- [Temporary table creation errors and mitigation](#)

## Storage engine for internal (implicit) temporary tables

When generating intermediate result sets, Aurora MySQL initially attempts to write to in-memory temporary tables. This might be unsuccessful, because of either incompatible data types or configured limits. If so, the temporary table is converted to an on-disk temporary table rather than being held in memory. More information on this can be found in the [Internal Temporary Table Use in MySQL](#) in the MySQL documentation.

In Aurora MySQL version 3, the way internal temporary tables work is different from earlier Aurora MySQL versions. Instead of choosing between the InnoDB and MyISAM storage engines for such temporary tables, now you choose between the TempTable and MEMORY storage engines.

With the TempTable storage engine, you can make an additional choice for how to handle certain data. The data affected overflows the memory pool that holds all the internal temporary tables for the DB instance.

Those choices can influence the performance for queries that generate high volumes of temporary data, for example while performing aggregations such as GROUP BY on large tables.

### Tip

If your workload includes queries that generate internal temporary tables, confirm how your application performs with this change by running benchmarks and monitoring performance-related metrics.

In some cases, the amount of temporary data fits within the TempTable memory pool or only overflows the memory pool by a small amount. In these cases, we recommend using

the `TempTable` setting for internal temporary tables and memory-mapped files to hold any overflow data. This setting is the default.

The `TempTable` storage engine is the default. `TempTable` uses a common memory pool for all temporary tables that use this engine, instead of a maximum memory limit per table. The size of this memory pool is specified by the [`temptable\_max\_ram`](#) parameter. It defaults to 1 GiB on DB instances with 16 or more GiB of memory, and 16 MB on DB instances with less than 16 GiB of memory. The size of the memory pool influences session-level memory consumption.

In some cases when you use the `TempTable` storage engine, the temporary data might exceed the size of the memory pool. If so, Aurora MySQL stores the overflow data using a secondary mechanism.

You can set the [`temptable\_max\_mmap`](#) parameter to choose whether the data overflows to memory-mapped temporary files or to InnoDB internal temporary tables on disk. The different data formats and overflow criteria of these overflow mechanisms can affect query performance. They do so by influencing the amount of data written to disk and the demand on disk storage throughput.

Aurora MySQL version 3 stores the overflow data in the following way:

- On the writer DB instance, data that overflows to InnoDB internal temporary tables or memory-mapped temporary files resides in local storage on the instance.
- On reader DB instances, overflow data always resides in memory-mapped temporary files in local storage.

Read-only instances can't store any data on the Aurora cluster volume.

The configuration parameters related to internal temporary tables apply differently to the writer and reader instances in your cluster:

- On reader instances, Aurora MySQL always uses the `TempTable` storage engine.
- The size for `temptable_max_mmap` defaults to 1 GiB for both writer and reader instances, regardless of the DB instance memory size. You can adjust this value on both writer and reader instances.
- Setting `temptable_max_mmap` to `0` turns off the use of memory-mapped temporary files on writer instances.

- You can't set `temptable_max_mmap` to 0 on reader instances.

### Note

We don't recommend using the [temptable\\_use\\_mmap](#) parameter. It has been deprecated, and support for it is expected to be removed in a future MySQL release.

## Limiting the size of internal, in-memory temporary tables

As discussed in [Storage engine for internal \(implicit\) temporary tables](#), you can control temporary table resources globally by using the [temptable\\_max\\_ram](#) and [temptable\\_max\\_mmap](#) settings.

You can also limit the size of any individual internal, in-memory temporary table by using the [tmp\\_table\\_size](#) DB parameter. This limit is intended to prevent individual queries from consuming an inordinate amount of global temporary table resources, which can affect the performance of concurrent queries that require these resources.

The `tmp_table_size` parameter defines the maximum size of temporary tables created by the MEMORY storage engine in Aurora MySQL version 3.

In Aurora MySQL version 3.04 and higher, `tmp_table_size` also defines the maximum size of temporary tables created by the TempTable storage engine when the `aurora_tmptable_enable_per_table_limit` DB parameter is set to ON. This behavior is disabled by default (OFF), which is the same behavior as in Aurora MySQL version 3.03 and lower versions.

- When `aurora_tmptable_enable_per_table_limit` is OFF, `tmp_table_size` isn't considered for internal, in-memory temporary tables created by the TempTable storage engine.

However, the global TempTable resources limit still applies. Aurora MySQL has the following behavior when the global TempTable resources limit is reached:

- Writer DB instances – Aurora MySQL automatically converts the in-memory temporary table to an InnoDB on-disk temporary table.
- Reader DB instances – The query ends with an error.

```
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlxx_xxx' is full
```

- When `aurora_tmptable_enable_per_table_limit` is ON, Aurora MySQL has the following behavior when the `tmp_table_size` limit is reached:
  - Writer DB instances – Aurora MySQL automatically converts the in-memory temporary table to an InnoDB on-disk temporary table.
  - Reader DB instances – The query ends with an error.

```
ERROR 1114 (HY000): The table '/rdsdbdata/tmp/#sqlxx_xxx' is full
```

Both the global TempTable resources limit and the per-table limit apply in this case.

### Note

The `aurora_tmptable_enable_per_table_limit` parameter has no effect when [internal\\_tmp\\_mem\\_storage\\_engine](#) is set to MEMORY. In this case, the maximum size of an in-memory temporary table is defined by the [tmp\\_table\\_size](#) or [max\\_heap\\_table\\_size](#) value, whichever is smaller.

The following examples show the behavior of the `aurora_tmptable_enable_per_table_limit` parameter for writer and reader DB instances.

### Example of writer DB instance with `aurora_tmptable_enable_per_table_limit` set to OFF

The in-memory temporary table isn't converted to an InnoDB on-disk temporary table.

## Mitigating fullness issues for internal temporary tables on Aurora Replicas

To avoid size limitation issues for temporary tables, set the `temptable_max_ram` and `temptable_max_mmap` parameters to a combined value that can fit the requirements of your workload.

Be careful when setting the value of the `temptable_max_ram` parameter. Setting the value too high reduces the available memory on the database instance, which can cause an out-of-memory condition. Monitor the average freeable memory on the DB instance. Then determine an appropriate value for `temptable_max_ram` so that you will still have a reasonable amount of free memory left on the instance. For more information, see [Freeable memory issues in Amazon Aurora](#).

It is also important to monitor the size of the local storage and the temporary table space consumption. You can monitor the temporary storage available for a specific DB instance with the `FreeLocalStorage` Amazon CloudWatch metric, described in [Amazon CloudWatch metrics for Amazon Aurora](#).

### Note

This procedure doesn't work when the `aurora_tmptable_enable_per_table_limit` parameter is set to `ON`. For more information, see [Limiting the size of internal, in-memory temporary tables](#).

## Example 1

You know that your temporary tables grow to a cumulative size of 20 GiB. You want to set in-memory temporary tables to 2 GiB and to grow to a maximum of 20 GiB on disk.

Set `temptable_max_ram` to **2,147,483,648** and `temptable_max_mmap` to **21,474,836,480**. These values are in bytes.

These parameter settings make sure that your temporary tables can grow to a cumulative total of 22 GiB.

## Example 2

Your current instance size is 16xlarge or larger. You don't know the total size of the temporary tables that you might need. You want to be able to use up to 4 GiB in memory and up to the maximum available storage size on disk.

Set `temptable_max_ram` to **4,294,967,296** and `temptable_max_mmap` to **1,099,511,627,776**. These values are in bytes.

Here you're setting `temptable_max_mmap` to 1 TiB, which is less than the maximum local storage of 1.2 TiB on a 16xlarge Aurora DB instance.

On a smaller instance size, adjust the value of `temptable_max_mmap` so that it doesn't fill up the available local storage. For example, a 2xlarge instance has only 160 GiB of local storage available. Hence, we recommend setting the value to less than 160 GiB. For more information on the available local storage for DB instance sizes, see [Temporary storage limits for Aurora MySQL](#).

### Optimizing the `temptable_max_mmap` parameter on Aurora MySQL DB instances

The `temptable_max_mmap` parameter in Aurora MySQL controls the maximum amount of local disk space that can be used by memory mapped files before overflowing to the on-disk InnoDB temporary tables (on writer DB instances) or causing an error (on reader DB instances). Setting this DB instance parameter properly can help optimize the performance of your DB instances.

### Prerequisites

1. Make sure that the Performance Schema is enabled. You can verify this by running the following SQL command:

```
SELECT @@performance_schema;
```

An output value of 1 indicates that it's enabled.

2. Confirm that the temporary table memory instrumentation is enabled. You can verify this by running the following SQL command:

```
SELECT name, enabled FROM performance_schema.setup_instruments WHERE name LIKE '%memory%temptable%';
```

The `enabled` column shows YES for the relevant temporary table memory instrumentation entries.

## Monitoring temporary table usage

When setting the initial value for `temptable_max_mmap`, we recommend that you start with 80% of the local storage size for the DB instance class that you're using. This ensures that the temporary tables have enough disk space to operate efficiently, while leaving room for other disk usage on the instance.

