OpsItems, that are related to your Amazon resources, provide an SNS topic ARN.
8. You can optionally enter tags to help you identify and organize your resources. CloudWatch Application Insights supports both tag-based and Amazon CloudFormation stack-based resource groups, with the exception of Application Auto Scaling groups. For more information, see Tag Editor in the *Amazon Resource Groups and Tags User Guide*.
9. To review detected components, choose **Next**.
10. On the **Review detected components** page, the monitored components and their workloads automatically detected by CloudWatch Application Insights are listed.

    - To edit the workload type and name, choose **Edit component**.

      > **Note**
      >
      > Components that contain a detected NetWeaver Distributed or NetWeaver High Availability workload support only one workload on a component.



11. Choose **Next**.
12. On the **Specify component details** page, choose **Next**.
13. Review your application monitoring configuration, then choose **Submit**.
14. The application details page opens, where you can view the **Application summary**, **Dashboard**, **Components**, and **Workloads**. You can also view the **Configuration history**, **Log patterns**, and any **Tags** that you have created. After you submit your application, CloudWatch Application Insights deploys all of the metrics and alarms for your SAP NetWeaver system, which can take up to an hour.

Manage monitoring of your SAP NetWeaver application servers

Use the following steps to manage monitoring of your SAP NetWeaver application servers.

To manage monitoring

1. Open the CloudWatch console.
2. From the left navigation pane, under **Insights**, select **Application Insights**.
3. Choose the **List view** tab.
4. The **Application Insights** page displays the list of applications that are monitored with Application Insights, and the monitoring status for each application.
5. Select your application.

6. Choose the **Components** tab.
7. Under **Monitored components**, select the radio button next to the component name. Then, select **Manage monitoring**.
8. Under **Instance logs**, you can update the existing log path, log pattern set, and log group name. In addition, you can add up to three additional **Application logs**.
9. Under **Metrics**, you can select the SAP NetWeaver metrics according to your requirements. SAP NetWeaver metric names are prefixed with `sap`. You can add up to 40 metrics per component.
10. Under **Custom alarms**, you can add additional alarms to be monitored by CloudWatch Application Insights.
11. Review your application monitoring configuration and choose **Save**. When you submit your configuration, your account updates all of the metrics and alarms for your SAP NetWeaver systems.

View and troubleshoot SAP NetWeaver problems detected by CloudWatch Application Insights

The following sections provide steps to help you resolve common troubleshooting scenarios that occur when you configure monitoring for SAP NetWeaver on Application Insights.

Troubleshooting topics

- SAP NetWeaver database connectivity issues
- SAP NetWeaver application availability issues

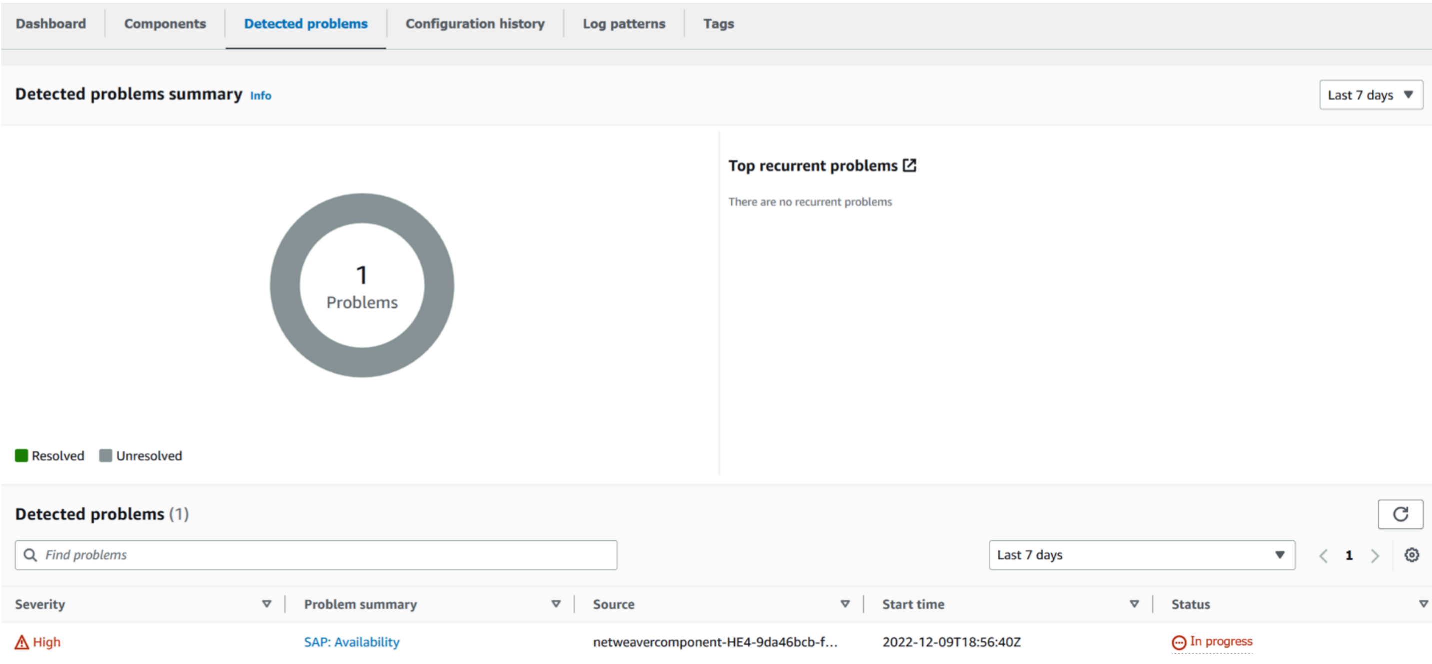
SAP NetWeaver database connectivity issues

Description

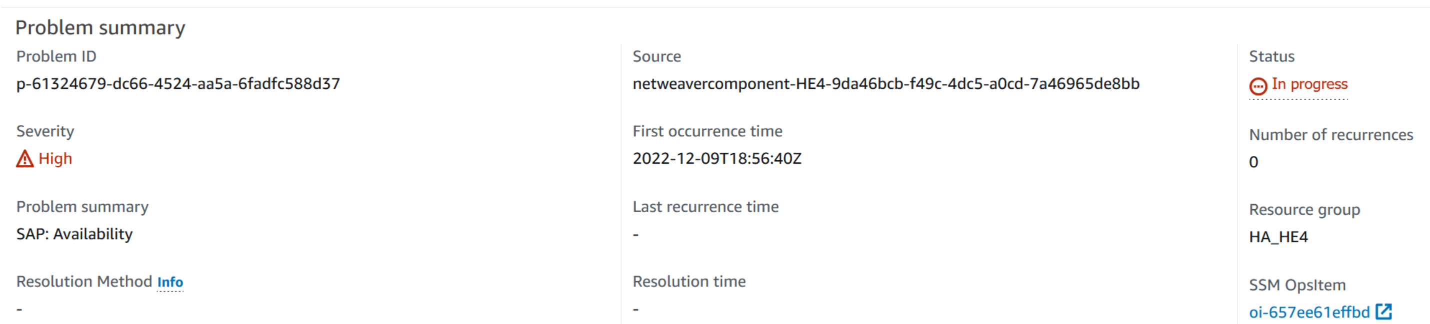
Your SAP NetWeaver application experiences database connectivity issues.

Cause

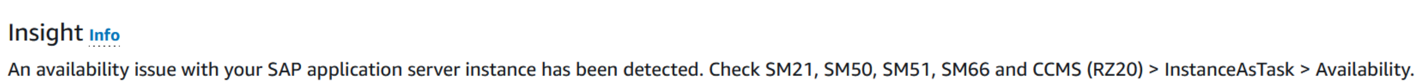
You can identify the connectivity issue by going to the CloudWatch Application Insights console and checking the SAP NetWeaver Application Insights problem dashboard. Select the link under **Problem summary** to see the specific issue.



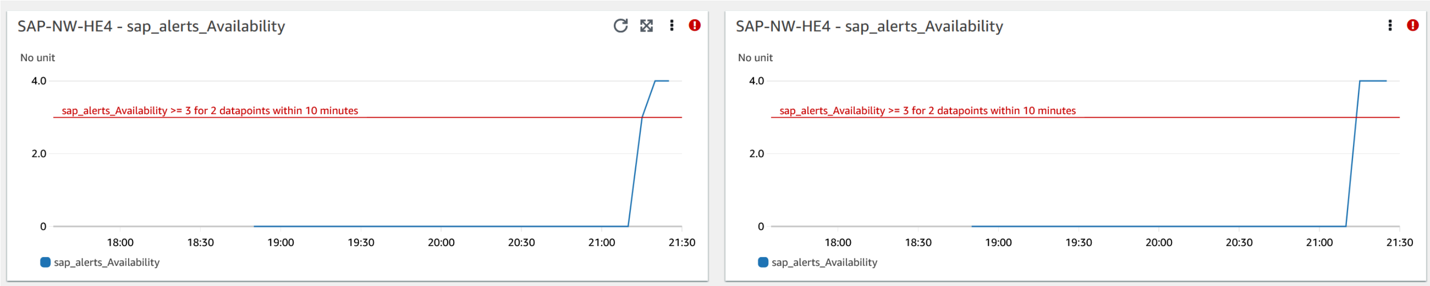
In the following example, under **Problem summary**, SAP: Availability is the issue.



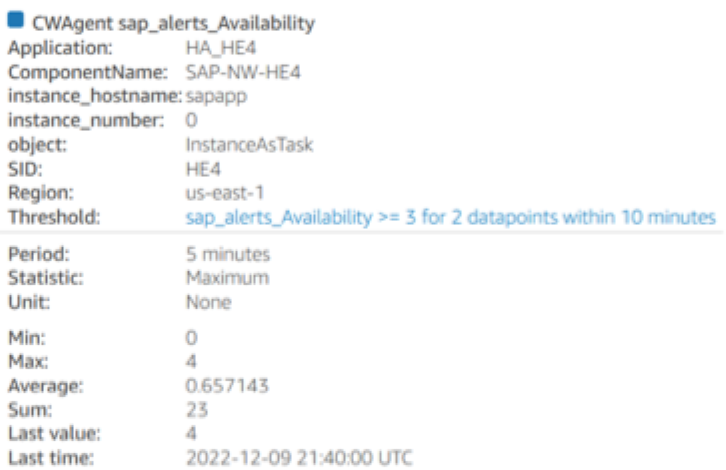
Immediately following the **Problem summary**, the **Insight** section provides more context about the error and where you can get more information about the causes of the issue.



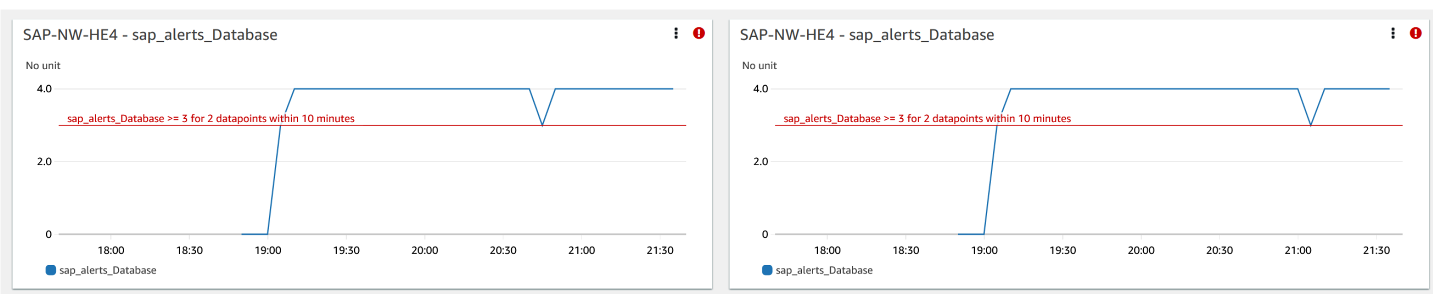
On the same problem dashboard, you can view related logs and metrics that problem detection has grouped together to help you isolate the cause of the error. The `sap_alerts_Availability` metric tracks the availability of the SAP NetWeaver system over time. You can use historical tracking to correlate when the metric initiated an error state or breached the alarm threshold. In the following example, there is an availability issue with the SAP NetWeaver system. The example shows two alarms because there are two SAP application server instances and an alarm was created for each instance.



For more information about each alarm, hover over the `sap_alerts_Availability` metric name.



In the following example, the `sap_alerts_Database` metric shows that the database layer has an issue or a failure. This alarm indicates that SAP NetWeaver had issues connecting to or communicating with its database.

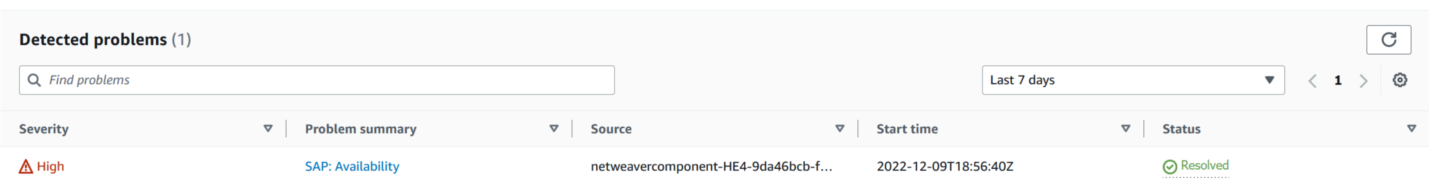


Since the database is a key resource for SAP NetWeaver, you may get many related alarms when the database has an issue or failure. In the following example, the `sap_alerts_FrontendResponseTime` and `sap_alerts_LongRunners` metrics are initiated because the database is not available.

Resolution

Application Insights monitors the detected problem hourly. If there are no new related log entries in your SAP NetWeaver log files, the older log entries will be treated as resolved. You must fix any error conditions related to the CloudWatch alarms. After the error conditions are fixed, the alarm is resolved when the alarms and logs are recovered. When all of the CloudWatch log errors and alarms are resolved, Application Insights stops detecting errors and the problem is automatically resolved within an hour. We recommend that you resolve all log error conditions and alarms so that you have the latest problems on the problem dashboard.

In the following example, the SAP Availability issue is resolved.



Detected problems (1)

Find problems | Last 7 days

Severity	Problem summary	Source	Start time	Status
High	SAP: Availability	netweavercomponent-HE4-9da46bcb-f...	2022-12-09T18:56:40Z	Resolved

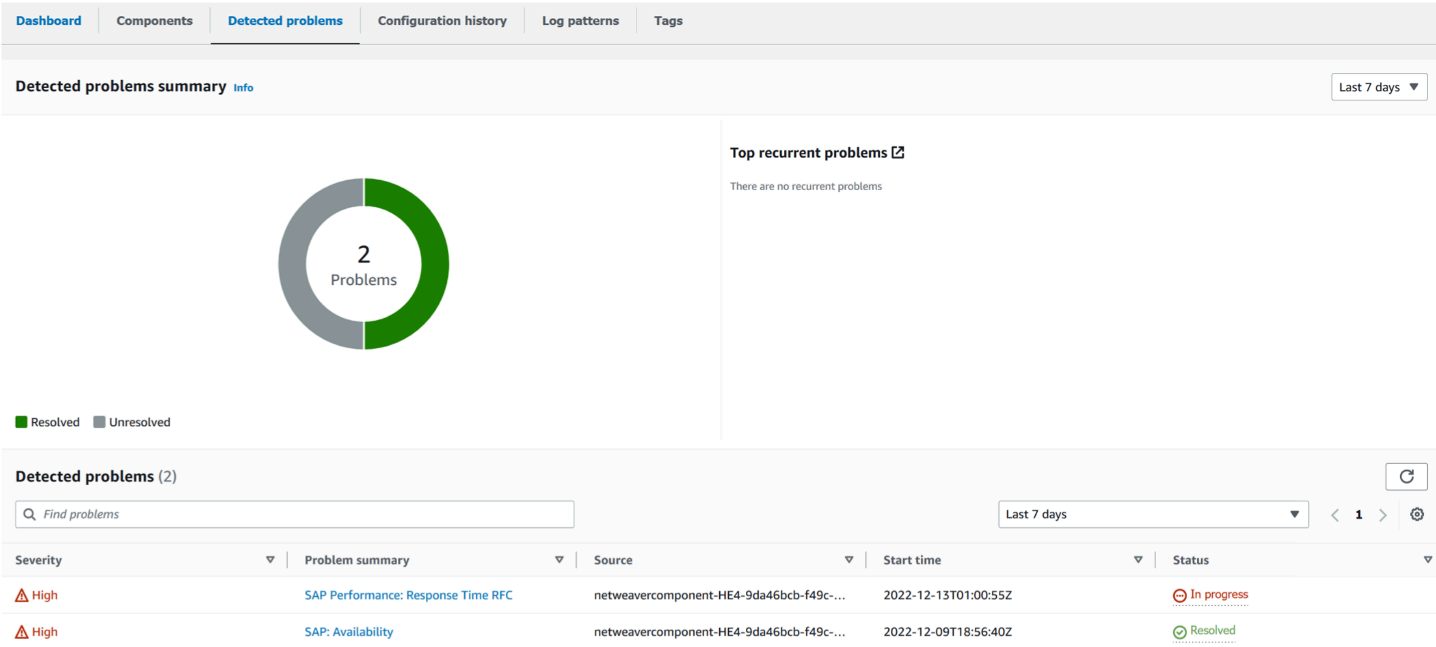
SAP NetWeaver application availability issues

Description

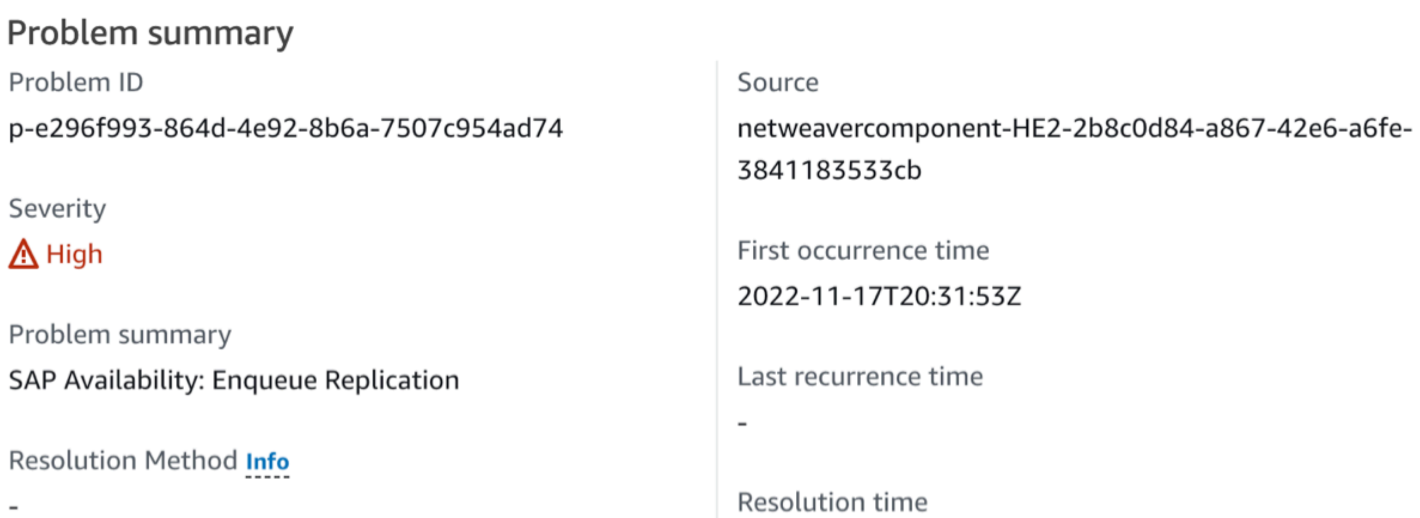
Your SAP NetWeaver High Availability Enqueue replication stopped working.

Cause

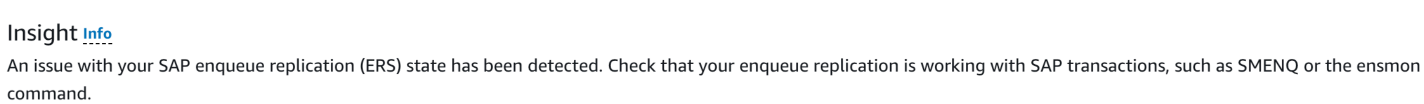
You can identify the connectivity issue by going to the CloudWatch Application Insights console and checking the SAP NetWeaver Application Insights problem dashboard. Select the link under **Problem summary** to see the specific issue.



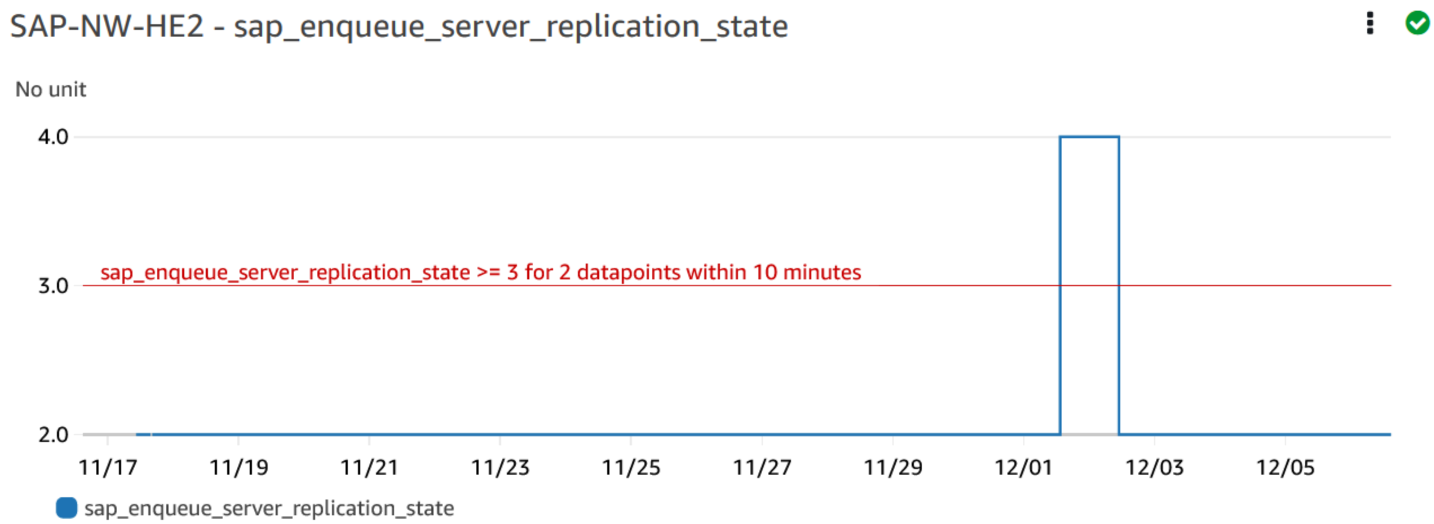
In the following example, under **Problem summary**, High Availability Enqueue Replication is the issue.



Immediately following the **Problem summary**, the **Insight** section provides more context about the error and where you can get more information about the causes of the issue.

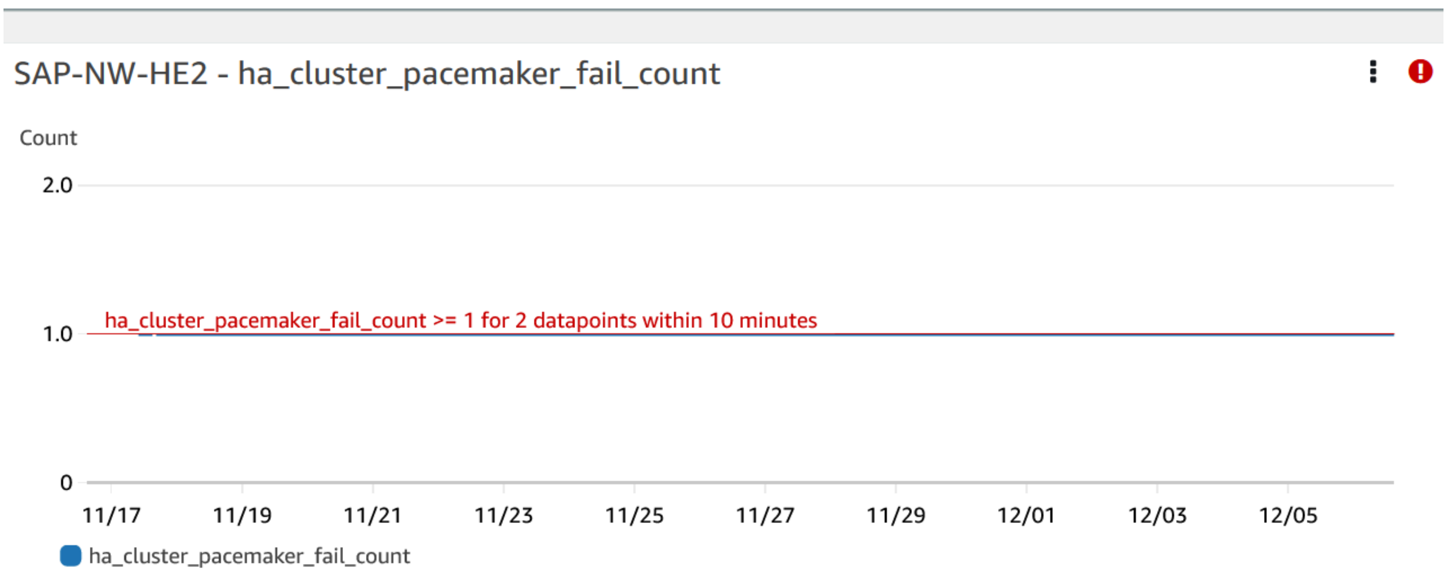


The following example shows the problem dashboard where you view logs and metrics which are grouped to help you isolate the causes of the error. The `sap_enqueue_server_replication_state` metric tracks the value over time. You can use historical tracking to correlate when the metric initiated an error state or breached the alarm threshold.

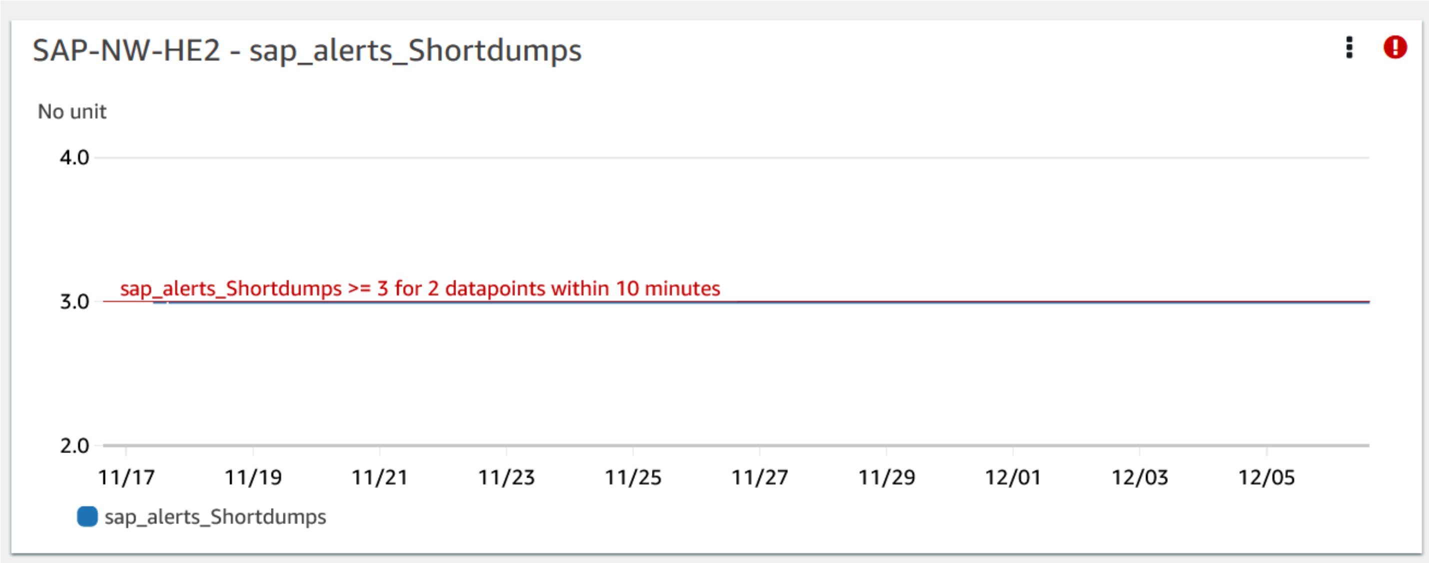


In the following example, the `ha_cluster_pacemaker_fail_count` metric shows that the high availability pacemaker cluster experienced a resource failure. The specific pacemaker resources that had a fail count greater than or equal to one are identified in the component dashboard.

EC2 instance group - SAP-NW-HE2

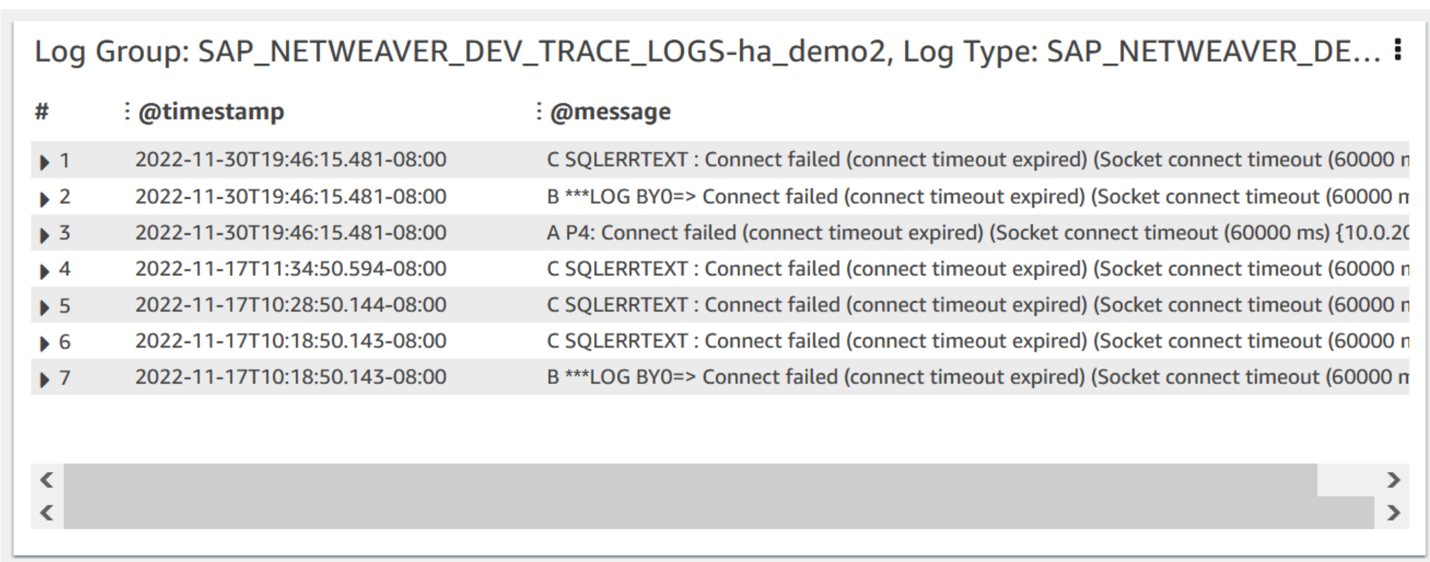


The following example shows the `sap_alerts_Shortdumps` metric, which indicates that the SAP application performance was reduced when the problem was detected.



Logs

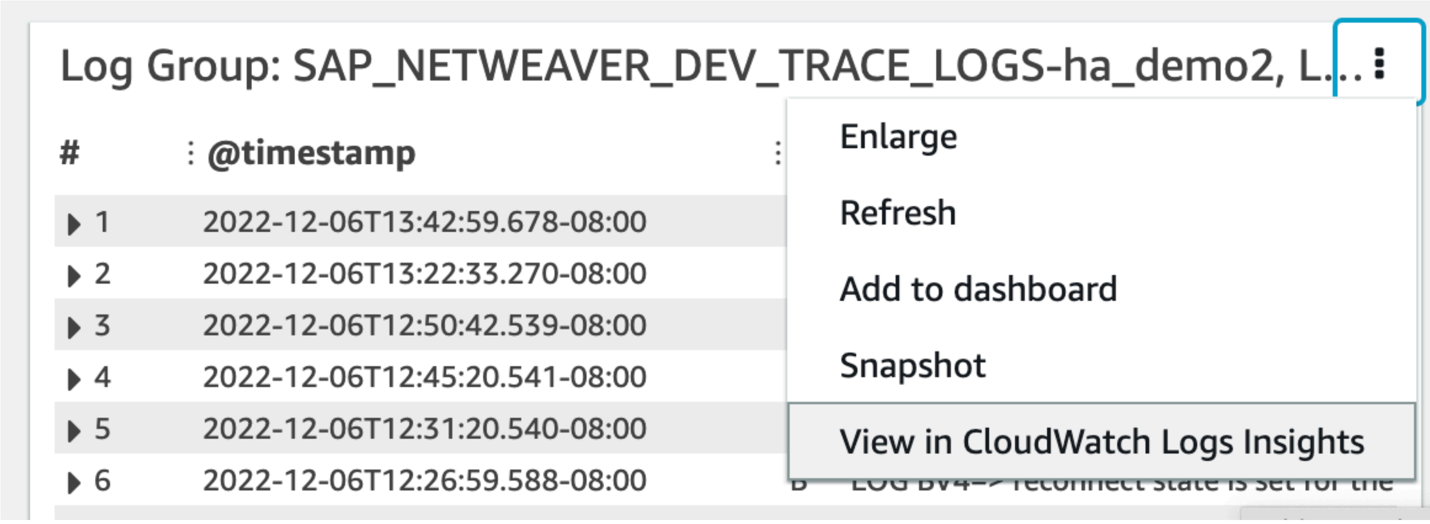
The log entries are helpful to get a better understanding of issues that occurred at the SAP NetWeaver layer when the problem was detected. The log group widget in the problem dashboard shows the specific time of the issue.



Log Group: SAP_NETWEAVER_DEV_TRACE_LOGS-ha_demo2, Log Type: SAP_NETWEAVER_DE...

#	@timestamp	@message
1	2022-11-30T19:46:15.481-08:00	C SQLERRTEXT : Connect failed (connect timeout expired) (Socket connect timeout (60000 n
2	2022-11-30T19:46:15.481-08:00	B ***LOG BY0=> Connect failed (connect timeout expired) (Socket connect timeout (60000 n
3	2022-11-30T19:46:15.481-08:00	A P4: Connect failed (connect timeout expired) (Socket connect timeout (60000 ms) {10.0.2(
4	2022-11-17T11:34:50.594-08:00	C SQLERRTEXT : Connect failed (connect timeout expired) (Socket connect timeout (60000 n
5	2022-11-17T10:28:50.144-08:00	C SQLERRTEXT : Connect failed (connect timeout expired) (Socket connect timeout (60000 n
6	2022-11-17T10:18:50.143-08:00	C SQLERRTEXT : Connect failed (connect timeout expired) (Socket connect timeout (60000 n
7	2022-11-17T10:18:50.143-08:00	B ***LOG BY0=> Connect failed (connect timeout expired) (Socket connect timeout (60000 n

To see detailed information about the logs, select the three vertical dots in the upper-right corner, and select **View in CloudWatch Logs Insights**.

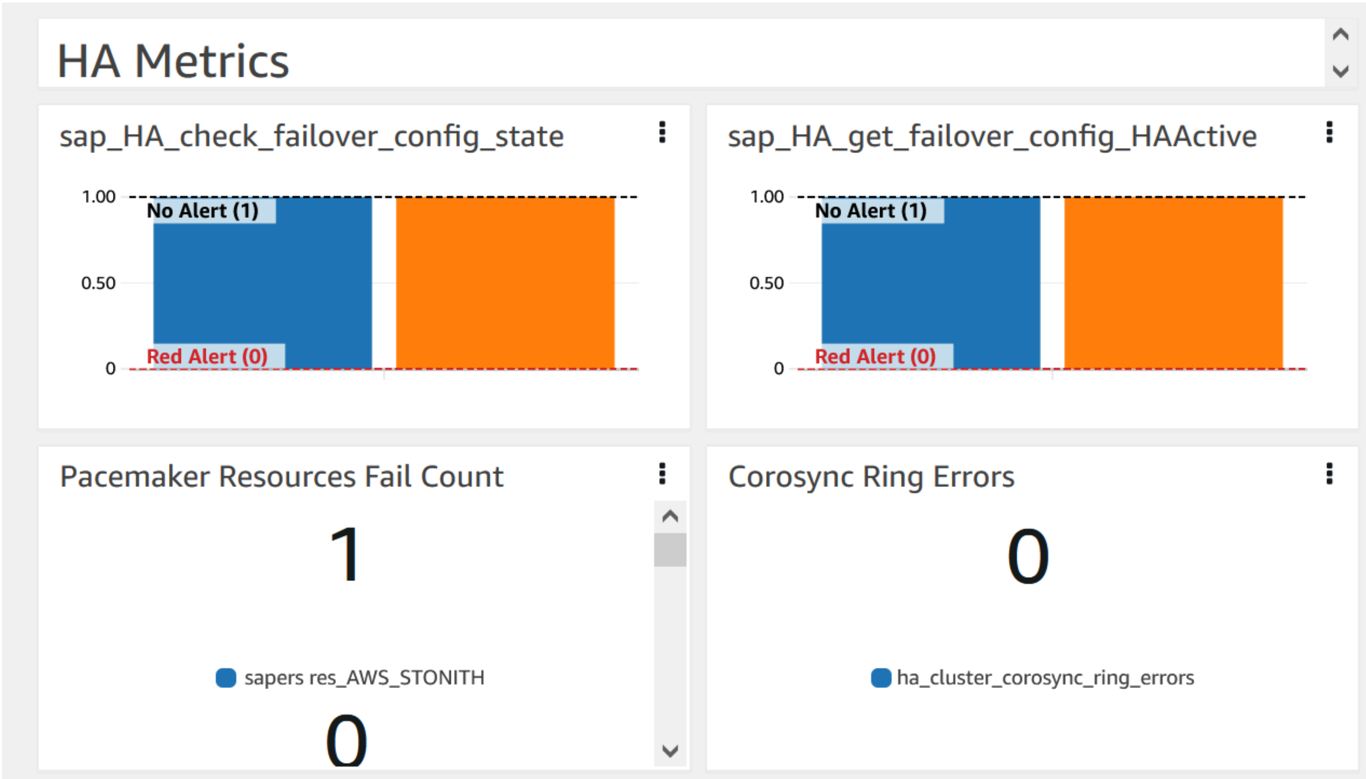


Use the following steps to get more information about the metrics and alarms displayed in the problem dashboard.

To get more information about metrics and alarms

1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/).
2. In the left navigation pane, under **Insights**, select **Application Insights**. Then, choose the **List view** tab, and select your application.
3. Select the **Components** tab. Then, select the SAP NetWeaver component about which you want to get more information.

   The following example shows the **HA Metrics** section with the `ha_cluster_pacemaker_fail_count` metric that was displayed in the problem dashboard.



Resolution

Application Insights monitors the detected problem hourly. If there are no new related log entries in your SAP NetWeaver log files, the older log entries will be treated as resolved. You must fix any error conditions related to this problem.

For the `sap_alerts_Shortdumps` alarm, you must resolve the alert in the SAP NetWeaver system by using transaction code `RZ20 # R3Abap # Shortdumps` to navigate to the CCMS alert. For more information about CCMS alerts, see the [SAP website.](#) Resolve all of the CCMS alerts in the Shortdumps tree. After all of the alerts are resolved in the SAP NetWeaver system, CloudWatch no longer reports the metric in an alarm state.

When all of the CloudWatch log errors and alarms are resolved, Application Insights stops detecting errors and the problem is automatically resolved within an hour. We recommend that you resolve all log error conditions and alarms so that you have the latest problems on the problem dashboard. In the following example, the SAP Netweaver High Availability Enqueue Replication problem is resolved.

Severity	Problem summary	Source	Start time	Status
High	SAP Availability: Enqueue Replication	netweavercomponent-HE2-2b8c0...	2022-12-08T20:01:43Z	Resolved

Troubleshooting Application Insights for SAP NetWeaver

This section provides steps to help you resolve common errors returned by the Application Insights dashboard.

Unable to add more than 60 monitor metrics

Error returned: `Component cannot have more than 60 monitored metrics.`

Root cause: `The current metric limit is 60 monitor metrics per component.`

Resolution: Remove metrics that are not necessary to adhere to the limit.

SAP metrics do not appear on the dashboard after the onboarding process

Root cause: Component Dashboard uses a five minute metric period to aggregate the data points.

Resolution: All metrics should show up on the dashboard after five minutes.

SAP metrics and alarms don't appear on the dashboard

Use the following steps to identify why SAP metrics and alarms don't appear on the dashboard after the onboarding process.

To identify the issue with metrics and alarms

1. Open the CloudWatch console.
2. In the left navigation pane, under **Insights**, select **Application Insights**. Then, choose the **List view** tab, and select your application.
3. Choose the **Configuration history** tab.
4. If you see missing metrics datapoints, check for errors related to `prometheus-sap_host_exporter`.
5. If you don't find an error in the previous step, Connect to your Linux instance. For High Availability deployments, connect to the primary cluster Amazon EC2 instance.
6. In your instance, verify that the exporter is running by using the following command. The default port is `9680`. If you are using a different port, replace `9680` with the port you are using.

   ```
   curl localhost:9680/metrics
   ```

   If no data is returned, then the exporter failed to start.

7. To find the correct naming convention to use for WORKLOAD_SHORT_NAME in the next two steps, run the following command.

   > **Note**
   >
   > Application Insights adds a suffix, WORKLOAD_SHORT_NAME, to the service name depending on the workload that is running. The short names for NetWeaver Distributed, Standard, and High Availability deployments are SAP_NWD, SAP_NWS, and SAP_NWH.

   ```
   sudo systemctl | grep exporter
   ```

8. To check for errors in the exporter service logs, run the following command:

   ```
   sudo journalctl -e --unit=prometheus-sap_host_exporter_WORKLOAD_SHORT_NAME.service
   ```

9. To check for errors in the exporter manager service logs, run the following command:

   ```
   sudo journalctl -e --unit=prometheus-
   sap_host_exporter_manager_WORKLOAD_SHORT_NAME.service
   ```

   > **Note**
   >
   > This service should be up and running at all times.

   If this command does not return an error, continue to the next step.

10. To manually start the exporter, run the following command. Then, check the exporter output.

   ```
   sudo /opt/aws/sap_host_exporter/sap_host_exporter
   ```

   You can exit the exporter process after you check for errors.

Root cause: There are several possible causes for this issue. A common cause is that the exporter is not able to connect to one of the application server instances.

Resolution

Use the following steps to connect the exporter to the application server instances. You will verify that the SAP application instance is running and use SAPControl to connect to the instance.

To connect the exporter to the application server instances

1. In your Amazon EC2 instance, run the following command to verify that the SAP application is running.

   ```
   sapcontrol -nr <App_InstNo> -function GetProcessList
   ```

2. You must establish a working SAPControl connection. If the SAPControl connection doesn't work, find the root cause of the issue on the relevant SAP application instance.
3. To manually start the exporter after you fix the SAP Control connection issue, run the following command:

   ```
   sudo systemctl start prometheus-sap_host_exporter.service
   ```

4. If you can't resolve the SAPControl connection issue, use the following procedure as a temporary fix.

   a. Open the Amazon Systems Manager console.

   b. From the left navigation pane, choose **State Manager**.

   c. Under **Associations** search for the SAP NetWeaver system's association.

      ```
      Association Name: Equal: AWS-ApplicationInsights-
      SSMSAPHostExporterAssociationForCUSTOMSAPNW<SID>-1
      ```

   d. Select the **Association id**.

   e. Choose the **Parameters** tab and remove the application server number from **additionalArguments**.

   f. Choose **Apply Association Now**.

      Note

      This is a temporary fix. If updates are made to the component's monitoring configurations, the instance will be added back.

View and troubleshoot problems detected by Amazon CloudWatch Application Insights

The topics in this section provide detailed information about the detected problems and insights displayed by Application Insights. It also provides suggested resolutions for detected issues with your account or your configuration.

Troubleshooting topics

CloudWatch console overview

An overview of problems that impact your monitored applications can be found under the CloudWatch Application Insights pane in the overview page of the CloudWatch console.

The CloudWatch Application Insights overview pane displays the following:

- The severity of the problems detected: High/Medium/Low
- A short summary of the problem
- The problem source
- The time the problem started
- The resolution status of the problem
- The affected resource group

To view the details of a specific problem, under **Problem Summary**, select the description of the problem. A detailed dashboard displays insights into the problem and related metric anomalies and snippets of log errors. You can provide feedback on the relevance of the insight by selecting whether it is useful.

If a new resource is detected that is not configured, the problem summary description takes you to the **Edit configuration** wizard to configure your new resource. You can view or edit your resource group configuration by choosing **View/edit configuration** in the upper right-hand corner of the detailed dashboard.

To return to the overview, choose **Back to overview**, which is next to the CloudWatch Application Insights detailed dashboard header.

Application Insights problem summary page

Application Insights problem summary page

CloudWatch Application Insights provides the following information about detected problems on the problem summary page:

- A short summary of the problem
- The start time and date of the problem
- The problem severity: High/Medium/Low
- The status of the detected problem: In-progress/Resolved
- Insights: Automatically generated insights on the detected problem and possible root cause
- Feedback on insights: Feedback you have provided about the usefulness of the insights generated by CloudWatch Application Insights
- Related observations: A detailed view of the metric anomalies and error snippets of relevant logs related to the problem across various application components

CloudWatch agent merge conflict failures

CloudWatch Application Insights installs and configures the CloudWatch agent on customer instances. This includes creation of a CloudWatch agent configuration file with configurations for metrics or logs. A merge conflict can occur if a customer's instance already has a CloudWatch agent configuration file with different configurations defined for the same metrics or logs. To resolve the merge conflict, use the following steps:

1. Identify the CloudWatch agent configuration files on your system. For more information about the file locations, see [CloudWatch agent files and locations]().

2. Remove the resource configurations that you want to use in Application Insights from the existing CloudWatch agent configuration file. If you want to only use Application Insights configurations, delete the existing CloudWatch agent configuration files.

High CPU usage from CloudWatch agent log processing

CloudWatch Application Insights installs and configures the CloudWatch agent on customer instances. If an Amazon EC2 instance is configured with log paths that have large amounts of log data, the instance might experience increases in CPU usage while the CloudWatch agent processes the logs. To reduce CPU usage, remove the log path in the Amazon EC2 instance component configuration.

Alarms are not created

For some metrics, Application Insights predicts the alarm threshold based on previous data points for the metric. To enable this prediction, the following criteria must be met.

- **Recent data points –** There must be a minimum of 100 data points from the last 24 hours. The data points don't need to be continuous and can be scattered throughout the 24 hour time frame.
- **Historical data –** There must be a minimum of 100 data points spanning the time frame from 15 days before the current date to 1 day before the current date. The data points don't need to be continuous and can be scattered throughout the 15 day time frame.

> **Note**
>
> For some metrics, Application Insights delays the creation of alarms until the preceding conditions are met. In this case, you get a configuration history event that the metric lacks sufficient data points to establish the alarm threshold.

Feedback

Feedback

You can provide feedback on the automatically generated insights on detected problems by designating them useful or not useful. Your feedback on the insights, along with your application diagnostics (metric anomalies and log exceptions), are used to improve the future detection of similar problems.

Configuration errors

CloudWatch Application Insights uses your configuration to create monitoring telemetries for the components. When Application Insights detects an issue with your account or your configuration, information is provided in the **Remarks** field of the Application summary about how to resolve the configuration issue for your application.

The following table shows suggested resolutions for specific remarks.

Remarks	Suggested resolution	Additional notes
The quota for CloudForm ation has already been reached.	Application Insights creates one CloudFormation stack for each application to manage CloudWatch agent installat ion and configuration for all application component s. By default, each Amazon account can have 2000 stacks. See [Amazon CloudFormation Limits](). To resolve this, raise the limit for CloudFormation stacks.	n/a
No SSM instance role on the following instances.	For Application Insights to be able to install and configure CloudWatch agent on application instances , AmazonSSMManagedIn stanceCore and CloudWatc hAgentServerPolicy policies must be attached to the instance role.	Application Insights calls the SSM [DescribeInstanceIn formation API]() to get the list of instances with SSM permission. After the role is attached to the instance, it takes time for SSM to include the instance in the DescribeInstanceInformation result. Until SSM includes the instance in the result,

Remarks	Suggested resolution	Additional notes
		NO_SSM_INSTANCE_ROLE error remains present for the application.
New components may need configuration.	Application Insights detects that there are new components in the applicati on Resource Group. To resolve this, configure the new components accordingly.	n/a

Logs and metrics supported by Amazon CloudWatch Application Insights

The following lists show the supported logs and metrics for Amazon CloudWatch Application Insights.

CloudWatch Application Insights supports the following logs:

- Microsoft Internet Information Services (IIS) logs
- Error log for SQL Server on EC2
- Custom .NET application logs, such as Log4Net
- Windows Event logs, including Windows logs (System, Application, and Security) and Applications and Services log
- Amazon CloudWatch Logs for Amazon Lambda
- Error log and slow log for RDS MySQL, Aurora MySQL, and MySQL on EC2
- Postgresql log for PostgreSQL RDS and PostgreSQL on EC2
- Amazon CloudWatch Logs for Amazon Step Functions
- Execution logs and access logs (JSON, CSV, and XML, but not CLF) for API Gateway REST API stages
- Prometheus JMX exporter logs (EMF)
- Alert logs and listener logs for Oracle on Amazon RDS and Oracle on Amazon EC2

- Container logs routing from Amazon ECS containers to CloudWatch using `awslogs` log driver.
- Container logs routing from Amazon ECS containers to CloudWatch using FireLens container log router.
- Container logs routing from Amazon EKS or Kubernetes running on Amazon EC2 to CloudWatch using Fluent Bit or Fluentd log processor with Container Insights.
- SAP HANA trace and error logs
- HA Pacemaker logs
- SAP ASE server logs
- SAP ASE backup server logs
- SAP ASE Replication server logs
- SAP ASE RMA agent logs
- SAP ASE Fault Manager logs
- SAP NetWeaver dev trace logs
- Process metrics for Windows processes using proctstat plugin for CloudWatch agent
- Public DNS query logs for hosted zone
- Amazon Route 53 Resolver DNS query logs

CloudWatch Application Insights supports the following log classes:

- **Standard** – Amazon CloudWatch Application Insights requires that log groups are configured with the CloudWatch Logs Standard log class to enable monitoring.

CloudWatch Application Insights supports metrics for the following application components:

- Amazon Elastic Compute Cloud (EC2)
  - CloudWatch built-in metrics
  - CloudWatch agent metrics (Windows server)
  - CloudWatch agent process metrics (Windows server)
  - CloudWatch agent metrics (Linux server)
- Elastic Block Store (EBS)
- Amazon Elastic File System (Amazon EFS)
- Elastic Load Balancer (ELB)

- Application ELB
- Amazon EC2 Auto Scaling groups
- Amazon Simple Queue Server (SQS)
- Amazon Relational Database Service (RDS)
  - RDS Database instances
  - RDS Database clusters
- Amazon Lambda function
- Amazon DynamoDB table
- Amazon S3 bucket
- Amazon Step Functions
  - Execution-level
  - Activity
  - Lambda function
  - Service integration
  - Step Functions API
- API Gateway REST API stages
- SAP HANA
- SAP ASE
- SAP ASE High Availability on Amazon EC2
- SAP NetWeaver
- HA Cluster
- Java
- Amazon Elastic Container Service (Amazon ECS)
  - CloudWatch built-in metrics
  - Container Insights metrics
  - Container Insights Prometheus metrics
- Kubernetes on Amazon
  - Container Insights metrics
  - Container Insights Prometheus metrics
- Amazon FSx

- Amazon VPC
- Amazon VPC NAT gateways
- Amazon Route 53 health check
- Amazon Route 53 hosted zone
- Amazon Route 53 Resolver endpoint
- Amazon Network Firewall rule group
- Amazon Network Firewall rule group association
- Metrics with data points requirements
  - AWS/ApplicationELB
  - AWS/AutoScaling
  - AWS/EC2
  - Elastic Block Store (EBS)
  - AWS/ELB
  - AWS/RDS
  - AWS/Lambda
  - AWS/SQS
  - AWS/CWAgent
  - AWS/DynamoDB
  - AWS/S3
  - AWS/States
  - AWS/ApiGateway
  - AWS/SNS
- Recommended metrics
- Performance Counter metrics

SAP NetWeaver

CloudWatch Application Insights supports the following metrics:

Metric	Description
sap_alerts_ResponseTime	The SAP response time alert from CCMS (RZ20)>R3Services>Dialog>ResponseTime.
sap_alerts_ResponseTimeDialog	The SAP response time dialog alert from CCMS (RZ20)>R3Services>Dialog> ResponseTimeDialog.
sap_alerts_ResponseTimeDialogRFC	The SAP response time alert from CCMS (RZ20)>R3Services> Dialog>ResponseTimeDialogRFC.
sap_alerts_DBRequestTime	The SAP response time alert from CCMS (RZ20)>R3Services>Dialog>DBRequestTime.
sap_alerts_FrontendResponseTime	The SAP response time alert from CCMS (RZ20)>R3Services > Dialog>FrontEndResponseTime.
sap_alerts_Database	The SAP system has logged database-related errors. Alert from SM21 or CCMS (RZ20)>R3 Syslog>Database.
sap_alerts_QueueTime	The SAP queue time alert from CCMS (RZ20)>R3Services>Dialog>QueueTime.
sap_alerts_AbortedJobs	Failed background jobs in SAP system. Alert from (RZ20)>R3Services > Background>AbortedJobs.

Metric	Description
sap_alerts_BasisSystem	SAP system logged system-level errors. Alert from SM21 or CCMS (RZ20)>R3Syslog>Ba sisSystem.
sap_alerts_Security	The SAP system logged security-related messages. Alert from SM21 or CCMS (RZ20)>R3Syslog>Security.
sap_alerts_System	The SAP system logged security or audit-rel ated messages. Alert from SM21 or CCMS (RZ20)>Security>System.
sap_alerts_LongRunners	There are long running programs in your SAP system. Alert from CCMS (RZ20)>R3Services > Dialog>LongRunners.
sap_alerts_SqlError	There are SAP database client layer error logs. Alert from CCMS(RZ20)>DatabaseClient>A bapSql>SqlError.
sap_alerts_State	State alert from CCMS (RZ20)>OS Collector >State.
sap_alerts_Shortdumps	Shortdumps alert from ST22 and CCMS (RZ20)>R3Abap>Shortdumps.
sap_alerts_Availability	Availability alert for SAP application server instance from SM21, SM50, SM51, SM66, and CCMS (RZ20)>InstanceAsTask>Availability.
sap_dispatcher_queue_high	The SAPControl Web Service function `GetQueueStatistic` provides the dispatcher queue high count.
sap_dispatcher_queue_max	The SAPControl Web Service function `GetQueueStatistic` provides the dispatcher queue max count.

Metric	Description
sap_dispatcher_queue_now	The SAPControl Web Service function `GetQueueStatistic` provides the dispatcher queue now count.
sap_dispatcher_queue_reads	The SAPControl Web Service function `GetQueueStatistic` provides the dispatcher queue reads count.
sap_dispatcher_queue_writes	The SAPControl Web Service function `GetQueueStatistic` provides the dispatcher queue writes count.
sap_enqueue_server_arguments_high	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue arguments high.
sap_enqueue_server_arguments_max	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue arguments max.
sap_enqueue_server_arguments_now	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue arguments now.
sap_enqueue_server_arguments_state	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue arguments state.
sap_enqueue_server_backup_requests	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue backup requests.
sap_enqueue_server_cleanup_requests	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue cleanup requests.

Metric	Description
sap_enqueue_server_dequeue_all_requests	The SAPControl Web Service function `EnqGetStatistic` provides the dequeue all requests.
sap_enqueue_server_dequeue_errors	The SAPControl Web Service function `EnqGetStatistic` provides the dequeue errors.
sap_enqueue_server_dequeue_requests	The SAPControl Web Service function `EnqGetStatistic` provides the dequeue requests.
sap_enqueue_server_enqueue_errors	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue errors.
sap_enqueue_server_enqueue_rejects	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue rejects.
sap_enqueue_server_enqueue_requests	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue requests.
sap_enqueue_server_lock_time	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue lock time.
sap_enqueue_server_lock_wait_time	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue lock wait time.
sap_enqueue_server_locks_high	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue locks high.

Metric	Description
sap_enqueue_server_locks_max	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue locks max.
sap_enqueue_server_locks_now	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue locks now.
sap_enqueue_server_locks_state	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue locks state.
sap_enqueue_server_owner_high	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue owner high.
sap_enqueue_server_owner_max	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue owner max.
sap_enqueue_server_owner_now	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue owner now.
sap_enqueue_server_owner_state	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue owner state.
sap_enqueue_server_replication_state	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue replication state status.
sap_enqueue_server_reporting_requests	The SAPControl Web Service function `EnqGetStatistic` provides the reqporting requests status.

Metric	Description
sap_enqueue_server_server_time	The SAPControl Web Service function `EnqGetStatistic` provides the enqueue server time.
sap_HA_check_failover_config_state	The SAPControl Web Service function `HACheckFailoverConfig` provides the SAP High Availability status.
sap_HA_get_failover_config_HAActive	The SAPControl Web Service function `HAGetFailoverConfig` provides the SAP High Availability Cluster configuration and status.
sap_start_service_processes	The SAPControl Web Service function `GetProcessList` provides the disp+work , IGS, gwrd, icman, message server, and enqueue server processes status.

Amazon Network Firewall rule group association

CloudWatch Application Insights supports the following metrics:

FirewallRuleGroupVpcQueryVolume

Metrics with data points requirements

For metrics without an obvious default threshold to alarm on, Application Insights waits until the metric has enough data points to predict a reasonable threshold to alarm on. The metric data points requirement that CloudWatch Application Insights checks before an alarm is created are:

- The metric has at least 100 data points from the past 15 to the past 2 days.
- The metric has at least 100 data points from the last day.

The following metrics follow these data points requirements. Note that CloudWatch agent metrics require up to one hour to create alarms.

Using the resource health view in the CloudWatch console

You can use the resource health view to automatically discover, manage, and visualize the health and performance of hosts across their applications in a single view. You can visualize the health of their hosts by a performance dimension such as CPU or memory, and slice and dice hundreds of hosts in a single view using filters. You can filter by tags or by use cases, such as hosts in the same Auto Scaling group or hosts that use the same load balancer,

Prerequisites

To make sure that you get the full benefit of the resource health view, check that you have the following prerequisites.

- To see the memory utilization of your hosts and use it as a filter, you must install the CloudWatch agent on your hosts and set it up to send a memory metric to CloudWatch in the default `CWAgent` namespace. On Linux and macOS instances, the CloudWatch agent must send the `mem_used_percent` metric. On Windows instances, the agent must send the `Memory % Committed Bytes In Use` metric. These metrics are included if you use the wizard to create the CloudWatch agent configuration file and select any of the pre-defined sets of metrics. Metrics collected by the CloudWatch agent are billed as custom metrics. For more information, see Install the CloudWatch agent.

  When you use the CloudWatch agent to collect these memory metrics to use with the resource health view, you must include the following section in the CloudWatch agent configuration file. This section contains the default dimension settings and is created by default, so do not change any part of this section to anything different than what is shown in the following example.

```
"append_dimensions": {
  "ImageId": "${aws:ImageId}",
  "InstanceId": "${aws:InstanceId}",
  "InstanceType": "${aws:InstanceType}",
  "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
```

```
},
```

- To view all the information available in the resource health view, you must be signed in to an account that has the following permissions. If you are signed on with fewer permissions, you can still use the resource health view but some performance data will not be visible.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "autoscaling:Describe*",
                "cloudwatch:Describe*",
                "cloudwatch:Describe*",
                "cloudwatch:Get*",
                "cloudwatch:List*",
                "logs:Get*",
                "logs:Describe*",
                "sns:Get*",
                "sns:List*",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceStatus",
                "ec2:DescribeRegions"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

To view resource health in your account

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Insights**, **EC2 Resource Health**.

   The resource health page appears, showing a square for each host in your account. Each square is colored based on the current status of that host, based on the setting for **Color by**. Host squares with an alarm symbol have one or more alarms currently in ALARM state.

   You can see up to 500 hosts in a single view. If you have more hosts in your account, use the filter settings in step 6 of this procedure.

3. To change what criteria is used to show each host's health, choose a setting for **Color by**. You can choose **CPU Utilization**, **Memory Utilization**, or **Status check**. Memory utilization metrics are available only for hosts that are running the CloudWatch agent and have it configured to collect memory metrics and send them to the default `CWAgent` namespace. For more information, see Collect metrics, logs, and traces with the CloudWatch agent.
4. To change the thresholds and the colors that are used for the health indicators in the grid, choose the gear icon above the grid.
5. To toggle whether to show alarms in the host grid, choose or clear **Show alarms across all metrics**.
6. To split the hosts in the map into groups, choose a grouping criteria for **Group by**.
7. To narrow the view to fewer hosts, choose a filter criteria for **Filter by**. You can filter by tags and by resource groupings such as Auto Scaling group, instance type, security group, and more.
8. To sort hosts, choose a sorting criteria for **Sort by**. You can sort by status check results, instance state, CPU or memory utilization, and the number of alarms that are in ALARM state.
9. To see more information about a host, choose the square that represents that host. A popup pane appears. To then dive deeper into information about that host, choose **View dashboard** or **View on list**.

Application performance monitoring (APM)

CloudWatch Application Signals provides application performance monitoring (APM) features such as pre-built, standardized dashboards for critical application metrics, correlated trace spans, and a service map to enable you to visualize interactions between applications and their dependencies. You can also search and analyze transaction spans and trace summaries to debug distributed application issues in a business context, for cases such as troubleshooting customer support tickets or finding top impacted customers. You can also create Service Level Objectives (SLOs) to closely track the performance KPIs of critical operations in your application, enabling you to easily identify and triage operations that do not meet your business KPIs.

See the following sections for an overview of these troubleshooting capabilities:

- Monitor the operational health of your applications with Application Signals
- Searching and analyzing spans

Start collecting application metrics and traces

Get the most integrated application performance monitoring experience by auto-instrumenting applications to easily collect telemetry, whether they are running in Amazon EKS clusters, Amazon EC2, Amazon ECS, Kubernetes, Lambda, or on-premise. Optionally, you can also use OpenTelemetry with Application Signals to collect telemetry.

> **Note**
>
> You must enable transaction search to get all APM features along with a new unified pricing for CloudWatch Application Signals, inclusive of X-Ray traces and application transaction spans. For more information about pricing, see Amazon CloudWatch Pricing.

Topics

- Application Signals
- Service level objectives (SLOs)
- Transaction Search
- Synthetic monitoring (canaries)
- CloudWatch RUM

- Perform launches and A/B experiments with CloudWatch Evidently

Application Signals

Use CloudWatch Application Signals to automatically instrument your applications on Amazon so that you can monitor current application health and track long-term application performance against your business objectives. Application Signals provides you with a unified, application-centric view of your applications, services, and dependencies, and helps you monitor and triage application health.

- Enable Application Signals to automatically collect metrics and traces from your applications, and display key metrics such as call volume, availability, latency, faults, and errors. Quickly see and triage current operational health, and whether your applications are meeting their longer-term performance goals, without writing custom code or creating dashboards.
- Create and monitor service-level objectives (SLOs) with Application Signals. Easily create and track status of SLOs related to CloudWatch metrics, including the new standard application metrics that Application Signals collects. See and track the service level indicator (SLI) status of your application services within a services list and topology map. Create alarms to track your SLOs, and track the new standard application metrics that Application Signals collects.
- See a map of your application topology that Application Signals automatically discovers, that gives you a visual representation of your applications, dependencies, and their connectivity.
- Application Signals works with CloudWatch RUM, CloudWatch Synthetics canaries, Amazon Service Catalog AppRegistry, and Amazon EC2 Auto Scaling to display your client pages, Synthetics canaries, and application names within dashboards and maps.

Topics

- Enable your applications on Kubernetes
- Enable your applications on Lambda
- Troubleshooting your Application Signals installation
- (Optional) Configuring Application Signals
- Monitor the operational health of your applications with Application Signals
- Metrics collected by Application Signals

Use Application Signals for daily application monitoring

Use Application Signals within the CloudWatch console, as part of daily application monitoring:

1. If you have created service level objectives (SLOs) for your services, start with the Service Level Objectives (SLO) page. This gives you an immediate view of the health of your most critical services, operations, and dependencies. Choose the service, operation, or dependency name for an SLO to open the Service detail page and see detailed service information as you troubleshoot issues.
2. Open the Services page to see a summary of all your services, and quickly see services with the highest fault rate or latency. If you have created SLOs, look at the Services table to see which services have unhealthy service level indicators (SLIs). If a particular service is in an unhealthy state, select the service to open the Service detail page and see service operations, dependencies, Synthetics canaries, and client requests. Select a point in a graph to see correlated traces so that you can troubleshoot and identify the root cause of operational issues.
3. If new services have been deployed or dependencies have changed, open the Service Map to inspect your application topology. See a map of your applications that shows the relationship between clients, Synthetics canaries, services, and dependencies. Quickly see SLI health, view key metrics such as call volume, fault rate, and latency, and drill down to see more detailed information in the Service detail page.

Using Application Signals incurs charges. For information about CloudWatch pricing, see Amazon CloudWatch Pricing.

> **Note**
>
> It is not necessary to enable Application Signals to use CloudWatch Synthetics, CloudWatch RUM, or CloudWatch Evidently. However, Synthetics and CloudWatch RUM work with Application Signals to provide benefits when you use these features together.

Application Signals cross-account

With Application Signals cross-account observability, you can monitor and troubleshoot your applications that span multiple Amazon accounts within a single Region.

You can use Amazon CloudWatch Observability Access Manager to set up one or more of your Amazon accounts as a monitoring account. You'll provide the monitoring account with the ability to view data in your source account by creating a sink in your monitoring account. You use the sink to create a link from your source account to your monitoring account. For more information, see CloudWatch cross-account observability.

Required resources

For proper functionality of Application Signals cross-account observability, ensure that the following telemetry types are shared through the CloudWatch Observability Access Manager.

- Application Signals services and service level objectives (SLOs)
- Metrics in Amazon CloudWatch
- Log groups in Amazon CloudWatch Logs
- Traces in Amazon X-Ray

Supported languages and architectures

Application Signals supports Java, Python, Node.js, and .NET applications.

Application Signals is supported and tested on Amazon EKS, Amazon ECS, and Amazon EC2. On Amazon EKS clusters, it automatically discovers the names of your services and clusters. On other architectures, you must supply the names of services and environments when you enable those services for Application Signals.

The instructions for enabling Application Signals on Amazon EC2 should work on any architecture that supports the CloudWatch agent and Amazon Distro for OpenTelemetry. However, the instructions have not been tested on architectures other than Amazon ECS and Amazon EC2.

Supported Regions

Application Signals is supported in every commercial Region except for Canada West (Calgary).

Permissions required for Application Signals

This section explains the permissions necessary for you to enable, manage, and operate Application Signals.

Permissions to enable and manage Application Signals

To manage Application Signals, you must be signed on with the following permissions:

```
{
 "Version": "2012-10-17",
 "Statement": [
    {
        "Sid": "CloudWatchApplicationSignalsFullAccessPermissions",
        "Effect": "Allow",
        "Action": "application-signals:*",
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsAlarmsPermissions",
        "Effect": "Allow",
        "Action": [
            "cloudwatch:DescribeAlarms"
        ],
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsMetricsPermissions",
        "Effect": "Allow",
        "Action": [
            "cloudwatch:GetMetricData",
            "cloudwatch:ListMetrics"
        ],
        "Resource": "*"
    },
```

```
    {
        "Sid": "CloudWatchApplicationSignalsLogGroupPermissions",
        "Effect": "Allow",
        "Action": [
            "logs:StartQuery",
            "logs:DescribeMetricFilters"
        ],
        "Resource": "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsLogsPermissions",
        "Effect": "Allow",
        "Action": [
            "logs:GetQueryResults",
            "logs:StopQuery"
        ],
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsSyntheticsPermissions",
        "Effect": "Allow",
        "Action": [
            "synthetics:DescribeCanaries",
            "synthetics:DescribeCanariesLastRun",
            "synthetics:GetCanaryRuns"
        ],
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsRumPermissions",
        "Effect": "Allow",
        "Action": [
            "rum:BatchCreateRumMetricDefinitions",
            "rum:BatchDeleteRumMetricDefinitions",
            "rum:BatchGetRumMetricDefinitions",
            "rum:GetAppMonitor",
            "rum:GetAppMonitorData",
            "rum:ListAppMonitors",
            "rum:PutRumMetricsDestination",
            "rum:UpdateRumMetricDefinition"
        ],
        "Resource": "*"
    },
    {
```

```
        "Sid": "CloudWatchApplicationSignalsXrayPermissions",
        "Effect": "Allow",
        "Action": [
            "xray:GetTraceSummaries"
        ],
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsPutMetricAlarmPermissions",
        "Effect": "Allow",
        "Action": "cloudwatch:PutMetricAlarm",
        "Resource": [
            "arn:aws:cloudwatch:*:*:alarm:SLO-AttainmentGoalAlarm-*",
            "arn:aws:cloudwatch:*:*:alarm:SLO-WarningAlarm-*",
            "arn:aws:cloudwatch:*:*:alarm:SLI-HealthAlarm-*"
        ]
    },
    {
        "Sid": "CloudWatchApplicationSignalsCreateServiceLinkedRolePermissions",
        "Effect": "Allow",
        "Action": "iam:CreateServiceLinkedRole",
        "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals",
        "Condition": {
            "StringLike": {
                "iam:AWSServiceName": "application-signals.cloudwatch.amazonaws.com"
            }
        }
    },
    {
        "Sid": "CloudWatchApplicationSignalsGetRolePermissions",
        "Effect": "Allow",
        "Action": "iam:GetRole",
        "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals"
    },
    {
        "Sid": "CloudWatchApplicationSignalsSnsWritePermissions",
        "Effect": "Allow",
        "Action": [
            "sns:CreateTopic",
            "sns:Subscribe"
        ],
        "Resource": "arn:aws:sns:*:*:cloudwatch-application-signals-*"
```

```
    },
    {
        "Sid": "CloudWatchApplicationSignalsSnsReadPermissions",
        "Effect": "Allow",
        "Action": "sns:ListTopics",
        "Resource": "*"
    }
  ]
}
```

To enable Application Signals on Amazon EC2, or custom architectures, see Enable Application Signals on Amazon EC2. To enable and manage Application Signals on Amazon EKS using the Amazon CloudWatch Observability EKS add-on, you need the following permissions.

> **Important**
>
> These permissions include `iam:PassRole` with `Resource "*"` and `eks:CreateAddon` with `Resource "*"`. These are powerful permissions and you should use caution in granting them.

```
{
"Version": "2012-10-17",
    "Statement": [
        {
"Sid": "CloudWatchApplicationSignalsEksAddonManagementPermissions",
            "Effect": "Allow",
            "Action": [
                "eks:AccessKubernetesApi",
                "eks:CreateAddon",
                "eks:DescribeAddon",
                "eks:DescribeAddonConfiguration",
                "eks:DescribeAddonVersions",
                "eks:DescribeCluster",
                "eks:DescribeUpdate",
                "eks:ListAddons",
                "eks:ListClusters",
                "eks:ListUpdates",
                "iam:ListRoles",
                "iam:PassRole"
            ],
            "Resource": "*"
```

```
        },
        {
"Sid":
 "CloudWatchApplicationSignalsEksCloudWatchObservabilityAddonManagementPermissions",
            "Effect": "Allow",
            "Action": [
                "eks:DeleteAddon",
                "eks:UpdateAddon"
            ],
            "Resource": "arn:aws:eks:*:*:addon/*/amazon-cloudwatch-observability/*"
        }
    ]
}
```

The Application Signals dashboard shows the Amazon Service Catalog AppRegistry applications that your SLOs are associated with. To see these applications in the SLO pages, you must have the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchApplicationSignalsTaggingReadPermissions",
            "Effect": "Allow",
            "Action": "tag:GetResources",
            "Resource": "*"
        }
    ]
}
```

Operating Application Signals

Service operators who are using Application Signals to monitor services and SLOs must be signed on to an account with the following read only permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchApplicationSignalsReadOnlyAccessPermissions",
            "Effect": "Allow",
            "Action": [
```

```
                "application-signals:BatchGet*",
                "application-signals:Get*",
                "application-signals:List*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsGetRolePermissions",
            "Effect": "Allow",
            "Action": "iam:GetRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals"
        },
        {
        "Sid": "CloudWatchApplicationSignalsLogGroupPermissions",
        "Effect": "Allow",
        "Action": [
            "logs:StartQuery",
            "logs:DescribeMetricFilters"
        ],
        "Resource": "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsLogsPermissions",
        "Effect": "Allow",
        "Action": [
            "logs:GetQueryResults",
            "logs:StopQuery"
        ],
        "Resource": "*"
    },
        {
            "Sid": "CloudWatchApplicationSignalsAlarmsReadPermissions",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:DescribeAlarms"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsMetricsReadPermissions",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetMetricData",
```

```
                "cloudwatch:ListMetrics"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsSyntheticsReadPermissions",
            "Effect": "Allow",
            "Action": [
                "synthetics:DescribeCanaries",
                "synthetics:DescribeCanariesLastRun",
                "synthetics:GetCanaryRuns"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsRumReadPermissions",
            "Effect": "Allow",
            "Action": [
                "rum:BatchGetRumMetricDefinitions",
                "rum:GetAppMonitor",
                "rum:GetAppMonitorData",
                "rum:ListAppMonitors"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsXrayReadPermissions",
            "Effect": "Allow",
            "Action": [
                "xray:GetTraceSummaries"
            ],
            "Resource": "*"
        }
    ]
}
```

To see which Amazon Service Catalog AppRegistry Applications that your SLOs are associated within the Application Signals dashboard, you must have the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "CloudWatchApplicationSignalsTaggingReadPermissions",
            "Effect": "Allow",
            "Action": "tag:GetResources",
            "Resource": "*"
        }
    ]
}
```

To check if Application Signals on Amazon EKS using the [Amazon CloudWatch Observability EKS add-on](#) is enabled, you need to have the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchApplicationSignalsEksReadPermissions",
            "Effect": "Allow",
            "Action": [
                "eks:ListAddons",
                "eks:ListClusters"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchApplicationSignalsEksDescribeAddonReadPermissions",
            "Effect": "Allow",
            "Action": [
                "eks:DescribeAddon"
            ],
            "Resource": "arn:aws:eks:*:*:addon/*/amazon-cloudwatch-observability/*"
        }
    ]
}
```

Supported systems

Application Signals is supported and tested on Amazon EKS, native Kubernetes, Amazon ECS, and Amazon EC2. The instructions for enabling Application Signals on Amazon EC2 should work on any platform that supports the CloudWatch agent and Amazon Distro for OpenTelemetry, but the instructions have not been tested on other platforms.

Topics

Java compatibility

Application Signals supports Java applications, and supports the same Java libraries and frameworks as the Amazon Distro for OpenTelemetry does. For more information, see Supported libraries, frameworks, application servers, and JVMs.

JVM versions 8, 11, 17, 21, and 23 are supported.

Python compatibility

Python compatibility

Application Signals supports the same libraries and frameworks as the Amazon Distro for OpenTelemetry does. For more information, see **Supported packages** at opentelemetry-python-contrib.

Python versions 3.8 and later are supported.

Before you enable Application Signals for your Python applications, be aware of the following considerations.

- In some containerized applications, a missing `PYTHONPATH` environment variable can sometimes cause the application to fail to start. To resolve this, ensure that you set the `PYTHONPATH` environment variable to the location of your application's working directory. This is due to a known issue with OpenTelemetry auto-instrumentation. For more information about this issue, see Python autoinstrumentation setting of PYTHONPATH is not compliant.
- For Django applications, there are additional required configurations, which are outlined in the OpenTelemetry Python documentation.
  - Use the `--noreload` flag to prevent automatic reloading.

- Set the `DJANGO_SETTINGS_MODULE` environment variable to the location of your Django application's `settings.py` file. This ensures that OpenTelemetry can correctly access and integrate with your Django settings.

.NET compatibility

Application Signals supports .NET applications with Amazon Distro for Open Telemetry (ADOT) instrumentation on Amazon EKS, Amazon EC2, Amazon ECS and Kubernetes running on Amazon EC2.

This release supports .NET 6 and 8, and .NET Framework 4.6.2 and higher.

Application Signals supports .NET applications that are running on x86-64 or ARM64 CPUs, and supports the Linux x64, Linux ARM64, Microsoft Windows Server 2022 x64, and Microsoft Windows Server 2019 x64 operating systems.

Node.js compatibility

Application Signals supports the same Node.js libraries and frameworks as the Amazon Distro for OpenTelemetry does. For more information, see Supported instrumentations.

This release supports Node.js versions 14, 16, 18, 20, and 22.

Known limitations about Node.js with ESM

The Amazon Distro for Opentelemetry Node.js supports two module systems: ECMAScript Modules (ESM) and CommonJS (CJS). To enable Application Signals, we recommend that you use the CJS module format because OpenTelemetry JavaScript's support of ESM is experimental and a work in progress. For more details, see ECMAScript Modules vs. CommonJS on GitHub.

To determine if your application is using CJS and not ESM, ensure that your application does not fulfill the conditions to enable ESM. For more information about these conditions, see Enabling in the Node.js documentation.

The Amazon Distro for Opentelemetry Node.js provides limited support for ESM based on OpenTelemetry JavaScript's experimental support for ESM. This means the following:

- The Node.js version must be 18.19.0 or later.

- The Node.js application that you want to instrument must include `@aws/aws-distro-opentelemetry-node-autoinstrumentation` and `@opentelemetry/instrumentation` as dependencies.
- The Node.js application that you want to instrument must start with the following node option:

```
NODE_OPTIONS=' --import @aws/aws-distro-opentelemetry-node-autoinstrumentation/
register --experimental-loader=@opentelemetry/instrumentation/hook.mjs'
```

To enable Application Signals with Node.js ESM module format, we provide the different setup for different platforms:

- **Amazon EKS** – the section called “Setting up a Node.js application with the ESM module format”
- **Amazon ECS with sidecar strategy** – Setting up a Node.js application with the ESM module format
- **Amazon ECS with daemon strategy** – Setting up a Node.js application with the ESM module format
- **Amazon ECS with Amazon CDK**
- **Amazon EC2** – Setting up a Node.js application with the ESM module format
- **Kubernetes** – the section called “Setting up a Node.js application with the ESM module format”

OpenTelemetry compatibility

CloudWatch Application Signals is fully compatible with OpenTelemetry. For information about how to get started, see OpenTelemetry with CloudWatch. If you want a more integrated experience, such as using the CloudWatch Agent with Amazon Distro for OpenTelemetry (ADOT) SDKs, see Getting started with Application Signals to find your preferred configuration method.

Known issues

The runtime metrics collection in the Java SDK release v1.32.5 is known to not work with applications using JBoss Wildfly. This issue extends to the Amazon CloudWatch Observability EKS add-on, affecting versions `2.3.0-eksbuild.1` through `2.6.0-eksbuild.1`. The issue is fixed in Java SDK release `v1.32.6` and the Amazon CloudWatch Observability EKS add-on version `v3.0.0-eksbuild.1`.

If you are impacted, either upgrade the Java SDK version or disable your runtime metrics collection by adding the environment variable `OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED=false` to your application.

Supported instrumentation setups

You can enable CloudWatch Application Signals with different instrumentation setups. This topic describes each of the setup methods and recommendations based on the method you choose.

Use Amazon Distro for OpenTelemetry with the CloudWatch Agent

The most integrated application performance monitoring(APM) experience in CloudWatch is delivered through the Amazon Distro for OpenTelemetry (ADOT) SDKs and are used with the CloudWatch Agent to collect application metrics and traces. This option works best if you want to get started with APM in CloudWatch quickly and also leverage out-of-the box integrations with features, such as Container Insights and CloudWatch Logs. For more information, see Enable Application Signals on Amazon EKS Clusters and Enable Application Signals on Amazon EC2, Amazon ECS, or Kubernetes.

Use the OpenTelemetry SDK and Collector

This setup works for the following use cases:

1. You instrumented your application or plan with OpenTelemetry SDKs and currently are using OpenTelemetry Collector.
2. You're using languages, such as Erlang and Rust, that aren't supported by Amazon Distro for OpenTelemetry (ADOT).

For more information, see OpenTelemetry with CloudWatch.

Use the Amazon X-Ray SDK and daemon

This option is best if you instrumented your application using X-Ray SDKs and haven't migrated ADOT SDKs or OpenTelemetry SDKs.

For more information, see Transaction Search.

Feature comparison

Feature	ADOT SDK + CloudWatch Agent	Open Telemetry SDK + OpenTelemetry Collector	X-Ray SDKs
Amazon Support	Yes	Only for data sent to Amazon	Yes
Nonstandard language support	No	Yes	No
Container Insights integration	Yes	No	No
Out of the box logging with CloudWatch Logs	Yes	No	No
Out of the box runtime metrics	Yes	Yes	No
Always gets metrics on 100% of traffic	Yes	Only at 100% sampling rate	Only at 100% sampl rate

Enable Application Signals in your account

If you haven't enabled Application Signals in this account yet, you must grant Application Signals the permissions it needs to discover your services. You need to do this only once for your account.

To enable CloudWatch Application Signals, do the following.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Services**.
3. Choose **Start discovering your Services**.
4. Select the check box and choose **Start discovering Services**.

Completing this step for the first time in your account creates the **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role. This role grants Application Signals the following permissions:

- `xray:GetServiceGraph`
- `logs:StartQuery`
- `logs:GetQueryResults`
- `cloudwatch:GetMetricData`
- `cloudwatch:ListMetrics`
- `tag:GetResources`

For more information about this role, see Service-linked role permissions for CloudWatch Application Signals.

5. Choose **Enable Application Signals**.

(Optional) Try out Application Signals with a sample app

To try out CloudWatch Application Signals on a sample app before you instrument your own applications with it, follow the instructions in this section. These instructions use scripts to help you create an Amazon EKS cluster, install a sample application, and instrument the sample application to work with Application Signals.

The sample application is a Spring "Pet Clinic" application that is composed of four microservices. These services run on Amazon EKS on Amazon EC2 and leverage Application Signals enablement scripts to enable the cluster with the Java, Python, or .NET auto-instrumentation agent.

Requirements

- Currently, Application Signals monitors only Java, Python, or .NET applications.
- You must have the Amazon CLI installed on the instance. We recommend Amazon CLI version 2, but version 1 should also work. For more information about installing the Amazon CLI, see Install or update the latest version of the Amazon CLI.
- The scripts in this section are intended to be run in Linux and macOS environments. For Windows instances, we recommend that you use an Amazon Cloud9 environment to run these scripts. For more information about Amazon Cloud9, see What is Amazon Cloud9?.

- Install a supported version of `kubectl`. You must use a version of `kubectl` within one minor version difference of your Amazon EKS cluster control plane. For example, a 1.26 `kubectl` client works with Kubernetes 1.25, 1.26, and 1.27 clusters. If you already have an Amazon EKS cluster, you might need to configure Amazon credentials for `kubectl`. For more information, see [Creating or updating a `kubeconfig` file for an Amazon EKS cluster].
- Install `eksctl`. `eksctl` uses the Amazon CLI to interact with Amazon, which means it uses the same Amazon credentials as the Amazon CLI. For more information, see [Installing or updating `eksctl`].
- Install `jq`. `jq` is required to run the Application Signals enablement scripts. For more information, see [Download jq].

Step 1: Download the scripts

To download the scripts to set up CloudWatch Application Signals with a sample app, you can download and uncompress the zipped GitHub project file to a local drive, or you can clone the GitHub project.

To clone the project, open a terminal window and enter the following Git command in a given working directory.

```
git clone https://github.com/aws-observability/application-signals-demo.git
```

Step 2: Build and deploy the sample application

To build and push the sample application images, [follow these instructions].

Step 3: Deploy and enable Application Signals and the sample application

Be sure that you have completed the requirements listed in [(Optional) Try out Application Signals with a sample app] before you complete the following steps.

To deploy and enable Application Signals and the sample application

1. Enter the following command. Replace *`new-cluster-name`* with the name that you want to use for the new cluster. Replace *`region-name`* with the name of the Amazon Region, such as `us-west-1`.

   This command sets up the sample app running in a new Amazon EKS cluster with Application Signals enabled.

```
# this script sets up a new cluster, enables Application Signals, and deploys the
# sample application
cd application-signals-demo/scripts/eks/appsignals/one-step && ./setup.sh new-cluster-name region-name
```

The setup script takes about 30 minutes to run, and does the following:

- Creates a new Amazon EKS cluster in the specified Region.
- Creates the necessary IAM permissions for Application Signals (`arn:aws:iam::aws:policy/AWSXrayWriteOnlyAccess` and `arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy`).
- Enables Application Signals by installing the CloudWatch agent and Auto-instrumenting the sample application for CloudWatch metrics and X-Ray traces.
- Deploys the PetClinic Spring sample application in the same Amazon EKS cluster.
- Creates five CloudWatch Synthetics canaries, named `pc-add-vist`, `pc-create-owners`, `pc-visit-pet`, `pc-visit-vet`, `pc-clinic-traffic`. These canaries will run at a one-minute frequency to generate synthetic traffic for the sample app and demonstrate how Synthetics canaries appear in Application Signals.
- Creates four service level objectives (SLOs) for the PetClinic application with the following names:
  - **Availability for Searching an Owner**
  - **Latency for Searching an Owner**
  - **Availability for Registering an Owner**
  - **Latency for Registering an Owner**
- Creates the required IAM role with a custom trust policy granting Application Signals the following permissions:
  - `cloudwatch:PutMetricData`
  - `cloudwatch:GetMetricData`
  - `xray:GetServiceGraph`
  - `logs:StartQuery`
  - `logs:GetQueryResults`

2. (Optional) If you want to review the source code for the PetClinic sample application, you can find them under the root folder.

```
- application-signals-demo
  - spring-petclinic-admin-server
  - spring-petclinic-api-gateway
  - spring-petclinic-config-server
  - spring-petclinic-customers-service
  - spring-petclinic-discovery-server
  - spring-petclinic-vets-service
  - spring-petclinic-visits-service
```

3. To view the deployed PetClinic sample application, run the following command to find the URL:

```
kubectl get ingress
```

Step 4: Monitor the sample application

After completing the steps in the previous section to create the Amazon EKS cluster and deploy the sample application, you can use Application Signals to monitor the application.

> **Note**
>
> For the Application Signals console to start populating, some traffic must reach the sample application. Part of the previous steps created CloudWatch Synthetics canaries that generate traffic to the sample application.

Service health monitoring

After it is enabled, CloudWatch Application Signals automatically discovers and populates a list of services without requiring any additional setup.

To view the list of discovered services and monitor their health

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Services**.
3. To view a service, its operations, and its dependencies, choose the name of one of the services in the list.

This unified, application-centric view helps provide a full perspective of how users are interacting with your service. This can help you triage issues if performance anomalies occur. For complete details about the **Services** view, see [Monitor the operational health of your applications with Application Signals].

4. Choose the **Service Operations** tab to see the standard application metrics for that service's operations. The operations are the API operations that the service calls, for example.

   Then, to view the graphs for a single operation of that service, choose that operation name.

5. Choose the **Dependencies** tab to see the dependencies that your application has, along with the critical application metrics for each dependency. Dependencies include Amazon services and third-party services that your application calls.

6. To view correlated traces from the service details page, choose a data point in one of the three graphs above the table. This populates a new pane with filtered traces from the time period. These traces are sorted and filtered based on the graph that you chose. For example, if you chose the **Latency** graph, the traces are sorted by service response time.

7. In the CloudWatch console navigation pane, choose **SLOs**. You see the SLOs that the script created for the sample application. For more information about SLOs, see [Service level objectives (SLOs)].

(Optional) Step 5: Cleanup

When you're finished testing Application signals, you can use a script provided by Amazon to clean up and delete the artifacts created in your account for the sample application. To perform the cleanup, enter the following command. Replace *`new-cluster-name`* with the name of the cluster that you created for the sample app, and replace *`region`*-name with the name of the Amazon Region, such as `us-west-1`.

```
cd application-signals-demo/scripts/eks/appsignals/one-step && ./cleanup.sh new-cluster-name region-name
```

Enable your applications on Amazon EKS clusters

CloudWatch Application Signals is supported for Java, Python, Node.js, and .NET applications. To enable Application Signals for your applications on an existing Amazon EKS cluster, you can use the Amazon Web Services Management Console or the Amazon CDK.

Topics

Enable Application Signals on an Amazon EKS cluster using the console

To enable CloudWatch Application Signals on your applications on an existing Amazon EKS cluster, use the instructions in this section.

> **Important**
>
> If you are already using OpenTelemetry with an application that you intend to enable for Application Signals, see OpenTelemetry compatibility before you enable Application Signals.

To enable Application Signals for your applications on an existing Amazon EKS cluster

> **Note**
>
> If you haven't already enabled Application Signals, follow the instructions in Enable Application Signals in your account and then follow the procedure below.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Application Signals**.
3. For **Specify platform**, choose **EKS**.
4. For **Select an EKS cluster**, select the cluster where you want to enable Application Signals.
5. If this cluster does not already have the Amazon CloudWatch Observability EKS add-on enabled, you are prompted to enable it. If this is the case, do the following:

    a. Choose **Add CloudWatch Observability EKS add-on**. The Amazon EKS console appears.

    b. Select the check box for **Amazon CloudWatch Observability** and choose **Next**.

       The CloudWatch Observability EKS add-on enables both Application Signals and CloudWatch Container Insights with enhanced observability for Amazon EKS. For more information about Container Insights, see Container Insights.

c. Select the most recent version of the add-on to install.

d. Select an IAM role to use for the add-on. If you choose **Inherit from node**, attach the correct permissions to the IAM role used by your worker nodes. Replace *my-worker-node-role* with the IAM role used by your Kubernetes worker nodes.

```
aws iam attach-role-policy \
--role-name my-worker-node-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
--policy-arn arn:aws:iam::aws:policy/AWSXRayWriteOnlyAccess
```

e. If you want to create a service role to use the add-on, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart.

f. Choose **Next**, confirm the information on the screen, and choose **Create**.

g. In the next screen, choose **Enable CloudWatch Application Signals** to return to the CloudWatch console and finish the process.

6. There are two options for enabling your applications for Application Signals. For consistency, we recommend that you choose one option per cluster.

- The **Console** option is simpler. Using this method causes your pods to restart immediately.
- The **Annotate Manifest File** method gives you more control of when your pods restart, and can also help you manage your monitoring in a more decentralized way if you don't want to centralize it.

> **Note**
>
> If you are enabling Application Signals for a Node.js application with ESM, skip to Setting up a Node.js application with the ESM module format instead.

Console

The **Console** option uses the advanced configuration of the Amazon CloudWatch Observability EKS add-on to setup Application Signals for your services. For more information about the add-on, see (Optional) Additional configuration.

If you don't see a list of workloads and namespaces, ensure you have the right permissions to view them for this cluster. For more information, see Required permissions.

You can monitor single workloads or entire namespaces.

To monitor a single workload:

1. Select the check box by the workload that you want to monitor.
2. Use the **Select language(s)** dropdown list to select the language of the workload. Select the languages that you want to enable Application Signals for, and then choose the check mark icon (✓) to save this selection.

   For Python applications, ensure your application follows the required prerequisites before continuing. For more information, see [Python application doesn't start after Application Signals is enabled].
3. Choose **Done**. The Amazon CloudWatch Observability EKS add-on will immediately inject Amazon Distro for OpenTelemetry autoinstrumentation (ADOT) SDKs into your pods and trigger pod restarts to enable collection of application metrics and traces.

To monitor an entire namespace:

1. Select the check box by the namespace that you want to monitor.
2. Use the **Select language(s)** dropdown list to select the language of the namespace. Select the languages that you want to enable Application Signals for, and then choose the check mark icon (✓) to save this selection. This applies it to all workloads in this namespace, whether they are currently deployed or will be deployed in the future.

   For Python applications, ensure your application follows the required prerequisites before continuing. For more information, see [Python application doesn't start after Application Signals is enabled].
3. Choose **Done**. The Amazon CloudWatch Observability EKS add-on will immediately inject Amazon Distro for OpenTelemetry autoinstrumentation (ADOT) SDKs into your pods and trigger pod restarts to enable collection of application metrics and traces.

To enable Application Signals in another Amazon EKS cluster, choose **Enable Application Signals** from the **Services** screen.

Annotate manifest file

In the CloudWatch console, the **Monitor Services** section explains that you must add an annotation to a manifest YAML in the cluster. Adding this annotation auto-instruments the application to send metrics, traces, and logs to Application Signals.

You have two options for the annotation:

- **Annotate Workload** auto-instruments a single workload in the cluster.
- **Annotate Namespace** auto-instruments all workloads deployed in the selected namespace.

Choose one of those options, and follow the appropriate steps:

- To annotate a single workload:
  1. Choose **Annotate Workload**.
  2. Paste one of the following lines into the `PodTemplate` section of the workload manifest file.
     - **For Java workloads:** `annotations: instrumentation.opentelemetry.io/inject-java: "true"`
     - **For Python workloads:** `annotations: instrumentation.opentelemetry.io/inject-python: "true"`

       For Python applications, there are additional required configurations. For more information, see Python application doesn't start after Application Signals is enabled.
     - **For .NET workloads** `annotations: instrumentation.opentelemetry.io/inject-dotnet: "true"`

     > **Note**
     >
     > To enable Application Signals for a .NET workload on Alpine Linux (`linux-musl-x64`) based images, add the following annotation.
     >
     > ```
     > instrumentation.opentelemetry.io/otel-dotnet-auto-runtime: "linux-musl-x64"
     > ```

    - **For Node.js workloads:** `annotations: instrumentation.opentelemetry.io/inject-nodejs: "true"`
  3. In your terminal, enter `kubectl apply -f your_deployment_yaml` to apply the change.
- To annotate all workloads in a namespace:
  1. Choose **Annotate Namespace**.
  2. Paste one of the following lines into the metadata section of the namespace manifest file. If the namespace includes Java, Python, and .NET workloads, paste all of the following lines into the namespace manifest file.
     - **If there are Java workloads in the namespace:** `annotations: instrumentation.opentelemetry.io/inject-java: "true"`
     - **If there are Python workloads in the namespace:** `annotations: instrumentation.opentelemetry.io/inject-python: "true"`

       For Python applications, there are additional required configurations. For more information, see Python application doesn't start after Application Signals is enabled.
     - **If there are .NET workloads in the namespace:** `annotations: instrumentation.opentelemetry.io/inject-dotnet: "true"`
     - **If there are Node.JS workloads in the namespace:** `annotations: instrumentation.opentelemetry.io/inject-nodejs: "true"`
  3. In your terminal, enter `kubectl apply -f your_namespace_yaml` to apply the change.
  4. In your terminal, enter a command to restart all pods in the namespace. An example command to restart deployment workloads is `kubectl rollout restart deployment -n namespace_name`

7. Choose **View Services when done**. This takes you to the Application Signals Services view, where you can see the data that Application Signals is collecting. It might take a few minutes for data to appear.

   To enable Application Signals in another Amazon EKS cluster, choose **Enable Application Signals** from the **Services** screen.

   For more information about the **Services** view, see Monitor the operational health of your applications with Application Signals.

Note

If you're using a WSGI server for your Python application, see No Application Signals data for Python application that uses a WSGI server for information to make Application Signals work.

We've also identified other considerations that you should keep in mind when enabling Python applications for Application Signals. For more information, see Python application doesn't start after Application Signals is enabled.

Setting up a Node.js application with the ESM module format

We provide limited support for Node.js applications with the ESM module format. For details, see the section called "Known limitations about Node.js with ESM".

For the ESM module format, enabling Application Signals through the console or by annotating the manifest file doesn't work. Skip step 8 of the previous procedure, and do the following instead.

To enable Application Signals for a Node.js application with ESM

1. Install the relevant dependencies to your Node.js application for autoinstrumentation:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
npm install @opentelemetry/instrumentation@0.54.0
```

2. Add the following environmental variables to the Dockerfile for your application and build the image.

```
...
ENV OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true
ENV OTEL_TRACES_SAMPLER_ARG='endpoint=http://cloudwatch-agent.amazon-
cloudwatch:2000'
ENV OTEL_TRACES_SAMPLER='xray'
ENV OTEL_EXPORTER_OTLP_PROTOCOL='http/protobuf'
ENV OTEL_EXPORTER_OTLP_TRACES_ENDPOINT='http://cloudwatch-agent.amazon-
cloudwatch:4316/v1/traces'
ENV OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT='http://cloudwatch-agent.amazon-
cloudwatch:4316/v1/metrics'
ENV OTEL_METRICS_EXPORTER='none'
ENV OTEL_LOGS_EXPORTER='none'
```

```
ENV NODE_OPTIONS='--import @aws/aws-distro-opentelemetry-node-autoinstrumentation/
register --experimental-loader=@opentelemetry/instrumentation/hook.mjs'
ENV OTEL_SERVICE_NAME='YOUR_SERVICE_NAME' #replace with a proper service name
ENV OTEL_PROPAGATORS='tracecontext,baggage,b3,xray'
...