To find the local storage size for your DB instance class, see [Temporary storage limits for Aurora MySQL](#).

For example, if you're using the `db.r5.large` DB instance class, the local storage size is 32 GiB. In this case, you would initially set the `temptable_max_mmap` parameter to 80% of 32 GiB, which is 25.6 GiB.

After setting the initial `temptable_max_mmap` value, run your peak workload on the Aurora MySQL instances. Monitor the current and high temporary table disk usage using the following SQL query:

```
SELECT event_name, current_count, current_alloc, current_avg_alloc, high_count,
       high_alloc, high_avg_alloc
FROM sys.memory_global_by_current_bytes WHERE event_name LIKE 'memory/temptable/%';
```

This query retrieves the following information:

- `event_name` – The name of the temporary table memory or disk usage event.
- `current_count` – The current number of allocated temporary table memory or disk blocks.
- `current_alloc` – The current amount of memory or disk allocated for temporary tables.
- `current_avg_alloc` – The current average size of temporary table memory or disk blocks.
- `high_count` – The highest number of allocated temporary table memory or disk blocks.
- `high_alloc` – The highest amount of memory or disk allocated for temporary tables.
- `high_avg_alloc` – The highest average size of temporary table memory or disk blocks.

If your queries fail with a Table is full error using this setting, it indicates that your workload requires more disk space for temporary table operations. In this case, consider increasing your DB instance size to one with more local storage space.

## Setting the optimal `temptable_max_mmap` value

Use the following procedure to monitor and set the right size for the `temptable_max_mmap` parameter.

1. Review the output of the previous query, and identify the peak temporary table disk usage, as indicated by the `high_alloc` column.
2. Based on the peak temporary table disk usage, adjust the `temptable_max_mmap` parameter in the DB parameter group for your Aurora MySQL DB instances.

Set the value to be slightly higher than the peak temporary table disk usage to accommodate future growth.

3. Apply the parameter group changes to your DB instances.
4. Monitor the temporary table disk usage again during your peak workload to make sure that the new `temptable_max_mmap` value is appropriate.
5. Repeat the previous steps as needed to fine tune the `temptable_max_mmap` parameter.

### User-created (explicit) temporary tables on reader DB instances

You can create explicit temporary tables using the `TEMPORARY` keyword in your `CREATE TABLE` statement. Explicit temporary tables are supported on the writer DB instance in an Aurora DB cluster. You can also use explicit temporary tables on reader DB instances, but the tables can't enforce the use of the InnoDB storage engine.

To avoid errors while creating explicit temporary tables on Aurora MySQL reader DB instances, make sure that you run all `CREATE TEMPORARY TABLE` statements in either or both of the following ways:

- Don't specify the `ENGINE=InnoDB` clause.
- Don't set the SQL mode to `NO_ENGINE_SUBSTITUTION`.

### Temporary table creation errors and mitigation

The error that you receive is different depending on whether you use a plain `CREATE TEMPORARY TABLE` statement or the variation `CREATE TEMPORARY TABLE AS SELECT`. The following examples show the different kinds of errors.

This temporary table behavior only applies to read-only instances. This first example confirms that's the kind of instance the session is connected to.

```
mysql> select @@innodb_read_only;
+-----+
```

```
| @@innodb_read_only |
+-----+
|                    1 |
+-----+
```

For plain `CREATE TEMPORARY TABLE` statements, the statement fails when the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. When `NO_ENGINE_SUBSTITUTION` is turned off (default), the appropriate engine substitution is made, and the temporary table creation succeeds.

```
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt2 (id int) ENGINE=InnoDB;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> CREATE TEMPORARY TABLE tt4 (id int) ENGINE=InnoDB;

mysql> SHOW CREATE TABLE tt4\G
***** 1. row *****
      Table: tt4
Create Table: CREATE TEMPORARY TABLE `tt4` (
  `id` int DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

For `CREATE TEMPORARY TABLE AS SELECT` statements, the statement fails when the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. When `NO_ENGINE_SUBSTITUTION` is turned off (default), the appropriate engine substitution is made, and the temporary table creation succeeds.

```
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt1 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> show create table tt3;
+-----+-----+
| Table | Create Table |
+-----+-----+
```