# command to start the application
# for example
# CMD ["node", "index.mjs"]
```

3. Add the environmental variables `OTEL_RESOURCE_ATTRIBUTES_POD_NAME`, `OTEL_RESOURCE_ATTRIBUTES_NODE_NAME`, `OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME`, `POD_NAMESPACE` and `OTEL_RESOURCE_ATTRIBUTES` to the deployment yaml file for the application. For example:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: nodejs-app
  labels:
    app: nodejs-app
spec:
  replicas: 2
  selector:
    matchLabels:
      app: nodejs-app
  template:
    metadata:
      labels:
        app: nodejs-app
      # annotations:
      # make sure this annotation doesn't exit
      #   instrumentation.opentelemetry.io/inject-nodejs: 'true'
    spec:
      containers:
      - name: nodejs-app
        image:your-nodejs-application-image #replace with a proper image uri
        imagePullPolicy: Always
        ports:
        - containerPort: 8000
        env:
          - name: OTEL_RESOURCE_ATTRIBUTES_POD_NAME
            valueFrom:
```

```
              fieldRef:
                fieldPath: metadata.name
          - name: OTEL_RESOURCE_ATTRIBUTES_NODE_NAME
            valueFrom:
              fieldRef:
                fieldPath: spec.nodeName
          - name: OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME
            valueFrom:
              fieldRef:
                fieldPath: metadata.labels['app'] # Assuming 'app' label is set to
 the deployment name
          - name: POD_NAMESPACE
            valueFrom:
              fieldRef:
                fieldPath: metadata.namespace
          - name: OTEL_RESOURCE_ATTRIBUTES
            value: "k8s.deployment.name=
$(OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME),k8s.namespace.name=
$(POD_NAMESPACE),k8s.node.name=$(OTEL_RESOURCE_ATTRIBUTES_NODE_NAME),k8s.pod.name=
$(OTEL_RESOURCE_ATTRIBUTES_POD_NAME)"
```

4. Deploy the Node.js application to the cluster.

Once you have enabled your applications on the Amazon EKS Clusters, you can monitor your application health. For more information, see Monitor the operational health of your applications with Application Signals.

Enable Application Signals on Amazon EKS using Amazon CDK

If you haven't enabled Application Signals in this account yet, you must grant Application Signals the permissions it needs to discover your services. See Enable Application Signals in your account.

1. Enable Application Signals for your applications.

```
import { aws_applicationsignals as applicationsignals } from 'aws-cdk-lib';

const cfnDiscovery = new applicationsignals.CfnDiscovery(this,
  'ApplicationSignalsServiceRole', { }
);
```

The Discovery CloudFormation resource grants Application Signals the following permissions:

- `xray:GetServiceGraph`
- `logs:StartQuery`
- `logs:GetQueryResults`
- `cloudwatch:GetMetricData`
- `cloudwatch:ListMetrics`
- `tag:GetResources`

For more information about this role, see Service-linked role permissions for CloudWatch Application Signals.

2. Install the `amazon-cloudwatch-observability` add-on.

   - Create an IAM role with the `CloudWatchAgentServerPolicy` and the OIDC associated with the cluster.

```
const cloudwatchRole = new Role(this, 'CloudWatchAgentAddOnRole', {
    assumedBy: new OpenIdConnectPrincipal(cluster.openIdConnectProvider),
    managedPolicies:
 [ManagedPolicy.fromAwsManagedPolicyName('CloudWatchAgentServerPolicy')],
});
```

3. Install the add-on with the IAM role created above.

```
new CfnAddon(this, 'CloudWatchAddon', {
    addonName: 'amazon-cloudwatch-observability',
    clusterName: cluster.clusterName,
    serviceAccountRoleArn: cloudwatchRole.roleArn
});
```

4. Add one of the following into the `PodTemplate` section of your workload manifest file.

Language	File
Java	instrumentation.opentelemetry.io/inject-java: "true"
Python	instrumentation.opentelemetry.io/inject-python: "true"

Language	File
.Net	instrumentation.opentelemetry.io/inject-dotnet: "true"
Node.js	instrumentation.opentelemetry.io/inject-nodejs: "true"

```
const deployment = {
  apiVersion: "apps/v1",
  kind: "Deployment",
  metadata: { name: "sample-app" },
  spec: {
    replicas: 3,
    selector: {
      matchLabels: {
        "app": "sample-app"
      }
    },
    template: {
      metadata: {
        labels: {
          "app": "sample-app"
        },
        annotations: {
          "instrumentation.opentelemetry.io/inject-$LANG": "true"
        }
      },
      spec: {...},
    },
  },
};

cluster.addManifest('sample-app', deployment)
```

5.

Enable your applications on Amazon EC2

Enable CloudWatch Application Signals on Amazon EC2 by using the custom setup steps described in this section.

For applications running on Amazon EC2, you install and configure the CloudWatch agent and Amazon Distro for OpenTelemetry yourself. On these architectures enabled with a custom Application Signals setup, Application Signals doesn't autodiscover the names of your services or the hosts or clusters they run on. You must specify these names during the custom setup, and the names that you specify are what is displayed on Application Signals dashboards.

The instructions in this section are for Java, Python, and .NET applications. The steps have been tested on Amazon EC2 instances, but are also expected to work on other architectures that support Amazon Distro for OpenTelemetry.

Requirements

- To get support for Application Signals, you must use the most recent version of both the CloudWatch agent and the Amazon Distro for OpenTelemetry agent.
- You must have the Amazon CLI installed on the instance. We recommend Amazon CLI version 2, but version 1 should also work. For more information about installing the Amazon CLI, see Install or update the latest version of the Amazon CLI.

> **Important**
>
> If you are already using OpenTelemetry with an application that you intend to enable for Application Signals, see OpenTelemetry compatibility before you enable Application Signals.

Step 1: Enable Application Signals in your account

You must first enable Application Signals in your account. If you haven't, see Enable Application Signals in your account.

Step 2: Download and start the CloudWatch agent

To install the CloudWatch agent as part of enabling Application Signals on an Amazon EC2 instance or on-premises host

1. Download the latest version of the CloudWatch agent to the instance. If the instance already has the CloudWatch agent installed, you might need to update it. Only versions of the agent released on November 30, 2023 or later support CloudWatch Application Signals.

   For information about downloading the CloudWatch agent, see Download the CloudWatch agent package.

2. Before you start the CloudWatch agent, configure it to enable Application Signals. The following example is a CloudWatch agent configuration that enables Application Signals for both metrics and traces on an EC2 host.

   We recommend that you place this file at `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json` on Linux systems.

```
{
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  },
  "logs": {
    "metrics_collected": {
      "application_signals": {}
    }
  }
}
```

3. Attach the **CloudWatchAgentServerPolicy** IAM policy to the IAM role of your Amazon EC2 instance. For permissions for on-premises hosts, see Permissions for on-premises servers.

   a. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

   b. Choose **Roles** and find the role used by your Amazon EC2 instance. Then choose the name of that role.

   c. In the **Permissions** tab, choose **Add permissions**, **Attach policies**.

   d. Find **CloudWatchAgentServerPolicy**. Use the search box if needed. Then select the check box for that policy and choose **Add permissions**.

4. Start the CloudWatch agent by entering the following commands. Replace *agent-config-file-path* with the path to the CloudWatch agent configuration file, such as `./amazon-cloudwatch-agent.json`. You must include the `file:` prefix as shown.

```
export CONFIG_FILE_PATH=./amazon-cloudwatch-agent.json
```

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl \
-a fetch-config \
-m ec2 -s -c file:agent-config-file-path
```

Permissions for on-premises servers

For an on-premises host, you will need to provide Amazon authorization to your device.

To set up permissions for an on-premises host

1. Create the IAM user to be used to provide permissions to your on-premises host:

   a. Open the IAM console at https://console.amazonaws.cn/iam/.
   b. Choose **Users**, **Create User**.
   c. In **User details**, for **User name**, enter a name for the new IAM user. This is the sign-in name for Amazon that will be used to authenticate your host. Then choose **Next**
   d. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.
   e. From the **Permissions policies** list, select the **CloudWatchAgentServerPolicy** policy to add to your user. Then choose **Next**.
   f. On the **Review and create** page, ensure that you are satisfied with the user name and that the **CloudWatchAgentServerPolicy** policy is in the **Permissions summary**.
   g. Choose **Create user**

2. Create and retrieve your Amazon access key and secret key:

   a. In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.
   b. On the user's page, choose the **Security credentials** tab. Then, in the **Access keys** section, choose **Create access key**.

c. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.

d. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.

e. For **Create access key Step 3**, select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.

f. Choose **Done**.

3. Configure your Amazon credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Step 3: Instrument your application and start it

The next step is to instrument your application for CloudWatch Application Signals.

Java

To instrument your Java applications as part of enabling Application Signals on an Amazon EC2 instance or on-premises host

1. Download the latest version of the Amazon Distro for OpenTelemetry Java auto-instrumentation agent. You can download the latest version by using this link. You can view information about all released versions at aws-otel-java-instrumentation Releases.

2. To optimize your Application Signals benefits, use environment variables to provide additional information before you start your application. This information will be displayed in Application Signals dashboards.

   - For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

     - (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.

- (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, one of the following defaults is used:
  - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:`*`name-of-Auto-Scaling-group`*
  - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
  - If this is an on-premises host, it is set to `generic:default`

  This environment variable is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.
- For the `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` variable, specify the base endpoint URL where traces are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces`
- For the `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT` variable, specify the base endpoint URL where metrics are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics`
- For the `JAVA_TOOL_OPTIONS` variable, specify the path where the Amazon Distro for OpenTelemetry Java auto-instrumentation agent is stored.

  ```
  export JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH"
  ```

  For example:

  ```
  export AWS_ADOT_JAVA_INSTRUMENTATION_PATH=./aws-opentelemetry-agent.jar
  ```
- For the `OTEL_METRICS_EXPORTER` variable, we recommend that you set the value to `none`. This disables other metrics exporters so that only the Application Signals exporter is used.

- Set `OTEL_AWS_APPLICATION_SIGNALS_ENABLED` to `true`. This generates Application Signals metrics from traces.

3. Start your application with the environment variables listed in the previous step. The following is an example of a starting script.

> **Note**
>
> The following configuration supports only versions 1.32.2 and later of the Amazon Distro for OpenTelemetry auto-instrumentation agent for Java.

```
JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH" \
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics
 \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
java -jar $MY_JAVA_APP.jar
```

4. (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *`$YOUR_APPLICATION_LOG_GROUP`* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

   The following is an example of a starting script that helps enable log correlation.

```
JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH" \
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORT=none \
```

```
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics
 \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
OTEL_RESOURCE_ATTRIBUTES="aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$
 \
java -jar $MY_JAVA_APP.jar
```

Python

Note

If you're using a WSGI server for your Python application, in addition to the following steps in this section, see No Application Signals data for Python application that uses a WSGI server for information to make Application Signals work.

To instrument your Python applications as part of enabling Application Signals on an Amazon EC2 instance

1. Download the latest version of the Amazon Distro for OpenTelemetry Python auto-instrumentation agent. Install it by running the following command.

   ```
   pip install aws-opentelemetry-distro
   ```

   You can view information about all released versions at Amazon Distro for OpenTelemetry Python instrumentation.

2. To optimize your Application Signals benefits, use environment variables to provide additional information before you start your application. This information will be displayed in Application Signals dashboards.

   a. For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

      - `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.

- `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, one of the following defaults is used:
  - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:`*`name-of-Auto-Scaling-group`*.
  - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
  - If this is an on-premises host, it is set to `generic:default`

  This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.

b. For the `OTEL_EXPORTER_OTLP_PROTOCOL` variable, specify `http/protobuf` to export telemetry data over HTTP to the CloudWatch agent endpoints listed in the following steps.

c. For the `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` variable, specify the base endpoint URL where traces are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port over HTTP. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces`

d. For the `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT` variable, specify the base endpoint URL where metrics are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port over HTTP. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics`

e. For the `OTEL_METRICS_EXPORTER` variable, we recommend that you set the value to none. This disables other metrics exporters so that only the Application Signals exporter is used.

f. Set the `OTEL_AWS_APPLICATION_SIGNALS_ENABLED` variable to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.

3. Start your application with the environment variables discussed in the previous step. The following is an example of a starting script.

- Replace $SVC_NAME with your application name. This will be displayed as the name of the application, in Application Signals dashboards.
- Replace $PYTHON_APP with the location and name of your application.

```
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
OTEL_PYTHON_DISTRO=aws_distro \
OTEL_PYTHON_CONFIGURATOR=aws_configurator \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_SAMPLER=xray \
OTEL_TRACES_SAMPLER_ARG="endpoint=http://localhost:2000" \
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics
 \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
OTEL_RESOURCE_ATTRIBUTES="service.name=$SVC_NAME" \
opentelemetry-instrument python $MY_PYTHON_APP.py
```

Before you enable Application Signals for your Python applications, be aware of the following considerations.

- In some containerized applications, a missing PYTHONPATH environment variable can sometimes cause the application to fail to start. To resolve this, ensure that you set the PYTHONPATH environment variable to the location of your application's working directory. This is due to a known issue with OpenTelemetry auto-instrumentation. For more information about this issue, see Python autoinstrumentation setting of PYTHONPATH is not compliant.
- For Django applications, there are additional required configurations, which are outlined in the OpenTelemetry Python documentation.
  - Use the `--noreload` flag to prevent automatic reloading.
  - Set the DJANGO_SETTINGS_MODULE environment variable to the location of your Django application's `settings.py` file. This ensures that OpenTelemetry can correctly access and integrate with your Django settings.

4. (Optional) To enable log correlation, in OTEL_RESOURCE_ATTRIBUTES, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be

correlated with the relevant log entries from these log groups. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

The following is an example of a starting script that helps enable log correlation.

```
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
OTEL_PYTHON_DISTRO=aws_distro \
OTEL_PYTHON_CONFIGURATOR=aws_configurator \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_SAMPLER=xray \
OTEL_TRACES_SAMPLER_ARG="endpoint=http://localhost:2000" \
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics
 \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
OTEL_RESOURCE_ATTRIBUTES="aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$
 \
java -jar $MY_PYTHON_APP.jar
```

.NET

To instrument your .NET applications as part of enabling Application Signals on an Amazon EC2 instance or on-premises host

1. Download the latest version of the Amazon Distro for OpenTelemetry .NET auto-instrumentation package. You can download the latest version at aws-otel-dotnet-instrumentation Releases.
2. To enable Application Signals, set the following environment variables to provide additional information before you start your application. These variables are necessary to set up the startup hook for .NET instrumentation, before you start your .NET application. Replace `dotnet-service-name` in the `OTEL_RESOURCE_ATTRIBUTES` environment variable with the service name of your choice.

- The following is an example for Linux.

```
export INSTALL_DIR=OpenTelemetryDistribution
export CORECLR_ENABLE_PROFILING=1
export CORECLR_PROFILER={918728DD-259F-4A6A-AC2B-B85E1B658318}
export CORECLR_PROFILER_PATH=${INSTALL_DIR}/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so
export DOTNET_ADDITIONAL_DEPS=${INSTALL_DIR}/AdditionalDeps
export DOTNET_SHARED_STORE=${INSTALL_DIR}/store
export DOTNET_STARTUP_HOOKS=${INSTALL_DIR}/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll
export OTEL_DOTNET_AUTO_HOME=${INSTALL_DIR}

export
 OTEL_DOTNET_AUTO_PLUGINS="AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"

export OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
export OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
export OTEL_EXPORTER_OTLP_ENDPOINT=http://127.0.0.1:4316
export OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://127.0.0.1:4316/
v1/metrics
export OTEL_METRICS_EXPORTER=none
export OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true
export OTEL_TRACES_SAMPLER=xray
export OTEL_TRACES_SAMPLER_ARG=http://127.0.0.1:2000
```

- The following is an example for Windows Server.

```
$env:INSTALL_DIR = "OpenTelemetryDistribution"
$env:CORECLR_ENABLE_PROFILING = 1
$env:CORECLR_PROFILER = "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
$env:CORECLR_PROFILER_PATH = Join-Path $env:INSTALL_DIR "win-x64/
OpenTelemetry.AutoInstrumentation.Native.dll"
$env:DOTNET_ADDITIONAL_DEPS = Join-Path $env:INSTALL_DIR "AdditionalDeps"
$env:DOTNET_SHARED_STORE = Join-Path $env:INSTALL_DIR "store"
$env:DOTNET_STARTUP_HOOKS = Join-Path $env:INSTALL_DIR "net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
$env:OTEL_DOTNET_AUTO_HOME = $env:INSTALL_DIR
```

```
$env:OTEL_DOTNET_AUTO_PLUGINS =
 "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"

$env:OTEL_RESOURCE_ATTRIBUTES = "service.name=dotnet-service-name"
$env:OTEL_EXPORTER_OTLP_PROTOCOL = "http/protobuf"
$env:OTEL_EXPORTER_OTLP_ENDPOINT = "http://127.0.0.1:4316"
$env:OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT = "http://127.0.0.1:4316/
v1/metrics"
$env:OTEL_METRICS_EXPORTER = "none"
$env:OTEL_AWS_APPLICATION_SIGNALS_ENABLED = "true"
$env:OTEL_TRACES_SAMPLER = "xray"
$env:OTEL_TRACES_SAMPLER_ARG = "http://127.0.0.1:2000"
```

3. Start your application with the environment variables listed in the previous step.

   (Optional) Alternatively, you can use the installation scripts provided to help installation and setup of Amazon Distro for OpenTelemetry .NET auto-instrumentation package.

   For Linux, download and install the Bash installation script from the GitHub releases page:

```
# Download and Install
curl -L -O https://github.com/aws-observability/aws-otel-dotnet-instrumentation/
releases/latest/download/aws-otel-dotnet-install.sh
chmod +x ./aws-otel-dotnet-install.sh
./aws-otel-dotnet-install.sh

# Instrument
. $HOME/.otel-dotnet-auto/instrument.sh
export OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
```

   For Windows Server, download and install the PowerShell installation script from the GitHub releases page:

```
# Download and Install
$module_url = "https://github.com/aws-observability/aws-otel-dotnet-
instrumentation/releases/latest/download/AWS.Otel.DotNet.Auto.psm1"
$download_path = Join-Path $env:temp "AWS.Otel.DotNet.Auto.psm1"
Invoke-WebRequest -Uri $module_url -OutFile $download_path
Import-Module $download_path
Install-OpenTelemetryCore
```

```
# Instrument
Import-Module $download_path
Register-OpenTelemetryForCurrentSession -OTelServiceName "dotnet-service-name"
Register-OpenTelemetryForIIS
```

You can find the NuGet package of the Amazon Distro for OpenTelemetry .NET auto-instrumentation package in the official NuGet repository. Be sure to check the README file for instructions.

Node.js

Note

If you are enabling Application Signals for a Node.js application with ESM, see Setting up a Node.js application with the ESM module format before you start these steps.

To instrument your Node.js applications as part of enabling Application Signals on an Amazon EC2 instance

1. Download the latest version of the Amazon Distro for OpenTelemetry JavaScript auto-instrumentation agent for Node.js. Install it by running the following command.

   ```
   npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
   ```

   You can view information about all released versions at Amazon Distro for OpenTelemetry JavaScript instrumentation.

2. To optimize your Application Signals benefits, use environment variables to provide additional information before you start your application. This information will be displayed in Application Signals dashboards.

   a. For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

      - `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used.

- `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, one of the following defaults is used:
  - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:name-of-Auto-Scaling-group`.
  - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
  - If this is an on-premises host, it is set to `generic:default`

  This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.

b. For the `OTEL_EXPORTER_OTLP_PROTOCOL` variable, specify `http/protobuf` to export telemetry data over HTTP to the CloudWatch agent endpoints listed in the following steps.

c. For the `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` variable, specify the base endpoint URL where traces are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port over HTTP. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces`

d. For the `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT` variable, specify the base endpoint URL where metrics are to be exported to. The CloudWatch agent exposes 4316 as its OTLP port over HTTP. On Amazon EC2, because applications communicate with the local CloudWatch agent, you should set this value to `OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics`

e. For the `OTEL_METRICS_EXPORTER` variable, we recommend that you set the value to none. This disables other metrics exporters so that only the Application Signals exporter is used.

f. Set the `OTEL_AWS_APPLICATION_SIGNALS_ENABLED` variable to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.

3. Start your application with the environment variables discussed in the previous step. The following is an example of a starting script.

- Replace $SVC_NAME with your application name. This will be displayed as the name of the application, in Application Signals dashboards.

```
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_TRACES_SAMPLER=xray \
OTEL_TRACES_SAMPLER_ARG="endpoint=http://localhost:2000" \
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/metrics
 \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
OTEL_RESOURCE_ATTRIBUTES="service.name=$SVC_NAME" \
node --require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/
register' your-application.js
```

4. (Optional) To enable log correlation, in `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

   The following is an example of a starting script that helps enable log correlation.

```
export OTEL_METRICS_EXPORTER=none \
export OTEL_LOGS_EXPORTER=none \
export OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true \
export OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
export OTEL_TRACES_SAMPLER=xray \
export OTEL_TRACES_SAMPLER_ARG=endpoint=http://localhost:2000 \
export OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT=http://localhost:4316/v1/
metrics \
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=http://localhost:4316/v1/traces \
```

```
export
 OTEL_RESOURCE_ATTRIBUTES="aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=
 \
node --require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/
register' your-application.js
```

Setting up a Node.js application with the ESM module format

We provide limited support for Node.js applications with the ESM module format. For details, see the section called "Known limitations about Node.js with ESM".

To enable Application Signals for a Node.js application with ESM, you need to modify the steps in the previous procedure.

First, install `@opentelemetry/instrumentation` for your Node.js application:

```
npm install @opentelemetry/instrumentation@0.54.0
```

Then, in steps 3 and 4 in the previous procedure, change the node options from:

```
--require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/register'
```

to the following:

```
--import @aws/aws-distro-opentelemetry-node-autoinstrumentation/register --
experimental-loader=@opentelemetry/instrumentation/hook.mjs
```

(Optional) Step 4: Monitor your application health

Once you have enabled your applications on Amazon EC2, you can monitor your application health. For more information, see Monitor the operational health of your applications with Application Signals.

Enable your applications on Amazon ECS

Enable CloudWatch Application Signals on Amazon ECS by using the custom setup steps described in this section.

For applications running on Amazon ECS, you install and configure the CloudWatch agent and Amazon Distro for OpenTelemetry yourself. On these architectures enabled with a custom Application Signals setup, Application Signals doesn't autodiscover the names of your services or the hosts or clusters they run on. You must specify these names during the custom setup, and the names that you specify are what is displayed on Application Signals dashboards.

Use a custom setup to enable Application Signals on Amazon ECS

Use these custom setup instructions to onboard your applications on Amazon ECS to CloudWatch Application Signals. You install and configure the CloudWatch agent and Amazon Distro for OpenTelemetry yourself.

There are two methods for deploying Application Signals on Amazon ECS. Choose the one that is best for your environment.

- Deploy using the sidecar strategy – You add a CloudWatch agent sidecar container to each task definition in the cluster.

  Advantages:

  - Supports both the `ec2` and `Fargate` launch types.
  - You can always use `localhost` as the IP address when you set up environment variables.

  Disadvantages:

  - You must set up the CloudWatch agent sidecar container for each service task that runs in the cluster.
  - Only the `awsvpc` network mode is supported.
- Deploy using the daemon strategy – You add a CloudWatch agent task only once in the cluster, and the Amazon ECS daemon scheduling strategy deploys it as needed. The ensures that each instance continuously receives traces and metrics, providing centralized visibility without the need for the agent to run as a sidecar with each application task definition.

  Advantages:

  - You need to set up the daemon service for the CloudWatch agent only once in the cluster.

  Disadvantages:

  - Doesn't support the Fargate launch type.
  - If you use the `awsvpc` or `bridge` network mode, you have to manually specify each container instance's private IP address in the environment variables.

With either method, on Amazon ECS clusters Application Signals doesn't autodiscover the names of your services. You must specify your service names during the custom setup, and the names that you specify are what is displayed on Application Signals dashboards.

Deploy using the sidecar strategy

Step 1: Enable Application Signals in your account

You must first enable Application Signals in your account. If you haven't, see Enable Application Signals in your account.

Step 2: Create IAM roles

You must create an IAM role. If you already have created this role, you might need to add permissions to it.

- **ECS task role—** Containers use this role to run. The permissions should be whatever your applications need, plus **CloudWatchAgentServerPolicy**.

For more information about creating IAM roles, see Creating IAM Roles.

Step 3: Prepare CloudWatch agent configuration

First, prepare the agent configuration with Application Signals enabled. To do this, create a local file named `/tmp/ecs-cwagent.json`.

```
{
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  },
  "logs": {
    "metrics_collected": {
      "application_signals": {}
    }
  }
}
```

Then upload this configuration to the SSM Parameter Store. To do this, enter the following command. In the file, replace *$REGION* with your actual Region name.

```
aws ssm put-parameter \
--name "ecs-cwagent" \
--type "String" \
--value "`cat /tmp/ecs-cwagent.json`" \
--region "$REGION"
```

Step 4: Instrument your application with the CloudWatch agent

The next step is to instrument your application for CloudWatch Application Signals.

Java

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

   ```
   "volumes": [
     {
       "name": "opentelemetry-auto-instrumentation"
     }
   ]
   ```

2. Add a CloudWatch agent sidecar definition. To do this, append a new container called `ecs-cwagent` to your application's task definition. Replace *$REGION* with your actual Region name. Replace *$IMAGE* with the path to the latest CloudWatch container image on Amazon Elastic Container Registry. For more information, see cloudwatch-agent on Amazon ECR.

   If you want to enable the CloudWatch agent with a daemon strategy instead, see the instructions at Deploy using the daemon strategy.

   ```
   {
     "name": "ecs-cwagent",
     "image": "$IMAGE",
     "essential": true,
     "secrets": [
       {
         "name": "CW_CONFIG_CONTENT",
         "valueFrom": "ecs-cwagent"
       }
     ],
     "logConfiguration": {
   ```

```
        "logDriver": "awslogs",
        "options": {
          "awslogs-create-group": "true",
          "awslogs-group": "/ecs/ecs-cwagent",
          "awslogs-region": "$REGION",
          "awslogs-stream-prefix": "ecs"
        }
      }
    }
```

3. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](#).

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
    "cp",
    "/javaagent.jar",
    "/otel-auto-instrumentation/javaagent.jar"
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation",
      "containerPath": "/otel-auto-instrumentation",
      "readOnly": false
    }
  ]
}
```

4. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

5. Add the following environment variables to your application container. You must be using version 1.32.2 or later of the Amazon Distro for OpenTelemetry auto-instrumentation agent for Java.

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions. (Optional) To enable log correlation for Application Signals, set an additional environment variable `aws.log.group.names` to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *`$YOUR_APPLICATION_LOG_GROUP`* with the log group names for your application. If you have multiple

Environment variable	Setting to enable Application Signals
	log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_LOGS_EXPORTER`	Set to none to disable other logs exporters.
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to Application Signals using HTTP.
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Set to `http://localhost:4316/v1/metrics` to send metrics to the CloudWatch sidecar.
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Set to `http://localhost:4316/v1/traces` to send traces to the CloudWatch sidecar.

Environment variable	Setting to enable Application Signals
OTEL_TRACES_SAMPLER	Set this to `xray` to set X-Ray as the traces sampler.
OTEL_PROPAGATORS	Set `xray` as one of the propagators.
JAVA_TOOL_OPTIONS	Set to " `-javaagent:$ AWS_ADOT_JAVA_INSTRUMENTATION_PATH` " Replace *AWS_ADOT_JAVA_INSTRUMENTATION_PATH* with the path where the Amazon Distro for OpenTelemetry Java auto-instrumentation agent is stored. For example, `/otel-auto-instrumentation/javaagent.jar`

6. Mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and traces, use the following example for a Java application. If you want to enable log correlation, see the next step instead.

```
{
  "name": "my-app",
   ...
  "environment": [
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value": "service.name=$SVC_NAME"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
```

```
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
    },
    {
      "name": "JAVA_TOOL_OPTIONS",
      "value": " -javaagent:/otel-auto-instrumentation/javaagent.jar"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://localhost:4316/v1/metrics"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://localhost:4316/v1/traces"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_PROPAGATORS",
      "value": "tracecontext,baggage,b3,xray"
    }
  ],
  "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation",
      "containerPath": "/otel-auto-instrumentation",
      "readOnly": false
    }
  ]
}
```

Python

Before you enable Application Signals for your Python applications, be aware of the following considerations.

- In some containerized applications, a missing PYTHONPATH environment variable can sometimes cause the application to fail to start. To resolve this, ensure that you set the PYTHONPATH environment variable to the location of your application's working directory. This is due to a known issue with OpenTelemetry auto-instrumentation. For more information about this issue, see [Python autoinstrumentation setting of PYTHONPATH is not compliant](#).
- For Django applications, there are additional required configurations, which are outlined in the [OpenTelemetry Python documentation](#).
  - Use the `--noreload` flag to prevent automatic reloading.
  - Set the `DJANGO_SETTINGS_MODULE` environment variable to the location of your Django application's `settings.py` file. This ensures that OpenTelemetry can correctly access and integrate with your Django settings.
- If you're using a WSGI server for your Python application, in addition to the following steps in this section, see [No Application Signals data for Python application that uses a WSGI server](#) for information to make Application Signals work.

To instrument your Python application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation-python"
  }
]
```

2. Add a CloudWatch agent sidecar definition. To do this, append a new container called `ecs-cwagent` to your application's task definition. Replace *$REGION* with your actual Region name. Replace *$IMAGE* with the path to the latest CloudWatch container image on Amazon Elastic Container Registry. For more information, see [cloudwatch-agent](#) on Amazon ECR.

   If you want to enable the CloudWatch agent with a daemon strategy instead, see the instructions at [Deploy using the daemon strategy](#).

```
{
  "name": "ecs-cwagent",
  "image": "$IMAGE",
  "essential": true,
  "secrets": [
    {
      "name": "CW_CONFIG_CONTENT",
      "valueFrom": "ecs-cwagent"
    }
  ],
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "true",
      "awslogs-group": "/ecs/ecs-cwagent",
      "awslogs-region": "$REGION",
      "awslogs-stream-prefix": "ecs"
    }
  }
}
```

3. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](https://gallery.ecr.aws/aws-observability/adot-autoinstrumentation-python).

```
{
    "name": "init",
    "image": "$IMAGE",
    "essential": false,
    "command": [
        "cp",
        "-a",
        "/autoinstrumentation/.",
        "/otel-auto-instrumentation-python"
    ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation-python",
            "containerPath": "/otel-auto-instrumentation-python",
            "readOnly": false
        }
    ]
```

```
}
```

4. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

5. Add the following environment variables to your application container.

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.

Environment variable	Setting to enable Application Signals
	(Optional) To enable log correlation for Application Signals, set an additional environment variable `aws.log.group.names` to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to CloudWatch using HTTP.

Environment variable	Setting to enable Application Signals
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Set to `http://127.0.0.1:4316/v1/metrics` to send metrics to the CloudWatch sidecar.
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Set to `http://127.0.0.1:4316/v1/traces` to send traces to the CloudWatch sidecar.
`OTEL_TRACES_SAMPLER`	Set this to `xray` to set X-Ray as the traces sampler.
`OTEL_PROPAGATORS`	Add `xray` as one of the propagators.
`OTEL_PYTHON_DISTRO`	Set to `aws_distro` to use the ADOT Python instrumentation.
`OTEL_PYTHON_CONFIGURATOR`	Set to `aws_configurator` to use the ADOT Python configuration.
`PYTHONPATH`	Replace `$APP_PATH` with the location of the application's working directory within the container. This is required for the Python interpreter to find your application modules.
`DJANGO_SETTINGS_MODULE`	Required only for Django applications. Set it to the location of your Django application's `settings.py` file. Replace `$PATH_TO_SETTINGS`.

6. Mount the volume `opentelemetry-auto-instrumentation-python` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and traces, use the following example for a Python application. If you want to enable log correlation, see the next step instead.

```
{
  "name": "my-app",
```

```
  ...
  "environment": [
    {
      "name": "PYTHONPATH",
      "value": "/otel-auto-instrumentation-python/opentelemetry/instrumentation/
auto_instrumentation:$APP_PATH:/otel-auto-instrumentation-python"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://localhost:2000"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_PYTHON_DISTRO",
      "value": "aws_distro"
    },
    {
      "name": "OTEL_PYTHON_CONFIGURATOR",
      "value": "aws_configurator"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://localhost:4316/v1/traces"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://localhost:4316/v1/metrics"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
```

```
        "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
        "value": "true"
      },
      {
        "name": "OTEL_RESOURCE_ATTRIBUTES",
        "value": "service.name=$SVC_NAME"
      },
      {
        "name": "DJANGO_SETTINGS_MODULE",
        "value": "$PATH_TO_SETTINGS.settings"
      }
    ],
    "mountPoints": [
      {
        "sourceVolume": "opentelemetry-auto-instrumentation-python",
        "containerPath": "/otel-auto-instrumentation-python",
        "readOnly": false
      }
    ]
}
```

7. (Optional) To enable log correlation, do the following before you mount the volume. In `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see [Enable metric to log correlation](). To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see [Enable trace to log correlation]().

   The following is an example. To enable log correlation, use this example when you mount the volume `opentelemetry-auto-instrumentation-python` that you defined in step 1 of this procedure.

```
{
  "name": "my-app",
  ...
  "environment": [
```

```
    {
      "name": "PYTHONPATH",
      "value": "/otel-auto-instrumentation-python/opentelemetry/instrumentation/
auto_instrumentation:$APP_PATH:/otel-auto-instrumentation-python"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://localhost:2000"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_PYTHON_DISTRO",
      "value": "aws_distro"
    },
    {
      "name": "OTEL_PYTHON_CONFIGURATOR",
      "value": "aws_configurator"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://localhost:4316/v1/traces"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://localhost:4316/v1/metrics"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
```

```
    },
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$SVC_NAME"
    },
    {
      "name": "DJANGO_SETTINGS_MODULE",
      "value": "$PATH_TO_SETTINGS.settings"
    }
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-python",
      "containerPath": "/otel-auto-instrumentation-python",
      "readOnly": false
    }
  ]
}
```

.NET

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation"
  }
]
```

2. Add a CloudWatch agent sidecar definition. To do this, append a new container called `ecs-cwagent` to your application's task definition. Replace *$REGION* with your actual Region name. Replace *$IMAGE* with the path to the latest CloudWatch container image on Amazon Elastic Container Registry. For more information, see [cloudwatch-agent](#) on Amazon ECR.

   If you want to enable the CloudWatch agent with a daemon strategy instead, see the instructions at [Deploy using the daemon strategy](#).

```
{
  "name": "ecs-cwagent",
  "image": "$IMAGE",
  "essential": true,
  "secrets": [
    {
      "name": "CW_CONFIG_CONTENT",
      "valueFrom": "ecs-cwagent"
    }
  ],
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "true",
      "awslogs-group": "/ecs/ecs-cwagent",
      "awslogs-region": "$REGION",
      "awslogs-stream-prefix": "ecs"
    }
  }
}
```

3. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](#).

   For a Linux container instance, use the following.

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
      "cp",
      "-a",
      "autoinstrumentation/.",
      "/otel-auto-instrumentation"
  ],
  "mountPoints": [
      {
          "sourceVolume": "opentelemetry-auto-instrumentation",
          "containerPath": "/otel-auto-instrumentation",
          "readOnly": false
```

```
        }
    ]
}
```

For a Windows Server container instance, use the following.

```
{
    "name": "init",
    "image": "$IMAGE",
    "essential": false,
    "command": [
        "CMD",
        "/c",
        "xcopy",
        "/e",
        "C:\\autoinstrumentation\\*",
        "C:\\otel-auto-instrumentation",
        "&&",
        "icacls",
        "C:\\otel-auto-instrumentation",
        "/grant",
        "*S-1-1-0:R",
        "/T"
    ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation",
            "containerPath": "C:\\otel-auto-instrumentation",
            "readOnly": false
        }
    ]
}
```

4. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
    {
        "containerName": "init",
        "condition": "SUCCESS"
    }
]
```

5. Add the following environment variables to your application container. You must be using version 1.1.0 or later of the Amazon Distro for OpenTelemetry [auto-instrumentation agent for .NET](#).

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_LOGS_EXPORTER`	Set to none to disable other logs exporters.

Environment variable	Setting to enable Application Signals
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to Application Signals using HTTP.
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Set to `http://localhost:4316/v1/metrics` to send metrics to the CloudWatch sidecar.
`OTEL_EXPORTER_OTLP_ENDPOINT`	Set to `http://localhost:4316/` to send traces to the CloudWatch sidecar.
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Set to `http://localhost:4316/v1/traces` to send traces to the CloudWatch sidecar.
`OTEL_DOTNET_AUTO_HOME`	Set to the installation location of ADOT .NET automatic instrumentation.
`OTEL_DOTNET_AUTO_PLUGINS`	Set to `AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin, AWS.Distro.OpenTelemetry.AutoInstrumentation` to enable the Application Signals plugin.
`CORECLR_ENABLE_PROFILING`	Set to 1 to enable the profiler.
`CORECLR_PROFILER`	Set to `{918728DD-259F-4A6A-AC2B-B85E1B658318}` as the CLSID of the profiler.

Environment variable	Setting to enable Application Signals
`CORECLR_PROFILER_PATH`	Set this to the path of the profiler. On Linux, set it to `${OTEL_DOTNET_AUTO_HOME}/linux-x64/OpenTelemetry.AutoInstrumentation.Native.so` On Windows Server, set it to `${OTEL_DOTNET_AUTO_HOME}/win-x64/OpenTelemetry.AutoInstrumentation.Native.dll`
`DOTNET_ADDITIONAL_DEPS`	Set this to the folder path of `${OTEL_DOTNET_AUTO_HOME}/AdditionalDeps` .
`DOTNET_SHARED_STORE`	Set this to the folder path of `${OTEL_DOTNET_AUTO_HOME}/store` .
`DOTNET_STARTUP_HOOKS`	Set this to path of the managed assembly `${OTEL_DOTNET_AUTO_HOME}/net/OpenTelemetry.AutoInstrumentation.StartupHook.dll` to run before the main application's entry point.

6. Mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure. For Linux, use the following.

```
{
    "name": "my-app",
   ...
    "environment": [
        {
           "name": "OTEL_RESOURCE_ATTRIBUTES",
           "value": "service.name=$SVC_NAME"
       },
        {
            "name": "CORECLR_ENABLE_PROFILING",
```

```
            "value": "1"
        },
        {
            "name": "CORECLR_PROFILER",
            "value": "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
        },
        {
            "name": "CORECLR_PROFILER_PATH",
            "value": "/otel-auto-instrumentation/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so"
        },
        {
            "name": "DOTNET_ADDITIONAL_DEPS",
            "value": "/otel-auto-instrumentation/AdditionalDeps"
        },
        {
            "name": "DOTNET_SHARED_STORE",
            "value": "/otel-auto-instrumentation/store"
        },
        {
            "name": "DOTNET_STARTUP_HOOKS",
            "value": "/otel-auto-instrumentation/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
        },
        {
            "name": "OTEL_DOTNET_AUTO_HOME",
            "value": "/otel-auto-instrumentation"
        },
        {
            "name": "OTEL_DOTNET_AUTO_PLUGINS",
            "value": "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
        },
        {
            "name": "OTEL_RESOURCE_ATTRIBUTES",
            "value": "aws.log.group.names=
$YOUR_APPLICATION_LOG_GROUP,service.name=aws-dotnet-service-name"
        },
        {
            "name": "OTEL_LOGS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_METRICS_EXPORTER",
```

```
            "value": "none"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
            "value": "http/protobuf"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
            "value": "true"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
            "value": "http://localhost:4316/v1/metrics"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
            "value": "http://localhost:4316/v1/traces"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_ENDPOINT",
            "value": "http://localhost:4316"
        },
        {
           "name": "OTEL_TRACES_SAMPLER",
           "value": "xray"
       },
       {
           "name": "OTEL_TRACES_SAMPLER_ARG",
           "value": "endpoint=http://localhost:2000"
       },
        {
            "name": "OTEL_PROPAGATORS",
            "value": "tracecontext,baggage,b3,xray"
        }
    ],
    "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation",
```

```
            "containerPath": "/otel-auto-instrumentation",
            "readOnly": false
        }
    ]
}
```

For Windows Server, use the following.

```
{
    "name": "my-app",
   ...
    "environment": [
       {
           "name": "OTEL_RESOURCE_ATTRIBUTES",
           "value": "service.name=$SVC_NAME"
       },
        {
            "name": "CORECLR_ENABLE_PROFILING",
            "value": "1"
        },
        {
            "name": "CORECLR_PROFILER",
            "value": "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
        },
        {
            "name": "CORECLR_PROFILER_PATH",
            "value": "C:\\otel-auto-instrumentation\\win-x64\
\OpenTelemetry.AutoInstrumentation.Native.dll"
        },
        {
            "name": "DOTNET_ADDITIONAL_DEPS",
            "value": "C:\\otel-auto-instrumentation\\AdditionalDeps"
        },
        {
            "name": "DOTNET_SHARED_STORE",
            "value": "C:\\otel-auto-instrumentation\\store"
        },
        {
            "name": "DOTNET_STARTUP_HOOKS",
            "value": "C:\\otel-auto-instrumentation\\net\
\OpenTelemetry.AutoInstrumentation.StartupHook.dll"
        },
        {
```

```
            "name": "OTEL_DOTNET_AUTO_HOME",
            "value": "C:\\otel-auto-instrumentation"
        },
        {
            "name": "OTEL_DOTNET_AUTO_PLUGINS",
            "value": "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
        },
        {
            "name": "OTEL_RESOURCE_ATTRIBUTES",
            "value": "aws.log.group.names=
$YOUR_APPLICATION_LOG_GROUP,service.name=dotnet-service-name"
        },
        {
            "name": "OTEL_LOGS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_METRICS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
            "value": "http/protobuf"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
            "value": "true"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
            "value": "http://localhost:4316/v1/metrics"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
            "value": "http://localhost:4316/v1/traces"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_ENDPOINT",
            "value": "http://localhost:4316"
        },
        {
           "name": "OTEL_TRACES_SAMPLER",
           "value": "xray"
```

```
        },
        {
            "name": "OTEL_TRACES_SAMPLER_ARG",
            "value": "endpoint=http://localhost:2000"
        },
         {
             "name": "OTEL_PROPAGATORS",
             "value": "tracecontext,baggage,b3,xray"
         }
    ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation",
            "containerPath": "C:\\otel-auto-instrumentation",
            "readOnly": false
        }
    ],
    "dependsOn": [
        {
            "containerName": "init",
            "condition": "SUCCESS"
        }
   ]
}
```

Node.js

Note

If you are enabling Application Signals for a Node.js application with ESM, see Setting up a Node.js application with the ESM module format before you start these steps.

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation-node"
```

```
  }
]
```

2. Add a CloudWatch agent sidecar definition. To do this, append a new container called `ecs-cwagent` to your application's task definition. Replace *$REGION* with your actual Region name. Replace *$IMAGE* with the path to the latest CloudWatch container image on Amazon Elastic Container Registry. For more information, see cloudwatch-agent on Amazon ECR.

   If you want to enable the CloudWatch agent with a daemon strategy instead, see the instructions at Deploy using the daemon strategy.

```
{
  "name": "ecs-cwagent",
  "image": "$IMAGE",
  "essential": true,
  "secrets": [
    {
      "name": "CW_CONFIG_CONTENT",
      "valueFrom": "ecs-cwagent"
    }
  ],
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "true",
      "awslogs-group": "/ecs/ecs-cwagent",
      "awslogs-region": "$REGION",
      "awslogs-stream-prefix": "ecs"
    }
  }
}
```

3. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the Amazon Distro for OpenTelemetry Amazon ECR image repository.

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
    "cp",
```

```
    "-a",
    "/autoinstrumentation/.",
    "/otel-auto-instrumentation-node"
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-node",
      "containerPath": "/otel-auto-instrumentation-node",
      "readOnly": false
    }
  ],
}
```

4. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

5. Add the following environment variables to your application container.

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your applicati

Environment variable	Setting to enable Application Signals
	on in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions. (Optional) To enable log correlation for Application Signals, set an additional environment variable `aws.log.group.names` to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

Environment variable	Setting to enable Application Signals
OTEL_AWS_APPLICATION_SIGNALS_ENABLED	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
OTEL_METRICS_EXPORTER	Set to none to disable other metrics exporters.
OTEL_LOGS_EXPORTER	Set to none to disable other logs exporters.
OTEL_EXPORTER_OTLP_PROTOCOL	Set to `http/protobuf` to send metrics and traces to Application Signals using OTLP/HTTP and protobuf.
OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT	Set to `http://localhost:4316/v1/metrics` to send metrics to the CloudWatch sidecar.
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT	Set to `http://localhost:4316/v1/traces` to send traces to the CloudWatch sidecar.
OTEL_TRACES_SAMPLER	Set this to `xray` to set X-Ray as the traces sampler.
OTEL_PROPAGATORS	Set `xray` as one of the propagators.
NODE_OPTIONS	Set to `--require` *`AWS_ADOT_NODE_INSTRUMENTATION_PATH`* . Replace *`AWS_ADOT_NODE_INSTRUMENTATION_PATH`* with the path where the Amazon Distro for OpenTelemetry Node.js auto-instrumentation is stored. For example, `/otel-auto-instrumentation-node/autoinstrumentation.js`

6. Mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and traces, use the following example for a Node.js application. If you want to enable log correlation, see the next step instead.

   For your Application Container, add a dependency on the `init` container to make sure that container finishes before your application container starts.

```
{
  "name": "my-app",
   ...
  "environment": [
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value": "service.name=$SVC_NAME"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://localhost:4316/v1/metrics"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://localhost:4316/v1/traces"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
```

```
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://localhost:2000"
    },
    {
      "name": "NODE_OPTIONS",
      "value": "--require /otel-auto-instrumentation-node/
autoinstrumentation.js"
    }
    ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-node",
      "containerPath": "/otel-auto-instrumentation-node",
      "readOnly": false
    }
  ],
  "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ]
}
```

7. (Optional) To enable log correlation, do the following before you mount the volume. In `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *`$YOUR_APPLICATION_LOG_GROUP`* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see [Enable metric to log correlation](). To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see [Enable trace to log correlation]().

   The following is an example. Use this example to enable log correlation when you mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure.

```
{
  "name": "my-app",
   ...
  "environment": [
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$SVC_NAME"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://localhost:4316/v1/metrics"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://localhost:4316/v1/traces"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://localhost:2000"
    },
    {
      "name": "NODE_OPTIONS",
```

```
      "value": "--require /otel-auto-instrumentation-node/
autoinstrumentation.js"
    }
    ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-node",
      "containerPath": "/otel-auto-instrumentation-node",
      "readOnly": false
    }
  ],
  "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ]
}
```

Setting up a Node.js application with the ESM module format

We provide limited support for Node.js applications with the ESM module format. For details, see the section called "Known limitations about Node.js with ESM".

For the ESM module format, using the `init` container to inject the Node.js instrumentation SDK doesn't apply. To enable Application Signals for Node.js with ESM, skip steps 1 and 3 of the previous procedure, and do the following instead.

To enable Application Signals for a Node.js application with ESM

1. Install the relevant dependencies to your Node.js application for autoinstrumentation:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
npm install @opentelemetry/instrumentation@0.54.0
```

2. In steps 5 and 6 in the previous procedure, remove the mounting of the volume `opentelemetry-auto-instrumentation-node`:

```
 "mountPoints": [
    {
```

```
            "sourceVolume": "opentelemetry-auto-instrumentation-node",
            "containerPath": "/otel-auto-instrumentation-node",
            "readOnly": false
        }
    ]
```

Replace the node options with the following.

```
{
    "name": "NODE_OPTIONS",
    "value": "--import @aws/aws-distro-opentelemetry-node-autoinstrumentation/
register --experimental-loader=@opentelemetry/instrumentation/hook.mjs"
}
```

Step 5: Deploy your application

Create a new revision of your task definition and deploy it to your application cluster. You should see three containers in the newly created task:

- `init`– A required container for initializing Application Signals.
- `ecs-cwagent`– A container running the CloudWatch agent
- *`my-app`*– This is the example application container in our documentation. In your actual workloads, this specific container might not exist or might be replaced with your own service containers.

(Optional) Step 6: Monitor your application health

Once you have enabled your applications on Amazon ECS, you can monitor your application health. For more information, see [Monitor the operational health of your applications with Application Signals](#).

Deploy using the daemon strategy

Step 1: Enable Application Signals in your account

You must first enable Application Signals in your account. If you haven't, see [Enable Application Signals in your account](#).

Step 2: Create IAM roles

You must create an IAM role. If you already have created this role, you might need to add permissions to it.

- **ECS task role—** Containers use this role to run. The permissions should be whatever your applications need, plus **CloudWatchAgentServerPolicy**.

For more information about creating IAM roles, see Creating IAM Roles.

Step 3: Prepare CloudWatch agent configuration

First, prepare the agent configuration with Application Signals enabled. To do this, create a local file named `/tmp/ecs-cwagent.json`.

```
{
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  },
  "logs": {
    "metrics_collected": {
      "application_signals": {}
    }
  }
}
```

Then upload this configuration to the SSM Parameter Store. To do this, enter the following command. In the file, replace *$REGION* with your actual Region name.

```
aws ssm put-parameter \
--name "ecs-cwagent" \
--type "String" \
--value "`cat /tmp/ecs-cwagent.json`" \
--region "$REGION"
```

Step 4: Deploy the CloudWatch agent daemon service

Create the following task definition and deploy it to your application cluster. Replace *$REGION* with your actual Region name. Replace *$TASK_ROLE_ARN* and *$EXECUTION_ROLE_ARN* with the

IAM roles you prepared in Step 2: Create IAM roles. Replace *$IMAGE* with the path to the latest CloudWatch container image on Amazon Elastic Container Registry. For more information, see cloudwatch-agent on Amazon ECR.

Note

The daemon service exposes two ports on the host, with 4316 used as endpoint for receiving metrics and traces and 2000 as the CloudWatch trace sampler endpoint. This setup allows the agent to collect and transmit telemetry data from all application tasks running on the host. Ensure that these ports are not used by other services on the host to avoid conflicts.

```
{
  "family": "ecs-cwagent-daemon",
  "taskRoleArn": "$TASK_ROLE_ARN",
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "networkMode": "bridge",
  "containerDefinitions": [
    {
      "name": "ecs-cwagent",
      "image": "$IMAGE",
      "essential": true,
      "portMappings": [
        {
          "containerPort": 4316,
          "hostPort": 4316
        },
        {
          "containerPort": 2000,
          "hostPort": 2000
        }
      ],
      "secrets": [
        {
          "name": "CW_CONFIG_CONTENT",
          "valueFrom": "ecs-cwagent"
        }
      ],
      "logConfiguration": {
        "logDriver": "awslogs",
```

```
        "options": {
          "awslogs-create-group": "true",
          "awslogs-group": "/ecs/ecs-cwagent",
          "awslogs-region": "$REGION",
          "awslogs-stream-prefix": "ecs"
        }
      }
    }
  ],
  "requiresCompatibilities": [
    "EC2"
  ],
  "cpu": "128",
  "memory": "64"
}
```

Step 5: Instrument your application

The next step is to instrument your application for Application Signals.

Java

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation"
  }
]
```

2. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](#).

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
    "cp",
```

```
    "/javaagent.jar",
    "/otel-auto-instrumentation/javaagent.jar"
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation",
      "containerPath": "/otel-auto-instrumentation",
      "readOnly": false
    }
  ]
}
```

3. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

4. Add the following environment variables to your application container. You must be using version 1.32.2 or later of the Amazon Distro for OpenTelemetry [auto-instrumentation agent for Java](https://).

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the

Environment variable	Setting to enable Application Signals
	Hosted In environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions. (Optional) To enable log correlation for Application Signals, set an additional environment variable `aws.log.group.names` to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *`$YOUR_APPLICATION_LOG_GROUP`* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see [Enable metric to log correlation](). To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see [Enable trace to log correlation]().

Environment variable	Setting to enable Application Signals
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_LOGS_EXPORTER`	Set to none to disable other logs exporters.
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to Application Signals using HTTP.
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Sends metrics to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/metrics` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*CW_CONTAINER_IP* :4316/v1/metrics, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).

Environment variable	Setting to enable Application Signals
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT	Sends traces to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/traces` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*CW_CONTAINER_IP* :4316/v1/traces, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
OTEL_TRACES_SAMPLER	Set this to `xray` to set X-Ray as the traces sampler.
OTEL_PROPAGATORS	Set `xray` as one of the propagators.
JAVA_TOOL_OPTIONS	Set to " `-javaagent:$` *AWS_ADOT_JAVA_INSTRUMENTATION_PATH* " Replace *AWS_ADOT_JAVA_INSTRUMENTATION_PATH* with the path where the Amazon Distro for OpenTelemetry Java auto-instrumentation agent is stored. For example, `/otel-auto-instrumentation/javaagent.jar`

5. Mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and traces, use the following example for a Java application. If you want to enable log correlation, see the next step instead.

```
{
  "name": "my-app",
```

```
...
"environment": [
  {
    "name": "OTEL_RESOURCE_ATTRIBUTES",
    "value": "service.name=$SVC_NAME"
  },
  {
    "name": "OTEL_LOGS_EXPORTER",
    "value": "none"
  },
  {
    "name": "OTEL_METRICS_EXPORTER",
    "value": "none"
  },
  {
    "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
    "value": "http/protobuf"
  },
  {
    "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
    "value": "true"
  },
  {
    "name": "JAVA_TOOL_OPTIONS",
    "value": " -javaagent:/otel-auto-instrumentation/javaagent.jar"
  },
  {
    "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
    "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
  },
  {
    "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
    "value": "http://CW_CONTAINER_IP:4316/v1/traces"
  },
  {
    "name": "OTEL_TRACES_SAMPLER",
    "value": "xray"
  },
  {
    "name": "OTEL_PROPAGATORS",
    "value": "tracecontext,baggage,b3,xray"
  }
],
  "dependsOn": [
```

```
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation",
      "containerPath": "/otel-auto-instrumentation",
      "readOnly": false
    }
  ]
}
```

Python

Before you enable Application Signals for your Python applications, be aware of the following considerations.

- In some containerized applications, a missing `PYTHONPATH` environment variable can sometimes cause the application to fail to start. To resolve this, ensure that you set the `PYTHONPATH` environment variable to the location of your application's working directory. This is due to a known issue with OpenTelemetry auto-instrumentation. For more information about this issue, see [Python autoinstrumentation setting of PYTHONPATH is not compliant].
- For Django applications, there are additional required configurations, which are outlined in the [OpenTelemetry Python documentation].
  - Use the `--noreload` flag to prevent automatic reloading.
  - Set the `DJANGO_SETTINGS_MODULE` environment variable to the location of your Django application's `settings.py` file. This ensures that OpenTelemetry can correctly access and integrate with your Django settings.
- If you're using a WSGI server for your Python application, in addition to the following steps in this section, see [No Application Signals data for Python application that uses a WSGI server] for information to make Application Signals work.

To instrument your Python application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation-python"
  }
]
```

2. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](https://gallery.ecr.aws/).

```
{
    "name": "init",
    "image": "$IMAGE",
    "essential": false,
    "command": [
        "cp",
        "-a",
        "/autoinstrumentation/.",
        "/otel-auto-instrumentation-python"
    ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation-python",
            "containerPath": "/otel-auto-instrumentation-python",
            "readOnly": false
        }
    ]
}
```

3. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

4. Add the following environment variables to your application container.

Environment variable	Setting to enable Application Signals
OTEL_RESOURCE_ATTRIBUTES	Specify the following information as key-value pairs: • service.name sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of UnknownService is used. • deployment.environment sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of generic:default is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions. (Optional) To enable log correlation for Application Signals, set an additional environment variable aws.log.group.names to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple

Environment variable	Setting to enable Application Signals
	log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to CloudWatch using HTTP.

Environment variable	Setting to enable Application Signals
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Sends metrics to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/metrics` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*`CW_CONTAINER_IP`* :4316/v1/metrics, where *`CW_CONTAINER_IP`* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Sends traces to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/traces` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*`CW_CONTAINER_IP`* :4316/v1/traces, where *`CW_CONTAINER_IP`* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_TRACES_SAMPLER`	Set this to `xray` to set X-Ray as the traces sampler.

Environment variable	Setting to enable Application Signals
OTEL_TRACES_SAMPLER_ARG	Sets the traces sampler endpoint. • For applications running in `host` mode, set this to `http://localhost:2000` . • For applications running in `bridge` mode or `awsvpc` mode, set this to `http://CW_CONTAINER_IP :2000`, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
OTEL_PROPAGATORS	Add `xray` as one of the propagators.
OTEL_PYTHON_DISTRO	Set to `aws_distro` to use the ADOT Python instrumentation.
OTEL_PYTHON_CONFIGURATOR	Set to `aws_configuration` to use the ADOT Python configuration.
PYTHONPATH	Replace `$APP_PATH` with the location of the application's working directory within the container. This is required for the Python interpreter to find your application modules.
DJANGO_SETTINGS_MODULE	Required only for Django applications. Set it to the location of your Django application's `settings.py` file. Replace `$PATH_TO_SETTINGS` .

5. Mount the volume `opentelemetry-auto-instrumentation-python` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and

traces, use the following example for a Python application. If you want to enable log correlation, see the next step instead.

```
{
  "name": "my-app",
  ...
  "environment": [
    {
      "name": "PYTHONPATH",
      "value": "/otel-auto-instrumentation-python/opentelemetry/instrumentation/
auto_instrumentation:$APP_PATH:/otel-auto-instrumentation-python"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://CW_CONTAINER_IP:2000"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_PYTHON_DISTRO",
      "value": "aws_distro"
    },
    {
      "name": "OTEL_PYTHON_CONFIGURATOR",
      "value": "aws_configurator"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/traces"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
```

```
      },
      {
        "name": "OTEL_METRICS_EXPORTER",
        "value": "none"
      },
      {
        "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
        "value": "true"
      },
      {
        "name": "OTEL_RESOURCE_ATTRIBUTES",
        "value": "service.name=$SVC_NAME"
      },
      {
        "name": "DJANGO_SETTINGS_MODULE",
        "value": "$PATH_TO_SETTINGS.settings"
      }
    ],
    "dependsOn": [
      {
        "containerName": "init",
        "condition": "SUCCESS"
      }
    ],
    "mountPoints": [
      {
        "sourceVolume": "opentelemetry-auto-instrumentation-python",
        "containerPath": "/otel-auto-instrumentation-python",
        "readOnly": false
      }
    ]
}
```

6. (Optional) To enable log correlation, do the following before you mount the volume. In `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *`$YOUR_APPLICATION_LOG_GROUP`* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to

log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

The following is an example. To enable log correlation, use this example when you mount the volume `opentelemetry-auto-instrumentation-python` that you defined in step 1 of this procedure.

```
{
  "name": "my-app",
  ...
  "environment": [
    {
      "name": "PYTHONPATH",
      "value": "/otel-auto-instrumentation-python/opentelemetry/instrumentation/
auto_instrumentation:$APP_PATH:/otel-auto-instrumentation-python"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://CW_CONTAINER_IP:2000"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_PYTHON_DISTRO",
      "value": "aws_distro"
    },
    {
      "name": "OTEL_PYTHON_CONFIGURATOR",
      "value": "aws_configurator"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/traces"
```

```
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
    },
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$SVC_NAME"
    },
    {
      "name": "DJANGO_SETTINGS_MODULE",
      "value": "$PATH_TO_SETTINGS.settings"
    }
  ],
  "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-python",
      "containerPath": "/otel-auto-instrumentation-python",
      "readOnly": false
    }
  ]
}
```

.NET

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation"
  }
]
```

2. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the [Amazon Distro for OpenTelemetry Amazon ECR image repository](https://gallery.ecr.aws/aws-observability/adot-autoinstrumentation-dotnet).

   For a Linux container instance, use the following.

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
      "cp",
      "-a",
      "autoinstrumentation/.",
      "/otel-auto-instrumentation"
  ],
  "mountPoints": [
      {
          "sourceVolume": "opentelemetry-auto-instrumentation",
          "containerPath": "/otel-auto-instrumentation",
          "readOnly": false
      }
  ]
}
```

   For a Windows Server container instance, use the following.

```
{
  "name": "init",
```

```
    "image": "$IMAGE",
    "essential": false,
    "command": [
        "CMD",
        "/c",
        "xcopy",
        "/e",
        "C:\\autoinstrumentation\\*",
        "C:\\otel-auto-instrumentation",
        "&&",
        "icacls",
        "C:\\otel-auto-instrumentation",
        "/grant",
        "*S-1-1-0:R",
        "/T"
    ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation",
            "containerPath": "C:\\otel-auto-instrumentation",
            "readOnly": false
        }
    ]
}
```

3. Add a dependency on the `init` container to make sure that container finishes before your application container starts.

```
"dependsOn": [
    {
        "containerName": "init",
        "condition": "SUCCESS"
    }
]
```

4. Add the following environment variables to your application container. You must be using version 1.1.0 or later of the Amazon Distro for OpenTelemetry auto-instrumentation agent for .NET.

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_LOGS_EXPORTER`	Set to none to disable other logs exporters.

Environment variable	Setting to enable Application Signals
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to Application Signals using HTTP.
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Sends metrics to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/metrics`. • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*CW_CONTAINER_IP*:4316/v1/metrics, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_EXPORTER_OTLP_ENDPOINT`	Sends traces to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316`. • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*CW_CONTAINER_IP*:4316, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).

Environment variable	Setting to enable Application Signals
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Sends traces to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/traces` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*CW_CONTAINER_IP* :4316/v1/traces, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_TRACES_SAMPLER_ARG`	Sets the traces sampler endpoint. • For applications running in `host` mode, set this to `http://localhost:2000` . • For applications running in `bridge` mode or `awsvpc` mode, set this to `http://`*CW_CONTAINER_IP* `:2000`, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_DOTNET_AUTO_HOME`	Set to the installation location of ADOT .NET automatic instrumentation.

Environment variable	Setting to enable Application Signals
OTEL_DOTNET_AUTO_PLUGINS	Set to AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin, AWS.Distro.OpenTelemetry.AutoInstrumentation to enable the Application Signals plugin.
CORECLR_ENABLE_PROFILING	Set to 1 to enable the profiler.
CORECLR_PROFILER	Set to {918728DD-259F-4A6A-AC2B-B85E1B658318} as the CLSID of the profiler.
CORECLR_PROFILER_PATH	Set this to the path of the profiler. On Linux, set it to ${OTEL_DOTNET_AUTO_HOME}/linux-x64/OpenTelemetry.AutoInstrumentation.Native.so On Windows Server, set it to ${OTEL_DOTNET_AUTO_HOME}/win-x64/OpenTelemetry.AutoInstrumentation.Native.dll
DOTNET_ADDITIONAL_DEPS	Set this to the folder path of ${OTEL_DOTNET_AUTO_HOME}/AdditionalDeps .
DOTNET_SHARED_STORE	Set this to the folder path of ${OTEL_DOTNET_AUTO_HOME}/store .
DOTNET_STARTUP_HOOKS	Set this to path of the managed assembly ${OTEL_DOTNET_AUTO_HOME}/net/OpenTelemetry.AutoInstrumentation.StartupHook.dll to run before the main application's entry point.

5. Mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure. For Linux, use the following.

```
{
    "name": "my-app",
   ...
    "environment": [
        {
           "name": "OTEL_RESOURCE_ATTRIBUTES",
           "value": "service.name=$SVC_NAME"
       },
        {
            "name": "CORECLR_ENABLE_PROFILING",
            "value": "1"
        },
        {
            "name": "CORECLR_PROFILER",
            "value": "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
        },
        {
            "name": "CORECLR_PROFILER_PATH",
            "value": "/otel-auto-instrumentation/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so"
        },
        {
            "name": "DOTNET_ADDITIONAL_DEPS",
            "value": "/otel-auto-instrumentation/AdditionalDeps"
        },
        {
            "name": "DOTNET_SHARED_STORE",
            "value": "/otel-auto-instrumentation/store"
        },
        {
            "name": "DOTNET_STARTUP_HOOKS",
            "value": "/otel-auto-instrumentation/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
        },
        {
            "name": "OTEL_DOTNET_AUTO_HOME",
            "value": "/otel-auto-instrumentation"
        },
        {
            "name": "OTEL_DOTNET_AUTO_PLUGINS",
```

```
            "value": "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
        },
        {
            "name": "OTEL_RESOURCE_ATTRIBUTES",
            "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=dotnet-service-
name"
        },
        {
            "name": "OTEL_LOGS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_METRICS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
            "value": "http/protobuf"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
            "value": "true"
        },
        {
            "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
            "value": "http://localhost:4316/v1/metrics"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
            "value": "http://CW_CONTAINER_IP:4316/v1/traces"
        },
        {
            "name": "OTEL_EXPORTER_OTLP_ENDPOINT",
            "value": "http://CW_CONTAINER_IP:4316"
        },
        {
           "name": "OTEL_TRACES_SAMPLER",
           "value": "xray"
       },
       {
           "name": "OTEL_TRACES_SAMPLER_ARG",
           "value": "endpoint=http://CW_CONTAINER_IP:2000"
```

```
        },
         {
             "name": "OTEL_PROPAGATORS",
             "value": "tracecontext,baggage,b3,xray"
         }
    ],
      "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ],
    "mountPoints": [
        {
            "sourceVolume": "opentelemetry-auto-instrumentation",
            "containerPath": "/otel-auto-instrumentation",
            "readOnly": false
        }
    ],
    "dependsOn": [
        {
            "containerName": "init",
            "condition": "SUCCESS"
        }
   ]
}
```

For Windows Server, use the following.

```
{
    "name": "my-app",
   ...
    "environment": [
       {
           "name": "OTEL_RESOURCE_ATTRIBUTES",
           "value": "service.name=$SVC_NAME"
       },
        {
            "name": "CORECLR_ENABLE_PROFILING",
            "value": "1"
        },
        {
            "name": "CORECLR_PROFILER",
```

```
            "value": "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
        },
        {
            "name": "CORECLR_PROFILER_PATH",
            "value": "C:\\otel-auto-instrumentation\\win-x64\
\OpenTelemetry.AutoInstrumentation.Native.dll"
        },
        {
            "name": "DOTNET_ADDITIONAL_DEPS",
            "value": "C:\\otel-auto-instrumentation\\AdditionalDeps"
        },
        {
            "name": "DOTNET_SHARED_STORE",
            "value": "C:\\otel-auto-instrumentation\\store"
        },
        {
            "name": "DOTNET_STARTUP_HOOKS",
            "value": "C:\\otel-auto-instrumentation\\net\
\OpenTelemetry.AutoInstrumentation.StartupHook.dll"
        },
        {
            "name": "OTEL_DOTNET_AUTO_HOME",
            "value": "C:\\otel-auto-instrumentation"
        },
        {
            "name": "OTEL_DOTNET_AUTO_PLUGINS",
            "value": "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
        },
        {
            "name": "OTEL_RESOURCE_ATTRIBUTES",
            "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=dotnet-service-
name"
        },
        {
            "name": "OTEL_LOGS_EXPORTER",
            "value": "none"
        },
        {
            "name": "OTEL_METRICS_EXPORTER",
            "value": "none"
        },
        {
```

```
                "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
                "value": "http/protobuf"
            },
            {
                "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
                "value": "true"
            },
            {
                "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
                "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
            },
            {
                "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
                "value": "http://CW_CONTAINER_IP:4316/v1/traces"
            },
            {
                "name": "OTEL_EXPORTER_OTLP_ENDPOINT",
                "value": "http://CW_CONTAINER_IP:4316"
            },
            {
               "name": "OTEL_TRACES_SAMPLER",
               "value": "xray"
           },
           {
               "name": "OTEL_TRACES_SAMPLER_ARG",
               "value": "endpoint=http://CW_CONTAINER_IP:2000"
           },
            {
                "name": "OTEL_PROPAGATORS",
                "value": "tracecontext,baggage,b3,xray"
            }
        ],
        "mountPoints": [
            {
                "sourceVolume": "opentelemetry-auto-instrumentation",
                "containerPath": "C:\\otel-auto-instrumentation",
                "readOnly": false
            }
        ],
        "dependsOn": [
            {
                "containerName": "init",
                "condition": "SUCCESS"
            }
```

```
    ]
}
```

Node.js

> **Note**
>
> If you are enabling Application Signals for a Node.js application with ESM, see Setting up a Node.js application with the ESM module format before you start these steps.

To instrument your application on Amazon ECS with the CloudWatch agent

1. First, specify a bind mount. The volume will be used to share files across containers in the next steps. You will use this bind mount later in this procedure.

```
"volumes": [
  {
    "name": "opentelemetry-auto-instrumentation-node"
  }
]
```

2. Append a new container `init` to your application's task definition. Replace *$IMAGE* with the latest image from the Amazon Distro for OpenTelemetry Amazon ECR image repository.

```
{
  "name": "init",
  "image": "$IMAGE",
  "essential": false,
  "command": [
    "cp",
    "-a",
    "/autoinstrumentation/.",
    "/otel-auto-instrumentation-node"
  ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-node",
      "containerPath": "/otel-auto-instrumentation-node",
      "readOnly": false
```

```
    }
  ],
}
```

3. Add a dependency on the `init` container to make sure that this container finishes before your application container starts.

```
"dependsOn": [
  {
    "containerName": "init",
    "condition": "SUCCESS"
  }
]
```

4. Add the following environment variables to your application container.

Environment variable	Setting to enable Application Signals
`OTEL_RESOURCE_ATTRIBUTES`	Specify the following information as key-value pairs: • `service.name` sets the name of the service. This will be diplayed as the service name for your application in Application Signals dashboards. If you don't provide a value for this key, the default of `UnknownService` is used. • `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. If you don't specify this, the default of `generic:default` is used. This attribute key is used only by Application Signals, and is converted into X-Ray

Environment variable	Setting to enable Application Signals
	trace annotations and CloudWatch metric dimensions. (Optional) To enable log correlation for Application Signals, set an additional environment variable `aws.log.group.names` to be the log group name for your application log. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from the log group. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2` . To enable metric to log correlation, setting this current environmental variable is enough. For more information, see [Enable metric to log correlation](). To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see [Enable trace to log correlation]().
`OTEL_AWS_APPLICATION_SIGNALS_ENABLED`	Set to `true` to have your container start sending X-Ray traces and CloudWatch metrics to Application Signals.
`OTEL_METRICS_EXPORTER`	Set to none to disable other metrics exporters.
`OTEL_LOGS_EXPORTER`	Set to none to disable other logs exporters.

Environment variable	Setting to enable Application Signals
`OTEL_EXPORTER_OTLP_PROTOCOL`	Set to `http/protobuf` to send metrics and traces to Application Signals using OTLP/HTTP and protobuf.
`OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT`	Sends metrics to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/metrics` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*`CW_CONTAINER_IP`* :4316/v1/metrics, where *`CW_CONTAINER_IP`* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_EXPORTER_OTLP_TRACES_ENDPOINT`	Sends traces to the CloudWatch daemon container. • For applications running in `host` mode, set this to `http://localhost:4316/v1/traces` . • For applications running in `bridge` mode or `awsvpc` mode, set this to http://*`CW_CONTAINER_IP`* :4316/v1/traces, where *`CW_CONTAINER_IP`* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).

Environment variable	Setting to enable Application Signals
`OTEL_TRACES_SAMPLER`	Set this to `xray` to set X-Ray as the traces sampler.
`OTEL_TRACES_SAMPLER_ARG`	Sets the traces sampler endpoint. • For applications running in `host` mode, set this to `http://localhost:2000` . • For applications running in `bridge` mode or `awsvpc` mode, set this to `http://CW_CONTAINER_IP :2000`, where *CW_CONTAINER_IP* is the private IP address of the EC2 container instance. You can retrieve this address from the Instance Metadata Service (IMDS).
`OTEL_PROPAGATORS`	Set `xray` as one of the propagators.
`NODE_OPTIONS`	Set to `--require AWS_ADOT_NODE_INSTRUMENTATION_PATH` . Replace *AWS_ADOT_NODE_INSTRUMENTATION_PATH* with the path where the Amazon Distro for OpenTelemetry Node.js auto-instrumentation is stored. For example, `/otel-auto-instrumentation-node/autoinstrumentation.js`

5. Mount the volume `opentelemetry-auto-instrumentation-node` that you defined in step 1 of this procedure. If you don't need to enable log correlation with metrics and traces, use the following example for a Node.js application. If you want to enable log correlation, see the next step instead.

   For your Application Container, add a dependency on the `init` container to make sure that container finishes before your application container starts.

```
{
  "name": "my-app",
   ...
  "environment": [
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
      "value": "service.name=$SVC_NAME"
    },
    {
      "name": "OTEL_LOGS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_METRICS_EXPORTER",
      "value": "none"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
      "value": "http/protobuf"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
      "value": "true"
    },
    {
      "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
    },
    {
      "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
      "value": "http://CW_CONTAINER_IP:4316/v1/traces"
    },
    {
      "name": "OTEL_TRACES_SAMPLER",
      "value": "xray"
    },
    {
      "name": "OTEL_TRACES_SAMPLER_ARG",
      "value": "endpoint=http://CW_CONTAINER_IP:2000"
    },
    {
      "name": "NODE_OPTIONS",
```

```
      "value": "--require /otel-auto-instrumentation-node/
autoinstrumentation.js"
    }
    ],
  "mountPoints": [
    {
      "sourceVolume": "opentelemetry-auto-instrumentation-node",
      "containerPath": "/otel-auto-instrumentation-node",
      "readOnly": false
    }
  ],
  "dependsOn": [
    {
      "containerName": "init",
      "condition": "SUCCESS"
    }
  ]
}
```

6. (Optional) To enable log correlation, do the following before you mount the volume. In `OTEL_RESOURCE_ATTRIBUTES`, set an additional environment variable `aws.log.group.names` for the log groups of your application. By doing so, the traces and metrics from your application can be correlated with the relevant log entries from these log groups. For this variable, replace *$YOUR_APPLICATION_LOG_GROUP* with the log group names for your application. If you have multiple log groups, you can use an ampersand (&) to separate them as in this example: `aws.log.group.names=log-group-1&log-group-2`. To enable metric to log correlation, setting this current environmental variable is enough. For more information, see Enable metric to log correlation. To enable trace to log correlation, you'll also need to change the logging configuration in your application. For more information, see Enable trace to log correlation.

   The following is an example. Use this example to enable log correlation when you mount the volume `opentelemetry-auto-instrumentation` that you defined in step 1 of this procedure.

```
{
  "name": "my-app",
   ...
  "environment": [
    {
      "name": "OTEL_RESOURCE_ATTRIBUTES",
```

```
        "value":
 "aws.log.group.names=$YOUR_APPLICATION_LOG_GROUP,service.name=$SVC_NAME"
      },
      {
        "name": "OTEL_LOGS_EXPORTER",
        "value": "none"
      },
      {
        "name": "OTEL_METRICS_EXPORTER",
        "value": "none"
      },
      {
        "name": "OTEL_EXPORTER_OTLP_PROTOCOL",
        "value": "http/protobuf"
      },
      {
        "name": "OTEL_AWS_APPLICATION_SIGNALS_ENABLED",
        "value": "true"
      },
      {
        "name": "OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT",
        "value": "http://CW_CONTAINER_IP:4316/v1/metrics"
      },
      {
        "name": "OTEL_EXPORTER_OTLP_TRACES_ENDPOINT",
        "value": "http://CW_CONTAINER_IP:4316/v1/traces"
      },
      {
        "name": "OTEL_TRACES_SAMPLER",
        "value": "xray"
      },
      {
        "name": "OTEL_TRACES_SAMPLER_ARG",
        "value": "endpoint=http://CW_CONTAINER_IP:2000"
      },
      {
        "name": "NODE_OPTIONS",
        "value": "--require /otel-auto-instrumentation-node/
autoinstrumentation.js"
      }
      ],
    "mountPoints": [
      {
        "sourceVolume": "opentelemetry-auto-instrumentation-node",
```

```
        "containerPath": "/otel-auto-instrumentation-node",
        "readOnly": false
      }
    ],
    "dependsOn": [
      {
        "containerName": "init",
        "condition": "SUCCESS"
      }
    ]
}
```

Setting up a Node.js application with the ESM module format

We provide limited support for Node.js applications with the ESM module format. For details, see the section called “Known limitations about Node.js with ESM”.

For the ESM module format, using the `init` container to inject the Node.js instrumentation SDK doesn’t apply. To enable Application Signals for Node.js with ESM, skip steps 1 and 2 in of the previous procedure, and do the following instead.

To enable Application Signals for a Node.js application with ESM

1. Install the relevant dependencies to your Node.js application for autoinstrumentation:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
npm install @opentelemetry/instrumentation@0.54.0
```

2. In steps 4 and 5 in the previous procedure, remove the mounting of the volume `opentelemetry-auto-instrumentation-node`:

```
"mountPoints": [
    {
        "sourceVolume": "opentelemetry-auto-instrumentation-node",
        "containerPath": "/otel-auto-instrumentation-node",
        "readOnly": false
    }
 ]
```

Replace the node options with the following.

```
{
    "name": "NODE_OPTIONS",
    "value": "--import @aws/aws-distro-opentelemetry-node-autoinstrumentation/
register --experimental-loader=@opentelemetry/instrumentation/hook.mjs"
}
```

Step 6: Deploy your application

Create a new revision of your task definition and deploy it to your application cluster. You should see two containers in the newly created task:

- `init`– A required container for initializing Application Signals
- *`my-app`*– This is the example application container in our documentation. In your actual workloads, this specific container might not exist or might be replaced with your own service containers.

(Optional) Step 7: Monitor your application health

Once you have enabled your applications on Amazon ECS, you can monitor your application health. For more information, see Monitor the operational health of your applications with Application Signals.

Enable Application Signals on Amazon ECS using Amazon CDK

To enable Application Signals on Amazon ECS using Amazon CDK, do the following.

1. Enable Application Signals for your applications – If you haven't enabled Application Signals in this account yet, you must grant Application Signals the permissions it needs to discover your services.

```
import { aws_applicationsignals as applicationsignals } from 'aws-cdk-lib';

const cfnDiscovery = new applicationsignals.CfnDiscovery(this,
  'ApplicationSignalsServiceRole', { }
);
```

The Discovery CloudFormation resource grants Application Signals the following permissions:

- `xray:GetServiceGraph`
- `logs:StartQuery`
- `logs:GetQueryResults`
- `cloudwatch:GetMetricData`
- `cloudwatch:ListMetrics`
- `tag:GetResources`

For more information about this role, see Service-linked role permissions for CloudWatch Application Signals.

2. Instrument your application with the AWS::ApplicationSignals Construct Library in the Amazon CDK. The code snippets in this document are provided in *TypeScript*. For other language-specific alternatives, see Supported programming languages for the Amazon CDK.

   - **Enable Application Signals on Amazon ECS with sidecar mode**

     a. Configure `instrumentation` to instrument the application with the Amazon Distro for OpenTelemetry (ADOT) SDK Agent. The following is an example of instrumenting a Java application. See InstrumentationVersion for all supported language versions.

     b. Specify `cloudWatchAgentSidecar` to configure the CloudWatch Agent as a sidecar container.

```
import { Construct } from 'constructs';
import * as appsignals from '@aws-cdk/aws-applicationsignals-alpha';
import * as cdk from 'aws-cdk-lib';
import * as ec2 from 'aws-cdk-lib/aws-ec2';
import * as ecs from 'aws-cdk-lib/aws-ecs';

class MyStack extends cdk.Stack {
  public constructor(scope?: Construct, id?: string, props: cdk.StackProps
 = {}) {
    super();
    const vpc = new ec2.Vpc(this, 'TestVpc', {});
    const cluster = new ecs.Cluster(this, 'TestCluster', { vpc });

    const fargateTaskDefinition = new ecs.FargateTaskDefinition(this,
 'SampleAppTaskDefinition', {
```

```
      cpu: 2048,
      memoryLimitMiB: 4096,
    });

    fargateTaskDefinition.addContainer('app', {
      image: ecs.ContainerImage.fromRegistry('test/sample-app'),
    });

    new appsignals.ApplicationSignalsIntegration(this,
 'ApplicationSignalsIntegration', {
      taskDefinition: fargateTaskDefinition,
      instrumentation: {
        sdkVersion: appsignals.JavaInstrumentationVersion.V2_10_0,
      },
      serviceName: 'sample-app',
      cloudWatchAgentSidecar: {
        containerName: 'ecs-cwagent',
        enableLogging: true,
        cpu: 256,
        memoryLimitMiB: 512,
      }
    });

    new ecs.FargateService(this, 'MySampleApp', {
      cluster: cluster,
      taskDefinition: fargateTaskDefinition,
      desiredCount: 1,
    });
  }
}
```

- **Enable Application Signals on Amazon ECS with daemon mode**

  Note

  The daemon deployment strategy is not supported on Amazon ECS Fargate and is only supported on Amazon ECS on Amazon EC2.

  a. Run CloudWatch Agent as a daemon service with `HOST` network mode.

  b. Configure `instrumentation` to instrument the application with the ADOT Python Agent.

```
import { Construct } from 'constructs';
import * as appsignals from '@aws-cdk/aws-applicationsignals-alpha';
import * as cdk from 'aws-cdk-lib';
import * as ec2 from 'aws-cdk-lib/aws-ec2';
import * as ecs from 'aws-cdk-lib/aws-ecs';

class MyStack extends cdk.Stack {
  public constructor(scope?: Construct, id?: string, props: cdk.StackProps
 = {}) {
    super(scope, id, props);

    const vpc = new ec2.Vpc(this, 'TestVpc', {});
    const cluster = new ecs.Cluster(this, 'TestCluster', { vpc });

    // Define Task Definition for CloudWatch agent (Daemon)
    const cwAgentTaskDefinition = new ecs.Ec2TaskDefinition(this,
 'CloudWatchAgentTaskDefinition', {
      networkMode: ecs.NetworkMode.HOST,
    });

    new appsignals.CloudWatchAgentIntegration(this,
 'CloudWatchAgentIntegration', {
      taskDefinition: cwAgentTaskDefinition,
      containerName: 'ecs-cwagent',
      enableLogging: false,
      cpu: 128,
      memoryLimitMiB: 64,
      portMappings: [
        {
          containerPort: 4316,
          hostPort: 4316,
        },
        {
          containerPort: 2000,
          hostPort: 2000,
        },
      ],
    });

    // Create the CloudWatch Agent daemon service
    new ecs.Ec2Service(this, 'CloudWatchAgentDaemon', {
      cluster,
      taskDefinition: cwAgentTaskDefinition,
```

```
      daemon: true,  // Runs one container per EC2 instance
    });

    // Define Task Definition for user application
    const sampleAppTaskDefinition = new ecs.Ec2TaskDefinition(this,
 'SampleAppTaskDefinition', {
      networkMode: ecs.NetworkMode.HOST,
    });

    sampleAppTaskDefinition.addContainer('app', {
      image: ecs.ContainerImage.fromRegistry('test/sample-app'),
      cpu: 0,
      memoryLimitMiB: 512,
    });

    // No CloudWatch Agent sidecar is needed as application container
 communicates to CloudWatch Agent daemon through host network
    new appsignals.ApplicationSignalsIntegration(this,
 'ApplicationSignalsIntegration', {
      taskDefinition: sampleAppTaskDefinition,
      instrumentation: {
        sdkVersion: appsignals.PythonInstrumentationVersion.V0_8_0
      },
      serviceName: 'sample-app'
    });

    new ecs.Ec2Service(this, 'MySampleApp', {
      cluster,
      taskDefinition: sampleAppTaskDefinition,
      desiredCount: 1,
    });
  }
}
```

- **Enable Application Signals on Amazon ECS with replica mode**

> **Note**
>
> Running CloudWatch Agent service using replica mode requires specific security group configurations to enable communication with other services. For Application Signals functionality, configure the security group with the minimum inbound

rules: Port 2000 (HTTP) and Port 4316 (HTTP). This configuration ensures proper connectivity between the CloudWatch Agent and dependent services.

a. Run CloudWatch Agent as a replica service with service connect.

b. Configure `instrumentation` to instrument the application with the ADOT Python Agent.

c. Override environment variables by configuring `overrideEnvironments` to use service connect endpoints to communicate to the CloudWatch agent server.

```
import { Construct } from 'constructs';
import * as appsignals from '@aws-cdk/aws-applicationsignals-alpha';
import * as cdk from 'aws-cdk-lib';
import * as ec2 from 'aws-cdk-lib/aws-ec2';
import * as ecs from 'aws-cdk-lib/aws-ecs';
import { PrivateDnsNamespace } from 'aws-cdk-lib/aws-servicediscovery';

class MyStack extends cdk.Stack {
  public constructor(scope?: Construct, id?: string, props: cdk.StackProps
 = {}) {
    super(scope, id, props);

    const vpc = new ec2.Vpc(this, 'TestVpc', {});
    const cluster = new ecs.Cluster(this, 'TestCluster', { vpc });
    const dnsNamespace = new PrivateDnsNamespace(this, 'Namespace', {
      vpc,
      name: 'local',
    });
    const securityGroup = new ec2.SecurityGroup(this, 'ECSSG', { vpc });
    securityGroup.addIngressRule(securityGroup, ec2.Port.tcpRange(0,
 65535));

    // Define Task Definition for CloudWatch agent (Replica)
    const cwAgentTaskDefinition = new ecs.FargateTaskDefinition(this,
 'CloudWatchAgentTaskDefinition', {});

    new appsignals.CloudWatchAgentIntegration(this,
 'CloudWatchAgentIntegration', {
      taskDefinition: cwAgentTaskDefinition,
      containerName: 'ecs-cwagent',
      enableLogging: false,
```

```
      cpu: 128,
      memoryLimitMiB: 64,
      portMappings: [
        {
          name: 'cwagent-4316',
          containerPort: 4316,
          hostPort: 4316,
        },
        {
          name: 'cwagent-2000',
          containerPort: 2000,
          hostPort: 2000,
        },
      ],
    });

    // Create the CloudWatch Agent replica service with service connect
    new ecs.FargateService(this, 'CloudWatchAgentService', {
      cluster: cluster,
      taskDefinition: cwAgentTaskDefinition,
      securityGroups: [securityGroup],
      serviceConnectConfiguration: {
        namespace: dnsNamespace.namespaceArn,
        services: [
          {
            portMappingName: 'cwagent-4316',
            dnsName: 'cwagent-4316-http',
            port: 4316,
          },
          {
            portMappingName: 'cwagent-2000',
            dnsName: 'cwagent-2000-http',
            port: 2000,
          },
        ],
      },
      desiredCount: 1,
    });

    // Define Task Definition for user application
    const sampleAppTaskDefinition = new ecs.FargateTaskDefinition(this,
 'SampleAppTaskDefinition', {});

    sampleAppTaskDefinition.addContainer('app', {
```

```
      image: ecs.ContainerImage.fromRegistry('test/sample-app'),
      cpu: 0,
      memoryLimitMiB: 512,
    });

    // Overwrite environment variables to connect to the CloudWatch Agent
 service just created
    new appsignals.ApplicationSignalsIntegration(this,
 'ApplicationSignalsIntegration', {
      taskDefinition: sampleAppTaskDefinition,
      instrumentation: {
        sdkVersion: appsignals.PythonInstrumentationVersion.V0_8_0,
      },
      serviceName: 'sample-app',
      overrideEnvironments: [
        {
          name:
 appsignals.CommonExporting.OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT,
          value: 'http://cwagent-4316-http:4316/v1/metrics',
        },
        {
          name:
 appsignals.TraceExporting.OTEL_EXPORTER_OTLP_TRACES_ENDPOINT,
          value: 'http://cwagent-4316-http:4316/v1/traces',
        },
        {
          name: appsignals.TraceExporting.OTEL_TRACES_SAMPLER_ARG,
          value: 'endpoint=http://cwagent-2000-http:2000',
        },
      ],
    });

    // Create ECS Service with service connect configuration
    new ecs.FargateService(this, 'MySampleApp', {
      cluster: cluster,
      taskDefinition: sampleAppTaskDefinition,
      serviceConnectConfiguration: {
        namespace: dnsNamespace.namespaceArn,
      },
      desiredCount: 1,
    });
  }
}
```

3. Setting up a Node.js application with the ESM module format. There is limited support for Node.js applications with the ESM module format. For more information, see [Known limitations about Node.js with ESM](#).

   For the ESM module format, enabling Application Signals by using the `init` container to inject the Node.js instrumentation SDK doesn't apply. Skip Step 2 in this procedure, and do the following instead.

   - Install the relevant dependencies to your Node.js application for autoinstrumentation.

     ```
     npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
     npm install @opentelemetry/instrumentation@0.54.
     ```

   - Update TaskDefinition.

     a. Add additional configuration to your application container.

     b. Configure `NODE_OPTIONS`.

     c. (Optional) Add CloudWatch Agent if you choose sidecar mode.

     ```
     import { Construct } from 'constructs';
     import * as appsignals from '@aws-cdk/aws-applicationsignals-alpha';
     import * as ecs from 'aws-cdk-lib/aws-ecs';

     class MyStack extends cdk.Stack {
       public constructor(scope?: Construct, id?: string, props: cdk.StackProps
      = {}) {
         super(scope, id, props);
         const fargateTaskDefinition = new ecs.FargateTaskDefinition(stack,
      'TestTaskDefinition', {
           cpu: 256,
           memoryLimitMiB: 512,
         });
         const appContainer = fargateTaskDefinition.addContainer('app', {
           image: ecs.ContainerImage.fromRegistry('docker/cdk-test'),
         });

         const volumeName = 'opentelemetry-auto-instrumentation'
         fargateTaskDefinition.addVolume({name: volumeName});

         // Inject additional configurations
         const injector = new appsignals.NodeInjector(volumeName,
      appsignals.NodeInstrumentationVersion.V0_5_0);
     ```

```
    injector.renderDefaultContainer(fargateTaskDefinition);
    // Configure NODE_OPTIONS
    appContainer.addEnvironment('NODE_OPTIONS', '--import @aws/aws-
distro-opentelemetry-node-autoinstrumentation/register --experimental-
loader=@opentelemetry/instrumentation/hook.mjs')

    // Optional: add CloudWatch agent
    const cwAgent = new appsignals.CloudWatchAgentIntegration(stack,
 'AddCloudWatchAgent', {
      containerName: 'ecs-cwagent',
      taskDefinition: fargateTaskDefinition,
      memoryReservationMiB: 50,
    });
    appContainer.addContainerDependencies({
      container: cwAgent.agentContainer,
      condition: ecs.ContainerDependencyCondition.START,
    });
}
```

4. Deploy the updated stack – Run the `cdk synth` command in your application's main directory. To deploy the service in your Amazon account, run the `cdk deploy` command in your application's main directory.

   If you used the sidecar strategy, you'll see one service created:

   - *`APPLICATION_SERVICE`* is the service of your application. It includes the three following containers:
     - `init`– A required container for initializing Application Signals.
     - `ecs-cwagent`– A container running the CloudWatch agent
     - *`my-app`*– This is the example application container in our documentation. In your actual workloads, this specific container might not exist or might be replaced with your own service containers.

   If you used the daemon strategy, you'll see two services created:

   - *`CloudWatchAgentDaemon`* is the CloudWatch agent daemon service.
   - *`APPLICATION_SERVICE`* is the service of your application. It includes the two following containers:
     - `init`– A required container for initializing Application Signals.

    - *my-app*– This is the example application container in our documentation. In your actual workloads, this specific container might not exist or might be replaced with your own service containers.

If you used the replica strategy, you'll see two services created:

- *CloudWatchAgentService* is the CloudWatch agent replica service.
- *APPLICATION_SERVICE* is the service of your application. It includes the two following containers:
    - `init`– A required container for initializing Application Signals.
    - *my-app*– This is the example application container in our documentation. In your actual workloads, this specific container might not exist or might be replaced with your own service containers.

Enable your applications on Kubernetes

Enable CloudWatch Application Signals on Kubernetes by using the custom setup steps described in this section.

For applications running on Kubernetes, you install and configure the CloudWatch agent and Amazon Distro for OpenTelemetry yourself. On these architectures enabled with a custom Application Signals setup, Application Signals doesn't autodiscover the names of your services or the hosts or clusters they run on. You must specify these names during the custom setup, and the names that you specify are what is displayed on Application Signals dashboards.

Requirements

- You have admininstrator permission on the Kubernetes cluster where you are enabling Application Signals.
- You must have the Amazon CLI installed on the environment where your Kubernetes cluster is running. For more information about installing the Amazon CLI, see [Install or update the latest version of the Amazon CLI].
- You have kubectl and helm installed on your local terminal. For more information, see the [kubectl] and [Helm] documentation.

Step 1: Enable Application Signals in your account

You must first enable Application Signals in your account. If you haven't, see Enable Application Signals in your account.

Step 2: Install the CloudWatch agent operator in your cluster

Installing the CloudWatch agent operator installs the operator, the CloudWatch agent, and other auto-instrumentation into your cluster. To do so, enter the following command. Replace *$REGION* with your Amazon Region. Replace *$YOUR_CLUSTER_NAME* with the name that you want to appear for your cluster in Application Signals dashboards.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm install amazon-cloudwatch-operator aws-observability/amazon-cloudwatch-observability \
--namespace amazon-cloudwatch --create-namespace \
--set region=$REGION \
--set clusterName=$YOUR_CLUSTER_NAME
```

For more information, see amazon-cloudwatch-observability on GitHub.

Step 3: Set up Amazon credentials for your Kubernetes clusters

> **Important**
>
> If your Kubernetes cluster is hosted on Amazon EC2, you can skip this section and proceed to Step 4: Add annotations.

If your Kubernetes cluster is hosted on-premises, you must use the instructions in this section to add Amazon credentials to your Kubernetes environment.

To set up permissions for an on-premises Kubernetes cluster

1. Create the IAM user to be used to provide permissions to your on-premises host:

   a. Open the IAM console at https://console.amazonaws.cn/iam/.

   b. Choose **Users**, **Create User**.

   c. In **User details**, for **User name**, enter a name for the new IAM user. This is the sign-in name for Amazon that will be used to authenticate your host. Then choose **Next**

d. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.

e. From the **Permissions policies** list, select the **CloudWatchAgentServerPolicy** policy to add to your user. Then choose **Next**.

f. On the **Review and create** page, ensure that you are satisfied with the user name and that the **CloudWatchAgentServerPolicy** policy is in the **Permissions summary**.

g. Choose **Create user**

2. Create and retrieve your Amazon access key and secret key:

   a. In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.

   b. On the user's page, choose the **Security credentials** tab. Then, in the **Access keys** section, choose **Create access key**.

   c. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.

   d. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.

   e. For **Create access key Step 3**, select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.

   f. Choose **Done**.

3. Configure your Amazon credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step. By default, the credential file is saved in `/home/user/.aws/credentials.`

```
$ aws configure --profile AmazonCloudWatchAgent
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

4. Edit the custom resource that the CloudWatch agent installed using the Helm chart to add the newly created Amazon credentials secret.

```
kubectl edit amazoncloudwatchagent cloudwatch-agent -n amazon-cloudwatch
```

5. While your file editor is open mount the Amazon credentials into the CloudWatch agent container by adding the following configuration to the top of the deployment. Replace the

path /home/*user*/.aws/credentials with the location of your local Amazon credentials file.