```
| tt3 | CREATE TEMPORARY TABLE `tt3` (  
  `id` int DEFAULT NULL  
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |  
+-----+-----+-----+-----+-----+-----+  
1 row in set (0.00 sec)
```

For more information about the storage aspects and performance implications of temporary tables in Aurora MySQL version 3, see the blog post [Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL](#).

## Comparing Aurora MySQL version 2 and Aurora MySQL version 3

Use the following to learn about changes to be aware of when you upgrade your Aurora MySQL version 2 cluster to version 3.

### Topics

- [Atomic Data Definition Language \(DDL\) support](#)
- [Feature differences between Aurora MySQL version 2 and 3](#)
- [Instance class support](#)
- [Parameter changes for Aurora MySQL version 3](#)
- [Status variables](#)
- [Inclusive language changes for Aurora MySQL version 3](#)
- [AUTO\\_INCREMENT values](#)
- [Binary log replication](#)

### Atomic Data Definition Language (DDL) support

One of the largest changes from MySQL 5.7 to 8.0 is the introduction of the [Atomic Data Dictionary](#). Before MySQL 8.0, the MySQL data dictionary used a file-based approach to store metadata such as table definitions (.frm), triggers (.trg), and functions separately from the storage engine's metadata (such as InnoDB's). This had some issues, including the risk of tables becoming "[orphaned](#)" if something unexpected happened during a DDL operation, causing the file-based and storage engine metadata to get out of sync.

To fix this, MySQL 8.0 introduced the Atomic Data Dictionary, which stores all metadata in a set of internal InnoDB tables in the `mysql` schema. This new architecture provides a transactional, [ACID-](#)

compliant way to manage database metadata, solving the "atomic DDL" problem from the old file-based approach. For more information on the Atomic Data Dictionary, see [Removal of file-based metadata storage](#) and [Atomic data definition statement support](#) in the *MySQL Reference Manual*.

Due to this architectural change, you must consider the following when upgrading from Aurora MySQL version 2 to version 3:

- The file-based metadata from version 2 must be migrated to the new data dictionary tables during the upgrade process to version 3. Depending on how many database objects are migrated, this could take some time.
- The changes have also introduced some new incompatibilities that might need to be addressed before you can upgrade from MySQL 5.7 to 8.0. For example, 8.0 has some new reserved keywords that could conflict with existing database object names.

To help you identify these incompatibilities before upgrading the engine, Aurora MySQL runs a series of upgrade compatibility checks (prechecks) to determine whether there are any incompatible objects in your database dictionary, before performing the data dictionary upgrade. For more information on the prechecks, see [Major version upgrade prechecks for Aurora MySQL](#).

### Feature differences between Aurora MySQL version 2 and 3

The following Amazon Aurora MySQL features are supported in Aurora MySQL for MySQL 5.7, but these features aren't supported in Aurora MySQL for MySQL 8.0:

- You can't use Aurora MySQL version 3 for Aurora Serverless v1 clusters. Aurora MySQL version 3 works with Aurora Serverless v2.
- Lab mode doesn't apply to Aurora MySQL version 3. There aren't any lab mode features in Aurora MySQL version 3. Instant DDL supersedes the fast online DDL feature that was formerly available in lab mode. For an example, see [Instant DDL \(Aurora MySQL version 3\)](#).
- The query cache is removed from community MySQL 8.0 and also from Aurora MySQL version 3.
- Aurora MySQL version 3 is compatible with the community MySQL hash join feature. The Aurora-specific implementation of hash joins in Aurora MySQL version 2 isn't used. For information about using hash joins with Aurora parallel query, see [Turning on hash join for parallel query clusters](#) and [Aurora MySQL hints](#). For general usage information about hash joins, see [Hash Join Optimization](#) in the *MySQL Reference Manual*.
- The `mysql.lambda_async` stored procedure that was deprecated in Aurora MySQL version 2 is removed in version 3. For version 3, use the asynchronous function `lambda_async` instead.

- The default character set in Aurora MySQL version 3 is `utf8mb4`. In Aurora MySQL version 2, the default character set was `latin1`. For information about this character set, see [The utf8mb4 Character Set \(4-Byte UTF-8 Unicode Encoding\)](#) in the *MySQL Reference Manual*.

Some Aurora MySQL features are available for certain combinations of Amazon Region and DB engine version. For details, see [Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine](#).

## Instance class support

Aurora MySQL version 3 supports a different set of instance classes from Aurora MySQL version 2:

- For larger instances, you can use the modern instance classes such as `db.r5`, `db.r6g`, and `db.x2g`.
- For smaller instances, you can use the modern instance classes such as `db.t3` and `db.t4g`.

### Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Using T instance classes for development and testing](#).

The following instance classes from Aurora MySQL version 2 aren't available for Aurora MySQL version 3:

- `db.r4`
- `db.r3`
- `db.t3.small`
- `db.t2`

Check your administration scripts for any CLI statements that create Aurora MySQL DB instances. Hardcode instance class names that aren't available for Aurora MySQL version 3. If necessary, modify the instance class names to ones that Aurora MySQL version 3 supports.

**Tip**

To check the instance classes that you can use for a specific combination of Aurora MySQL version and Amazon Region, use the `describe-orderable-db-instance-options` Amazon CLI command.

For full details about Aurora instance classes, see [Amazon Aurora DB instance classes](#).

**Parameter changes for Aurora MySQL version 3**

Aurora MySQL version 3 includes new cluster-level and instance-level configuration parameters. Aurora MySQL version 3 also removes some parameters that were present in Aurora MySQL version 2. Some parameter names are changed as a result of the initiative for inclusive language. For backward compatibility, you can still retrieve the parameter values using either the old names or the new names. However, you must use the new names to specify parameter values in a custom parameter group.

In Aurora MySQL version 3, the value of the `lower_case_table_names` parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading. Then specify the parameter group during the create cluster or snapshot restore operation.

**Note**

With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on. Use the snapshot restore method instead.

In Aurora MySQL version 3, the `init_connect` and `read_only` parameters don't apply for users who have the `CONNECTION_ADMIN` privilege. This includes the Aurora master user. For more information, see [Role-based privilege model](#).

For the full list of Aurora MySQL cluster parameters, see [Cluster-level parameters](#). The table covers all the parameters from Aurora MySQL version 2 and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 or were removed from Aurora MySQL version 3.

For the full list of Aurora MySQL instance parameters, see [Instance-level parameters](#). The table covers all the parameters from Aurora MySQL version 2 and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 and which parameters were removed from Aurora MySQL version 3. It also includes notes showing which parameters were modifiable in earlier versions but not Aurora MySQL version 3.

For information about parameter names that changed, see [Inclusive language changes for Aurora MySQL version 3](#).

## Status variables

For information about status variables that aren't applicable to Aurora MySQL, see [MySQL status variables that don't apply to Aurora MySQL](#).

## Inclusive language changes for Aurora MySQL version 3

Aurora MySQL version 3 is compatible with version 8.0.23 from the MySQL community edition. Aurora MySQL version 3 also includes changes from MySQL 8.0.26 related to keywords and system schemas for inclusive language. For example, the `SHOW REPLICA STATUS` command is now preferred instead of `SHOW SLAVE STATUS`.

The following Amazon CloudWatch metrics have new names in Aurora MySQL version 3.

In Aurora MySQL version 3, only the new metric names are available. Make sure to update any alarms or other automation that relies on metric names when you upgrade to Aurora MySQL version 3.

Old name	New name	
ForwardingMasterDMLLatency	ForwardingWriterDMLLatency	
ForwardingMasterOpenSessions	ForwardingWriterOpenSessions	
AuroraDMLRejectedMasterFull	AuroraDMLRejectedWriterFull	
ForwardingMasterDMLThroughput	ForwardingWriterDMLThroughput	

The following status variables have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old status variable names are to be removed in a future release.

Name to be removed	New or preferred name	
Aurora_fwd_master_dml_stmt_duration	Aurora_fwd_writer_dml_stmt_duration	
Aurora_fwd_master_dml_stmt_count	Aurora_fwd_writer_dml_stmt_count	
Aurora_fwd_master_select_stmt_duration	Aurora_fwd_writer_select_stmt_duration	
Aurora_fwd_master_select_stmt_count	Aurora_fwd_writer_select_stmt_count	
Aurora_fwd_master_errors_session_timeout	Aurora_fwd_writer_errors_session_timeout	
Aurora_fwd_master_open_sessions	Aurora_fwd_writer_open_sessions	
Aurora_fwd_master_errors_session_limit	Aurora_fwd_writer_errors_session_limit	
Aurora_fwd_master_errors_rpc_timeout	Aurora_fwd_writer_errors_rpc_timeout	

The following configuration parameters have new names in Aurora MySQL version 3.

For compatibility, you can check the parameter values in the `mysql` client by using either name in the initial Aurora MySQL version 3 release. You can use only the new names when modifying values in a custom parameter group. The old parameter names are to be removed in a future release.

Name to be removed	New or preferred name	
aurora_fwd_master_idle_timeout	aurora_fwd_writer_idle_timeout	
aurora_fwd_master_max_connections_pct	aurora_fwd_writer_max_connections_pct	
master_verify_checksum	source_verify_checksum	
sync_master_info	sync_source_info	
init_slave	init_replica	
rpl_stop_slave_timeout	rpl_stop_replica_timeout	
log_slow_slave_statements	log_slow_replica_statements	
slave_max_allowed_packet	replica_max_allowed_packet	
slave_compressed_protocol	replica_compressed_protocol	
slave_exec_mode	replica_exec_mode	
slave_type_conversions	replica_type_conversions	
slave_sql_verify_checksum	replica_sql_verify_checksum	
slave_parallel_type	replica_parallel_type	

Name to be removed	New or preferred name	
slave_preserve_commit_order	replica_preserve_commit_order	
log_slave_updates	log_replica_updates	
slave_allow_batching	replica_allow_batching	
slave_load_tmpdir	replica_load_tmpdir	
slave_net_timeout	replica_net_timeout	
sql_slave_skip_counter	sql_replica_skip_counter	
slave_skip_errors	replica_skip_errors	
slave_checkpoint_period	replica_checkpoint_period	
slave_checkpoint_group	replica_checkpoint_group	
slave_transaction_retries	replica_transaction_retries	
slave_parallel_workers	replica_parallel_workers	
slave_pending_jobs_size_max	replica_pending_jobs_size_max	
pseudo_slave_mode	pseudo_replica_mode	

The following stored procedures have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old procedure names are to be removed in a future release.

Name to be removed	New or preferred name
<code>mysql.rds_set_master_auto_position</code>	<code>mysql.rds_set_source_auto_position</code>
<code>mysql.rds_set_external_master</code>	<code>mysql.rds_set_external_source</code>
<code>mysql.rds_set_external_master_with_auto_position</code>	<code>mysql.rds_set_external_source_with_auto_position</code>
<code>mysql.rds_reset_external_master</code>	<code>mysql.rds_reset_external_source</code>
<code>mysql.rds_next_master_log</code>	<code>mysql.rds_next_source_log</code>

## AUTO\_INCREMENT values

In Aurora MySQL version 3, Aurora preserves the `AUTO_INCREMENT` value for each table when it restarts each DB instance. In Aurora MySQL version 2, the `AUTO_INCREMENT` value wasn't preserved after a restart.

The `AUTO_INCREMENT` value isn't preserved when you set up a new cluster by restoring from a snapshot, performing a point-in-time recovery, and cloning a cluster. In these cases, the `AUTO_INCREMENT` value is initialized to the value based on the largest column value in the table at the time the snapshot was created. This behavior is different than in RDS for MySQL 8.0, where the `AUTO_INCREMENT` value is preserved during these operations.

## Binary log replication

In MySQL 8.0 community edition, binary log replication is turned on by default. In Aurora MySQL version 3, binary log replication is turned off by default.

### Tip

If your high availability requirements are fulfilled by the Aurora built-in replication features, you can leave binary log replication turned off. That way, you can avoid the performance

overhead of binary log replication. You can also avoid the associated monitoring and troubleshooting that are needed to manage binary log replication.

Aurora supports binary log replication from a MySQL 5.7–compatible source to Aurora MySQL version 3. The source system can be an Aurora MySQL DB cluster, an RDS for MySQL DB instance, or an on-premises MySQL instance.

As does community MySQL, Aurora MySQL supports replication from a source running a specific version to a target running the same major version or one major version higher. For example, replication from a MySQL 5.6–compatible system to Aurora MySQL version 3 isn't supported. Replicating from Aurora MySQL version 3 to a MySQL 5.7–compatible or MySQL 5.6–compatible system isn't supported. For details about using binary log replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

Aurora MySQL version 3 includes improvements to binary log replication in community MySQL 8.0, such as filtered replication. For details about the community MySQL 8.0 improvements, see [How Servers Evaluate Replication Filtering Rules](#) in the *MySQL Reference Manual*.

### Transaction compression for binary log replication

For usage information about binary log compression, see [Binary Log Transaction Compression](#) in the MySQL Reference Manual.

The following limitations apply to binary log compression in Aurora MySQL version 3:

- Transactions whose binary log data is larger than the maximum allowed packet size aren't compressed. This is true regardless of whether the Aurora MySQL binary log compression setting is turned on. Such transactions are replicated without being compressed.
- If you use a connector for change data capture (CDC) that doesn't support MySQL 8.0 yet, you can't use this feature. We recommend that you test any third-party connectors thoroughly with binary log compression. Also, we recommend that you do so before turning on binlog compression on systems that use binlog replication for CDC.

## Comparing Aurora MySQL version 3 and MySQL 8.0 Community Edition

You can use the following information to learn about the changes to be aware of when you convert from a different MySQL 8.0–compatible system to Aurora MySQL version 3.

In general, Aurora MySQL version 3 supports the feature set of community MySQL 8.0.23. Some new features from MySQL 8.0 community edition don't apply to Aurora MySQL. Some of those features aren't compatible with some aspect of Aurora, such as the Aurora storage architecture. Other features aren't needed because the Amazon RDS management service provides equivalent functionality. The following features in community MySQL 8.0 aren't supported or work differently in Aurora MySQL version 3.

For release notes for all Aurora MySQL version 3 releases, see [Database engine updates for Amazon Aurora MySQL version 3](#) in the *Release Notes for Aurora MySQL*.

## Topics

- [MySQL 8.0 features not available in Aurora MySQL version 3](#)
- [Role-based privilege model](#)
- [Finding the database server ID](#)
- [Authentication](#)

## MySQL 8.0 features not available in Aurora MySQL version 3

The following features from community MySQL 8.0 aren't available or work differently in Aurora MySQL version 3.

- Resource groups and associated SQL statements aren't supported in Aurora MySQL.
- Aurora MySQL doesn't support user-defined undo tablespaces and associated SQL statements, such as `CREATE UNDO TABLESPACE`, `ALTER UNDO TABLESPACE . . . SET INACTIVE`, and `DROP UNDO TABLESPACE`.
- Aurora MySQL doesn't support undo tablespace truncation for Aurora MySQL versions lower than 3.06. In Aurora MySQL version 3.06 and higher, [automated undo tablespace truncation](#) is supported.
- Password validation plugin is supported.
- You can't modify the settings of any MySQL plugins, including password validation plugin.
- The X plugin isn't supported.
- Multisource replication isn't supported.

## Role-based privilege model

With Aurora MySQL version 3, you can't modify the tables in the `mysql` database directly. In particular, you can't set up users by inserting into the `mysql.user` table. Instead, you use SQL statements to grant role-based privileges. You also can't create other kinds of objects such as stored procedures in the `mysql` database. You can still query the `mysql` tables. If you use binary log replication, changes made directly to the `mysql` tables on the source cluster aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the `mysql` tables. If so, change your application code to use the corresponding statements such as `CREATE USER`. If your application creates stored procedures or other objects in the `mysql` database, use a different database instead.

To export metadata for database users during the migration from an external MySQL database, you can use a MySQL Shell command instead of `mysqldump`. For more information, see [Instance Dump Utility, Schema Dump Utility, and Table Dump Utility](#).

To simplify managing permissions for many users or applications, you can use the `CREATE ROLE` statement to create a role that has a set of permissions. Then you can use the `GRANT` and `SET ROLE` statements and the `current_role` function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see [Using Roles](#) in the MySQL Reference Manual.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

## Topics

- [rds\\_superuser\\_role](#)
- [Privilege checks user for binary log replication](#)
- [Roles for accessing other Amazon services](#)

## **rds\_superuser\_role**

Aurora MySQL version 3 includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each cluster already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

- ALTER
- APPLICATION\_PASSWORD\_ADMIN
- ALTER ROUTINE
- CONNECTION\_ADMIN
- CREATE
- CREATE ROLE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- DROP ROLE
- EVENT
- EXECUTE
- FLUSH\_OPTIMIZER\_COSTS (Aurora MySQL version 3.09 and higher)
- FLUSH\_STATUS (Aurora MySQL version 3.09 and higher)
- FLUSH\_TABLES (Aurora MySQL version 3.09 and higher)
- FLUSH\_USER\_RESOURCES (Aurora MySQL version 3.09 and higher)
- INDEX
- INSERT
- LOCK TABLES
- PROCESS

- REFERENCES
- RELOAD
- REPLICATION CLIENT
- REPLICATION SLAVE
- ROLE\_ADMIN
- SET\_USER\_ID
- SELECT
- SHOW DATABASES
- SHOW\_ROUTINE (Aurora MySQL version 3.04 and higher)
- SHOW VIEW
- TRIGGER
- UPDATE
- XA\_RECOVER\_ADMIN

The role definition also includes `WITH GRANT OPTION` so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the Aurora MySQL cluster as the target.

### Tip

To see the full details of the permissions, enter the following statements.