```
apiVersion: cloudwatch.aws.amazon.com/v1alpha1
kind: AmazonCloudWatchAgent
metadata:
  name: cloudwatch-agent
  namespace: amazon-cloudwatch
spec:
  volumeMounts:
  - mountPath: /rootfs
    volumeMounts:
    - name: aws-credentials
      mountPath: /root/.aws
      readOnly: true
    volumes:
    - hostPath:
      path: /home/user/.aws/credentials
    name: aws-credentials
---
```

Step 4: Add annotations

> **Note**
>
> If you are enabling Application Signals for a Node.js application with ESM, skip the steps in this section and see the section called "Setting up a Node.js application with the ESM module format" instead.

The next step is to instrument your application for CloudWatch Application Signals by adding a language-specific annotation to your Kubernetes workload or namespace. This annotation auto-instruments your application to send metrics, traces, and logs to Application Signals.

To add the annotations for Application Signals

1. You have two options for the annotation:

   - **Annotate Workload** auto-instruments a single workload in a cluster.
   - **Annotate Namespace** auto-instruments all workloads deployed in the selected namespace.

Choose one of those options, and follow the appropriate steps.

2. To annotate a single workload, enter one of the following commands. Replace *$WORKLOAD_TYPE* and *$WORKLOAD_NAME* with the values for your workload.

   - For Java workloads:

     ```
     kubectl patch $WORKLOAD_TYPE $WORKLOAD_NAME -p '{"spec": {"template":
      {"metadata": {"annotations": {"instrumentation.opentelemetry.io/inject-java":
      "true"}}}}}'
     ```

   - For Python workloads:

     ```
     kubectl patch $WORKLOAD_TYPE $WORKLOAD_NAME -p '{"spec": {"template":
      {"metadata": {"annotations": {"instrumentation.opentelemetry.io/inject-python":
      "true"}}}}}'
     ```

     For Python applications, there are additional required configurations. For more information, see Python application doesn't start after Application Signals is enabled.

   - For .NET workloads:

     ```
     kubectl patch $WORKLOAD_TYPE $WORKLOAD_NAME -p '{"spec": {"template":
      {"metadata": {"annotations": {"instrumentation.opentelemetry.io/inject-dotnet":
      "true"}}}}}'
     ```

     Note

     To enable Application Signals for a .NET workload on Alpine Linux (`linux-musl-x64`) based images, add the following additional annotation.

     ```
     instrumentation.opentelemetry.io/otel-dotnet-auto-runtime: "linux-musl-
     x64"
     ```

   - For Node.js workloads:

     ```
     kubectl patch $WORKLOAD_TYPE $WORKLOAD_NAME -p '{"spec": {"template":
      {"metadata": {"annotations": {"instrumentation.opentelemetry.io/inject-nodejs":
      "true"}}}}}'
     ```

3. To annotate all workloads in a namespace, enter enter one of the following commands. Replace *$NAMESPACE* with the name of your namespace.

   If the namespace includes Java, Python, and .NET workloads, add all annotations to the namespace.

   - For Java workloads in the namespace:

     ```
     kubectl annotate ns $NAMESPACE instrumentation.opentelemetry.io/inject-java=true
     ```

   - For Python workloads in the namespace:

     ```
     kubectl annotate ns $NAMESPACE instrumentation.opentelemetry.io/inject-
     python=true
     ```

     For Python applications, there are additional required configurations. For more information, see Python application doesn't start after Application Signals is enabled.

   - For .NET workloads in the namespace:

     ```
     kubectl annotate ns $NAMESPACE instrumentation.opentelemetry.io/inject-
     dotnet=true
     ```

   - For Node.js workloads in the namespace:

     ```
     kubectl annotate ns $NAMESPACE instrumentation.opentelemetry.io/inject-
     nodejs=true
     ```

   After adding the annotations, restart all pods in the namespace by entering the following command:

   ```
   kubectl rollout restart
   ```

4. When the previous steps are completed, in the CloudWatch console, choose **Application Signals**, **Services**. This opens the dashboards where you can see the data that Application Signals collects. It might take a few minutes for data to appear.

   For more information about the **Services** view, see Monitor the operational health of your applications with Application Signals.

Setting up a Node.js application with the ESM module format

We provide limited support for Node.js applications with the ESM module format. For details, see the section called "Known limitations about Node.js with ESM".

For the ESM module format, enabling Application Signals by annotating the manifest file doesn't work. Skip the previous procedure and do the following instead:

To enable Application Signals for a Node.js application with ESM

1. Install the relevant dependencies to your Node.js application for autoinstrumentation:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
npm install @opentelemetry/instrumentation@0.54.0
```

2. Add the following environmental variables to the Dockerfile for your application and build the image.

```

...
ENV OTEL_AWS_APPLICATION_SIGNALS_ENABLED=true
ENV OTEL_TRACES_SAMPLER_ARG='endpoint=http://cloudwatch-agent.amazon-
cloudwatch:2000'
ENV OTEL_TRACES_SAMPLER='xray'
ENV OTEL_EXPORTER_OTLP_PROTOCOL='http/protobuf'
ENV OTEL_EXPORTER_OTLP_TRACES_ENDPOINT='http://cloudwatch-agent.amazon-
cloudwatch:4316/v1/traces'
ENV OTEL_AWS_APPLICATION_SIGNALS_EXPORTER_ENDPOINT='http://cloudwatch-agent.amazon-
cloudwatch:4316/v1/metrics'
ENV OTEL_METRICS_EXPORTER='none'
ENV OTEL_LOGS_EXPORTER='none'
ENV NODE_OPTIONS='--import @aws/aws-distro-opentelemetry-node-autoinstrumentation/
register --experimental-loader=@opentelemetry/instrumentation/hook.mjs'
ENV OTEL_SERVICE_NAME='YOUR_SERVICE_NAME' #replace with a proper service name
ENV OTEL_PROPAGATORS='tracecontext,baggage,b3,xray'
...

# command to start the application
# for example
# CMD ["node", "index.mjs"]
```

3. Add the environmental variables `OTEL_RESOURCE_ATTRIBUTES_POD_NAME`, `OTEL_RESOURCE_ATTRIBUTES_NODE_NAME`,

OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME, POD_NAMESPACE and OTEL_RESOURCE_ATTRIBUTES to the deployment yaml file for the application. For example:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: nodejs-app
  labels:
    app: nodejs-app
spec:
  replicas: 2
  selector:
    matchLabels:
      app: nodejs-app
  template:
    metadata:
      labels:
        app: nodejs-app
      # annotations:
      # make sure this annotation doesn't exit
      #   instrumentation.opentelemetry.io/inject-nodejs: 'true'
    spec:
      containers:
      - name: nodejs-app
        image:your-nodejs-application-image #replace it with a proper image uri
        imagePullPolicy: Always
        ports:
        - containerPort: 8000
        env:
          - name: OTEL_RESOURCE_ATTRIBUTES_POD_NAME
            valueFrom:
              fieldRef:
                fieldPath: metadata.name
          - name: OTEL_RESOURCE_ATTRIBUTES_NODE_NAME
            valueFrom:
              fieldRef:
                fieldPath: spec.nodeName
          - name: OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME
            valueFrom:
              fieldRef:
                fieldPath: metadata.labels['app'] # Assuming 'app' label is set to
 the deployment name
          - name: POD_NAMESPACE
```

```
            valueFrom:
              fieldRef:
                fieldPath: metadata.namespace
          - name: OTEL_RESOURCE_ATTRIBUTES
            value: "k8s.deployment.name=
$(OTEL_RESOURCE_ATTRIBUTES_DEPLOYMENT_NAME),k8s.namespace.name=
$(POD_NAMESPACE),k8s.node.name=$(OTEL_RESOURCE_ATTRIBUTES_NODE_NAME),k8s.pod.name=
$(OTEL_RESOURCE_ATTRIBUTES_POD_NAME)"
```

4. Deploy the Node.js application to the Kubernetes cluster.

(Optional) Step 5: Monitor your application health

Once you have enabled your applications on Kubernetes, you can monitor your application health. For more information, see Monitor the operational health of your applications with Application Signals.

Enable your applications on Lambda

You can enable Application Signals for your Lambda functions. Application Signals automatically instruments your Lambda functions using enhanced Amazon Distro for OpenTelemetry (ADOT) libraries, provided through a Lambda layer. This Amazon Lambda Layer for OpenTelemetry packages and deploys the libraries that are required for auto-instrumentation for Application Signals.

In addition to supporting Application Signals, this Lambda layer is also a component of Lambda OpenTelemetry support and provides tracing functionality.

Topics

- [Amazon Lambda Layer for OpenTelemetry ARNs]
- [Deploy Lambda functions using Amazon ECR container]

Getting started

There are three methods for enabling Application Signals for your Lambda functions.

After you enable Application Signals for a Lambda function, it takes a few minutes for telemetry from that function to appear in the Application Signals console.

- Use the CloudWatch Application Signals console
- Use the Lambda console
- Manually add the Amazon Lambda Layer for OpenTelemetry to your Lambda function runtime.

Each of these methods adds the Amazon Lambda Layer for OpenTelemetry to your function.

Use the CloudWatch Application Signals console

Use these steps to use the Application Signals console to enable Application Signals for a Lambda function.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Services**.
3. In the **Services** list area, choose **Enable Application Signals**.
4. Choose the **Lambda** tile.
5. Select each function that you want to enable for Application Signals, and then choose **Done**.

Use the Lambda console

Use these steps to use the Lambda console to enable Application Signals for a Lambda function.

1. Open the Amazon Lambda console at https://console.amazonaws.cn/lambda/.
2. In the navigation pane, choose **Functions** and then choose the name of the function that you want to enable.
3. Choose the **Configuration** tab, and then choose **Monitoring and operations tools**.

4. Choose **Edit**.
5. In the **CloudWatch Application Signals and X-Ray** section, select both **Automatically collect application traces and standard application metrics with Application Signals** and **Automatically collect Lambda service traces for end to end visibility with X-Ray.**.
6. Choose **Save**.

Enable Application Signals on Lambda using Amazon CDK

If you haven't enabled Application Signals in this account yet, you must grant Application Signals the permissions it needs to discover your services. For more information, see Enable Application Signals in your account.

1. Enable Application Signals for your applications

```
import { aws_applicationsignals as applicationsignals } from 'aws-cdk-lib';

const cfnDiscovery = new applicationsignals.CfnDiscovery(this,
  'ApplicationSignalsServiceRole', { }
);
```

   The Discovery CloudFormation resource grants Application Signals the following permissions:

   - `xray:GetServiceGraph`
   - `logs:StartQuery`
   - `logs:GetQueryResults`
   - `cloudwatch:GetMetricData`
   - `cloudwatch:ListMetrics`
   - `tag:GetResources`

   For more information about this role, see Service-linked role permissions for CloudWatch Application Signals.

2. Add the IAM policy `CloudWatchLambdaApplicationSignalsExecutionRolePolicy` to the lambda function.

```
const fn = new Function(this, 'DemoFunction', {
    code: Code.fromAsset('$YOUR_LAMBDA.zip'),
```

```
    runtime: Runtime.PYTHON_3_12,
    handler: '$YOUR_HANDLER'
})

fn.role?.addManagedPolicy(ManagedPolicy.fromAwsManagedPolicyName('CloudWatchLambdaApplicati
```

3. Replace $AWS_LAMBDA_LAYER_FOR_OTEL_ARN with the actual Amazon Lambda Layer for OpenTelemetry ARN in the corresponding region.

```
fn.addLayers(LayerVersion.fromLayerVersionArn(
    this, 'AwsLambdaLayerForOtel',
    '$AWS_LAMBDA_LAYER_FOR_OTEL_ARN'
))
fn.addEnvironment("AWS_LAMBDA_EXEC_WRAPPER", "/opt/otel-instrument");
```

(Optional) Monitor your application health

Once you have enabled your applications on Lambda, you can monitor your application health. For more information, see Monitor the operational health of your applications with Application Signals.

Manually enable Application Signals.

Use these steps to manually enable Application Signals for a Lambda function.

1. Add the Amazon Lambda Layer for OpenTelemetry to your Lambda runtime. To find the layer ARN, see Amazon Lambda Layer for OpenTelemetry ARNs.
2. Add the environment variable `AWS_LAMBDA_EXEC_WRAPPER=/opt/otel-instrument`

   Add the environment variable `LAMBDA_APPLICATION_SIGNALS_REMOTE_ENVIRONMENT` to configure custom Lambda environments. By default, lambda environments are configured to `lambda:default`.
3. Attach the Amazon managed IAM policy **CloudWatchLambdaApplicationSignalsExecutionRolePolicy** to the Lambda execution role.
4. (Optional) We recommend that you enable Lambda active tracing to get a better tracing experience. For more information, see Visualize Lambda function invocations using Amazon X-Ray.

Manually disable Application Signals

To manually disable Application Signals for a Lambda function, remove the Amazon Lambda Layer for OpenTelemetry from your Lambda runtime, and remove the `AWS_LAMBDA_EXEC_WRAPPER=/opt/otel-instrument` environment variable.

Configuring Application Signals

You can use this section to configure Application Signals in Lambda.

Grouping multiple Lambda functions into one service

Environment variable `OTEL_SERVICE_NAME` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. You can assign the same service name to multiple Lambda functions, and they will be merged into a single service in Application Signals. When you don't provide a value for this key, the default Lambda Function name is used.

Sampling

By default, the trace sampling strategy is parent based. You can adjust the sampling strategy by setting environment variables `OTEL_TRACES_SAMPLER`.

For example, set trace sampling rate to 30%.

```
OTEL_TRACES_SAMPLER=traceidratio
OTEL_TRACES_SAMPLER_ARG=0.3
```

For more information , see OpenTelemetry Environment Variable Specification.

Enabling all library instrumentation’s

To reduce Lambda cold starts, by default, only Amazon SDK and HTTP instrumentation’s are enabled for Python, Node, and Java. You can set environment variables to enable instrumentation for other libraries used in your Lambda function.

- Python – `OTEL_PYTHON_DISABLED_INSTRUMENTATIONS=none`
- Node – `OTEL_NODE_DISABLED_INSTRUMENTATIONS=none`
- Java – `OTEL_INSTRUMENTATION_COMMON_DEFAULT_ENABLED=true`

Amazon Lambda Layer for OpenTelemetry ARNs

The following tables list the ARNs to use the Amazon Lambda Layer for OpenTelemetry for each Region where it's supported.

Python

Region	ARN
US East (N. Virginia)	arn:aws:lambda:us-east-1:615299751070:layer:AWSOpenTelemetryDistroPython:12
US East (Ohio)	arn:aws:lambda:us-east-2:615299751070:layer:AWSOpenTelemetryDistroPython:9
US West (N. California)	arn:aws:lambda:us-west-1:615299751070:layer:AWSOpenTelemetryDistroPython:16
US West (Oregon)	arn:aws:lambda:us-west-2:615299751070:layer:AWSOpenTelemetryDistroPython:16
Africa (Cape Town)	arn:aws:lambda:af-south-1:904233096616:layer:AWSOpenTelemetryDistroPython:6

Deploy Lambda functions using Amazon ECR container

Lambda functions deployed as container images do not support Lambda Layers in the traditional way. When using container images, you cannot attach a layer as you would with other Lambda deployment methods. Instead, you must manually incorporate the layer's contents into your container image during the build process.

Java

You can learn how to integrate the Amazon Lambda Layer for OpenTelemetry into your containerized Java Lambda function, download the `layer.zip` artifact, and integrate it into your Java Lambda function container to enable Application Signals monitoring.

Prerequisites

- Amazon CLI configured with your credentials
- Docker installed
- These instructions assume you are on x86_64 platform

1. **Set Up Project Structure**

   Create a directory for your Lambda function

   ```
   mkdir java-appsignals-container-lambda && \
   cd java-appsignals-container-lambda
   ```

   Create a Maven project structure

   ```
   mkdir -p src/main/java/com/example/java/lambda
   mkdir -p src/main/resources
   ```

2. **Create Dockerfile**

   Download and integrate the OpenTelemetry Layer with Application Signals support directly into your Lambda container image. To do this, the `Dockerfile` file is created.

   ```
   FROM public.ecr.aws/lambda/java:21

   # Install utilities
   RUN dnf install -y unzip wget maven

   # Download the OpenTelemetry Layer with AppSignals Support
   RUN wget https://github.com/aws-observability/aws-otel-java-instrumentation/
   releases/latest/download/layer.zip -O /tmp/layer.zip

   # Extract and include Lambda layer contents
   RUN mkdir -p /opt && \
   ```

```
    unzip /tmp/layer.zip -d /opt/ && \
    chmod -R 755 /opt/ && \
    rm /tmp/layer.zip

# Copy and build function code
COPY pom.xml ${LAMBDA_TASK_ROOT}
COPY src ${LAMBDA_TASK_ROOT}/src
RUN mvn clean package -DskipTests

# Copy the JAR file to the Lambda runtime directory (from inside the container)
RUN mkdir -p ${LAMBDA_TASK_ROOT}/lib/
RUN cp ${LAMBDA_TASK_ROOT}/target/function.jar ${LAMBDA_TASK_ROOT}/lib/

# Set the handler
CMD ["com.example.java.lambda.App::handleRequest"]
```

> **Note**
>
> The `layer.zip` file contains the OpenTelemetry instrumentation necessary for Amazon Application Signals support to monitor your Lambda function.
> The layer extraction steps ensures:
>
> - The layer.zip contents are properly extracted to the `/opt/ directory`
> - The `otel-instrument` script receives proper execution permissions
> - The temporary layer.zip file is removed to keep the image size smaller

3. **Lambda function code** – Create a Java file for your Lambda handler at `src/main/java/com/example/lambda/App.java:`

   Your project should look something like:

```
.
### Dockerfile
### pom.xml
### src
    ### main
        ### java
        #   ### com
        #       ### example
        #           ### java
        #               ### lambda
```

```
        #                    ### App.java
        ### resources
```

4. **Build and deploy the container image**

   Set up environment variables

```
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
AWS_REGION=$(aws configure get region)

# For fish shell users:
# set AWS_ACCOUNT_ID (aws sts get-caller-identity --query Account --output
 text)
# set AWS_REGION (aws configure get region)
```

   Authenticate with ECR

   First with public ECR (for base image):

```
aws ecr-public get-login-password --region us-east-1 | docker login --username
 AWS --password-stdin public.ecr.aws
```

   Then with your private ECR:

```
aws ecr get-login-password --region $AWS_REGION | docker login --username AWS --
password-stdin $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com
```

   Build, tag and push your image

```
# Build the Docker image
docker build -t lambda-appsignals-demo .

# Tag the image
docker tag lambda-appsignals-demo:latest $AWS_ACCOUNT_ID.dkr.ecr.
$AWS_REGION.amazonaws.com/lambda-appsignals-demo:latest

# Push the image
docker push $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com/lambda-appsignals-
demo:latest
```

5. **Create and configure the Lambda function**

Create a new function using the Lambda console.

Select **Container image** as the deployment option.

Choose **Browse images** to select your Amazon ECR image.

6. **Testing and verifications – Test your Lambda with a simple event. If the layer integration is successful, your Lambda appears under the Application Signals service map.**

   You will see traces and metrics for your Lambda function in the CloudWatch console.

Troubleshooting

If Application Signals is not working, check the following:

- Check the function logs for any errors related to the OpenTelemetry instrumentation
- Verify if the environment variable `AWS_LAMBDA_EXEC_WRAPPER` is set correctly
- Make sure the layer extraction in the Docker file completed successfully
- Confirm if the IAM permissions are properly attached
- If needed, increase the *Timeout and Memory* settings in the general configuration of the Lambda function

.Net

You can learn how to integrate the OpenTelemetry Layer with Application Signals support into your containerized .Net Lambda function, download the `layer.zip` artifact, and integrate it into your .Net Lambda function to enable Application Signals monitoring.

Prerequisites

- Amazon CLI configured with your credentials
- Docker installed
- .Net 8 SDK
- These instructions assume you are on x86_64 platform

1. **Set Up Project Structure**

   Create a directory for your Lambda function container image

```
mkdir dotnet-appsignals-container-lambda && \
cd dotnet-appsignals-container-lambda
```

2. **Create Dockerfile**

   Download and integrate the OpenTelemetry Layer with Application Signals support directly into your Lambda container image. To do this, the `Dockerfile` file is created.

```
FROM public.ecr.aws/lambda/dotnet:8

# Install utilities
RUN dnf install -y unzip wget dotnet-sdk-8.0 which

# Add dotnet command to docker container's PATH
ENV PATH="/usr/lib64/dotnet:${PATH}"

# Download the OpenTelemetry Layer with AppSignals Support
RUN wget https://github.com/aws-observability/aws-otel-dotnet-instrumentation/
releases/latest/download/layer.zip -O /tmp/layer.zip

# Extract and include Lambda layer contents
RUN mkdir -p /opt && \
    unzip /tmp/layer.zip -d /opt/ && \
    chmod -R 755 /opt/ && \
    rm /tmp/layer.zip

WORKDIR ${LAMBDA_TASK_ROOT}

# Copy the project files
COPY dotnet-lambda-function/src/dotnet-lambda-function/*.csproj
 ${LAMBDA_TASK_ROOT}/
COPY dotnet-lambda-function/src/dotnet-lambda-function/Function.cs
 ${LAMBDA_TASK_ROOT}/
COPY dotnet-lambda-function/src/dotnet-lambda-function/aws-lambda-tools-
defaults.json ${LAMBDA_TASK_ROOT}/

# Install dependencies and build the application
RUN dotnet restore

# Use specific runtime identifier and disable ReadyToRun optimization
RUN dotnet publish -c Release -o out --self-contained false /
p:PublishReadyToRun=false
```

```
# Copy the published files to the Lambda runtime directory
RUN cp -r out/* ${LAMBDA_TASK_ROOT}/

CMD ["dotnet-lambda-function::dotnet_lambda_function.Function::FunctionHandler"]
```

> **Note**
>
> The `layer.zip` file contains the OpenTelemetry instrumentation necessary for Amazon Application Signals support to monitor your Lambda function.
> The layer extraction steps ensures:
>
> - The layer.zip contents are properly extracted to the `/opt/ directory`
> - The `otel-instrument` script receives proper execution permissions
> - The temporary layer.zip file is removed to keep the image size smaller

3. **Lambda function code** – Initialize your Lambda project using the Amazon Lambda .NET template:

```
# Install the Lambda templates if you haven't already
dotnet new -i Amazon.Lambda.Templates

# Create a new Lambda project
dotnet new lambda.EmptyFunction -n dotnet-lambda-function
```

Your project should look something like:

```
.
### Dockerfile
### dotnet-lambda-function
    ### src
    #   ### dotnet-lambda-function
    #       ### Function.cs
    #       ### Readme.md
    #       ### aws-lambda-tools-defaults.json
    #       ### dotnet-lambda-function.csproj
    ### test
        ### dotnet-lambda-function.Tests
            ### FunctionTest.cs
            ### dotnet-lambda-function.Tests.csproj
```

4. **Build and deploy the container image**

   Set up environment variables

```
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
AWS_REGION=$(aws configure get region)

# For fish shell users:
# set AWS_ACCOUNT_ID (aws sts get-caller-identity --query Account --output
 text)
# set AWS_REGION (aws configure get region)
```

   Update the `Function.cs` code to:

   Update the `dotnet-lambda-function.csproj` code to:

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <TargetFramework>net8.0>/TargetFramework>
   <ImplicitUsings>enable</ImplicitUsings>
    <Nullable>enable</Nullable>
    <GenerateRuntimeConfigurationFiles>true</GenerateRuntimeConfigurationFiles>
    <AWSProjectType>Lambda</AWSProjectType>

    <CopyLocalLockFileAssemblies>true</CopyLocalLockFileAssemblies>

    <PublishReadyToRun>true</PublishReadyToRun>
 </PropertyGroup>
  <ItemGroup>
    <PackageReference Include="Amazon.Lambda.Core" Version="2.5.0" />
    <PackageReference Include="Amazon.Lambda.Serialization.SystemTextJson"
 Version="2.4.4" />
    <PackageReference Include="AWSSDK.S3" Version="3.7.305.23" />
  </ItemGroup>
</Project>
```

5. **Build and deploy the container image**

   Set up environment variables

```
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
AWS_REGION=$(aws configure get region)
```

```
# For fish shell users:
# set AWS_ACCOUNT_ID (aws sts get-caller-identity --query Account --output
 text)
# set AWS_REGION (aws configure get region)
```

Authenticate with public Amazon ECR

```
aws ecr-public get-login-password --region us-east-1 | docker login --username
 AWS --password-stdin public.ecr.aws
```

Authenticate with private Amazon ECR

```
aws ecr get-login-password --region $AWS_REGION | docker login --username AWS --
password-stdin $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com
```

Create Amazon ECR repository (if needed)

```
aws ecr create-repository \
    --repository-name lambda-appsignals-demo \
    --region $AWS_REGION
```

Build, tag, and push your image

```
# Build the Docker image
docker build -t lambda-appsignals-demo .

# Tag the image
docker tag lambda-appsignals-demo:latest $AWS_ACCOUNT_ID.dkr.ecr.
$AWS_REGION.amazonaws.com/lambda-appsignals-demo:latest

# Push the image
docker push $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com/lambda-appsignals-
demo:latest

5. Create and Configure the Lambda Function
```

6. **Create and configure the Lambda function**

   Create a new function using the Lambda console.

Select **Container image** as the deployment option.

Choose **Browse images** to select your Amazon ECR image.

7. **Testing and verifications – Test your Lambda with a simple event. If the layer integration is successful, your Lambda appears under the Application Signals service map.**

   You will see traces and metrics for your Lambda function in the CloudWatch console.

Troubleshooting

If Application Signals is not working, check the following:

- Check the function logs for any errors related to the OpenTelemetry instrumentation
- Verify if the environment variable `AWS_LAMBDA_EXEC_WRAPPER` is set correctly
- Make sure the layer extraction in the Docker file completed successfully
- Confirm if the IAM permissions are properly attached
- If needed, increase the *Timeout and Memory* settings in the general configuration of the Lambda function

Node.js

You can learn how to integrate the OpenTelemetry Layer with Application Signals support into your containerized Node.js Lambda function, download the `layer.zip` artifact, and integrate it into your Node.js Lambda function to enable Application Signals monitoring.

Prerequisites

- Amazon CLI configured with your credentials
- Docker installed
- These instructions assume you are on x86_64 platform

1. **Set Up Project Structure**

   Create a directory for your Lambda function container image

```
mkdir nodejs-appsignals-container-lambda &&\
```

```
cd nodejs-appsignals-container-lambda
```

2. **Create Dockerfile**

   Download and integrate the OpenTelemetry Layer with Application Signals support directly into your Lambda container image. To do this, the `Dockerfile` file is created.

```
# Dockerfile
FROM public.ecr.aws/lambda/nodejs:22

# Install utilities
RUN dnf install -y unzip wget

# Download the OpenTelemetry Layer with AppSignals Support
RUN wget https://github.com/aws-observability/aws-otel-js-instrumentation/
releases/latest/download/layer.zip -O /tmp/layer.zip

# Extract and include Lambda layer contents
RUN mkdir -p /opt && \
    unzip /tmp/layer.zip -d /opt/ && \
    chmod -R 755 /opt/ && \
    rm /tmp/layer.zip

# Install npm dependencies
RUN npm init -y
RUN npm install

# Copy function code
COPY *.js ${LAMBDA_TASK_ROOT}/

# Set the CMD to your handler
CMD [ "index.handler" ]
```

> **Note**
>
> The `layer.zip` file contains the OpenTelemetry instrumentation necessary for Amazon Application Signals support to monitor your Lambda function.
> The layer extraction steps ensures:
>
> - The layer.zip contents are properly extracted to the `/opt/ directory`
> - The `otel-instrument` script receives proper execution permissions

- The temporary layer.zip file is removed to keep the image size smaller

3. **Lambda function code**

   Create an `index.js` file with the following content:

```
const { S3Client, ListBucketsCommand } = require('@aws-sdk/client-s3');

// Initialize S3 client
const s3Client = new S3Client({ region: process.env.AWS_REGION });

exports.handler = async function(event, context) {
  console.log('Received event:', JSON.stringify(event, null, 2));
  console.log('Handler initializing:', exports.handler.name);

  const response = {
    statusCode: 200,
    body: {}
  };

  try {
    // List S3 buckets
    const command = new ListBucketsCommand({});
    const data = await s3Client.send(command);

    // Extract bucket names
    const bucketNames = data.Buckets.map(bucket => bucket.Name);

    response.body = {
      message: 'Successfully retrieved buckets',
      buckets: bucketNames
    };

  } catch (error) {
    console.error('Error listing buckets:', error);

    response.statusCode = 500;
    response.body = {
      message: `Error listing buckets: ${error.message}`
    };
  }

  return response;
```

```
};
```

Your project structure should look something like this:

```
.
### Dockerfile
### index.js
```

4. **Build and deploy the container image**

   Set up environment variables

```
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
AWS_REGION=$(aws configure get region)

# For fish shell users:
# set AWS_ACCOUNT_ID (aws sts get-caller-identity --query Account --output
 text)
# set AWS_REGION (aws configure get region)
```

   Authenticate with public Amazon ECR

```
aws ecr-public get-login-password --region us-east-1 | docker login --username
 AWS --password-stdin public.ecr.aws
```

   Authenticate with private Amazon ECR

```
aws ecr get-login-password --region $AWS_REGION | docker login --username AWS --
password-stdin $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com
```

   Create Amazon ECR repository (if needed)

```
aws ecr create-repository \
    --repository-name lambda-appsignals-demo \
    --region $AWS_REGION
```

   Build, tag, and push your image

```
# Build the Docker image
docker build -t lambda-appsignals-demo .
```

```
# Tag the image
docker tag lambda-appsignals-demo:latest $AWS_ACCOUNT_ID.dkr.ecr.
$AWS_REGION.amazonaws.com/lambda-appsignals-demo:latest

# Push the image
docker push $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com/lambda-appsignals-
demo:latest

5. Create and Configure the Lambda Function
```

5. **Create and configure the Lambda function**

   Create a new function using the Lambda console.

   Select **Container image** as the deployment option.

   Choose **Browse images** to select your Amazon ECR image.

6. **Testing and verifications – Test your Lambda with a simple event. If the layer integration is successful, your Lambda appears under the Application Signals service map.**

   You will see traces and metrics for your Lambda function in the CloudWatch console.

Troubleshooting

If Application Signals is not working, check the following:

- Check the function logs for any errors related to the OpenTelemetry instrumentation
- Verify if the environment variable `AWS_LAMBDA_EXEC_WRAPPER` is set correctly
- Make sure the layer extraction in the Docker file completed successfully
- Confirm if the IAM permissions are properly attached
- If needed, increase the *Timeout and Memory* settings in the general configuration of the Lambda function

Python

You can learn how to integrate the OpenTelemetry Layer with Application Signals support into your containerized Python Lambda function, download the `layer.zip` artifact, and integrate it into your Python Lambda function to enable Application Signals monitoring.

Prerequisites

- Amazon CLI configured with your credentials
- Docker installed
- These instructions assume you are on x86_64 platform

1. **Set Up Project Structure**

   Create a directory for your Lambda function container image

   ```
   mkdir python-appsignals-container-lambda &&\
   cd python-appsignals-container-lambda
   ```

2. **Create Dockerfile**

   Download and integrate the OpenTelemetry Layer with Application Signals support directly into your Lambda container image. To do this, the `Dockerfile` file is created.

   > **Note**
   >
   > The `layer.zip` file contains the OpenTelemetry instrumentation necessary for Amazon Application Signals support to monitor your Lambda function.
   > The layer extraction steps ensures:
   >
   > - The layer.zip contents are properly extracted to the `/opt/ directory`
   > - The `otel-instrument` script receives proper execution permissions
   > - The temporary layer.zip file is removed to keep the image size smaller

3. **Lambda function code**

   Create your Lambda function in an `app.py` file:

   ```
   import json
   import boto3

   def lambda_handler(event, context):
       """
       Sample Lambda function that can be used in a container image.
   ```

```
    Parameters:
    -----------
    event: dict
        Input event data
    context: LambdaContext
        Lambda runtime information

    Returns:
    --
    dict
        Response object
    """
    print("Received event:", json.dumps(event, indent=2))

    # Create S3 client
    s3 = boto3.client('s3')

    try:
        # List buckets
        response = s3.list_buckets()

        # Extract bucket names
        buckets = [bucket['Name'] for bucket in response['Buckets']]

        return {
            'statusCode': 200,
            'body': json.dumps({
                'message': 'Successfully retrieved buckets',
                'buckets': buckets
            })
        }
    except Exception as e:
        print(f"Error listing buckets: {str(e)}")
        return {
            'statusCode': 500,
            'body': json.dumps({
                'message': f'Error listing buckets: {str(e)}'
            })
        }
```

Your project structure should look something like this:

```
.
```

```
### Dockerfile
### app.py
### instructions.md
```

4. **Build and deploy the container image**

   Set up environment variables

```
AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query Account --output text)
AWS_REGION=$(aws configure get region)

# For fish shell users:
# set AWS_ACCOUNT_ID (aws sts get-caller-identity --query Account --output
 text)
# set AWS_REGION (aws configure get region)
```

   Authenticate with public Amazon ECR

```
aws ecr-public get-login-password --region us-east-1 | docker login --username
 AWS --password-stdin public.ecr.aws
```

   Authenticate with private Amazon ECR

```
aws ecr get-login-password --region $AWS_REGION | docker login --username AWS --
password-stdin $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com
```

   Create Amazon ECR repository (if needed)

```
aws ecr create-repository \
    --repository-name lambda-appsignals-demo \
    --region $AWS_REGION
```

   Build, tag, and push your image

```
# Build the Docker image
docker build -t lambda-appsignals-demo .

# Tag the image
docker tag lambda-appsignals-demo:latest $AWS_ACCOUNT_ID.dkr.ecr.
$AWS_REGION.amazonaws.com/lambda-appsignals-demo:latest
```

```
# Push the image
docker push $AWS_ACCOUNT_ID.dkr.ecr.$AWS_REGION.amazonaws.com/lambda-appsignals-
demo:latest

5. Create and Configure the Lambda Function
```

5. **Create and configure the Lambda function**

   Create a new function using the Lambda console.

   Select **Container image** as the deployment option.

   Choose **Browse images** to select your Amazon ECR image.

6. **Testing and verifications – Test your Lambda with a simple event. If the layer integration is successful, your Lambda appears under the Application Signals service map.**

   You will see traces and metrics for your Lambda function in the CloudWatch console.

Troubleshooting

If Application Signals is not working, check the following:

- Check the function logs for any errors related to the OpenTelemetry instrumentation
- Verify if the environment variable `AWS_LAMBDA_EXEC_WRAPPER` is set correctly
- Make sure the layer extraction in the Docker file completed successfully
- Confirm if the IAM permissions are properly attached
- If needed, increase the *Timeout and Memory* settings in the general configuration of the Lambda function

Troubleshooting your Application Signals installation

This section contains troubleshooting tips for CloudWatch Application Signals.

Topics

Application Signals Java layer cold start performance

Adding the Application Signals Layer to Java Lambda functions increases the startup latency (cold start time). The following tips can help reduce latency for time-sensitive functions.

Fast startup for Java agent – The Application Signals Java Lambda Layer includes a Fast Startup feature that's turned off by default but can be enabled by setting the OTEL_JAVA_AGENT_FAST_STARTUP_ENABLED variable to true. When enabled, this feature configures the JVM to use tiered compilation level 1 C1 compiler to generate quick optimized native code for faster cold starts. The C1 compiler prioritizes speed at the cost of long-term optimization whereas the C2 compiler provides superior overall performance by profiling data over time.

For more information, see Fast startup for Java agent .

Reduce cold start times with Provisioned Concurrency – Amazon Lambda provisioned concurrency pre-allocates a specified number of function instances, keeping them initialized and ready to handle requests immediately. This reduces cold-start times by eliminating the need to initialize the function environment during execution, ensuring faster and more consistent performance, especially for latency-sensitive workloads. For more information, see Configuring provisioned concurrency for a function .

Optimize startup performance using Lambda SnapStart – Amazon Lambda SnapStart is a feature that optimizes the startup performance of Lambda functions by creating a pre-initialized snapshot of the execution environment after the function's initialization phase. This snapshot is then reused to start new instances, significantly reducing cold-start times by skipping the initialization process during function invocation. For information, see Improving startup performance with Lambda SnapStart

Application doesn't start after Application Signals is enabled

If your application on an Amazon EKS cluster doesn't start after you enable Application Signals on the cluster, check for the following:

- Check if the application has been instrumented by another monitoring solution. Application Signals might not support co-existing with other instrumentation solutions.
- Confirm that your the application meets the compatibility requirements to use Application Signals. For more information, see Supported systems.
- If your application failed to pull the Application Signals artifacts such as the Amazon Distro for OpenTelemetery Java or Python agent and CloudWatch agent images, it could be a network issue.

To mitigate the issue, remove the annotation `instrumentation.opentelemetry.io/inject-java: "true"` or `instrumentation.opentelemetry.io/inject-python: "true"` from your application deployment manifest, and re-deploy your application. Then check if the application is working.

Known issues

The runtime metrics collection in the Java SDK release v1.32.5 is known to not work with applications using JBoss Wildfly. This issue extends to the Amazon CloudWatch Observability EKS add-on, affecting versions `2.3.0-eksbuild.1` through `2.5.0-eksbuild.1`.

If you are impacted, either downgrade the version or disable your runtime metrics collection by adding the environment variable `OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED=false` to your application.

Python application doesn't start after Application Signals is enabled

It is a known issue in OpenTelemetry auto-instrumentation that a missing `PYTHONPATH` environment variable can sometimes cause the application to fail to start . To resolve this, ensure that you set the PYTHONPATH environment variable to the location of your application's working directory. For more information about this issue, see [Python autoinstrumentation setting of PYTHONPATH is not compliant with Python's module resolution behavior, breaking Django applications].

For Django applications, there are additional required configurations, which are outlined in the [OpenTelemetry Python documentation].

- Use the `--noreload` flag to prevent automatic reloading.
- Set the `DJANGO_SETTINGS_MODULE` environment variable to the location of your Django application's `settings.py` file. This ensures that OpenTelemetry can correctly access and integrate with your Django settings.

No Application Signals data for Python application that uses a WSGI server

If you are using a WSGI server such as Gunicorn or uWSGI, you must make additional changes to make the ADOT Python auto-instrumentation work.

> **Note**
>
> Be sure that you are using the latest version of ADOT Python and the Amazon CloudWatch Observability EKS add-on before proceeding.

Additional steps to enable Application Signals with a WSGI server

1. Import the auto-instrumentation in the forked worker processes.

   For Gunicorn, use the `post_fork` hook:

```
# gunicorn.conf.py
def post_fork(server, worker):
    from opentelemetry.instrumentation.auto_instrumentation import sitecustomize
```

   For uWSGI, use the `import` directive.

```
#  uwsgi.ini
[uwsgi]
; required for the instrumentation of worker processes
```

```
enable-threads = true
lazy-apps = true
import = opentelemetry.instrumentation.auto_instrumentation.sitecustomize
```

2. Enable the configuration for ADOT Python auto-instrumentation to skip the main process and defer to workers by setting the `OTEL_AWS_PYTHON_DEFER_TO_WORKERS_ENABLED` environment variable to `true`.

My Node.js application is not instrumented or isn't generating Application Signals telemetry

To enable Application Signals for Node.js, you must ensure that your Node.js application uses the CommonJS (CJS) module format. Currently, the Amazon Distro for OpenTelemetry Node.js doesn't support the ESM module format, because OpenTelemetry JavaScript's support of ESM is experimental and is a work in progress.

To determine if your application is using CJS and not ESM, ensure that your application does not fulfill the conditions to enable ESM.

No application data in Application Signals dashboard

If metrics or traces are missing in the Application Signals dashboards, the following might be causes. Investigate these causes only if you have waited 15 minutes for Application Signals to collect and display data since your last update.

- Make sure that your library and framework you are using is supported by the ADOT Java agent. For more information, see Libraries / Frameworks.
- Make sure that the CloudWatch agent is running. First check the status of the CloudWatch agent pods and make sure they are all in `Running` status.

  ```
  kubectl -n amazon-cloudwatch get pods.
  ```

  Add the following to the CloudWatch agent configuration file to enable debugging logs, and then restart the agent.

  ```
  "agent": {

    "region": "${REGION}",
    "debug": true
  ```

```
},
```

Then check for errors in the CloudWatch agent pods.

- Check for configuration issues with the CloudWatch agent. Confirm that the following is still in the CloudWatch agent configuration file and the agent has been restarted since it was added.

  ```
  "agent": {
    "region": "${REGION}",
    "debug": true
  },
  ```

  Then check the OpenTelemetry debugging logs for error messages such as `ERROR io.opentelemetry.exporter.internal.grpc.OkHttpGrpcExporter - Failed to export ...`. These messages might indicate the problem.

  If that doesn't solve the issue, dump and check the environment variables with names that start with `OTEL_` by describing the pod with the `kubectl describe pod` command.

- To enable the OpenTelemetry Python debug logging, set the environment variable `OTEL_PYTHON_LOG_LEVEL` to `debug` and redeploy the application.
- Check for wrong or insufficient permissions for exporting data from the CloudWatch agent. If you see `Access Denied` messages in the CloudWatch agent logs, this might be the issue. It is possible that the permissions applied when you installed the CloudWatch agent were later changed or revoked.
- Check for an Amazon Distro for OpenTelemetry (ADOT) issue when generating telemetry data.

  Make sure that the instrumentation annotations `instrumentation.opentelemetry.io/inject-java` and `sidecar.opentelemetry.io/inject-java` are applied to the application deployment and the value is `true`. Without these, the application pods will not be instrumented even if the ADOT addon is installed correctly.

  Next, check if the `init` container is applied on the application and the `Ready` state is `True`. If the `init` container is not ready, see the status for the reason.

  If the issue persists, enable debug logging on the OpenTelemetry Java SDK by setting the environment variable `OTEL_JAVAAGENT_DEBUG` to true and redeploying the application. Then look for messages that start with `ERROR io.telemetry`.

- The metric/span exporter might be dropping data. To find out, check the application log for messages that include `Failed to export...`
- The CloudWatch agent might be getting throttled when sending metrics or spans to Application Signals. Check for messages indicating throttling in the CloudWatch agent logs.
- Make sure that you've enabled the service discovery setup. You need to do this only once in your Region.

  To confirm this, in the CloudWatch console choose **Application Signals**, **Services**. If Step 1 is not marked **Complete**, choose **Start discovering your services**. Data should start flowing in within five minutes.

Service metrics or dependency metrics have Unknown values

If you see **UnknownService**, **UnknownOperation**, **UnknownRemoteService**, or **UnknownRemoteOperation** for a dependency name or operation in the Application Signals dashboards, check whether the occurrence of data points for the unknown remote service and unknown remote operation are coinciding with their deployments.

- **UnknownService** means that the name of an instrumented application is unknown. If the `OTEL_SERVICE_NAME` environment variable is undefined and `service.name` isn't specified in `OTEL_RESOURCE_ATTRIBUTES`, the service name is set to `UnknownService`. To fix this, specify the service name in `OTEL_SERVICE_NAME` or `OTEL_RESOURCE_ATTRIBUTES`.
- **UnknownOperation** means that the name of an invoked operation is unknown. This occurs when Application Signals is unable to discover an operation name which invokes the remote call, or when the extracted operation name contains high cardinality values.
- **UnknownRemoteService** means that the name of the destination service is unknown. This occurs when the system is unable to extract the destination service name that the remote call accesses.

  One solution is to create a custom span around the function that sends out the request, and add the attribute `aws.remote.service` with the designated value. Another option is to configure the CloudWatch agent to customize the metric value of `RemoteService`. For more information about customizations in the CloudWatch agent, see [Enable CloudWatch Application Signals](#).
- **UnknownRemoteOperation** means that the name of the destination operation is unknown. This occurs when the system is unable to extract the destination operation name that the remote call accesses.

One solution is to create a custom span around the function that sends out the request, and add the attribute `aws.remote.operation` with the designated value. Another option is to configure the CloudWatch agent to customize the metric value of `RemoteOperation`. For more information about customizations in the CloudWatch agent, see Enable CloudWatch Application Signals.

Handling a ConfigurationConflict when managing the Amazon CloudWatch Observability EKS add-on

When you install or update the Amazon CloudWatch Observability EKS add-on, if you notice a failure caused by a `Health Issue` of type `ConfigurationConflict` with a description that starts with `Conflicts found when trying to apply. Will not continue due to resolve conflicts mode`, it is likely because you already have the CloudWatch agent and its associated components such as the ServiceAccount, the ClusterRole and the ClusterRoleBinding installed on the cluster. When the add-on tries to install the CloudWatch agent and its associated components, if it detects any change in the contents, it by default fails the installation or update to avoid overwriting the state of the resources on the cluster.

If you are trying to onboard to the Amazon CloudWatch Observability EKS add-on and you see this failure, we recommend deleting an existing CloudWatch agent setup that you had previously installed on the cluster and then installing the EKS add-on. Be sure to back up any customizations you might have made to the original CloudWatch agent setup such as a custom agent configuration, and provide these to the Amazon CloudWatch Observability EKS add-on when you next install or update it. If you had previously installed the CloudWatch agent for onboarding to Container Insights, see Deleting the CloudWatch agent and Fluent Bit for Container Insights for more information.

Alternatively, the add-on supports a conflict resolution configuration option that has the capability to specify `OVERWRITE`. You can use this option to proceed with installing or updating the add-on by overwriting the conflicts on the cluster. If you are using the Amazon EKS console, you'll find the **Conflict resolution method** when you choose the **Optional configuration settings** when you create or update the add-on. If you are using the Amazon CLI, you can supply the `--resolve-conflicts OVERWRITE` to your command to create or update the add-on.

I want to filter out unnecessary metrics and traces

If Application Signals is collecting traces and metrics that you don't want, see Manage high-cardinality operations for information about configuring the CloudWatch agent with custom rules to reduce cardinality.

For information about customizing trace sampling rules, see Configure sampling rules in the X-Ray documentation.

What does `InternalOperation` mean?

An `InternalOperation` is an operation that is triggered by the application internally rather than by an external invocation. Seeing `InternalOperation` is expected, healthy behavior.

Some typical examples where you would see `InternalOperation` include the following:

- **Preloading on start**– Your application performs an operation named `loadDatafromDB` which reads metadata from a database during the warm up phase. Instead of observing `loadDatafromDB` as a service operation, you'll see it categorized as an `InternalOperation`.
- **Async execution in the background**– Your application subscribes to an event queue, and processes streaming data accordingly whenever there's an update. Each triggered operation will be under `InternalOperation` as a service operation.
- **Retrieving host information from a service registry**– Your application talks to a service registry for service discovery. All interactions with the discovery system are classified as an `InternalOperation`.

How do I enable logging for .NET applications?

To enable logging for .NET applications, configure the following environment variables. For more information about how to configure these environment variables, see Troubleshooting .NET automatic instrumentation issues in the OpenTelemetry documentation.

- `OTEL_LOG_LEVEL`
- `OTEL_DOTNET_AUTO_LOG_DIRECTORY`
- `COREHOST_TRACE`
- `COREHOST_TRACEFILE`

How can I resolve assembly version conflicts in .NET applications?

If you get the following error, see Assembly version conflicts in the OpenTelemetry documentation for resolution steps.

```
Unhandled exception. System.IO.FileNotFoundException: Could not load file or
 assembly 'Microsoft.Extensions.DependencyInjection.Abstractions, Version=7.0.0.0,
 Culture=neutral, PublicKeyToken=adb9793829ddae60'. The system cannot find the file
 specified.

File name: 'Microsoft.Extensions.DependencyInjection.Abstractions, Version=7.0.0.0,
 Culture=neutral, PublicKeyToken=adb9793829ddae60'
   at Microsoft.AspNetCore.Builder.WebApplicationBuilder..ctor(WebApplicationOptions
 options, Action`1 configureDefaults)
   at Microsoft.AspNetCore.Builder.WebApplication.CreateBuilder(String[] args)
   at Program.<Main>$(String[] args) in /Blog.Core/Blog.Core.Api/Program.cs:line 26
```

Can I disable FluentBit?

You can disable FluentBit by configuring the Amazon CloudWatch Observability EKS add-on. For more information, see (Optional) Additional configuration.

Can I filter container logs before exporting to CloudWatch Logs?

No, filtering container logs is not yet supported.

Update to required versions of agents or Amazon EKS add-on

After August 9, 2024, CloudWatch Application Signals will no longer support older versions of the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent, and the Amazon Distro for OpenTelemetry auto-instrumentation agent.

- For the Amazon CloudWatch Observability EKS add-on, versions older than `v1.7.0-eksbuild.1` won't be supported.
- For the CloudWatch agent, versions older than `1.300040.0` won't be supported.
- For the Amazon Distro for OpenTelemetry auto-instrumentation agent:
  - For Java, versions older than `1.32.2` aren't supported.
  - For Python, versions older than `0.2.0` aren't supported.
  - For .NET, versions older than `1.3.2` aren't supported.
  - For Node.js, versions older than `0.3.0` aren't supported.

> **Important**
>
> The latest versions of the agents include updates to the Application Signals metric schema. These updates are not backward compatible, and this can result in data issues if incompatible versions are used. To help ensure a seamless transition to the new functionality, do the following:
>
> - If your application is running on Amazon EKS, be sure to restart all instrumented applications after you update the Amazon CloudWatch Observability add-on.
> - For applications running on other platforms, be sure to upgrade **both** the CloudWatch agent and the Amazon OpenTelemetry auto-instrumentation agent to the latest versions.

The instructions in the following sections can help you update to a supported version.

Contents

Update the Amazon CloudWatch Observability EKS add-on

To the Amazon CloudWatch Observability EKS add-on, you can use the Amazon Web Services Management Console or the Amazon CLI.

Use the console

To upgrade the add-on using the console

1. Open the Amazon EKS console at https://console.amazonaws.cn/eks/home#/clusters.
2. Choose the name of the Amazon EKS cluster to update.
3. Choose the **Add-ons** tab, then choose **Amazon CloudWatch Observability**.

4. Choose **Edit**, select the version you want to update to, and then choose **Save changes**.

   Be sure to choose `v1.7.0-eksbuild.1` or later.

5. Enter one of the following Amazon CLI commands to restart your services.

```
# Restart a deployment
kubectl rollout restart deployment/name
# Restart a daemonset
kubectl rollout restart daemonset/name
# Restart a statefulset
kubectl rollout restart statefulset/name
```

Use the Amazon CLI

To upgrade the add-on using the Amazon CLI

1. Enter the following command to find the latest version.

```
aws eks describe-addon-versions \
--addon-name amazon-cloudwatch-observability
```

2. Enter the following command to update the add-on. Replace *$VERSION* with a version that is `v1.7.0-eksbuild.1` or later. Replace *$AWS_REGION* and *$CLUSTER* with your Region and cluster name.

```
aws eks update-addon \
--region $AWS_REGION \
--cluster-name $CLUSTER \
--addon-name amazon-cloudwatch-observability \
--addon-version $VERSION \
# required only if the advanced configuration is used.
--configuration-values $JSON_CONFIG
```

> **Note**
>
> If you're using an custom configuration for the add-on, you can find an example of the configuration to use for *$JSON_CONFIG* in Enable CloudWatch Application Signals.

3. Enter one of the following Amazon CLI commands to restart your services.

```
# Restart a deployment
kubectl rollout restart deployment/name
# Restart a daemonset
kubectl rollout restart daemonset/name
# Restart a statefulset
kubectl rollout restart statefulset/name
```

Update the CloudWatch agent and ADOT agent

If your services are running on architectures other than Amazon EKS, you will need to upgrade both the CloudWatch agent and the ADOT auto-instrumentation agent to use the latest Application Signals features.

Update on Amazon ECS

To upgrade your agents for services running on Amazon ECS

1. Create a new task definition revision. For more information, see Updating a task definition using the console.
2. Replace the `$IMAGE` of the `ecs-cwagent` container with the latest image tag from cloudwatch-agent on Amazon ECR.

   If you upgrade to a fixed version, be sure to use a version equal to or later than `1.300040.0`.
3. Replace the `$IMAGE` of the `init` container with the latest image tag from the following locations:

   - For Java, use aws-observability/adot-autoinstrumentation-java.

     If you upgrade to a fixed version, be sure to use a version equal to or later than `1.32.2`.
   - For Python, use aws-observability/adot-autoinstrumentation-python.

     If you upgrade to a fixed version, be sure to use a version equal to or later than `0.2.0`.
   - For .NET, use aws-observability/adot-autoinstrumentation-dotnet.

     If you upgrade to a fixed version, be sure to use a version equal to or later than `1.3.2`.
   - For Node.js, use aws-observability/adot-autoinstrumentation-node.

     If you upgrade to a fixed version, be sure to use a version equal to or later than `0.3.0`.

4. Update the Application Signals environment variables in your app container by following the instructions at Step 4: Instrument your application with the CloudWatch agent.
5. Deploy your service with the new task definition.

Update on Amazon EC2 or other architectures

To upgrade your agents for services running on Amazon EC2 or other architectures

1. Follow the instructions at Download the CloudWatch agent package and upgrade the CloudWatch agent to the latest version. Be sure to select version `1.300040.0` or later.
2. Download the latest version of the Amazon Distro for OpenTelemetry auto-instrumentation agent from one of the following locations:

   - For Java, use aws-otel-java-instrumentation .

     If you upgrade to a fixed version, be sure to choose `1.32.2` or later.
   - For Python, use aws-otel-python-instrumentation .

     If you upgrade to a fixed version, be sure to choose `0.2.0` or later.
   - For .NET, use aws-otel-dotnet-instrumentation.

     If you upgrade to a fixed version, be sure to choose `1.3.2` or later.
   - For Node.js, use aws-otel-js-instrumentation .

     If you upgrade to a fixed version, be sure to choose `0.3.0` or later.
3. Apply the updated Application Signals environment variables to your application, then start your application. For more information, see Step 3: Instrument your application and start it.

(Optional) Configuring Application Signals

This section contains information about configuring CloudWatch Application Signals.

Topics

Trace sampling rate

By default, when you enable Application Signals X-Ray centralized sampling is enabled using the default sampling rate settings of `reservoir=1/s` and `fixed_rate=5%`. The environment variables for the Amazon Distro for OpenTelemetry (ADOT) SDK agent as set as follows.

Environment variable	Value	Note
`OTEL_TRACES_SAMPLER`	`xray`	
`OTEL_TRACES_SAMPLER_ARG`	`endpoint=http://cloudwatch-agent.amazon-cloudwatch:2000`	Endpoint of the CloudWatch agent

For information about changing the sampling configuration, see the following:

- To change X-Ray sampling, see [Configure sampling rules](#)
- To change ADOT sampling, see [Configuring the OpenTelemetry Collector for X-Ray remote sampling](#)

If you want to disable X-Ray centralized sampling and use local sampling instead, set the following values for the ADOT SDK Java agent as below. The following example sets the sampling rate at 5%.

Environment variable	Value
`OTEL_TRACES_SAMPLER`	`parentbased_traceidratio`
`OTEL_TRACES_SAMPLER_ARG`	`0.05`

For information about more advanced sampling settings, see [OTEL_TRACES_SAMPLER](#).

Enable trace to log correlation

You can enable *trace to log correlation* in Application Signals. This automatically injects trace IDs and span IDs into the relevant application logs. Then, when you open a trace detail page in the Application Signals console, the relevant log entries (if any) that correlate with the current trace automatically appear at the bottom of the page.

For example, suppose you notice a spike in a latency graph. You can choose the point on the graph to load the diagnostics information for that point in time. You then choose the relevant trace to get more information. When you view the trace information, you can scroll down to see the logs associated with the trace. These logs might reveal patterns or error codes associated with the issues causing the latency spike.

To achieve trace log correlation, Application Signals relies on the following:

- Logger MDC auto-instrumentation for Java.
- OpenTelemetry Logging Instrumentation for Python.
- The Pino, Winston, or Bunyan auto-instrumentations for Node.js.

All of these isntrumentations are provided by OpenTelemetry community. Application Signals uses them to inject trace contexts such as trace ID and span ID into application logs. To enable this, you must manually change your logging configuration to enable the auto-instrumentation.

Depending on the architecture that your application runs on, you might have to also set an environment variable to enable trace log correlation, in addition to following the steps in this section.

- On Amazon EKS, no further steps are needed.
- On Amazon ECS, no further steps are needed.
- On Amazon EC2, see the step 4 in the procedure in Step 3: Instrument your application and start it.

After you enable trace log correlation,

Trace log correlation setup examples

This section contains examples of setting up trace log correlation in several environments.

Spring Boot for Java

Suppose you have a Spring Boot application in a folder called `custom-app`. The application configuration is usually a YAML file named `custom-app/src/main/resources/application.yml` that might look like this:

```
spring:
```

```
  application:
    name: custom-app
  config:
    import: optional:configserver:${CONFIG_SERVER_URL:http://localhost:8888/}

...
```

To enable trace log correlation, add the following logging configuration.

```
spring:
  application:
    name: custom-app
  config:
    import: optional:configserver:${CONFIG_SERVER_URL:http://localhost:8888/}

...

logging:
  pattern:
    level: trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=%mdc{trace_flags}
 %5p
```

Logback for Java

In the logging configuration (such as logback.xml), insert the trace context `trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=%mdc{trace_flags} %5p` into `pattern` of Encoder. For example, the following configuration prepends the trace context before the log message.

```
<appender name="FILE" class="ch.qos.logback.core.FileAppender">
  <file>app.log</file>
  <append>true</append>
  <encoder>
    <pattern>trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=
%mdc{trace_flags} %5p - %m%n</pattern>
  </encoder>
</appender>
```

For more information about encoders in Logback, see [Encoders](#) in the Logback documentation.

Log4j2 for Java

In the logging configuration (such as log4j2.xml), insert the trace context `trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=%mdc{trace_flags} %5p` into `PatternLayout`. For example, the following configuration prepends the trace context before the log message.

```
<Appenders>
  <File name="FILE" fileName="app.log">
    <PatternLayout pattern="trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=
%mdc{trace_flags} %5p - %m%n"/>
  </File>
</Appenders>
```

For more information about pattern layouts in Log4j2, see Pattern Layout in the Log4j2 documentation.

Log4j for Java

In the logging configuration (such as log4j.xml), insert the trace context `trace_id=%mdc{trace_id} span_id=%mdc{span_id} trace_flags=%mdc{trace_flags} %5p` into `PatternLayout`. For example, the following configuration prepends the trace context before the log message.

```
<appender name="FILE" class="org.apache.log4j.FileAppender">;
  <param name="File" value="app.log"/>;
  <param name="Append" value="true"/>;
  <layout class="org.apache.log4j.PatternLayout">;
    <param name="ConversionPattern" value="trace_id=%mdc{trace_id} span_id=
%mdc{span_id} trace_flags=%mdc{trace_flags} %5p - %m%n"/>;
  </layout>;
</appender>;
```

For more information about pattern layouts in Log4j, see Class Pattern Layout in the Log4j documentation.

Python

Set the environment variable `OTEL_PYTHON_LOG_CORRELATION` to `true` while running your application. For more information, see Enable trace context injectionin the Python OpenTelemetry documentation.

Node.js

For more information about enabling trace context injection in Node.js for the logging libraries that support it, see the NPM usage documentations of the Pino, Winston, or Bunyan auto-instrumentations for Node.js.

Enable metric to log correlation

If you publish application logs to log groups in CloudWatch Logs, you can enable *metric to application log correlation* in Application Signals. With metric log correlation, the Application Signals console automatically displays the relevant log groups associated with a metric.

For example, suppose you notice a spike in a latency graph. You can choose a point on the graph to load the diagnostics information for that point in time. The diagnostics information will show the relevant application log groups that are associated with the current service and metric. Then you can choose a button to run a CloudWatch Logs Insights query on those log groups. Depending on the information contained in the application logs, this might help you to investigate the cause of the latency spike.

Depending on the architecture that your application runs on, you might have to also set an environment variable to enable metric to application log correlation.

- On Amazon EKS, no further steps are needed.
- On Amazon ECS, no further steps are needed.
- On Amazon EC2, see step 4 in the procedure in Step 3: Instrument your application and start it.

Manage high-cardinality operations

Application Signals includes settings in the CloudWatch agent that you can use to manage the cardinality of your operations and manage the metric exportation to optimize costs. By default, the metric limiting function becomes active when the number of distinct operations for a service over time exceeds the default threshold of 500. You can tune the behavior by adjusting the configuration settings.

Determine if metric limiting is activated

You can use the following methods to find if the default metric limiting is happening. If it is, you should consider optimizing the cardinality control by following the steps in the next section.

- In the CloudWatch console, choose **Application Signals**, **Services**. If you see an **Operation** named **AllOtherOperations** or a **RemoteOperation** named **AllOtherRemoteOperations**, then metric limiting is happening.
- If any metrics collected by Application Signals have the value `AllOtherOperations` for their `Operation` dimension, then metric limiting is happening.
- If any metrics collected by Application Signals have the value `AllOtherRemoteOperations` for their `RemoteOperation` dimension, then metric limiting is happening.

Optimize cardinality control

To optimize your cardinality control, you can do the following:

- Create custom rules to aggregate operations.
- Configure your metric limiting policy.

Create custom rules to aggregate operations

High-cardinality operations can sometimes be caused by inappropriate unique values extracted from the context. For example, sending out HTTP/S requests that include user IDs or session IDs in the path can lead to hundreds of disparate operations. To resolve such issues, we recommend that you configure the CloudWatch agent with customization rules to rewrite these operations.

In cases where there is a surge in generating numerous different metrics through individual `RemoteOperation` calls, such as `PUT /api/customer/owners/123`, `PUT /api/customer/owners/456`, and similar requests, we recommend that you consolidate these operations into a single `RemoteOperation`. One approach is to standardize all `RemoteOperation` calls that start with `PUT /api/customer/owners/` to a uniform format, specifically `PUT /api/customer/owners/{ownerId}`. The following example illustrates this. For information about other customization rules, see Enable CloudWatch Application Signals.

```
{
   "logs":{
      "metrics_collected":{
         "application_signals":{
            "rules":[
               {
                  "selectors":[
                     {
```

```
                        "dimension":"RemoteOperation",
                        "match":"PUT /api/customer/owners/*"
                     }
                  ],
                  "replacements":[
                     {
                        "target_dimension":"RemoteOperation",
                        "value":"PUT /api/customer/owners/{ownerId}"
                     }
                  ],
                  "action":"replace"
               }
            ]
         }
      }
   }
}
```

In other cases, high-cardinality metrics might have been aggregated to `AllOtherRemoteOperations`, and it might be unclear what specific metrics are included. The CloudWatch agent is able to log the dropped operations. To identify dropped operations, use the configuration in the following example to activate logging until the problem resurfaces. Then inspect the CloudWatch agent logs (accessible by container `stdout` or EC2 log files) and search for the keyword `drop metric data`.

```
{
  "agent": {
    "config": {
      "agent": {
        "debug": true
      },
      "traces": {
        "traces_collected": {
          "application_signals": {
          }
        }
      },
      "logs": {
        "metrics_collected": {
          "application_signals": {
            "limiter": {
              "log_dropped_metrics": true
```

```
                }
              }
            }
          }
        }
      }
    }
```

Create your metric limiting policy

If the default metric limiting configuration doesn't address the cardinality for your service, you can customize the metric limiter configuration. To do this, add a `limiter` section under the `logs/metrics_collected/application_signals` section in the CloudWatch Agent configuration file.

The following example lowers the threshold of metric limiting from 500 distinct metrics to 100.

```
{
  "logs": {
    "metrics_collected": {
      "application_signals": {
        "limiter": {
          "drop_threshold": 100
        }
      }
    }
  }
}
```

Monitor the operational health of your applications with Application Signals

Use Application Signals within the CloudWatch console to monitor and troubleshoot the operational health of your applications:

- **Monitor your application services** — As part of daily operational monitoring, use the Services page to see a summary of all your services. See services with the highest fault rate or latency, and see which services have unhealthy service level indicators (SLIs). Select a service to open the Service detail page and see detailed metrics, service operations, Synthetics canaries, and client requests. This can help you troubleshoot and identify the root cause of operational issues.

- **Inspect your application topology** — Use the Service Map to understand and monitor your application topology over time, including the relationships between clients, Synthetics canaries, services, and dependencies. Instantly see service level indicator (SLI) health and view key metrics such as call volume, fault rate, and latency. Drill down to see more detailed information in the Service detail page.

Explore an example scenario that demonstrates how these pages can be used to quickly troubleshoot an operational service health issue, from initial detection to identifying root cause.

How Application Signals enables operational health monitoring

After you enable your application for Application Signals, your application services, APIs, and their dependencies are automatically discovered and displayed in the **Services**, **Service detail**, and **Service Map** pages. Application Signals collects information from multiple sources to enable service discovery and operational health monitoring:

- Amazon Distro for OpenTelemetry (ADOT) — As part of enabling Application Signals, OpenTelemetry Java and Python auto-instrumentation libraries are configured to emit metrics and traces that are collected by the CloudWatch agent. The metrics and traces are used to enable discovery of services, operations, dependencies, and other service information.
- Service-level objectives (SLOs) — After you create service level objectives for your services, the Services, Service detail, and Service Map pages display service level indicator (SLI) health. SLIs can monitor latency, availability, and other operational metrics.
- CloudWatch Synthetics canaries — When you configure X-Ray tracing on your canaries, calls to your services from your canary scripts are associated with your service and displayed within the Service detail page.
- CloudWatch Real user monitoring (RUM) — When X-Ray tracing is enabled on your CloudWatch RUM web client, requests to your services are automatically associated and displayed within the service detail page.
- Amazon Service Catalog AppRegistry — Application Signals auto-discovers Amazon resources within your account and allows you to group them into logical applications created in AppRegistry. The application name displayed in the Services page is based on the underlying compute resource that your services are running on.

> **Note**
>
> Application Signals displays your services and operations based on metrics and traces emitted within the current time filter that you chose. (By default, this is the past three hours.) If there is no activity within the current time filter for a service, operation, dependency, Synthetics canary, or client page, it won't be displayed.
> Currently, up to 1,000 services can be displayed. Discovery of your services and service topology might be delayed up to 10 minutes. Evaluation of your service level indicator (SLI) health might be delayed up to 15 minutes.

> **Note**
>
> Application Signals console currently only supports choosing a maximum of one day within the 30 days time range.

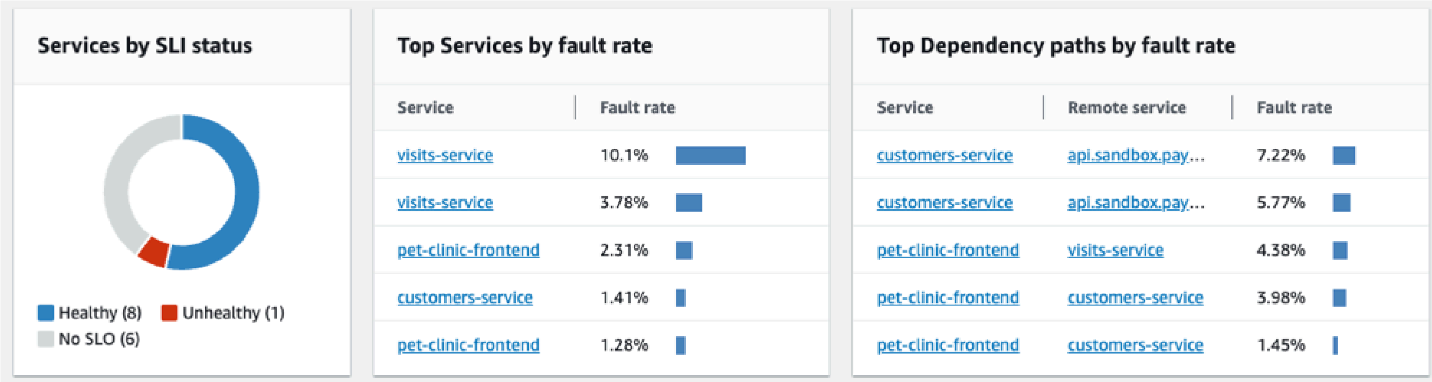
View overall service activity and operational health with the Services page

Use the Services page to see a list of your services that are enabled for Application Signals. You can also view operational metrics and quickly see which services have unhealthy service level indicators (SLIs). Drill down to look for performance anomalies as you identify the root cause of operational issues. To view this page, open the CloudWatch console and choose **Services** under the **Application Signals** section in the left navigation pane.

Explore operational health metrics for your services

The top of the Services page includes an overall service operational health graph and several tables displaying top services and service dependencies by fault rate. The Services graph on the left displays a breakdown of the number of services that have healthy or unhealthy service level indicators (SLIs) during the current page-level time filter. SLIs can monitor latency, availability, and other operational metrics.

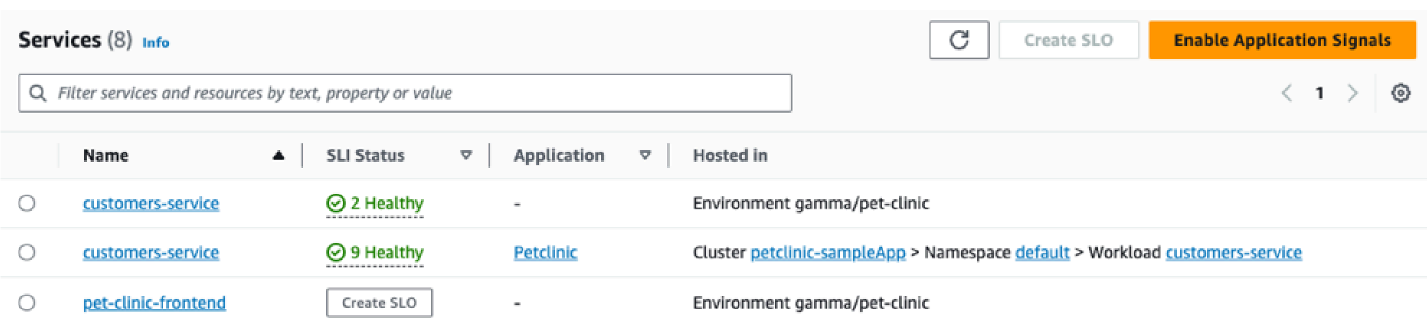
The two tables next to the graph display a list of top services by fault rate. Choose any service name in either table to open a service detail page and see detailed service operation details. Choose a dependency path to open the detail page and see service dependency details. Both tables display information for up to the past three hours, even if a longer time period filter is chosen at the top right of the page.



Monitor operational health with the Services table

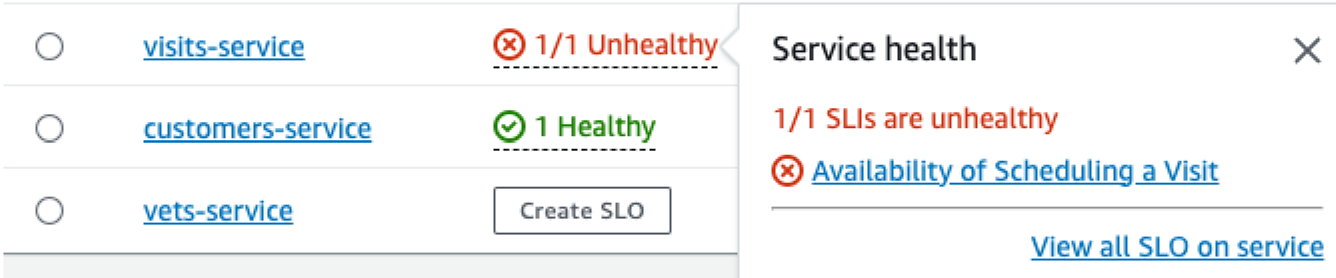
The Services table displays a list of your services that have been enabled for Application Signals. Choose **Enable Application Signals** to open a setup page and start configuring your services. For more information, see Enable Application Signals.

Filter the Services table to make it easier to find what you're looking for, by choosing one or more properties from the filter text box. As you choose each property, you are guided through filter criteria. You will see the complete filter below the filter text box. Choose **Clear filters** at any time to remove the table filter.



Choose the name of any service in the table to view a service detail page containing service-level metrics, operations, and additional details. If you have associated the service's underlying compute resource with an application in AppRegistry or the Applications card on the Amazon Web Services Management Console home page, choose the application name to display the application details in the myApplications console page. For services hosted in Amazon EKS, choose any link within the **Hosted in** column to view Cluster, Namespace, or Workload within CloudWatch Container Insights. For services running on Amazon ECS or Amazon EC2, the Environment value is shown.

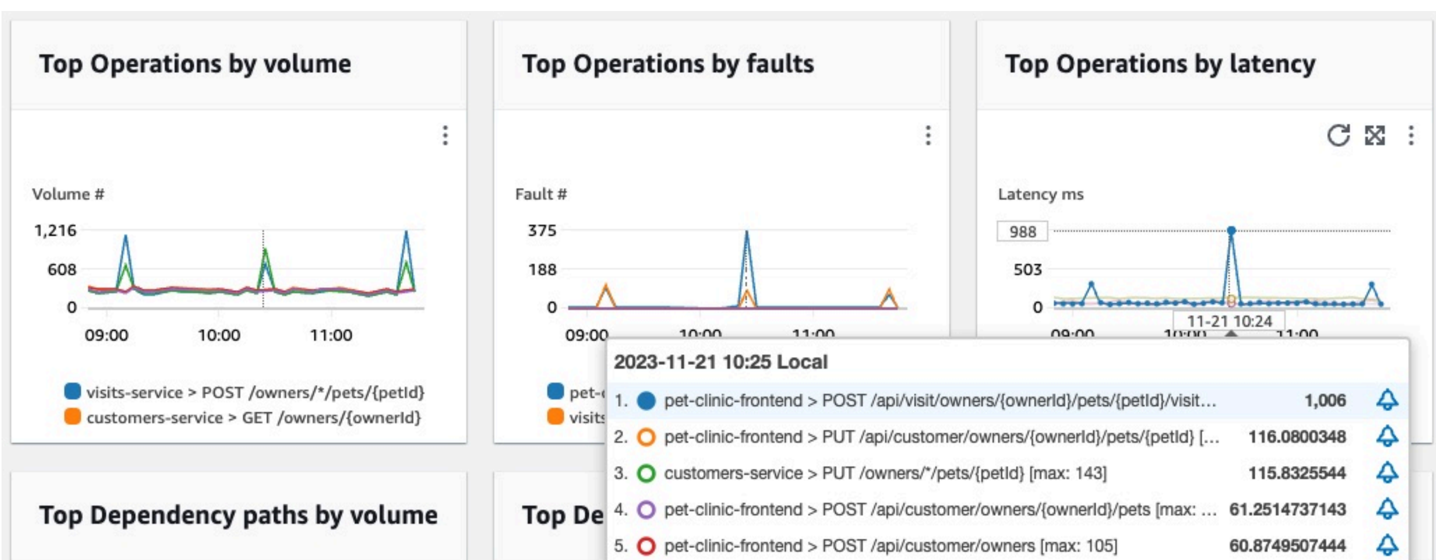
Service level indicator (SLI) status is displayed for each service in the table. Choose the SLI status for a service to display a pop-up containing a link to any unhealthy SLIs, and a link to see all SLOs for the service.



If no SLOs have been created for a service, choose the **Create SLO** button within the **SLI Status** column. To create additional SLOs for any service, select the option button next to the service name, and then choose **Create SLO** at the top-right of the table. When you create SLOs, you can see at a glance which of your services and operations are performing well and which are unhealthy. See service level objectives (SLOs) for more information.

View top operation and dependency metrics

Below the Services table, you can view top operations and dependencies across all services by call volume, faults, and latency. This set of graphs gives you critical information about which operations or dependencies may be unhealthy across all services. Choose any point in a graph to see a pop-up containing more detailed series information. Hover over the series descriptions at the bottom of a graph to see a pop-up containing detailed metrics for a specific operation or dependency path. Select the context menu button at the top-right corner of a graph to see additional options, including viewing CloudWatch metrics or logs pages.



View detailed service activity and operational health with the service detail page

When you instrument your application, Amazon CloudWatch Application Signals maps all of the services that your application discovers. Use the service detail page to see an overview of your services, operations, dependencies, canaries, and client requests for a single service. To view the service detail page, do the following:

- Open the CloudWatch console.
- Choose **Services** under the **Application Signals** section in the left navigation pane.
- Choose the name of any service from the **Services**, **Top services**, or dependency tables.

Under **schedule-visits**, you will see the account label and ID under the service name.

The service detail page is organized into the following tabs:

- Overview — Use this tab to see an overview of a single service, including the number of operations, dependencies, synthetics, and client pages. The tab shows key metrics for your entire service, top operations and dependencies. These metrics include time series data on latency, faults, and errors across all service operations for that service.
- Service operations — Use this tab to see a list of the operations that your service calls and interactive graphs with key metrics that measure the health of each operation. You can select a data point in a graph to obtain information about traces, logs, or metrics associated with that data point.
- Dependencies — Use this tab to see a list of dependencies that your service calls, and a list of metrics for those dependencies.
- Synthetics canaries — Use this tab to see a list of synthetics canaries that simulate user calls to your service, and key performance metrics for how those canaries.
- Client pages — Use this tab to see a list of client pages that call your service, and metrics that measure the quality of client interactions with your application.

View your service overview

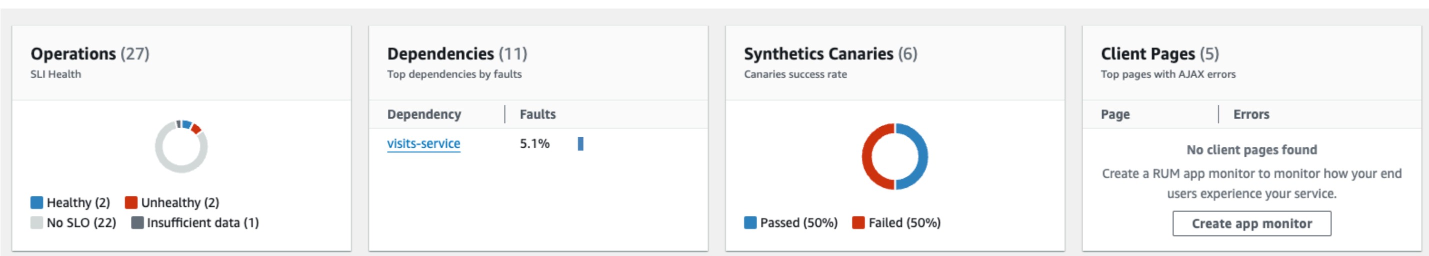
Use the service overview page to view a high-level summary of metrics for all service operations in a single location. Check the performance of all the operations, dependencies, client pages and synthetics canaries that interact with your application. Use this information to help you determine where to focus efforts to identify issues, troubleshoot errors, and find opportunities for optimization.

Choose any link in **Service Details** to view information that is related to a specific service. For example, for services hosted in Amazon EKS, the service details page shows **Cluster**, **Namespace**, and **Workload** information. For services hosted in Amazon ECS or Amazon EC2, the service details page shows the **Environment** value.

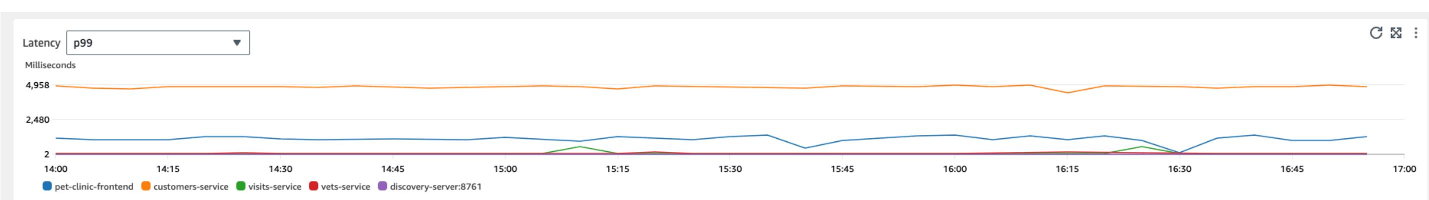
Under **Services**, the **Overview** tab displays a summary of the following:

- Operations – Use this tab to see the health of your service operations. The health status is determined by service level indicators (SLI) that are defined as a part of a service level objective (SLO).
- Dependencies – Use this tab to see the top dependencies of the services called by your application, listed by fault rate and to see the health of your service dependencies. The health status is determined by service level indicators (SLI) that are defined as a part of a service level objective (SLO).
- Synthetics canaries – Use this tab to see the result of simulated calls to endpoints or APIs associated with your service, and the number of failed canaries.
- Client pages – Use this tab to see top pages called by clients that have asynchronous JavaScript and XML (AJAX) errors.

The following illustration shows an overview of your services:

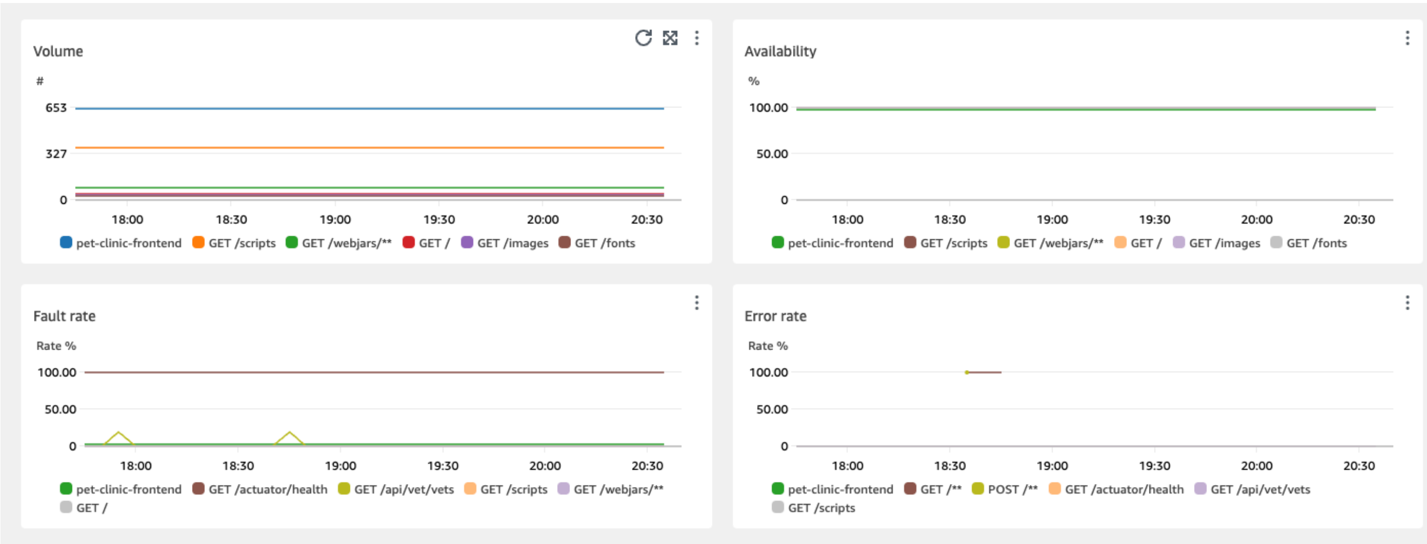


The **Overview** tab also displays a graph of dependencies with the highest latency across all services. Use the **p99**, **p90** and **p50** latency metrics to quickly assess which dependencies are contributing to your total service latency, as follows:



For example, the previous graph shows that 99% of the requests made to the **customer-service** dependency were completed in approximately 4,950 milliseconds. The other dependencies took less time.

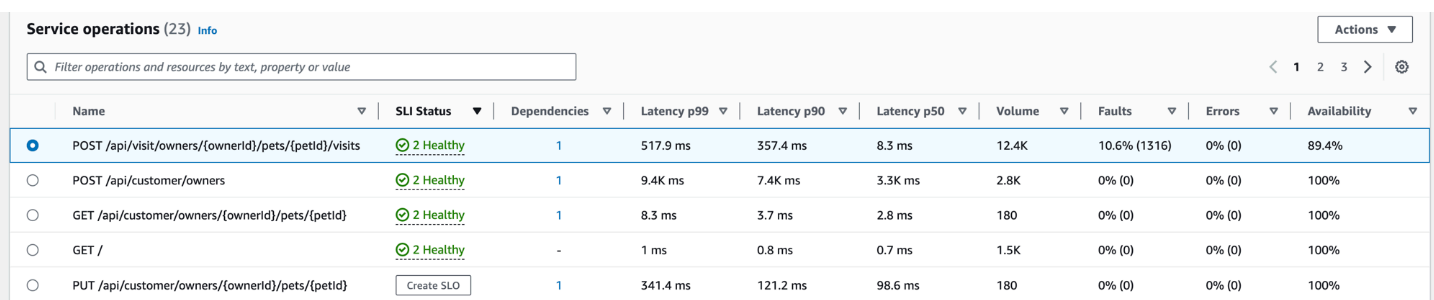
Graphs displaying the top four service operations by latency show the volume of requests, availability, fault rate, and error rate for those services, as shown in the following image:



The **Service details** section displays the details of the service including the **Account ID** and **Account label**.

View your service operations

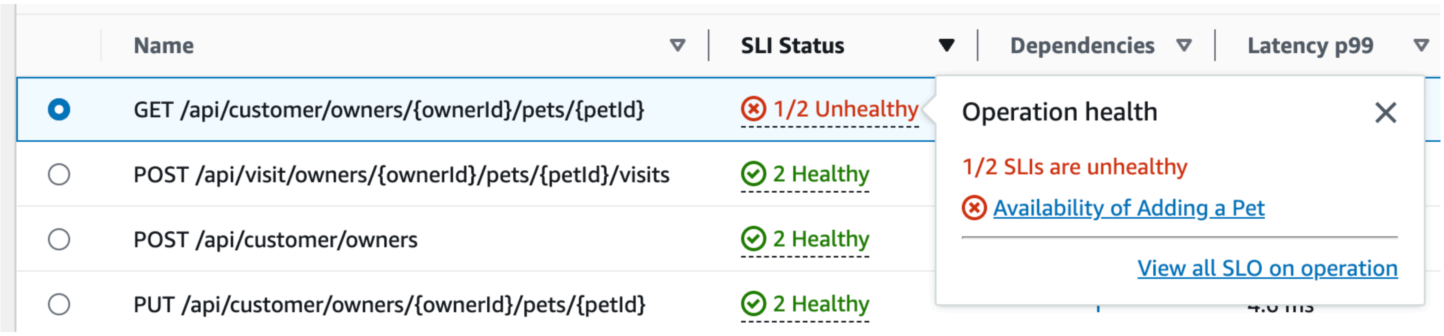
When you instrument your application, Application Signals discovers all of the service operations that your application calls. Use the **Service operations** tab to see a table that contains the service operations and a set of metrics that measure the performance of a selected operation. These metrics include SLI status, number of dependencies, latency, volume, faults, errors, and availability, as shown in the following image:



Name	SLI Status	Dependencies	Latency p99	Latency p90	Latency p50	Volume	Faults	Errors	Availability
POST /api/visit/owners/{ownerId}/pets/{petId}/visits	2 Healthy	1	517.9 ms	357.4 ms	8.3 ms	12.4K	10.6% (1316)	0% (0)	89.4%
POST /api/customer/owners	2 Healthy	1	9.4K ms	7.4K ms	3.3K ms	2.8K	0% (0)	0% (0)	100%
GET /api/customer/owners/{ownerId}/pets/{petId}	2 Healthy	1	8.3 ms	3.7 ms	2.8 ms	180	0% (0)	0% (0)	100%
GET /	2 Healthy	-	1 ms	0.8 ms	0.7 ms	1.5K	0% (0)	0% (0)	100%
PUT /api/customer/owners/{ownerId}/pets/{petId}	Create SLO	1	341.4 ms	121.2 ms	98.6 ms	180	0% (0)	0% (0)	100%

Filter the table to make it easier to find a service operation by choosing one or more properties from the filter text box. As you choose each property, you are guided through filter criteria and will see the complete filter below the filter text box. Choose **Clear filters** at any time to remove the table filter.

Choose the SLI status for an operation to display a popup containing a link to any unhealthy SLI, and a link to see all SLOs for the operation, as shown in the following table:



The service operations table lists the SLI status, the number of healthy or unhealthy SLIs, and the total number of SLOs for each operation.

Use SLIs to monitor latency, availability, and other operational metrics that measure the operational health of a service. Use an SLO to check the performance and health status of your services and operations.

To create an SLO, do the following:

- If an operation does not have an SLO, choose the **Create SLO** button within the **SLI Status** column.
- If an operation already has an SLO, do the following:
  - Select the radio button next to the operation name.
  - Choose **Create SLO** from the **Actions** down arrow at the top right of the table.

For more information, see service level objectives (SLOs).

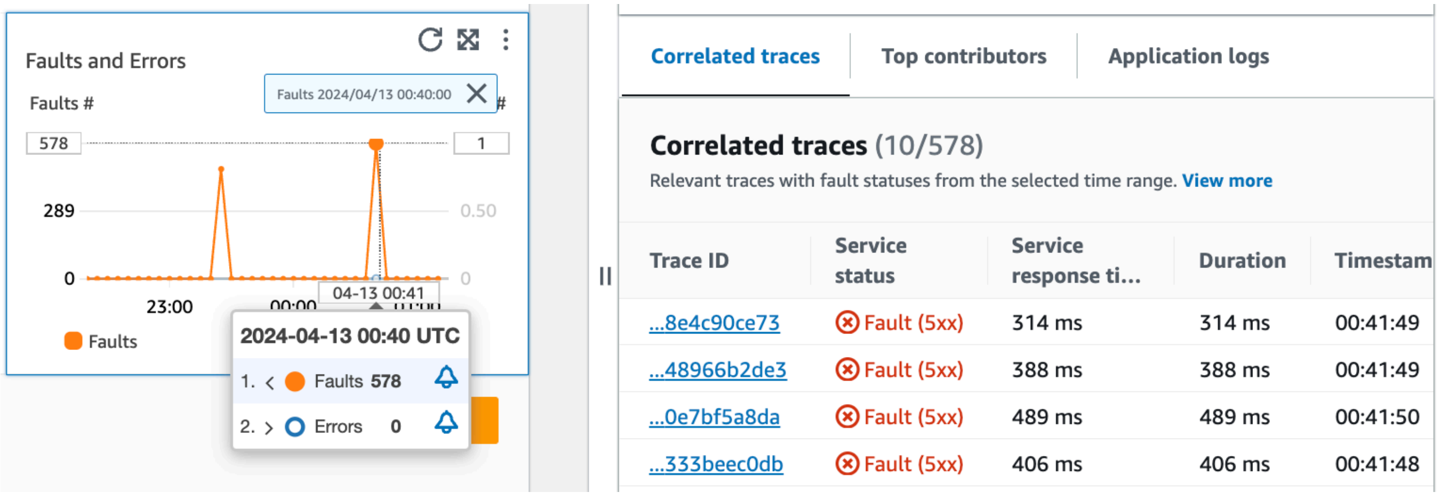
The **Dependencies** column shows the number of dependencies this operation calls. Choose this number to open the **Dependencies** tab filtered to the selected operation.

View service operations metrics, correlated traces, and application logs

Application Signals correlates service operation metrics with Amazon X-Ray traces, CloudWatch Container Insights, and application logs. Use these metrics to troubleshoot operational health issues. To view metrics as graphical information, do the following:

1. Select a service operation in the **Service operations** table to see a set of graphs for the selected operation above the table with metrics for **Volume and Availability**, **Latency**, and **Faults and Errors**.
2. Hover over a point in a graph to view more information.
3. Select a point to open a diagnostic pane that shows correlated traces, metrics, and application logs for the selected point in the graph.

The following image shows the tooltip that appears after hovering over a point in the graph, and the diagnostic pane which appears after clicking on a point. The tooltip contains information about the associated data point in the **Faults and Errors** graph. The pane contains **Correlated traces**, **Top contributors**, and **Application logs** associated with the selected point.



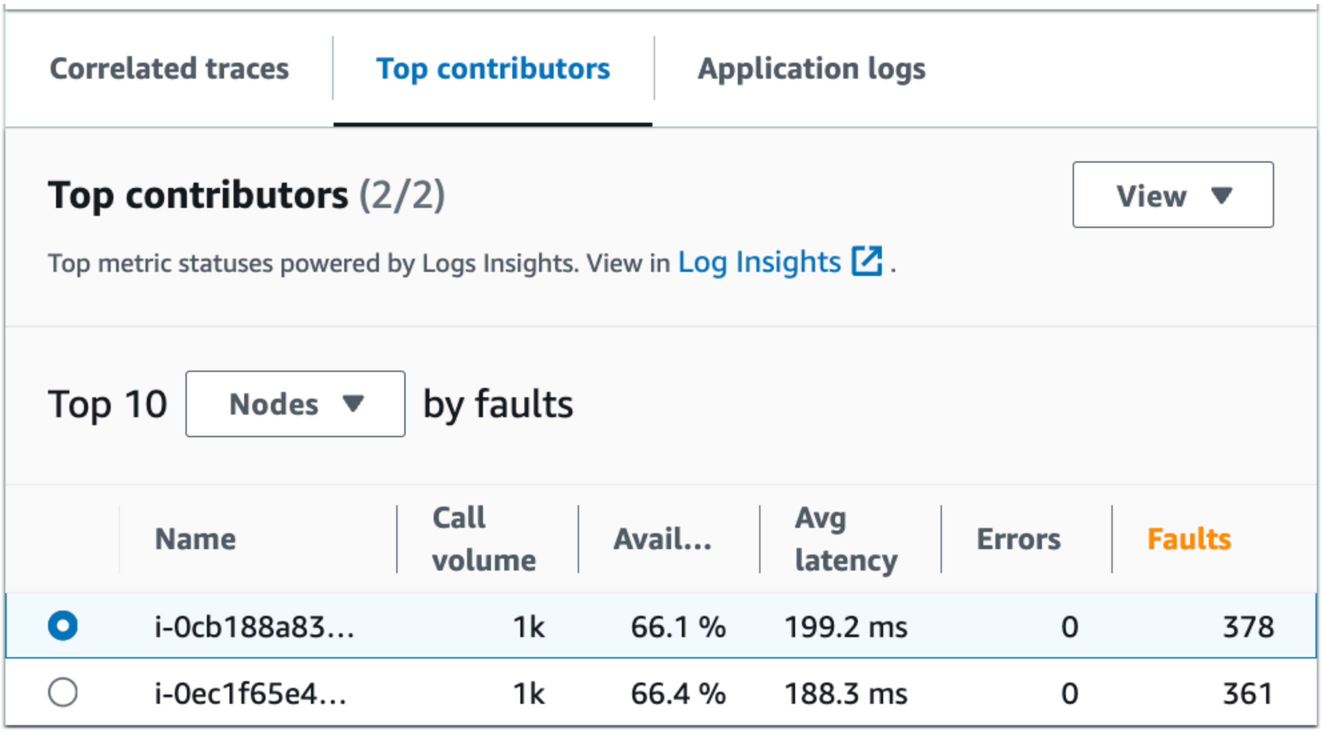
Correlated traces

Look at related traces to understand an underlying issue with a trace. You can check to see if correlated traces or any service nodes associated with them behave similarly. To examine correlated traces, choose a **Trace ID** from the **Correlated traces** table to open the X-Ray trace details page for the chosen trace. The trace details page contains a map of service nodes that are associated with the selected trace and a timeline of trace segments.

Top contributors

View the top contributors to find main input sources to a metric. Group contributors by different components to look for similarities within the group and understand how trace behavior differs between them.

The **Top contributors** tab gives metrics for **Call volume**, **Availability**, **Avg latency**, **Errors**, and **Faults** for each group. The following example image shows top contributors to a suite of metrics for an application deployed on an Amazon EKS platform:



The top contributors contains the following metrics:

- **Call volume** - Use the call volume to understand the number of requests per time interval for a group.
- **Availability** - Use availability to see what percentage of time that no faults were detected for a group.
- **Avg latency** - Use latency to check the average time that requests ran for a group over a time interval that depends on how long ago the requests that you are investigating were made. Requests that were made less than 15 days prior are evaluated over 1 minute intervals. Requests that were made between 15 and 30 days prior, inclusive, are evaluated over 5 minute intervals. For example, if you are investigating requests that caused a fault 15 days ago, the call volume metric is equal to the number of requests per 5 minute interval.
- **Errors** - The number of errors per group measured over a time interval.
- **Faults** - The number of faults per group over a time interval.

Top contributors using Amazon EKS or Kubernetes

Use information about the top contributors for applications deployed on Amazon EKS or Kubernetesto see operational health metrics grouped by **Node**, **Pod** and **PodTemplateHash**. The following definitions apply:

- A **pod** is a group of one or more Docker containers that share storage and resources. A pod is the smallest unit that can be deployed on a Kubernetes platform. Group by pods to check if errors are related to pod-specific limitations.
- A **node** is a server that runs pods. Group by nodes to check if errors are related to node-specific limitations.
- A **pod template hash** is used to find a particular version of a deployment. Group by pod template hash to check if errors are related to a particular deployment.

Top contributors using Amazon EC2

Use information about the top contributors for applications deployed on Amazon EKS to see operational health metrics grouped by instance ID, and auto scaling group. The following definitions apply:

- An **Instance ID** is a unique identifier for the Amazon EC2 instance that your service runs. Group by instance ID to check if errors are related to a specific Amazon EC2 instance.
- An auto scaling group is a collection of Amazon EC2 instances that allow you to scale up or down the resources you need to serve your application requests. Group by auto scaling group if you want to check if errors are limited in scope to the instances inside the group.