```
SHOW GRANTS FOR rds_superuser_role@'%';  
SHOW GRANTS FOR name_of_administrative_user_for_your_cluster@'%';
```

## Privilege checks user for binary log replication

Aurora MySQL version 3 includes a privilege checks user for binary log (binlog) replication, `rdsrepladmin_priv_checks_user`. In addition to the privileges of `rds_superuser_role`, this user has the `replication_applier` privilege.

When you turn on binlog replication by calling the `mysql.rds_start_replication` stored procedure, `rdsrepladmin_priv_checks_user` is created.

The `rdsrepladmin_priv_checks_user@localhost` user is a reserved user. Don't modify it.

## Roles for accessing other Amazon services

Aurora MySQL version 3 includes roles that you can use to access other Amazon services. You can set many of these roles as an alternative to granting privileges. For example, you specify `GRANT AWS_LAMBDA_ACCESS TO user` instead of `GRANT INVOKE LAMBDA ON *.* TO user`. For the procedures to access other Amazon services, see [Integrating Amazon Aurora MySQL with other Amazon services](#). Aurora MySQL version 3 includes the following roles related to accessing other Amazon services:

- `AWS_LAMBDA_ACCESS` – An alternative to the `INVOKE LAMBDA` privilege. For usage information, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](#).
- `AWS_LOAD_S3_ACCESS` – An alternative to the `LOAD FROM S3` privilege. For usage information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).
- `AWS_SELECT_S3_ACCESS` – An alternative to the `SELECT INTO S3` privilege. For usage information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).
- `AWS_COMPREHEND_ACCESS` – An alternative to the `INVOKE COMPREHEND` privilege. For usage information, see [Granting database users access to Aurora machine learning](#).
- `AWS_SAGEMAKER_ACCESS` – An alternative to the `INVOKE SAGEMAKER` privilege. For usage information, see [Granting database users access to Aurora machine learning](#).
- `AWS_BEDROCK_ACCESS` – There's no analogous `INVOKE` privilege for Amazon Bedrock. For usage information, see [Granting database users access to Aurora machine learning](#).

When you grant access by using roles in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. The following example shows how. Substitute the appropriate role name for `AWS_SELECT_S3_ACCESS`.

```
# Grant role to user.

mysql> GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the AWS_SELECT_S3_ACCESS role
has not been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
```

```

+-----+
| CURRENT_ROLE()          |
+-----+
| `rds_superuser_role`@`%` |
+-----+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)

# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE()          |
+-----+
| `AWS_SELECT_S3_ACCESS`@`%`,`rds_superuser_role`@`%` |
+-----+

```

## Finding the database server ID

The database server ID (`server_id`) is required for binary logging (binlog) replication. The way to find the server ID is different in Aurora MySQL from Community MySQL.

In Community MySQL, the server ID is a number, which you obtain by using the following syntax while logged into the server:

```

mysql> select @@server_id;

+-----+
| @@server_id |
+-----+
| 2           |
+-----+
1 row in set (0.00 sec)

```

In Aurora MySQL, the server ID is the DB instance ID, which you obtain by using the following syntax while logged into the DB instance:

```

mysql> select @@aurora_server_id;

```

```
+-----+
| @@aurora_server_id |
+-----+
| mydbcluster-instance-2 |
+-----+
1 row in set (0.00 sec)
```

For more information on binlog replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

## Authentication

In community MySQL 8.0, the default authentication plugin is `caching_sha2_password`. Aurora MySQL version 3 still uses the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting. You can, however, create new users and alter current users, and their individual passwords use the new authentication plugin. Following is an example.

```
mysql> CREATE USER 'testnewsha'@'%' IDENTIFIED WITH caching_sha2_password BY
      'aNewShaPassword';
Query OK, 0 rows affected (0.74 sec)
```

## Upgrading to Aurora MySQL version 3

For information on upgrading your database from Aurora MySQL version 2 to version 3, see [Upgrading the major version of an Amazon Aurora MySQL DB cluster](#).

## Aurora MySQL version 2 compatible with MySQL 5.7

This topic describes the differences between Aurora MySQL version 2 and MySQL 5.7 Community Edition.

### Important

Aurora MySQL version 2 reached the end of standard support on October 31, 2024. For more information, see [Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support](#).

## Features not supported in Aurora MySQL version 2

The following features are supported in MySQL 5.7, but are currently not supported in Aurora MySQL version 2:

- CREATE TABLESPACE SQL statement
- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin – You can install the plugin, but it isn't supported. You can't customize the plugin.
- Query rewrite plugins
- Replication filtering
- X Protocol

For more information about these features, see the [MySQL 5.7 documentation](#).

## Temporary tablespace behavior in Aurora MySQL version 2

In MySQL 5.7, the temporary tablespace is autoextending and increases in size as necessary to accommodate on-disk temporary tables. When temporary tables are dropped, freed space can be reused for new temporary tables, but the temporary tablespace remains at the extended size and doesn't shrink. The temporary tablespace is dropped and re-created when engine is restarted.

In Aurora MySQL version 2, the following behavior applies:

- For new Aurora MySQL DB clusters created with version 2.10 and higher, the temporary tablespace is removed and re-created when you restart the database. This allows the dynamic resizing feature to reclaim the storage space.
- For existing Aurora MySQL DB clusters upgraded to:
  - Version 2.10 or higher – The temporary tablespace is removed and re-created when you restart the database. This allows the dynamic resizing feature to reclaim the storage space.

- Version 2.09 – Temporary table space isn't removed when you restart the database.

You can check the size of the temporary tablespace on your Aurora MySQL version 2 DB cluster by using the following query:

```
SELECT
  FILE_NAME,
  TABLESPACE_NAME,
  ROUND((TOTAL_EXTENTS * EXTENT_SIZE) / 1024 / 1024 / 1024, 4) AS SIZE
FROM
  INFORMATION_SCHEMA.FILES
WHERE
  TABLESPACE_NAME = 'innodb_temporary';
```

For more information, see [The Temporary Tablespace](#) in the MySQL documentation.

## Storage engine for on-disk temporary tables

Aurora MySQL version 2 uses different storage engines for on-disk internal temporary tables depending on the role of the instance.

- On the writer instance, on-disk temporary tables use the InnoDB storage engine by default. They're stored in the temporary tablespace in the Aurora cluster volume.

You can change this behavior on the writer instance by modifying the value for the DB parameter `internal_tmp_disk_storage_engine`. For more information, see [Instance-level parameters](#).

- On reader instances, on-disk temporary tables use the MyISAM storage engine, which uses local storage. That's because read-only instances can't store any data on the Aurora cluster volume.

# Security with Amazon Aurora MySQL

Security for Amazon Aurora MySQL is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora MySQL DB clusters and DB instances, you use Amazon Identity and Access Management (IAM). When you connect to Amazon using IAM credentials, your Amazon account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management for Amazon Aurora](#)

If you are using IAM to access the Amazon RDS console, make sure to first sign in to the Amazon Web Services Management Console with your IAM user credentials. Then go to the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

- Make sure to create Aurora MySQL DB clusters in a virtual public cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora MySQL DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see [Amazon VPC and Amazon Aurora](#).

The supported VPC tenancy depends on the DB instance class used by your Aurora MySQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t2, db.t3, and db.t4g DB instance classes. All other Aurora MySQL DB instance classes support both default and dedicated VPC tenancy.

## Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Using T instance classes for development and testing](#).

For more information about instance classes, see [Amazon Aurora DB instance classes](#). For more information about default and dedicated VPC tenancy, see [Dedicated instances](#) in the *Amazon Elastic Compute Cloud User Guide*.

- To authenticate login and permissions for an Amazon Aurora MySQL DB cluster, you can take either of the following approaches, or a combination of them:
  - You can take the same approach as with a standalone instance of MySQL.

Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in on-premises databases, as does directly modifying database schema tables. For more information, see [Access control and account management](#) in the MySQL documentation.

- You can also use IAM database authentication.

With IAM database authentication, you authenticate to your DB cluster by using an IAM user or IAM role and an authentication token. An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your Amazon resources and your databases. For more information, see [IAM database authentication](#).

#### Note

For more information, see [Security in Amazon Aurora](#).

In the following sections, see information about user permissions for Aurora MySQL and TLS connections with Aurora MySQL DB clusters.

### Topics

- [Master user privileges with Amazon Aurora MySQL](#)
- [TLS connections to Aurora MySQL DB clusters](#)

## Master user privileges with Amazon Aurora MySQL

When you create an Amazon Aurora MySQL DB instance, the master user has the default privileges listed in [Master user account privileges](#).

To provide management services for each DB cluster, the `admin` and `rdadmin` users are created when the DB cluster is created. Attempting to drop, rename, change the password, or change privileges for the `rdadmin` account results in an error.

In Aurora MySQL version 2 DB clusters, the `admin` and `rdsadmin` users are created when the DB cluster is created. In Aurora MySQL version 3 DB clusters, the `admin`, `rdsadmin`, and `rds_superuser_role` users are created.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

For management of the Aurora MySQL DB cluster, the standard `kill` and `kill_query` commands have been restricted. Instead, use the Amazon RDS commands `rds_kill` and `rds_kill_query` to terminate user sessions or queries on Aurora MySQL DB instances.

### Note

Encryption of a database instance and snapshots is not supported for the China (Ningxia) region.

## TLS connections to Aurora MySQL DB clusters

Amazon Aurora MySQL DB clusters support Transport Layer Security (TLS) connections from applications using the same process and public key as RDS for MySQL DB instances.

Amazon RDS creates an TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The TLS certificate includes the DB instance endpoint as the Common Name (CN) for the TLS certificate to guard against spoofing attacks. As a result, you can only use the DB cluster endpoint to connect to a DB cluster using TLS if your client supports Subject Alternative Names (SAN). Otherwise, you must use the instance endpoint of a writer instance.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

We recommend the Amazon JDBC Driver as a client that supports SAN with TLS. For more information about the Amazon JDBC Driver and complete instructions for using it, see the [Amazon Web Services \(Amazon\) JDBC Driver GitHub repository](#).

## Topics

- [Requiring a TLS connection to an Aurora MySQL DB cluster](#)
- [TLS versions for Aurora MySQL](#)
- [Configuring cipher suites for connections to Aurora MySQL DB clusters](#)
- [Encrypting connections to an Aurora MySQL DB cluster](#)

## Requiring a TLS connection to an Aurora MySQL DB cluster

You can require that all user connections to your Aurora MySQL DB cluster use TLS by using the `require_secure_transport` DB cluster parameter. By default, the `require_secure_transport` parameter is set to `OFF`. You can set the `require_secure_transport` parameter to `ON` to require TLS for connections to your DB cluster.

You can set the `require_secure_transport` parameter value by updating the DB cluster parameter group for your DB cluster. You don't need to reboot your DB cluster for the change to take effect. For more information on parameter groups, see [Parameter groups for Amazon Aurora](#).

### Note

The `require_secure_transport` parameter is available for Aurora MySQL version 2 and 3. You can set this parameter in a custom DB cluster parameter group. The parameter isn't available in DB instance parameter groups.

When the `require_secure_transport` parameter is set to `ON` for a DB cluster, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

## TLS versions for Aurora MySQL

Aurora MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. Starting in Aurora MySQL version 3.04.0 and higher, you can use the TLS 1.3 protocol to secure your connections. The following table shows the TLS support for Aurora MySQL versions.

Aurora MySQL version	TLS 1.0	TLS 1.1	TLS 1.2	TLS 1.3	Default
Aurora MySQL version 2	Deprecated	Deprecated	Supported	Not supported	All supported TLS versions
Aurora MySQL version 3 (lower than 3.04.0)	Deprecated	Deprecated	Supported	Not supported	All supported TLS versions
Aurora MySQL version 3 (3.04.0 and higher)	Not supported	Not supported	Supported	Supported	All supported TLS versions

### Important

If you're using custom parameter groups for your Aurora MySQL clusters with version 2 and versions lower than 3.04.0, we recommend using TLS 1.2 because TLS 1.0 and 1.1 are less secure. The community edition of MySQL 8.0.26 and Aurora MySQL 3.03 and its minor versions deprecated support for TLS versions 1.1 and 1.0.

The community edition of MySQL 8.0.28 and compatible Aurora MySQL versions 3.04.0 and higher do not support TLS 1.1 and TLS 1.0. If you're using Aurora MySQL version 3.04.0 or higher, do not set the TLS protocol to 1.0 and 1.1 in your custom parameter group.

For Aurora MySQL versions 3.04.0 and higher, the default setting is TLS 1.3 and TLS 1.2.

You can use the `tls_version` DB cluster parameter to indicate the permitted protocol versions. Similar client parameters exist for most client tools or database drivers. Some older clients might not support newer TLS versions. By default, the DB cluster attempts to use the highest TLS protocol version allowed by both the server and client configuration.

Set the `tls_version` DB cluster parameter to one of the following values:

- TLSv1.3
- TLSv1.2
- TLSv1.1
- TLSv1

You can also set the `tls_version` parameter as a string of comma-separated list. If you want to use both TLS 1.2 and TLS 1.3 protocols, the `tls_version` parameter must include all protocols from the lowest to the highest protocol. In this case, `tls_version` is set as:

```
tls_version=TLSv1.2,TLSv1.3
```

For information about modifying parameters in a DB cluster parameter group, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#). If you use the Amazon CLI to modify the `tls_version` DB cluster parameter, the `ApplyMethod` must be set to `pending-reboot`. When the application method is `pending-reboot`, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

## Configuring cipher suites for connections to Aurora MySQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of insecure or deprecated ciphers.

Configurable cipher suites are supported in Aurora MySQL version 3 and Aurora MySQL version 2. To specify the list of permissible TLS 1.2, TLS 1.1, TLS 1.0 ciphers for encrypting connections, modify the `ssl_cipher` cluster parameter. Set the `ssl_cipher` parameter in a cluster parameter group using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

Set the `ssl_cipher` parameter to a string of comma-separated cipher values for your TLS version. For the client application, you can specify the ciphers to use for encrypted connections by using the `--ssl-cipher` option when connecting to the database. For more about connecting to your database, see [Connecting to an Amazon Aurora MySQL DB cluster](#).

Starting in Aurora MySQL version 3.04.0 and higher, you can specify TLS 1.3 cipher suites. To specify the permissible TLS 1.3 cipher suites, modify the `tls_ciphersuites` parameter in your parameter group. TLS 1.3 has reduced the number of available cipher suites due to changes in the naming convention that removes the key exchange mechanism and certificate used. Set the `tls_ciphersuites` to a string of comma-separated cipher values for TLS 1.3.

The following table shows the supported ciphers along with the TLS encryption protocol and valid Aurora MySQL engine versions for each cipher.

Cipher	Encryption protocol	Supported Aurora MySQL versions
ECDHE-RSA-AES128-SHA	TLS 1.0	3.04.0 and higher, 2.11.0 and higher
ECDHE-RSA-AES128-SHA256	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
ECDHE-RSA-AES128-GCM-SHA256	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
ECDHE-RSA-AES256-SHA	TLS 1.0	3.04.0 and higher, 2.11.0 and higher
ECDHE-RSA-AES256-GCM-SHA384	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
ECDHE-RSA-CHACHA20-POLY1305	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
ECDHE-ECDSA-AES128-SHA	TLS 1.0	3.04.0 and higher, 2.11.0 and higher
ECDHE-ECDSA-AES256-SHA	TLS 1.0	3.04.0 and higher, 2.11.0 and higher
ECDHE-ECDSA-AES128-GCM-SHA256	TLS 1.2	3.04.0 and higher, 2.11.0 and higher

Cipher	Encryption protocol	Supported Aurora MySQL versions
ECDHE-ECDSA-AES256-GCM-SHA384	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
ECDHE-ECDSA-CHACHA20-POLY1305	TLS 1.2	3.04.0 and higher, 2.11.0 and higher
TLS_AES_128_GCM_SHA256	TLS 1.3	3.04.0 and higher
TLS_AES_256_GCM_SHA384	TLS 1.3	3.04.0 and higher
TLS_CHACHA20_POLY1305_SHA256	TLS 1.3	3.04.0 and higher

For information about modifying parameters in a DB cluster parameter group, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#). If you use the CLI to modify the `ssl_cipher` DB cluster parameter, make sure to set the `ApplyMethod` to `pending-reboot`. When the application method is `pending-reboot`, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

You can also use the [describe-engine-default-cluster-parameters](#) CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora MySQL version 2.

```
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-mysql5.7
```

```
...some output truncated...
```

```
{
  "ParameterName": "ssl_cipher",
  "ParameterValue": "ECDHE-RSA-AES128-SHA, ECDHE-RSA-AES128-SHA256, ECDHE-RSA-AES128-GCM-SHA256, ECDHE-RSA-AES256-SHA, ECDHE-RSA-AES256-GCM-SHA384, ECDHE-RSA-CHACHA20-POLY1305, ECDHE-ECDSA-AES256-SHA, ECDHE-ECDSA-CHACHA20-POLY1305, ECDHE-ECDSA-AES256-GCM-SHA384, ECDHE-ECDSA-AES128-GCM-SHA256, ECDHE-ECDSA-AES128-SHA",
```

```

    "Description": "The list of permissible ciphers for connection encryption.",
    "Source": "system",
    "ApplyType": "static",
    "DataType": "list",
    "AllowedValues": "ECDHE-RSA-AES128-SHA,ECDHE-RSA-AES128-SHA256,ECDHE-RSA-

POLY1305,ECDHE-ECDSA-AES256-SHA,ECDHE-ECDSA-CHACHA20-POLY1305,ECDHE-ECDSA-AES256-GCM-
SHA384,ECDHE-ECDSA-AES128-GCM-SHA256,ECDHE-ECDSA-AES128-SHA",
    "IsModifiable": true,
    "SupportedEngineModes": [
        "provisioned"
    ]
},
...some output truncated...

```

For more information about ciphers, see the [ssl\\_cipher](#) variable in the MySQL documentation. For more information about cipher suite formats, see the [openssl-ciphers list format](#) and [openssl-ciphers string format](#) documentation on the OpenSSL website.

## Encrypting connections to an Aurora MySQL DB cluster

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, for example:

For MySQL 5.7 and 8.0:

```
mysql -h myinstance.123456789012.rds-cn-north-1.amazonaws.com
--ssl-ca=full_path_to_CA_certificate --ssl-mode=VERIFY_IDENTITY
```

For MySQL 5.6:

```
mysql -h myinstance.123456789012.rds-cn-north-1.amazonaws.com
--ssl-ca=full_path_to_CA_certificate --ssl-verify-server-cert
```

Replace *full\_path\_to\_CA\_certificate* with the full path to your Certificate Authority (CA) certificate. For information about downloading a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

You can require TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require TLS connections on the user account `encrypted_user`.

### For MySQL 5.7 and 8.0:

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

### For MySQL 5.6:

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

When you use an RDS Proxy, you connect to the proxy endpoint instead of the usual cluster endpoint. You can make SSL/TLS required or optional for connections to the proxy, in the same way as for connections directly to the Aurora DB cluster. For information about using RDS Proxy, see [Amazon RDS Proxy for Aurora](#).

#### Note

For more information on TLS connections with MySQL, see the [MySQL documentation](#).

# Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Transport Layer Security (TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

## Note

Some applications are configured to connect to Aurora MySQL DB clusters only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster](#). For information about using TLS with Aurora MySQL DB clusters, see [TLS connections to Aurora MySQL DB clusters](#).

## Topics

- [Determining whether any applications are connecting to your Aurora MySQL DB cluster using TLS](#)
- [Determining whether a client requires certificate verification to connect](#)
- [Updating your application trust store](#)
- [Example Java code for establishing TLS connections](#)

## Determining whether any applications are connecting to your Aurora MySQL DB cluster using TLS

If you are using Aurora MySQL version 2 (compatible with MySQL 5.7) and the Performance Schema is enabled, run the following query to check if connections are using TLS. For information about enabling the Performance Schema, see [Performance Schema quick start](#) in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
        FROM performance_schema.threads pst
        INNER JOIN information_schema.processlist isp
        ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using TLS.

```
+----+-----+-----+-----+
| id | user          | host          | connection_type |
+----+-----+-----+-----+
|  8 | admin         | 10.0.4.249:42590 | SSL/TLS         |
|  4 | event_scheduler | localhost      | NULL            |
| 10 | webapp1       | 159.28.1.1:42189 | SSL/TLS       |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
```

## Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

### JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an TLS connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

### Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use TLS when connecting to your databases, these client drivers default to using TLS. In addition, when using TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

## MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an TLS connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
--ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
--ssl-verify-server-cert
```

## Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

## Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for TLS connections.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);  
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -  
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

## Example Java code for establishing TLS connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {
```

```
private static final String DB_USER = "user name";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void test(String[] args) throws Exception {
    Class.forName("com.mysql.jdbc.Driver");

    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

    Properties properties = new Properties();
    properties.setProperty("sslMode", "VERIFY_IDENTITY");
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);

    Connection connection = DriverManager.getConnection("jdbc:mysql://jagdeeps-ssl-
test.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306",properties);
    Statement stmt=connection.createStatement();

    ResultSet rs=stmt.executeQuery("SELECT 1 from dual");