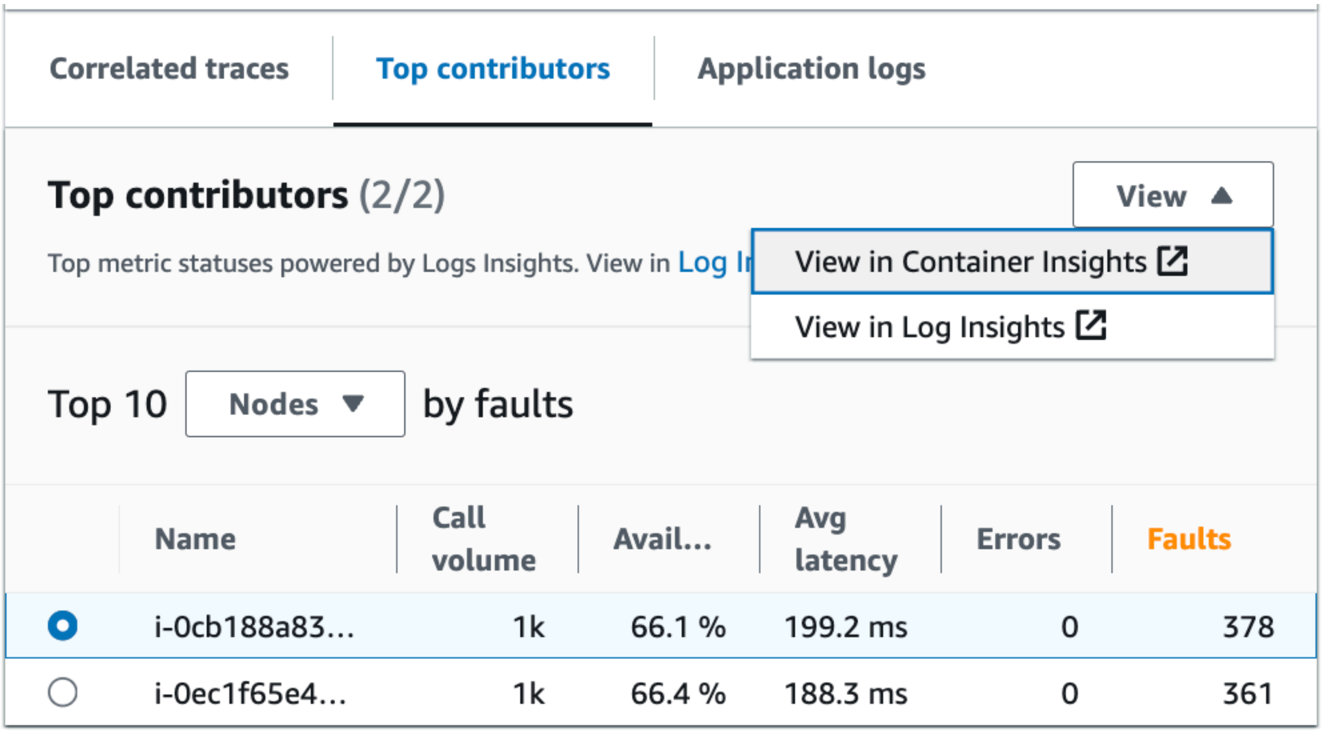
Top contributors using a custom platform

Use information about the top contributors for applications deployed using custom instrumentation to see operational health metrics grouped by **Host name**. The following definitions apply:

- A host name identifies a device such as an endpoint or Amazon EC2 instance that is connected to a network. Group by host name to check if your errors are related to a specific physical or virtual device.

View top contributors in Log Insights and Container Insights

View and modify the automatic query that generated metrics for your top contributors in Log Insights. View infrastructure performance metrics by specific groups such as pods or nodes in Container Insights. You can sort clusters, nodes or workloads by resource consumption and quickly identify anomalies or and mitigate risks pro-actively before end user experience is impacted. An image showing how to select these options follows:



In **Container Insights**, you can view metrics for your Amazon EKS or Amazon ECS container that are specific to the grouping of your top contributors. For example, if you grouped by pod for an EKS container to generate top contributors, container insights will show metrics and statistics filtered for your pod.

In **Log Insights**, you can modify the query that generated the metrics under **Top contributors** using the following steps:

1. Select **View in Log Insights**. The **Logs Insights** page that opens contains an query that is automatically generated and contains the following information:

   - The log cluster group name.
   - The operation that you were investigating with CloudWatch.
   - The aggregate of the operational health metric interacted with on the graph.

The log results are automatically filtered to show data from the last five minutes before you selected the data point on the service graph.

2. To edit the query, replace the generated text with your changes. You can also use the **Query generator** to help you generate a new query, or update the existing query.

Application logs

Use the query in the **Application logs** tab to generate logged information for your current log group, service and insert a timestamp. A log group is a group of log streams that you can define when you configure your application.

Use a log group to organize logs with similar characteristics including the following:

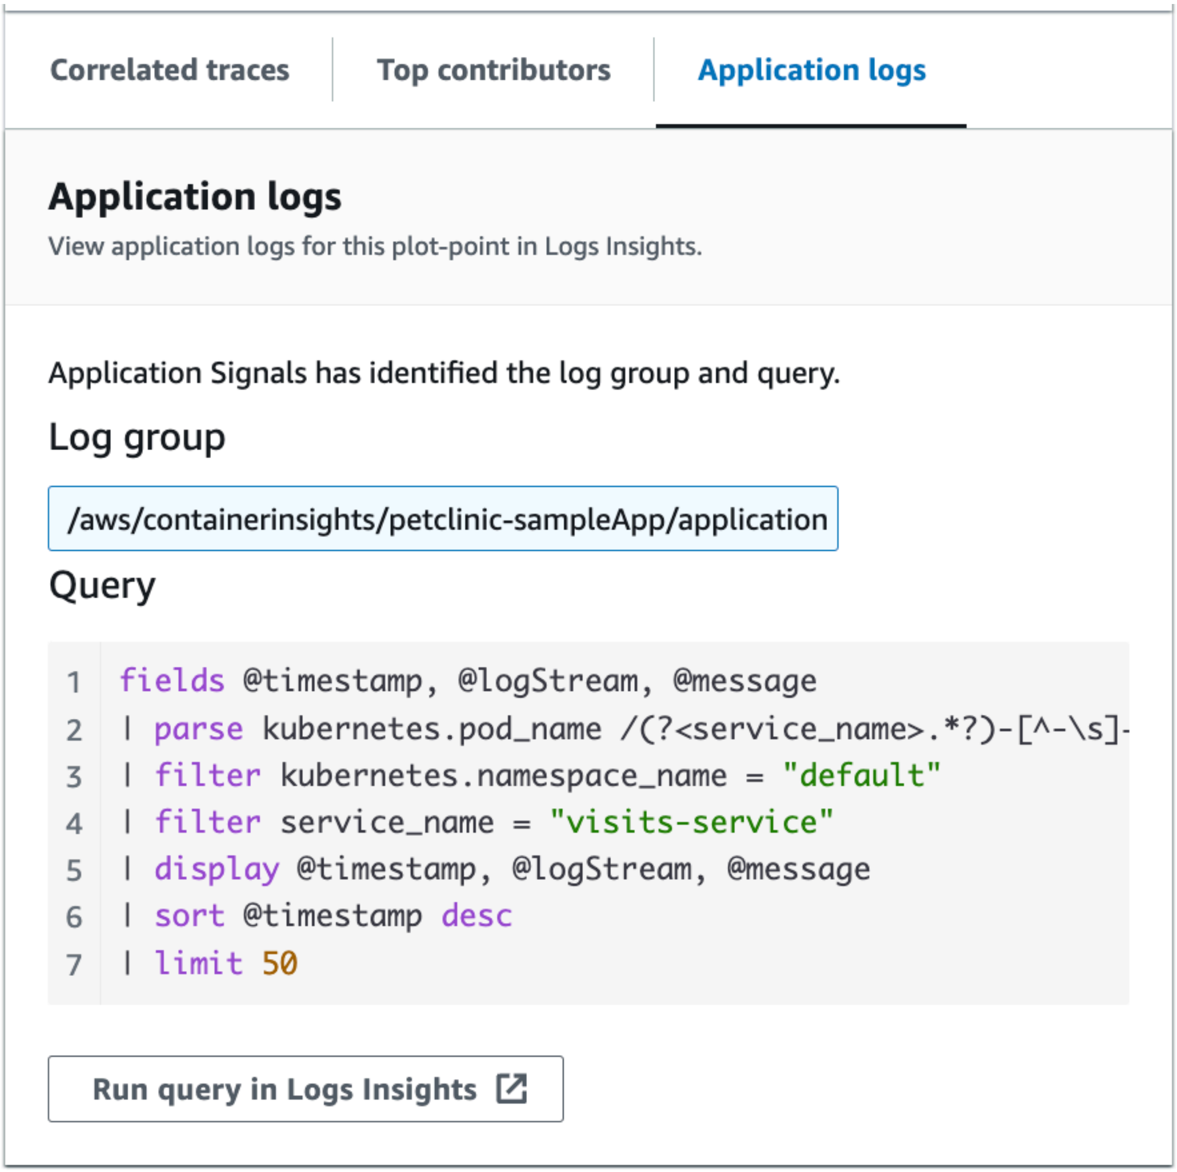
- Capture logs from a specific organization, source or function.
- Capture logs that are accessed by a particular user.
- Capture logs for a specific time period.

Use these log streams to track specific groups or time frames. You can also set up monitoring rules, alarms and notifications for these log groups. For more information about log groups, see Working with log groups and log streams.

The application logs query returns the logs, recurring text patterns and graphical visualizations for your log groups.

To run the query, select **Run query in Logs Insights** to either run the automatically generated query or modify the query. To edit the query, replace the automatically generated text with your changes. You can also use the **Query generator** to help you generate a new query or update the existing query.

The following image shows the sample query that is automatically generated based on the selected point in the service operations graph:



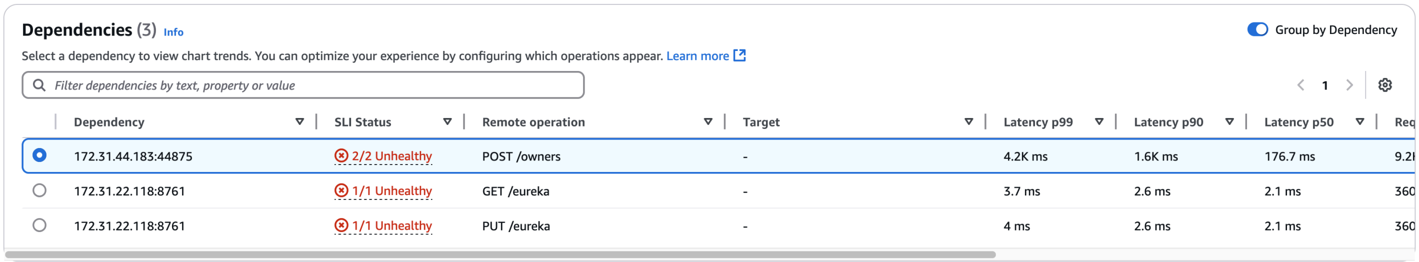
In the preceding image, CloudWatch has automatically detected the log group that is associated with your selected point, and included it in a generated query.

View your service dependencies

Choose the **Dependencies** tab to display the **Dependencies** table and a set of metrics for the dependencies of all service operations or a single operation. The table contains a list of dependencies discovered by Application Signals, including metrics for SLI status, latency, call volume, fault rate, error rate, and availability.

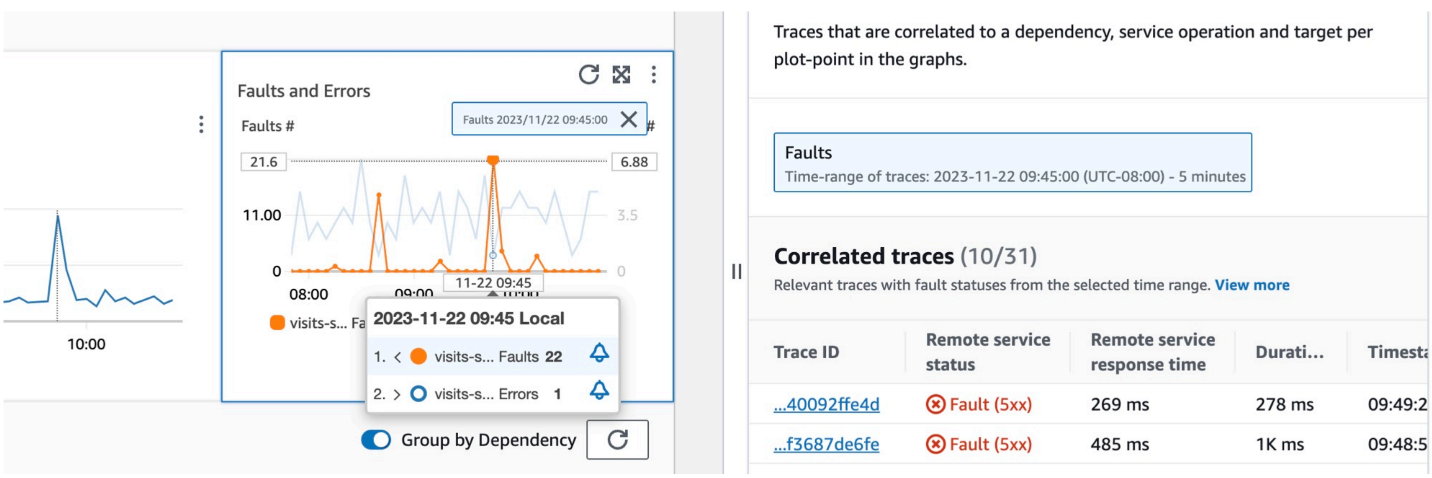
At the top of the page, choose an operation from the down arrow list to view its dependencies, or choose **All** to see dependencies for all operations.

Filter the table to make it easier to find what you're looking for, by choosing one or more properties from the filter text box. As you choose each property, you are guided through filter criteria and will see the complete filter below the filter text box. Choose **Clear filters** at any time to remove the table filter. Select **Group by Dependency** at the top right of the table to group dependencies by service and operation name. When grouping is turned on, expand or collapse a group of dependencies with the **+** icon next to the dependency name.



The **Dependency** column displays the dependency service name, while the **Remote Operation** column displays the service operation name. The **SLI status** column displays the number of healthy or unhealthy SLIs along with the total number of SLIs for each dependency. When calling Amazon services, the **Target** column displays the Amazon resource, such as DynamoDB table or Amazon SNS queue.

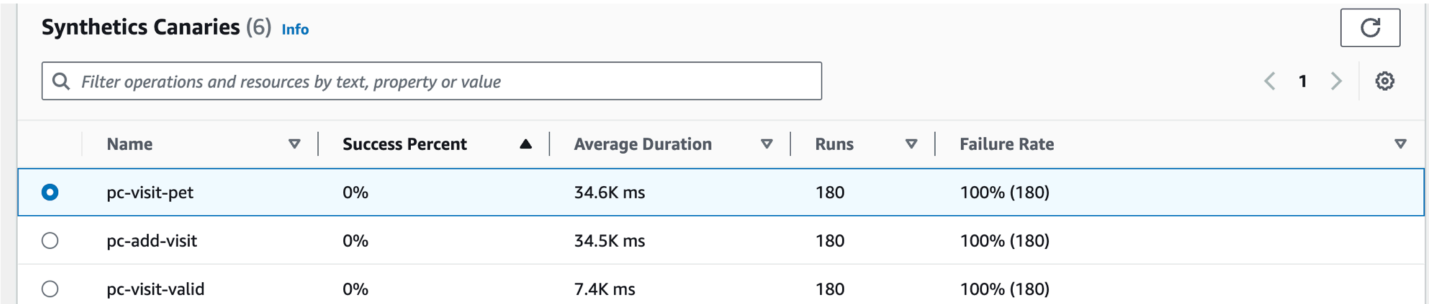
To select a dependency, select the option next to a dependency in the **Dependencies** table. This shows a set of graphs that display detailed metrics for call volume, availability, faults, and errors. Hover over a point in a graph to see a popup containing more information. Select a point in a graph to open a diagnostic pane that shows correlated traces for the selected point in the graph. Choose a trace ID from the **Correlated traces** table to open the [X-Ray Trace details](#) page for the selected trace.



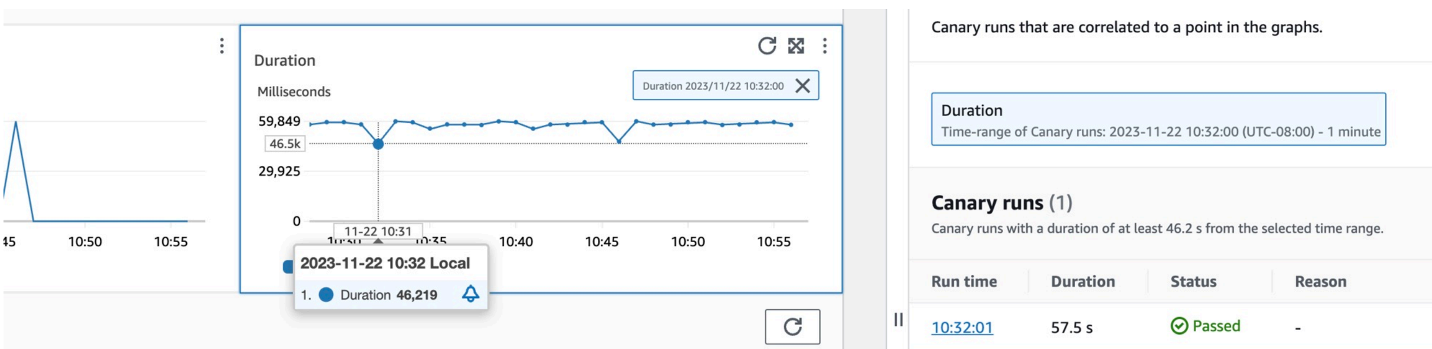
View your Synthetics canaries

Choose the **Synthetics Canaries** tab to display the **Synthetics Canaries** table, and a set of metrics for each canary in the table. The table includes metrics for success percentage, average duration, runs, and failure rate. Only canaries that are enabled for Amazon X-Ray tracing are displayed.

Use the filter text box in the synthetics canaries table to find the canary that you are interested in. Each filter that you create appears below the filter text box. Choose **Clear filters** at any time to remove the table filter.



Select the radio button next to the name of the canary to see a set of tabs containing graphs detailed metrics including success percentage, errors and duration. Hover over a point in a graph to see a popup containing more information. Select a point in a graph to open a diagnostic pane that shows canary runs that correlate to the selected point. Select a canary run and choose the **Run time** to see artifacts for your selected canary run including logs, HTTP Archive (HAR) files, screenshots, and suggested steps to help you troubleshoot problems. Choose **Larn more** to open the CloudWatch Synthetics Canaries page next to **Canary runs**.

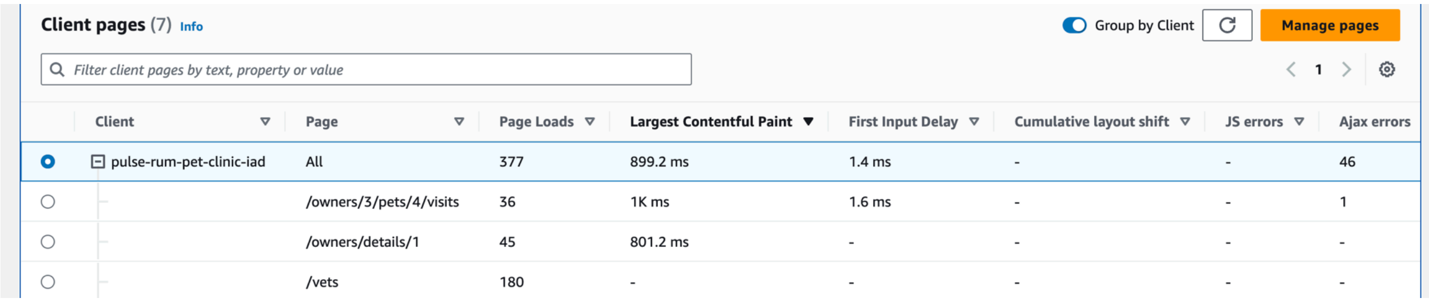


View your client pages

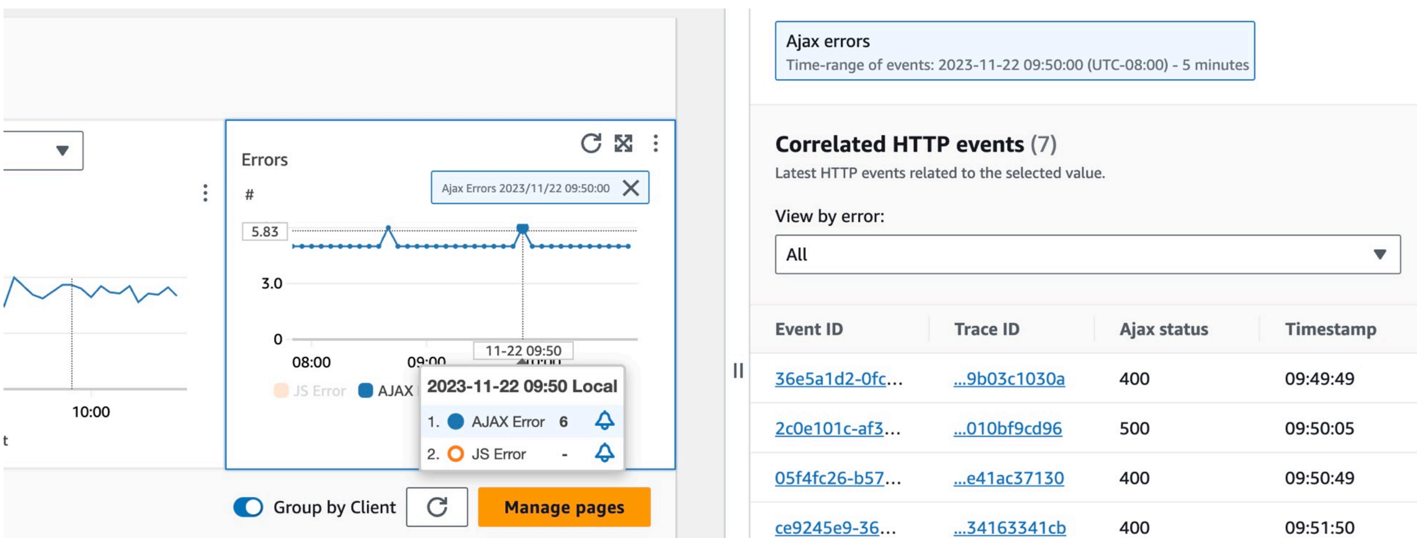
Choose the **Client pages** tab to display a list of client web pages that call your service. Use the set of metrics for the selected client page to measure the quality of your client's experience when interacting with a service or application. These metrics include page loads, web vitals, and errors.

To display your client pages in the table, you must configure your CloudWatch RUM web client for X-Ray tracing and turn on Application Signals metrics for your client pages. Choose **Manage pages** to select which pages are enabled for Application Signals metrics.

Use the filter text box to find the client page or application monitor that you are interested in below the filter text box. Choose **Clear filters** to remove the table filter. Select **Group by Client** to group client pages by client. When grouped, choose the **+** icon next to a client name to expand the row and see all pages for that client.



To select a client page, select the option next to a client page in the **Client pages** table. You will see a set of graphs that display detailed metrics. Hover over a point in a graph to see a popup containing more information. Select a point in a graph to open a diagnostic pane that shows correlated performance navigation events for the selected point in the graph. Choose an event ID from the list of navigation events to open the CloudWatch RUM Page view for the chosen event.



> **Note**
>
> To see AJAX errors within your client pages, use the CloudWatch RUM web client version 1.15 or newer.

Currently, up to 100 operations, canaries, and client pages, and up to 250 dependencies, can be shown per service.

View your application topology and monitor operational health with the CloudWatch service map

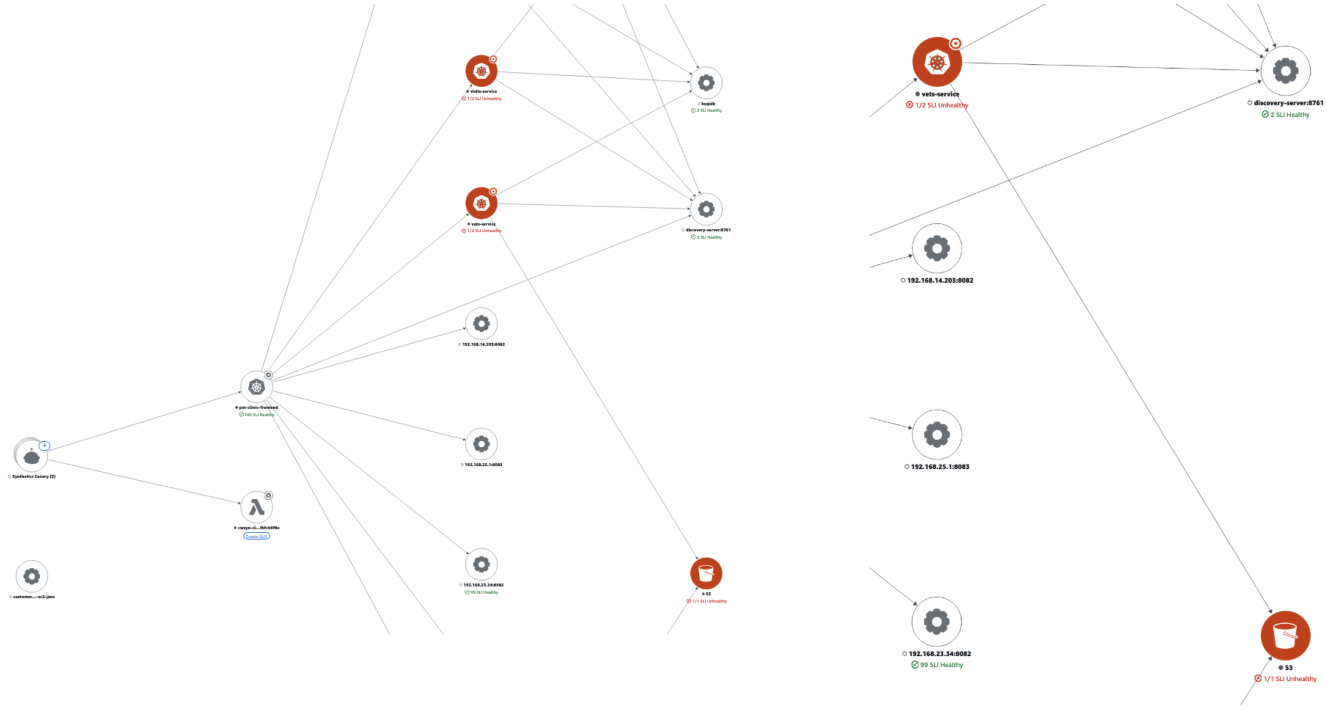
> **Note**
>
> The CloudWatch service map replaces the ServiceLens map. To see a map of your application based on Amazon X-Ray traces, open the X-Ray Trace Map. Choose **Trace Map** under the **X-Ray** section in the left navigation pane of the CloudWatch console.

Use the service map to view the topology of your application clients, synthetics canaries, services and dependencies, and monitor operational health. To view the service map, open the CloudWatch console and choose **Service Map** under the **Application Signals** section in the left navigation pane.

After you enable your application for Application Signals, use the service map to make it easier to monitor your application's operational health:

- View connections between client, canary, service, and dependency nodes to help you understand your application topology and execution flow. This is especially helpful if your service operators are not your development team.
- See which services are meeting or not meeting your service level objectives (SLOs). When a service is not meeting your SLOs, you can quickly identify whether a downstream service or dependency might be contributing to the issue or impacting multiple upstream services.
- Select an individual client, synthetics canary, service, or dependency node to see related metrics. The Service details page shows more detailed information about operations, dependencies, synthetics canaries, and client pages.
- Filter and zoom the service map to make it easier to focus on a part of your application topology, or see the entire map. Create a filter by choosing one or more properties from the filter text box. As you choose each property, you are guided through filter criteria. You will see the complete filter below the filter text box. Choose **Clear filters** at any time to remove the filter.

The following example service map shows services with edges connecting them to components that they interact with. If an SLO is defined, the service map also shows health status.

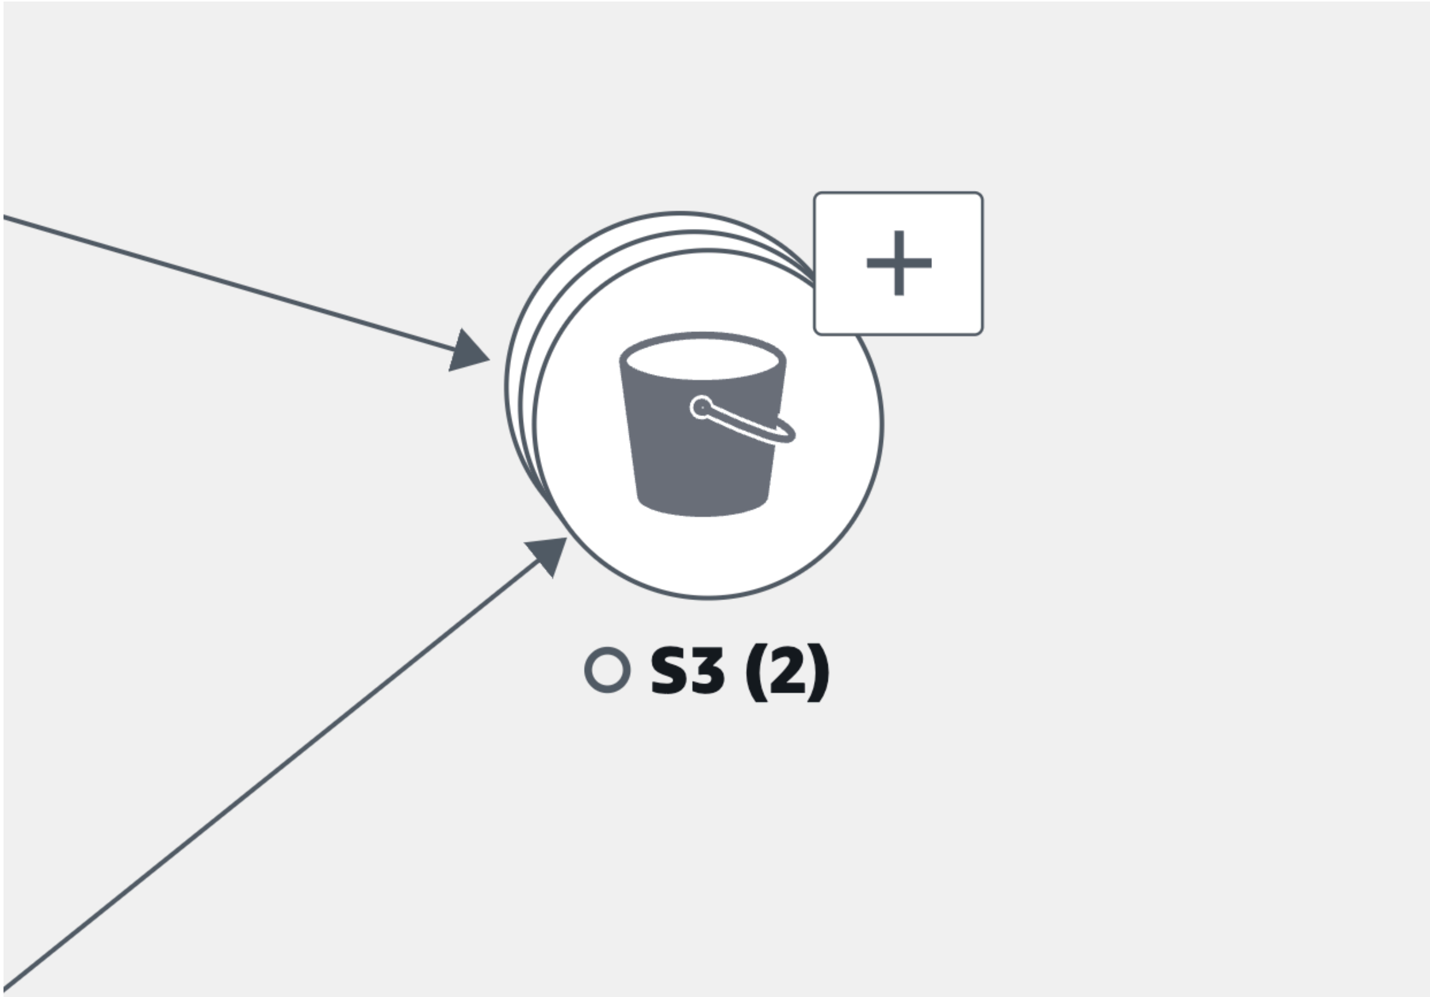


Explore the service map

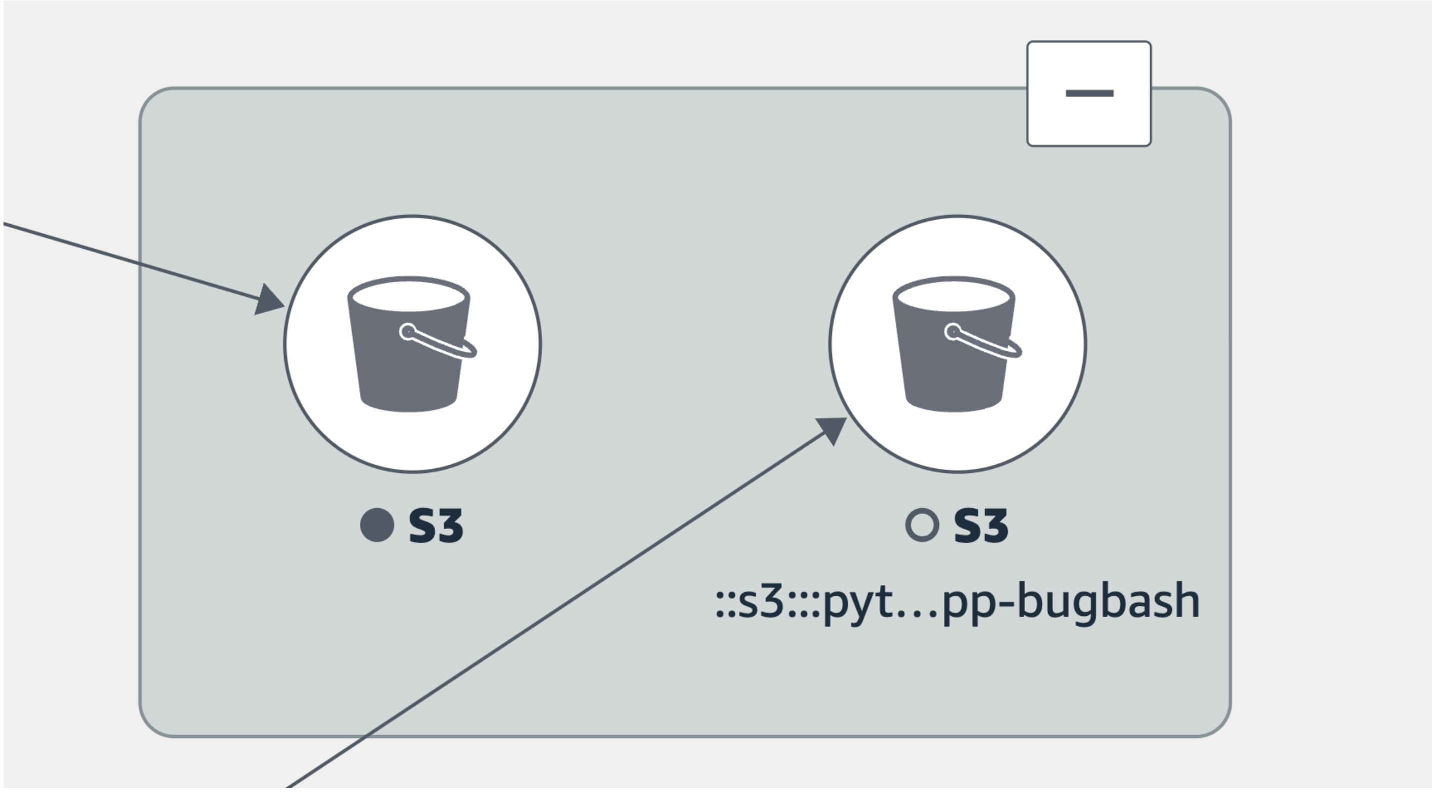
After you have enabled your application for Application Signals, the service map displays nodes representing your services and their dependencies.

Turn on active tracing for your CloudWatch RUM clients and synthetics canaries to see client and canary nodes on the map.

By default, canaries, RUM clients, and Amazon service dependencies of the same kind are grouped together into a single expandable icon in the service map. Service dependencies outside of Amazon are not grouped together by default. For example, in the following image, all Amazon S3 buckets are grouped together under one expandable icon:



In the previous image, the label between the Amazon S3 grouping and originating service displays the number of edges to the group in parenthesis under the dependency's icon. Select the (+) icon to expand the group and see its individual elements, as shown in the following image:

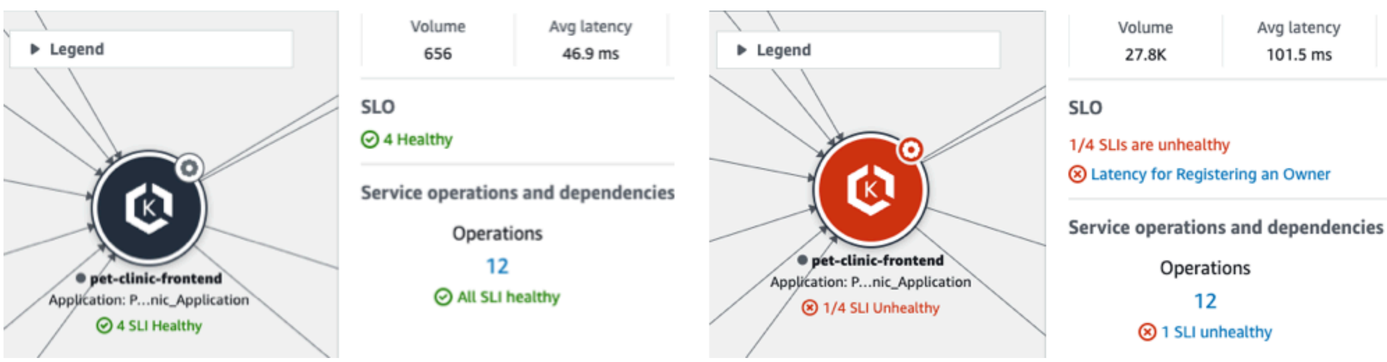


Choose a tab for information about exploring each kind of node and the edges (connections) between them.

View your application services

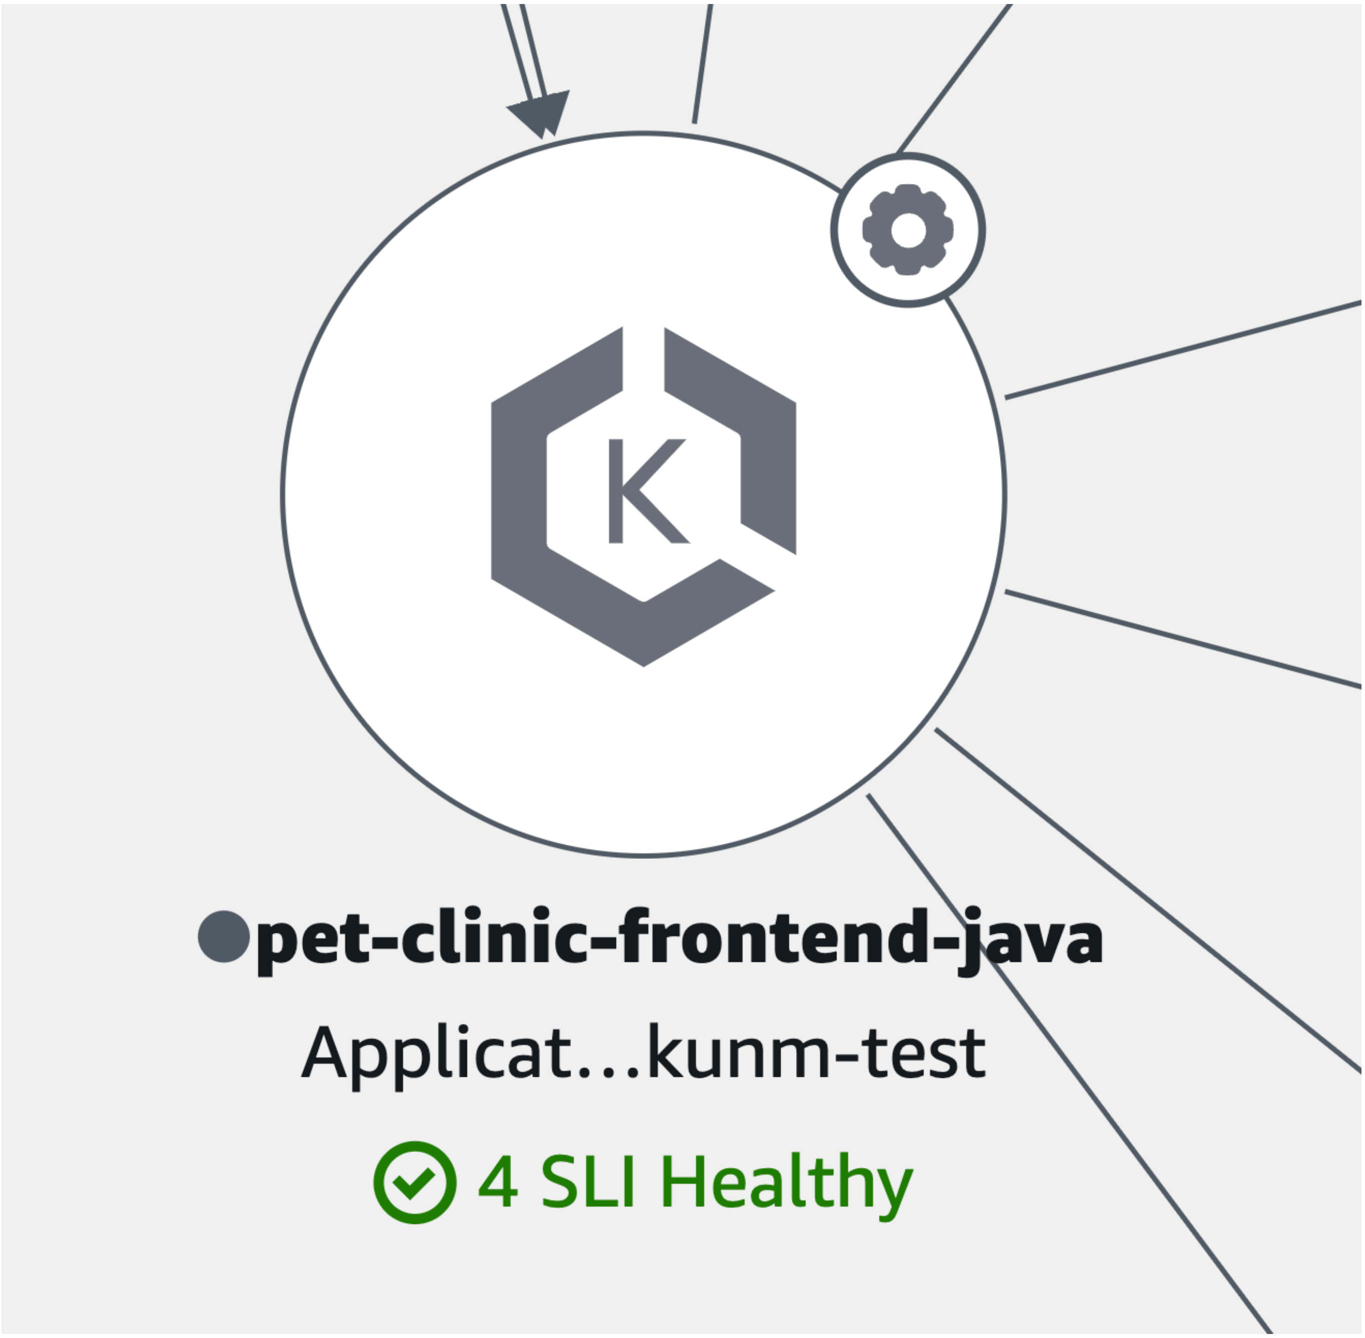
You can view your application services and the status of their SLOs and service level indicators (SLIs) in the **Service Map**. If you didn't create SLOs for a service, choose the **Create SLO** button below the service node.

The **Service Map** displays all of your services. It also shows the customers and canaries that consume the service and the dependencies that your services calls, as shown in the following image:



The following icons represent examples of application services in the service map:

- Amazon Elastic Kubernetes Service:



- A Kubernetes container:

- Amazon Elastic Compute Cloud (Amazon EC2):

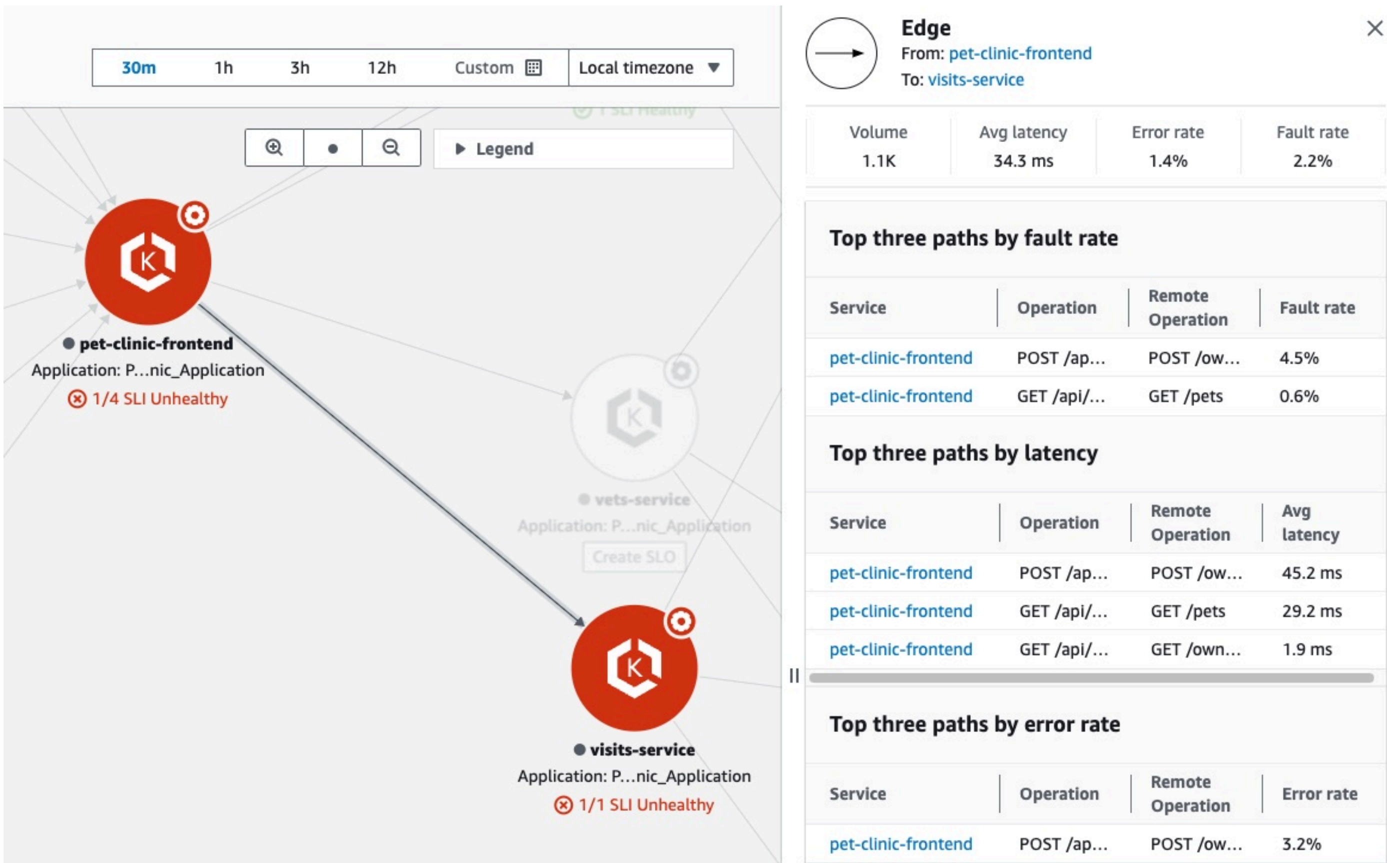
- Other application service types not previously listed:

When you select a service node, a pane opens displaying detailed service information:

- Metrics for call volume, latency, error, and fault rate.
- The number of SLIs and SLOs that are `healthy` or `unhealthy`.
- The option to view more information about an SLO.
- The number of service operations, dependencies, synthetics canaries, and client pages.
- The option to select each number to open the Service details page for it.
- The application name, if you have associated the underlying compute resource with an application using AppRegistry or the Applications card on the Amazon Web Services Management Console home page.

  - Choose the application name to display the application details in the myApplications console page.
- The `Cluster`, `Namespace`, and `Workload` for services hosted in Amazon EKS, or `Environment` for services hosted in Amazon ECS or Amazon EC2. For Amazon EKS-hosted services, choose any link to open CloudWatch Container Insights.

Select an edge or connection between a service node and a downstream service or dependency node. This opens a pane containing top paths by fault rate, latency, and error rate, as shown in the following example image. Choose any link in the pane to open the Service details page and see detailed information for the chosen service or dependency.