    return;
}
}
```

### Important

After you have determined that your database connections use TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance](#).

# Using Kerberos authentication for Aurora MySQL

You can use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB cluster. To do so, configure your DB cluster to use Amazon Directory Service for Microsoft Active Directory for Kerberos authentication. Amazon Directory Service for Microsoft Active Directory is also called Amazon Managed Microsoft AD. It's a feature available with Amazon Directory Service. To learn more, see [What is Amazon Directory Service?](#) in the *Amazon Directory Service Administration Guide*.

To start, create an Amazon Managed Microsoft AD directory to store user credentials. Then, provide the Active Directory's domain and other information to your Aurora MySQL DB cluster. When users authenticate with the Aurora MySQL DB cluster, authentication requests are forwarded to the Amazon Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized location for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the Amazon Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your Aurora MySQL DB clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, Amazon Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, because Kerberos and IAM authentication provide different authentication methods, a specific user can log in to a database using only one or the other authentication method, but not both. For more information about IAM authentication, see [IAM database authentication](#).

## Overview of Kerberos authentication for Aurora MySQL DB clusters

To set up Kerberos authentication for an Aurora MySQL DB cluster, complete the following general steps. These steps are described in more detail later.

1. Use Amazon Managed Microsoft AD to create an Amazon Managed Microsoft AD directory. You can use the Amazon Web Services Management Console, the Amazon CLI, or the Amazon Directory Service to create the directory. For detailed instructions, see [Create your Amazon Managed Microsoft AD directory](#) in the *Amazon Directory Service Administration Guide*.
2. Create an Amazon Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The role allows Amazon Aurora to make calls to your directory.

For the role to allow access, the Amazon Security Token Service (Amazon STS) endpoint must be activated in the Amazon Web Services Region for your Amazon account. Amazon STS endpoints are active by default in all Amazon Web Services Regions, and you can use them without any further action. For more information, see [Activating and deactivating Amazon STS in an Amazon Web Services Region](#) in the *IAM User Guide*.

3. Create and configure users in the Amazon Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in Amazon managed Microsoft AD](#) in the *Amazon Directory Service Administration Guide*.
4. Create or modify an Aurora MySQL DB cluster. If you use either the CLI or RDS API in the create request, specify a domain identifier with the `Domain` parameter. Use the `d-*` identifier that was generated when you created your directory and the name of the IAM role that you created.

If you modify an existing Aurora MySQL DB cluster to use Kerberos authentication, set the domain and IAM role parameters for the DB cluster. Locate the DB cluster in the same VPC as the domain directory.

5. Use the Amazon RDS primary user credentials to connect to the Aurora MySQL DB cluster. Create the database user in Aurora MySQL by using the instructions in [Step 6: Create Aurora MySQL users that use Kerberos authentication](#).

Users that you create this way can log in to the Aurora MySQL DB cluster using Kerberos authentication. For more information, see [Connecting to Aurora MySQL with Kerberos authentication](#).

To use Kerberos authentication with an on-premises or self-hosted Microsoft Active Directory, create a *forest trust*. A forest trust is a trust relationship between two groups of domains. The trust can be one-way or two-way. For more information about setting up forest trusts using Amazon Directory Service, see [When to create a trust relationship](#) in the *Amazon Directory Service Administration Guide*.

## Limitations of Kerberos authentication for Aurora MySQL

The following limitations apply to Kerberos authentication for Aurora MySQL:

- Kerberos authentication is supported for Aurora MySQL version 3.03 and higher.

For information about Amazon Web Services Region support, see [Kerberos authentication with Aurora MySQL](#).

- To use Kerberos authentication with Aurora MySQL, your MySQL client or connector must use version 8.0.26 or higher on Unix platforms, 8.0.27 or higher on Windows. Otherwise, the client-side `authentication_kerberos_client` plugin isn't available and you can't authenticate.

- Only Amazon Managed Microsoft AD is supported on Aurora MySQL. However, you can join Aurora MySQL DB clusters to shared Managed Microsoft AD domains owned by different accounts in the same Amazon Web Services Region.

You can also use your own on-premises Active Directory. For more information, see [Step 2: \(Optional\) Create a trust for an on-premises Active Directory](#).

- When using Kerberos to authenticate a user connecting to the Aurora MySQL cluster from MySQL clients or from drivers on the Windows operating system, by default the character case of the database username must match the case of the user in the Active Directory. For example, if the user in the Active Directory appears as Admin, the database username must be Admin.

However, you can now use case-insensitive username comparison with the `authentication_kerberos` plugin. For more information, see [Step 8: \(Optional\) Configure case-insensitive username comparison](#).

- You must reboot the reader DB instances after turning on the feature to install the `authentication_kerberos` plugin.
- Replicating to DB instances that don't support the `authentication_kerberos` plugin can lead to replication failure.
- For Aurora global databases to use Kerberos authentication, you must configure it for every DB cluster in the global database.
- The domain name must be less than 62 characters long.
- Don't modify the DB cluster port after turning on Kerberos authentication. If you modify the port, then Kerberos authentication will no longer work.

## Setting up Kerberos authentication for Aurora MySQL DB clusters

Use Amazon Managed Microsoft AD to set up Kerberos authentication for an Aurora MySQL DB cluster. To set up Kerberos authentication, take the following steps.

### Topics

- [Step 1: Create a directory using Amazon Managed Microsoft AD](#)
- [Step 2: \(Optional\) Create a trust for an on-premises Active Directory](#)
- [Step 3: Create an IAM role for use by Amazon Aurora](#)
- [Step 4: Create and configure users](#)
- [Step 5: Create or modify an Aurora MySQL DB cluster](#)

- [Step 6: Create Aurora MySQL users that use Kerberos authentication](#)
- [Step 7: Configure a MySQL client](#)
- [Step 8: \(Optional\) Configure case-insensitive username comparison](#)

## Step 1: Create a directory using Amazon Managed Microsoft AD

Amazon Directory Service creates a fully managed Active Directory in the Amazon Cloud. When you create an Amazon Managed Microsoft AD directory, Amazon Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an Amazon Managed Microsoft AD directory, Amazon Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the username `Admin` and the specified password. You use this account to manage your directory.

### Note

Be sure to save this password. Amazon Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an Amazon Managed Microsoft AD, Amazon creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you entered when you created your directory. It is located in the domain root, which is owned and managed by Amazon.

The `Admin` account that was created with your Amazon Managed Microsoft AD directory has permissions for the most common administrative activities for your OU, including:

- Create, update, or delete users
- Add resources to your domain, such as file or print servers, and then assign permissions for those resources to users in your OU

- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

### To create a directory with Amazon Managed Microsoft AD

1. Sign in to the Amazon Web Services Management Console and open the Amazon Directory Service console at <https://console.amazonaws.cn/directoryservicev2/>.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **Amazon Managed Microsoft AD**. Amazon Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

#### Directory DNS name

The fully qualified name for the directory, such as **corp.example.com**.

#### Directory NetBIOS name

The short name for the directory, such as **CORP**.

#### Directory description

(Optional) A description for the directory.

#### Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the username Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#\$%^&\* \_-+= ` \(){}[];:"'<>,.?/)

### Confirm password

The administrator password re-entered.

5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

### VPC

The VPC for the directory. Create the Aurora MySQL DB cluster in this same VPC.

### Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

Directory details page during creation

It takes several minutes to create the directory. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Aurora MySQL DB cluster.

Directory ID in the Directory details page

## Step 2: (Optional) Create a trust for an on-premises Active Directory

If you don't plan to use your own on-premises Microsoft Active Directory, skip to [Step 3: Create an IAM role for use by Amazon Aurora](#).

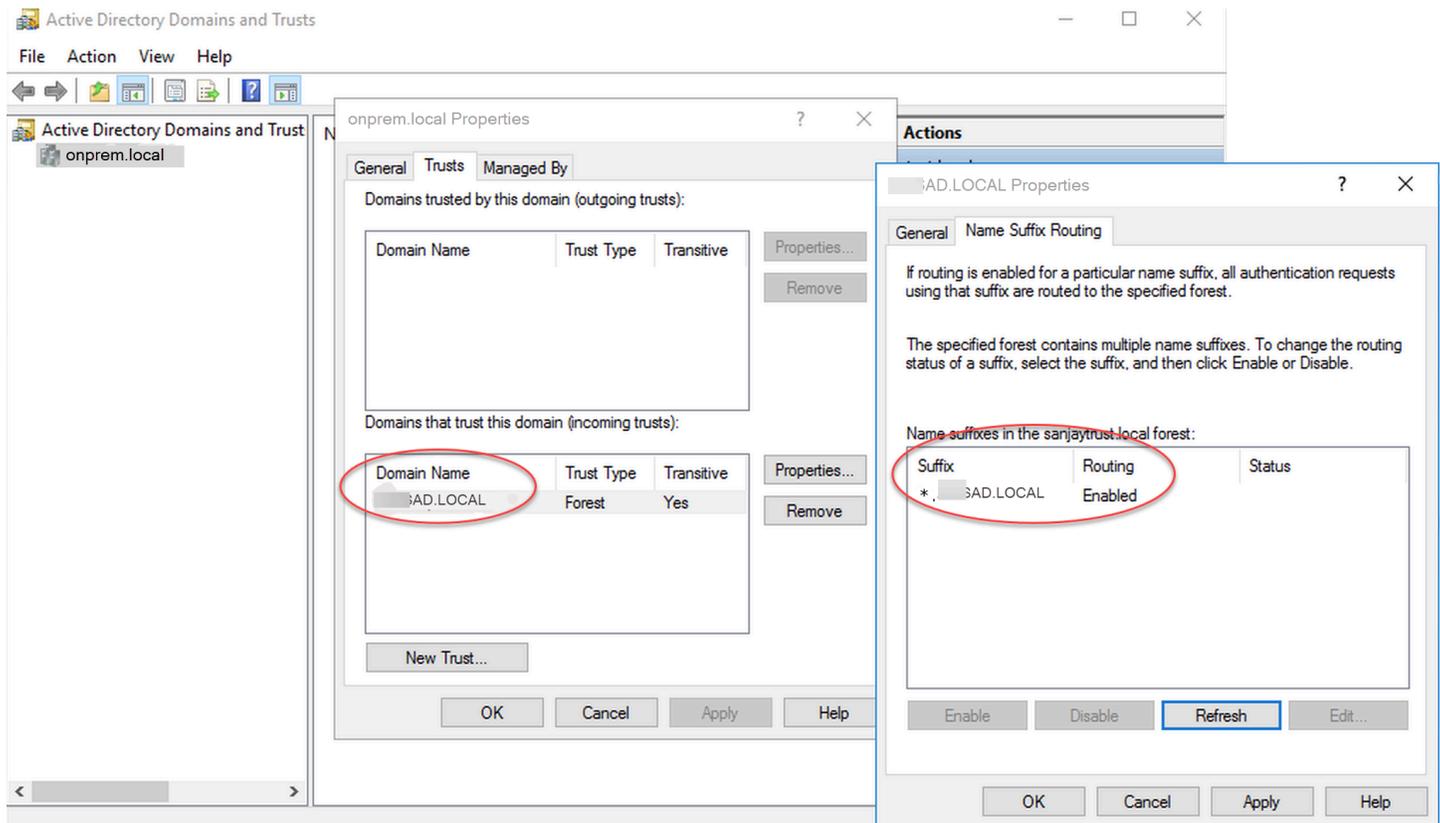

To use Kerberos authentication with your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the Amazon Managed Microsoft AD directory (created in [Step 1: Create a directory using Amazon Managed Microsoft AD](#)). The trust can be one-way, where the Amazon Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using Amazon Directory Service, see [When to create a trust relationship](#) in the *Amazon Directory Service Administration Guide*.

 **Note**

If you use an on-premises Microsoft Active Directory:

- Windows clients can't connect using Aurora custom endpoints. To learn more, see [Amazon Aurora endpoint connections](#).
- For [global databases](#):
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary Amazon Web Services Region of the global database only.
  - Windows clients can't connect using cluster endpoints in secondary Amazon Web Services Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

### Step 3: Create an IAM role for use by Amazon Aurora

For Amazon Aurora to call Amazon Directory Service for you, you need an Amazon Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Aurora to make calls to the Amazon Directory Service.

When you create a DB cluster using the Amazon Web Services Management Console, and you have the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the Amazon managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an Amazon service](#) in the *IAM User Guide*.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

## Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an Amazon Directory Service directory, you use an on-premises or Amazon EC2 instance based on Microsoft Windows that is joined to your Amazon Directory Service directory. You must be logged in to the instance as a user that has privileges to create users. For more information, see [Manage users and groups in Amazon Managed Microsoft AD](#) in the *Amazon Directory Service Administration Guide*.

## Step 5: Create or modify an Aurora MySQL DB cluster

Create or modify an Aurora MySQL DB cluster for use with your directory. You can use the console, Amazon CLI, or RDS API to associate a DB cluster with a directory. You can do this task in one of the following ways:

- Create a new Aurora MySQL DB cluster using the console, the [create-db-cluster](#) CLI command, or the [CreateDBCluster](#) RDS API operation.

For instructions, see [Creating an Amazon Aurora DB cluster](#).

- Modify an existing Aurora MySQL DB cluster using the console, the [modify-db-cluster](#) CLI command, or the [ModifyDBCluster](#) RDS API operation.

For instructions, see [Modifying an Amazon Aurora DB cluster](#).

- Restore an Aurora MySQL DB cluster from a DB snapshot using the console, the [restore-db-cluster-from-snapshot](#) CLI command, or the [RestoreDBClusterFromSnapshot](#) RDS API operation.

For instructions, see [Restoring from a DB cluster snapshot](#).

- Restore an Aurora MySQL DB cluster to a point-in-time using the console, the [restore-db-cluster-to-point-in-time](#) CLI command, or the [RestoreDBClusterToPointInTime](#) RDS API operation.

For instructions, see [Restoring a DB cluster to a specified time](#).

Kerberos authentication is only supported for Aurora MySQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster's VPC must have a VPC security group that allows outbound communication to your directory.

## Console

When you use the console to create, modify, or restore a DB cluster, choose **Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

Kerberos authentication setting when creating a DB cluster

## Amazon CLI

When you use the Amazon CLI or RDS API, associate a DB cluster with a directory. The following parameters are required for the DB cluster to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB cluster to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --domain d-ID \  
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --domain d-ID ^  
  --domain-iam-role-name role-name
```