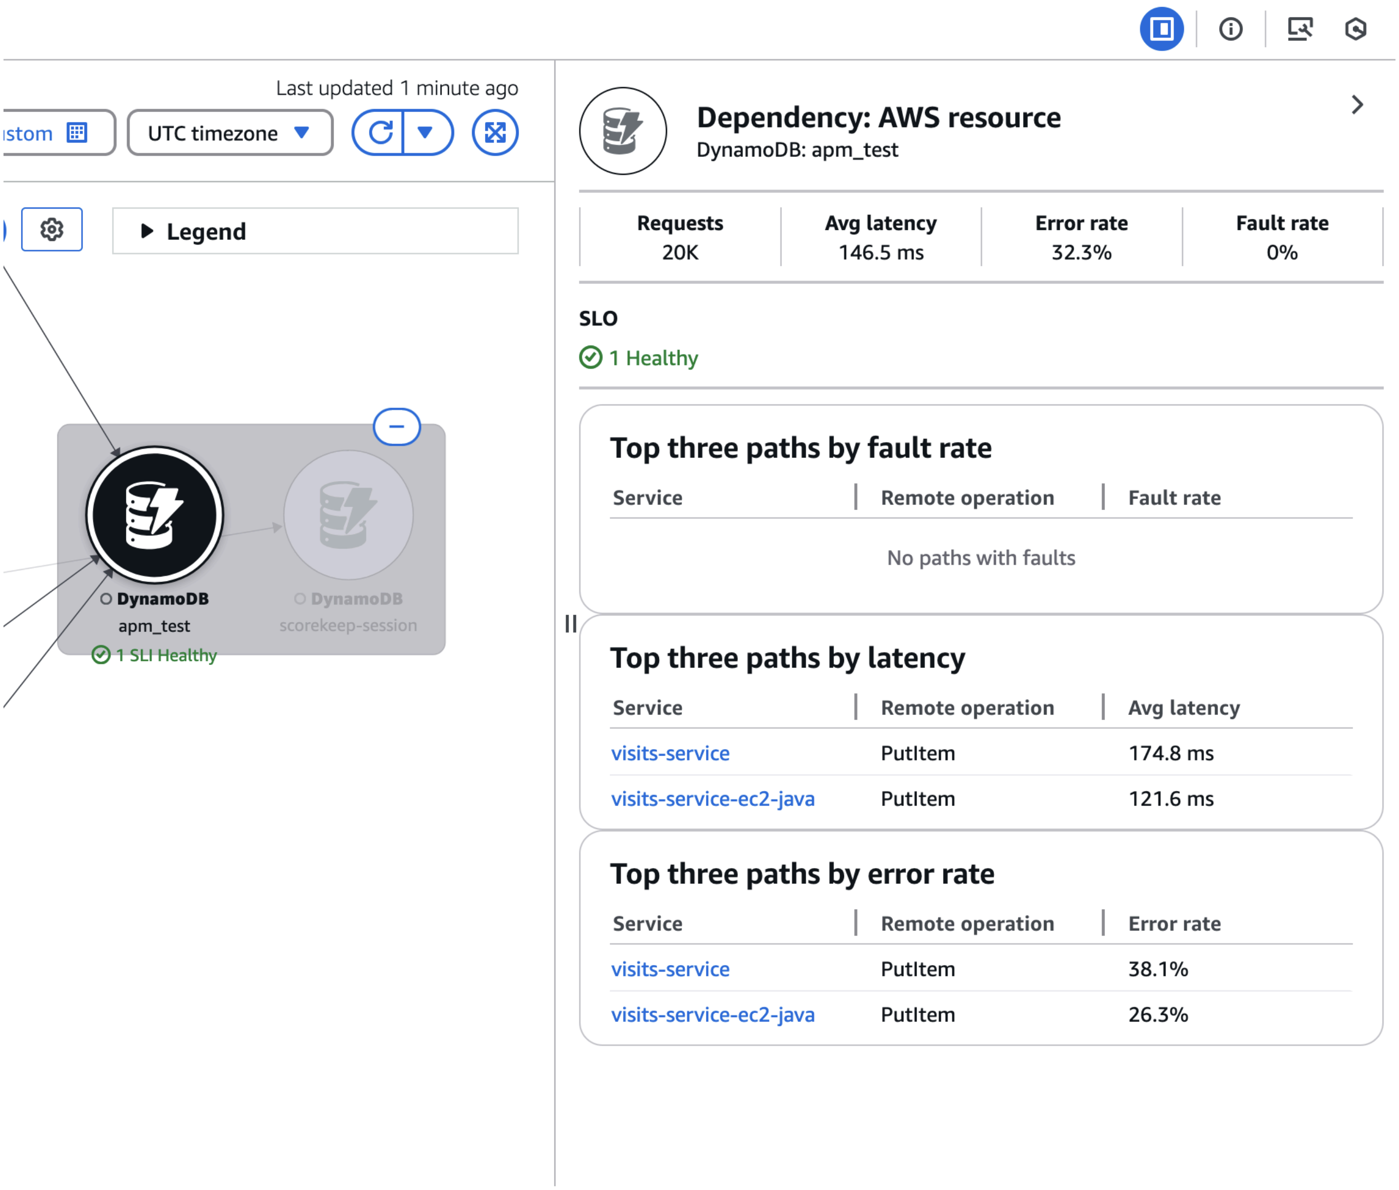


View dependencies

Your application dependencies are displayed on the service map, connected to the services that call them.

Choose a dependency node to open a pane containing top paths by fault rate, latency, and error rate. Choose any service or target link to open the Service Details page and see detailed information about the chosen service or dependency target, as shown in the example image below:

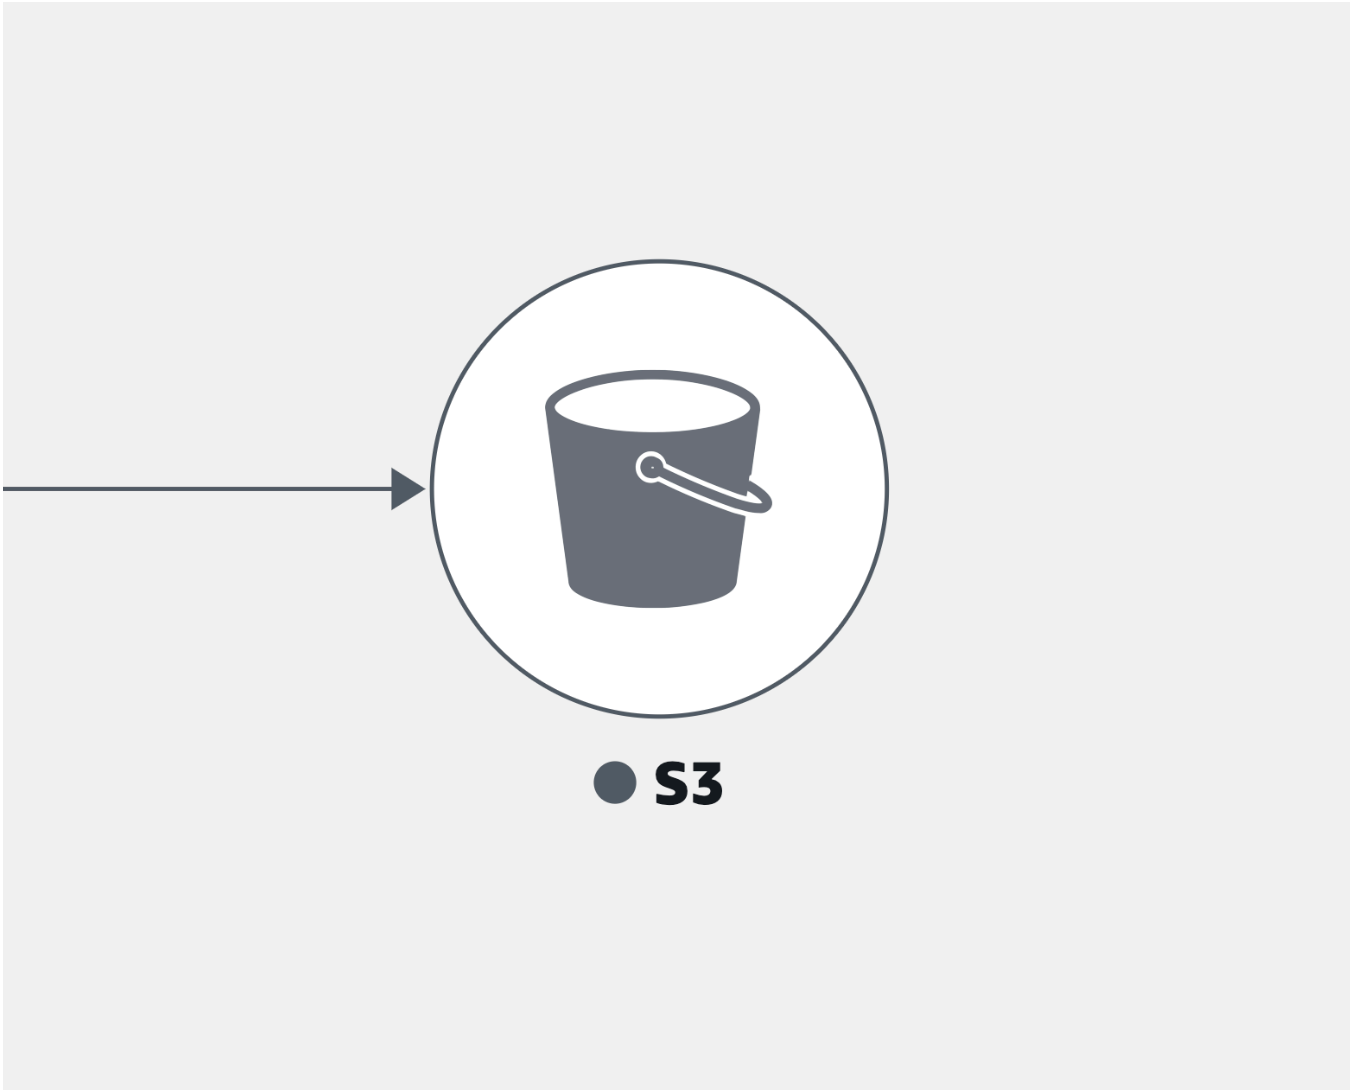
You can view the dependencies and the status of SLOs created on the dependencies.



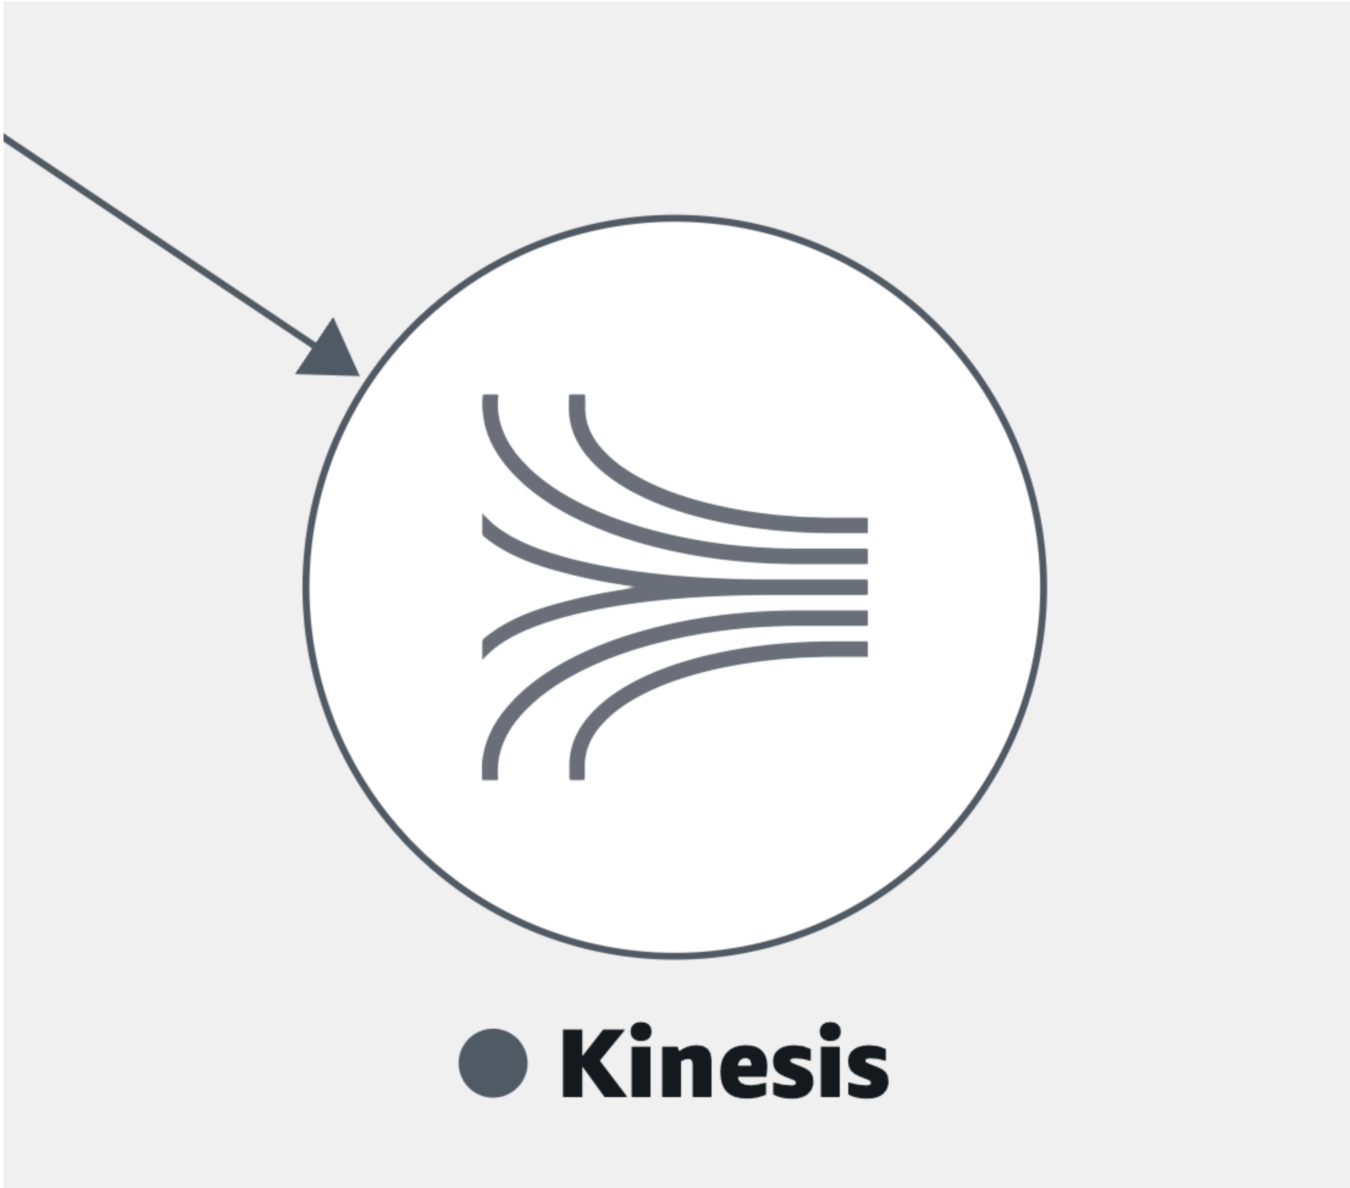
Service dependencies are grouped together by default into a single expandable icon. Select the (+) icon, as shown in the previous image, to expand the group and see its individual elements.

The following icons represent examples of dependency nodes in the service map:

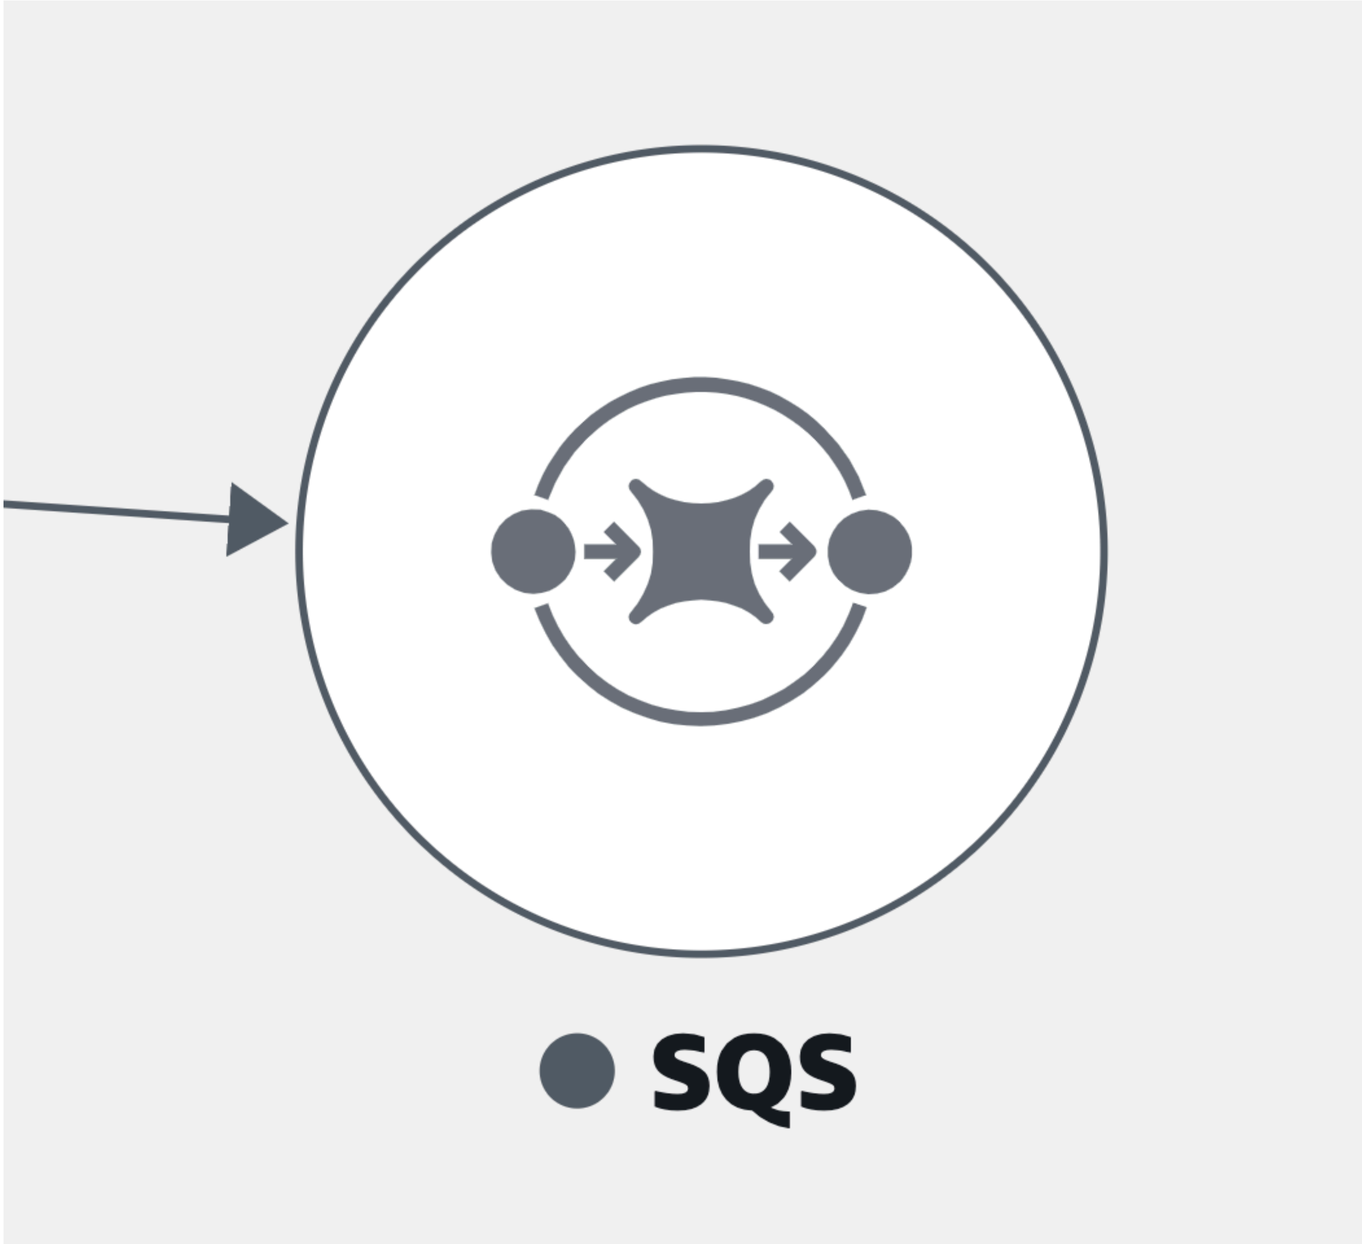
- An [Amazon S3](https://aws.amazon.com/s3/) bucket:



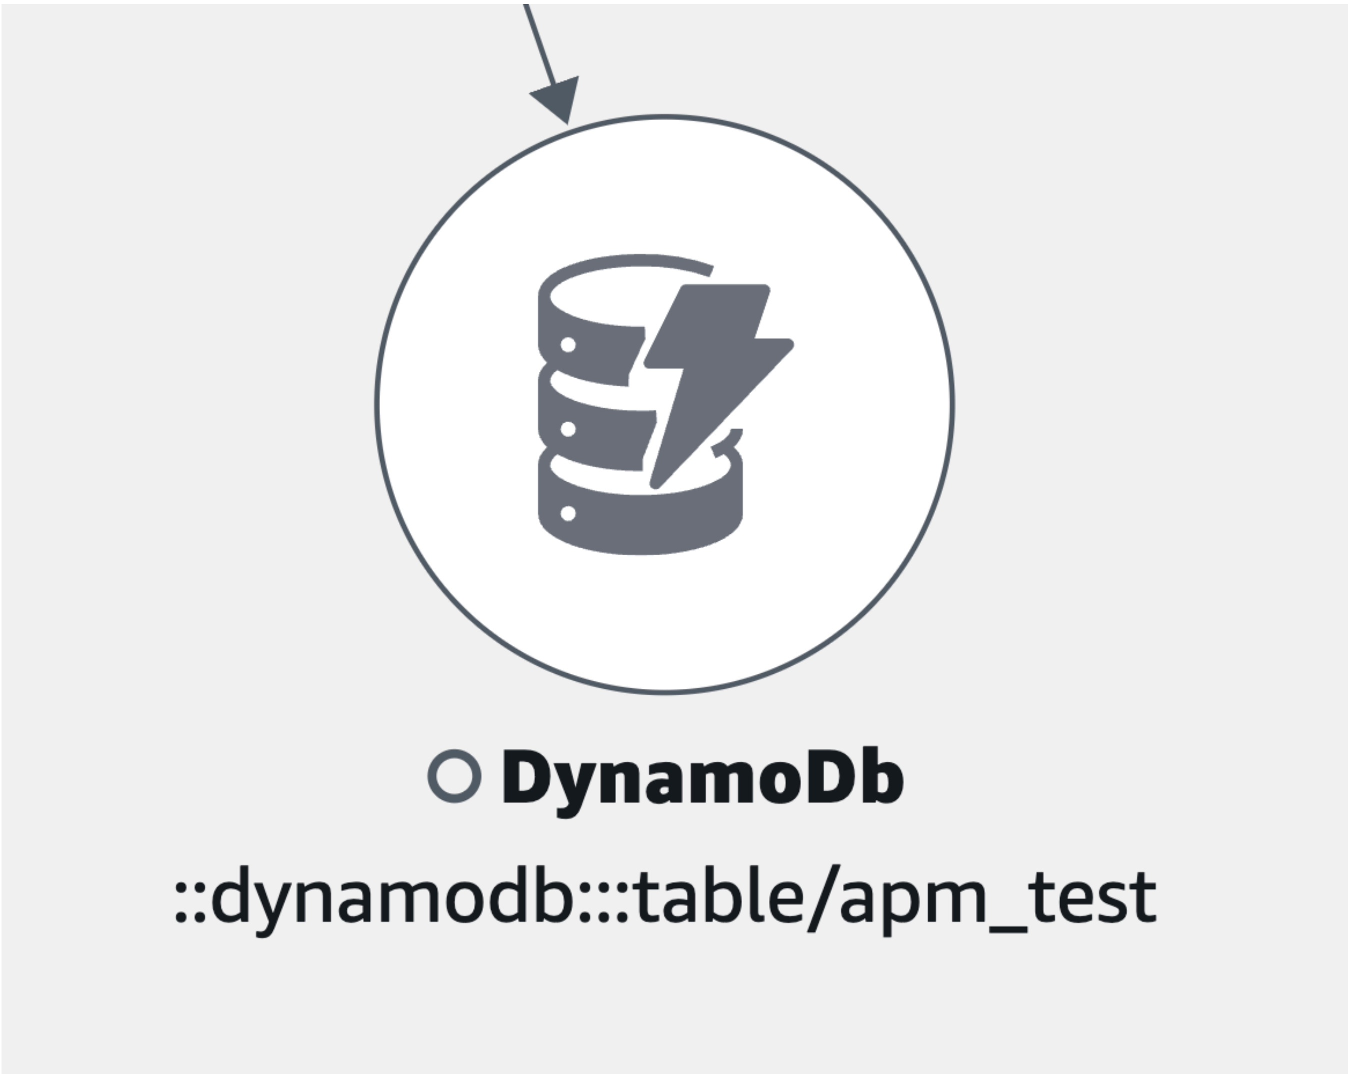
- An [Amazon Kinesis](https://docs.aws.amazon.com/kinesis/) stream:



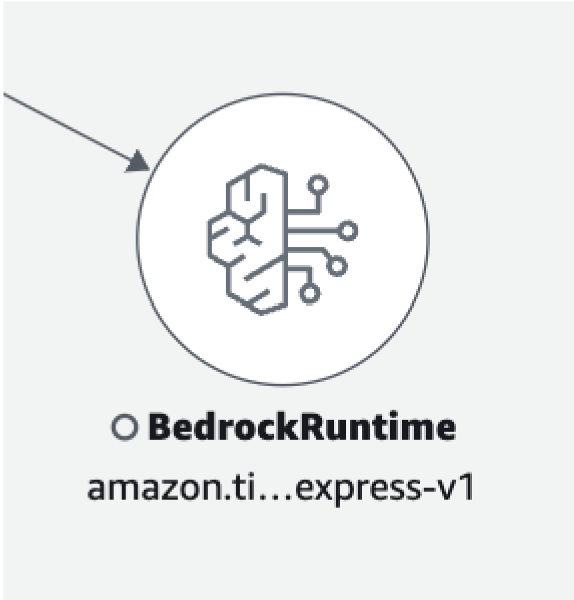
- Amazon Simple Queue Service (Amazon SQS):



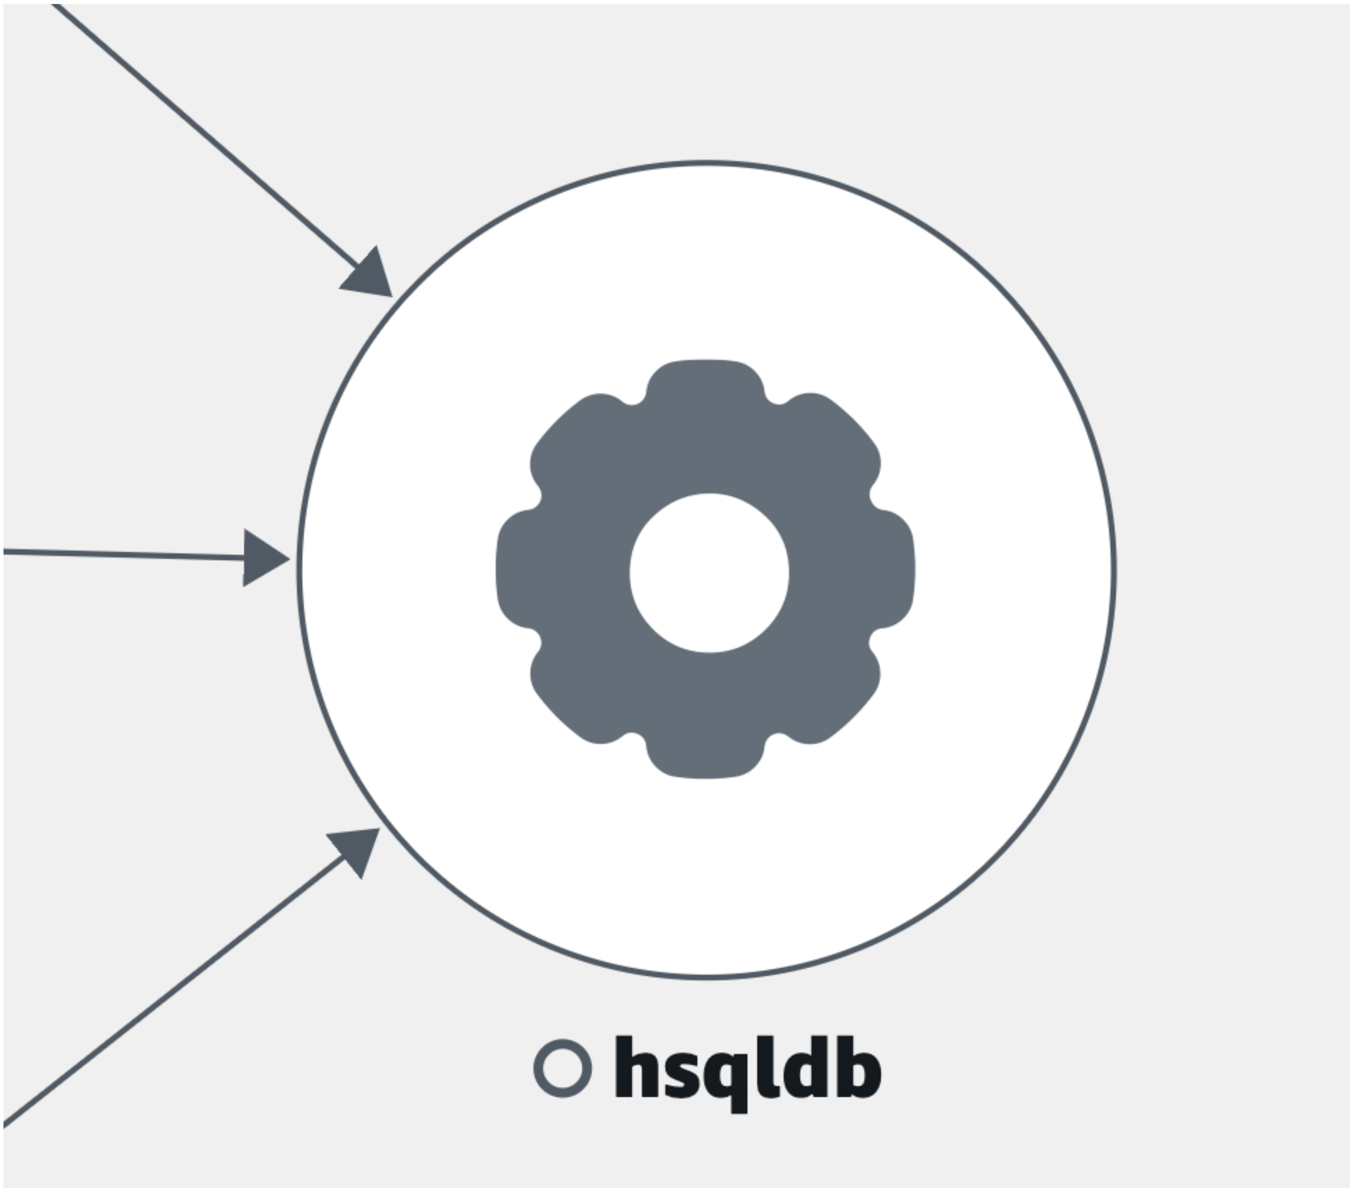
- An [Amazon DynamoDB](https://docs.aws.amazon.com/dynamodb/) table:



- An Amazon Bedrock model:



- Other dependency types not previously listed:



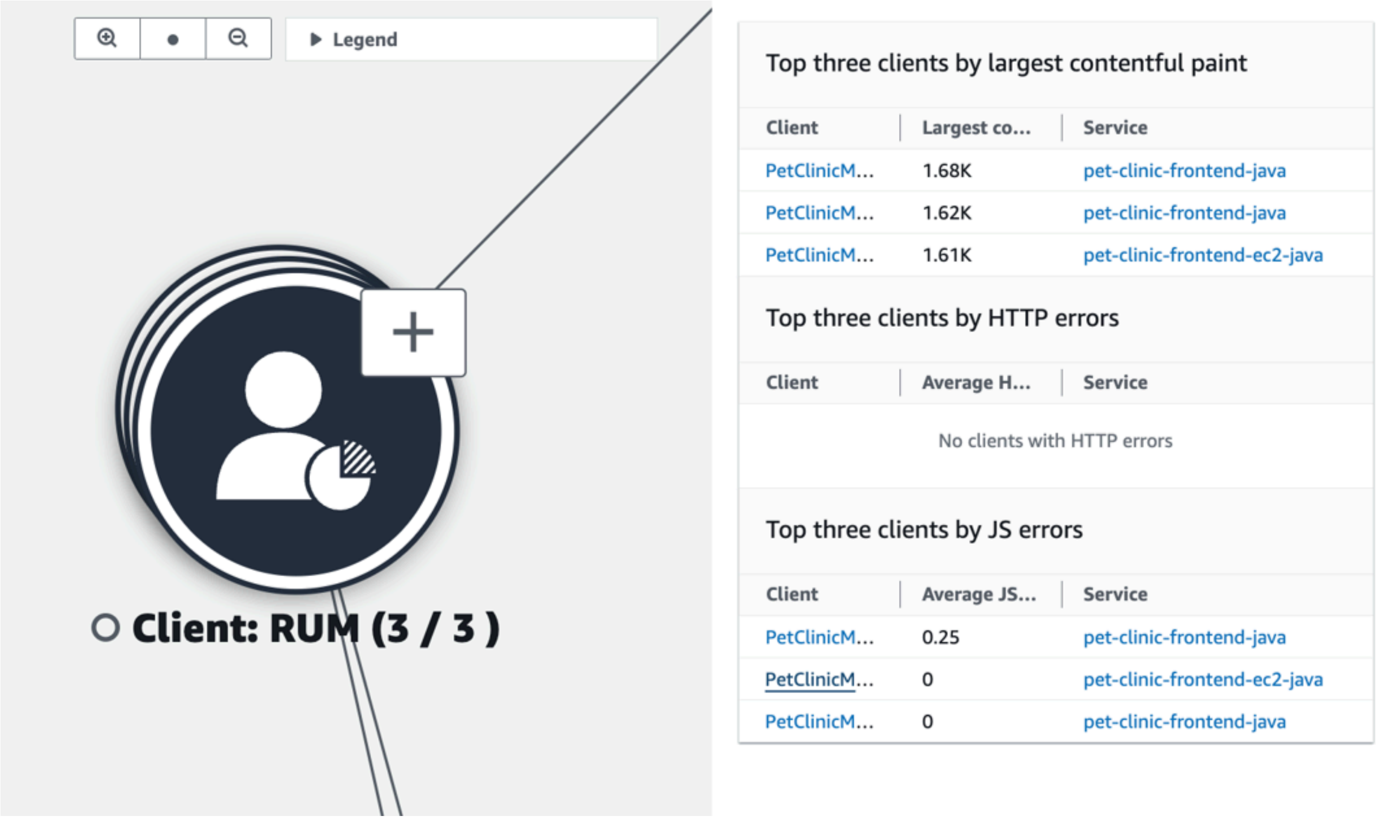
View clients

After you turn on X-Ray tracing for your CloudWatch RUM web clients, they display on the service map connected to services they call.

Choose a client node to open a pane displaying detailed client information:

- Metrics for page loads, average load time, errors, and average web vitals.
- A graph displaying a breakdown of errors.
- A link to display the client details in CloudWatch RUM.

RUM clients are grouped together by default into a single expandable icon. Select the (+) icon, as shown in the following image, to expand the group and see its individual elements.



The following icon represents an example of a RUM client in the service map:

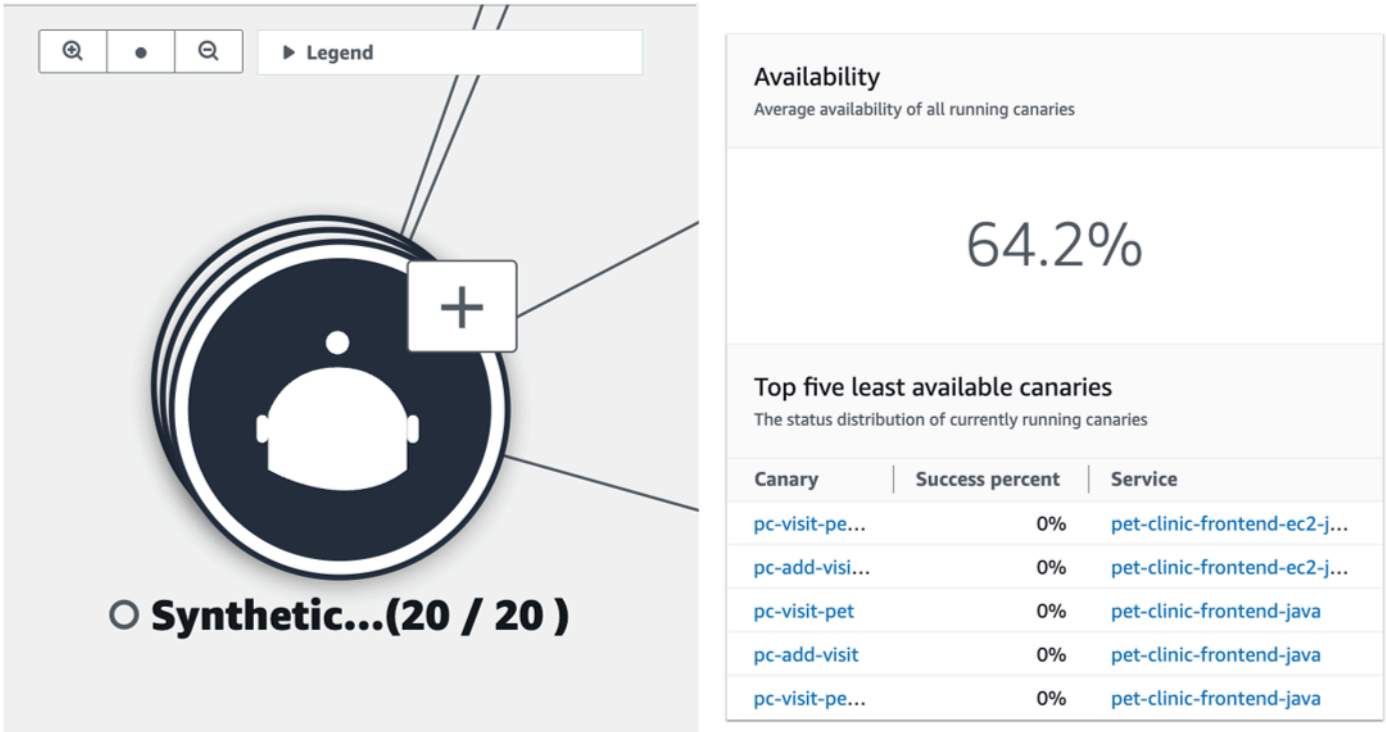
- A RUM client –

> **Note**
>
> To see AJAX errors within your client pages, use the CloudWatch RUM web client version 1.15 or newer.

View synthetics canaries

After you turn on Amazon X-Ray tracing for your CloudWatch Synthetics canaries, they display on the service map connected to services they call, as shown in the following example image:

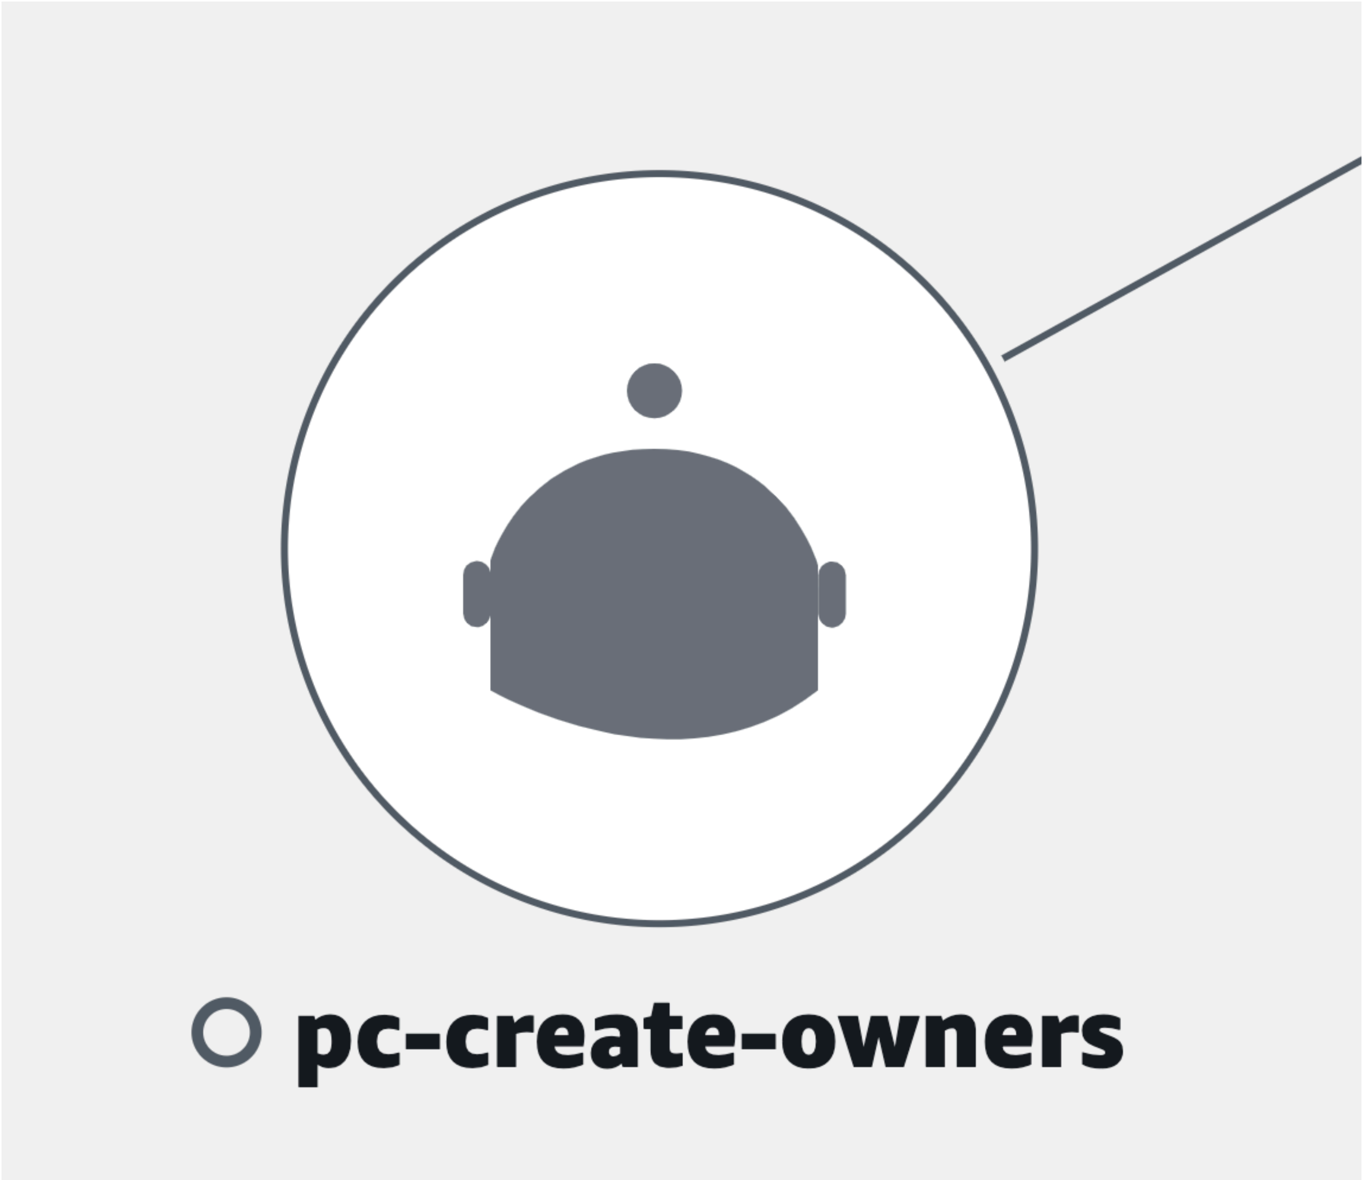
Choose a canary node to open a pane displaying detailed canary information, as shown in the following image:



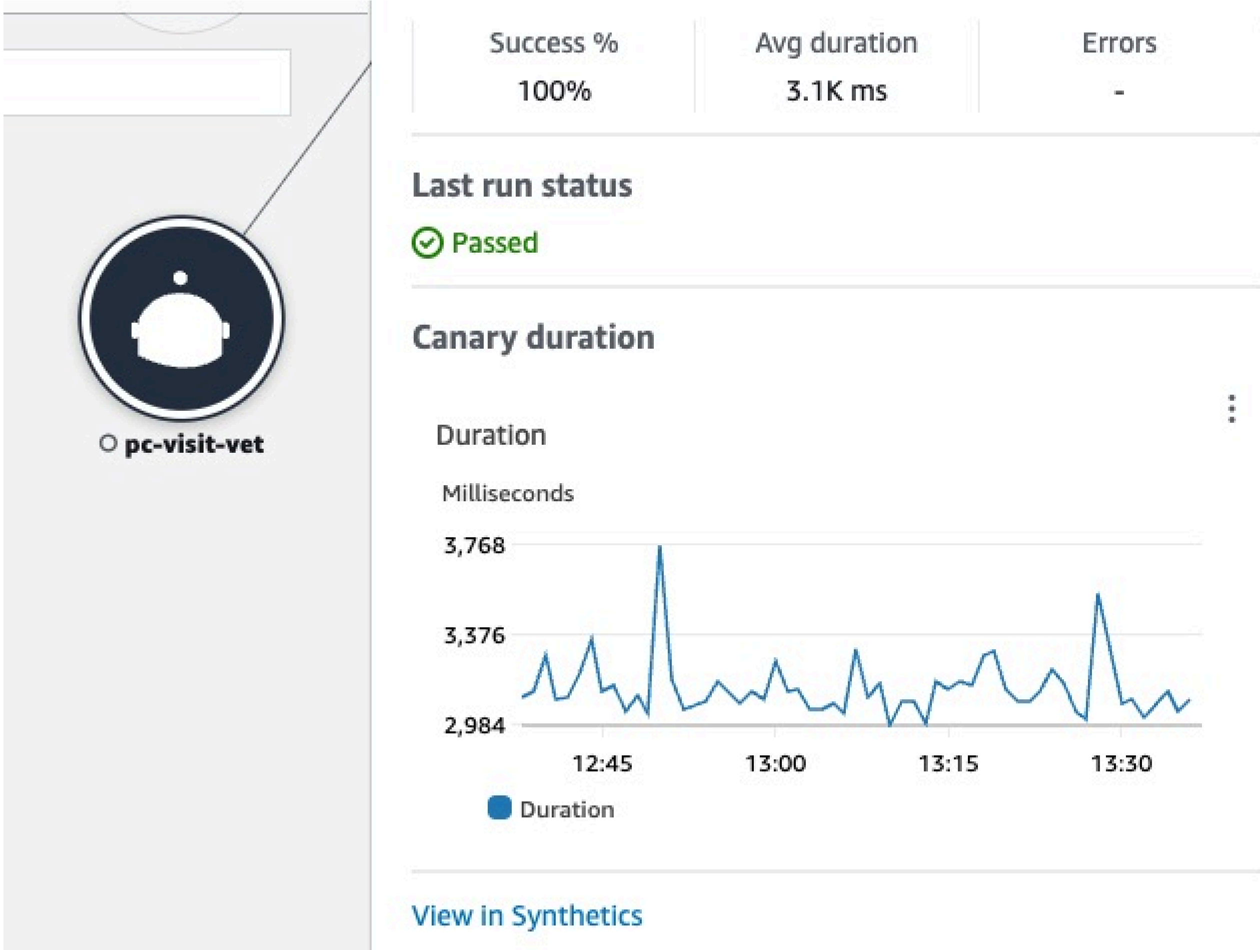
Canaries are grouped together by default into a single expandable icon. Select the (+) icon, as shown in the previous image, to expand the group and see its individual elements.

The following icons represent examples of clients in the service map:

- A synthetics canary –



pc-create-owners



In the pane for canary nodes, you can see the following:

- Metrics for success percentage, average duration, and errors.
- The status of the last canary run.
- A graph displaying canary run duration. Hover over a graph series to see a pop-up containing more information.
- A link to display canary details in **CloudWatch Synthetics**.

Example: Use Application Signals to resolve an operational health issue

The following scenario provides an example of how Application Signals can be used to monitor your services and identify service quality issues. Drill down to identify potential root causes and take action to resolve the issue. This example is focused on a pet clinic application composed of several microservices that call Amazon Web Services services such as DynamoDB.