### Important

If you modify a DB cluster to turn on Kerberos authentication, reboot the reader DB instances after making the change.

## Step 6: Create Aurora MySQL users that use Kerberos authentication

The DB cluster is joined to the Amazon Managed Microsoft AD domain. Thus, you can create Aurora MySQL users from the Active Directory users in your domain. Database permissions are managed through standard Aurora MySQL permissions that are granted to and revoked from these users.

You can allow an Active Directory user to authenticate with Aurora MySQL. To do this, first use the Amazon RDS primary user credentials to connect to the Aurora MySQL DB cluster as with any other DB cluster. After you're logged in, create an externally authenticated user with Kerberos authentication in Aurora MySQL as shown here:

```
CREATE USER user_name@'host_name' IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';
```

- Replace *user\_name* with the username. Users (both humans and applications) from your domain can now connect to the DB cluster from a domain-joined client machine using Kerberos authentication.
- Replace *host\_name* with the hostname. You can use % as a wild card. You can also use specific IP addresses for the hostname.
- Replace *realm\_name* with the directory realm name of the domain. The realm name is usually the same as the DNS domain name in uppercase letters, such as CORP . EXAMPLE . COM. A realm is a group of systems that use the same Kerberos Key Distribution Center.

The following example creates a database user with the name Admin that authenticates against the Active Directory with the realm name MYSQL . LOCAL.

```
CREATE USER Admin@'%' IDENTIFIED WITH 'authentication_kerberos' BY 'MYSQL.LOCAL';
```

### Modifying an existing Aurora MySQL login

You can also modify an existing Aurora MySQL login to use Kerberos authentication by using the following syntax:

```
ALTER USER user_name IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';
```

## Step 7: Configure a MySQL client

To configure a MySQL client, take the following steps:

1. Create a `krb5.conf` file (or equivalent) to point to the domain.
2. Verify that traffic can flow between the client host and Amazon Directory Service. Use a network utility such as Netcat, for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for Amazon Directory Service.
3. Verify that traffic can flow between the client host and the DB instance over the database port. For example, use `mysql` to connect and access the database.

The following is sample `krb5.conf` content for Amazon Managed Microsoft AD.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
  EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
  }
[domain_realm]
  .example.com = EXAMPLE.COM
  example.com = EXAMPLE.COM
```

The following is sample `krb5.conf` content for an on-premises Microsoft Active Directory.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
  EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
  }
  ONPREM.COM = {
    kdc = onprem.com
    admin_server = onprem.com
  }
[domain_realm]
  .example.com = EXAMPLE.COM
  example.com = EXAMPLE.COM
  .onprem.com = ONPREM.COM
  onprem.com = ONPREM.COM
```

```
.rds.amazonaws.com = EXAMPLE.COM  
.amazonaws.com.cn = EXAMPLE.COM  
.amazon.com = EXAMPLE.COM
```

## Step 8: (Optional) Configure case-insensitive username comparison

By default, the character case of the MySQL database username must match that of the Active Directory login. However, you can now use case-insensitive username comparison with the `authentication_kerberos` plugin. To do so, you set the `authentication_kerberos_caseins_cmp` DB cluster parameter to `true`.

### To use case-insensitive username comparison

1. Create a custom DB cluster parameter group. Follow the procedures in [Creating a DB cluster parameter group in Amazon Aurora](#).
2. Edit the new parameter group to set the value of `authentication_kerberos_caseins_cmp` to `true`. Follow the procedures in [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).
3. Associate the DB cluster parameter group with your Aurora MySQL DB cluster. Follow the procedures in [Associating a DB cluster parameter group with a DB cluster in Amazon Aurora](#).
4. Reboot the DB cluster.

## Connecting to Aurora MySQL with Kerberos authentication

To avoid errors, use a MySQL client with version 8.0.26 or higher on Unix platforms, 8.0.27 or higher on Windows.

### Using the Aurora MySQL Kerberos login to connect to the DB cluster

To connect to Aurora MySQL with Kerberos authentication, you log in as a database user that you created using the instructions in [Step 6: Create Aurora MySQL users that use Kerberos authentication](#).

At a command prompt, connect to one of the endpoints associated with your Aurora MySQL DB cluster. When you're prompted for the password, enter the Kerberos password associated with that username.

When you authenticate with Kerberos, a *ticket-granting ticket* (TGT) is generated if one doesn't already exist. The `authentication_kerberos` plugin uses the TGT to get a *service ticket*, which is then presented to the Aurora MySQL database server.

You can use the MySQL client to connect to Aurora MySQL with Kerberos authentication using either Windows or Unix.

## Unix

You can connect by using either one of the following methods:

- Obtain the TGT manually. In this case, you don't need to supply the password to the MySQL client.
- Supply the password for the Active Directory login directly to the MySQL client.

The client-side plugin is supported on Unix platforms for MySQL client versions 8.0.26 and higher.

### To connect by obtaining the TGT manually

1. At the command line interface, use the following command to obtain the TGT.

```
kinit user_name
```

2. Use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

```
mysql -h DB_instance_endpoint -P 3306 -u user_name -p
```

#### Note

Authentication can fail if the keytab is rotated on the DB instance. In this case, obtain a new TGT by rerunning `kinit`.

### To connect directly

1. At the command line interface, use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

```
mysql -h DB_instance_endpoint -P 3306 -u user_name -p
```

2. Enter the password for the Active Directory user.

## Windows

On Windows, authentication is usually done at login time, so you don't need to obtain the TGT manually to connect to the Aurora MySQL DB cluster. The case of the database username must match the character case of the user in the Active Directory. For example, if the user in the Active Directory appears as Admin, the database username must be Admin.

The client-side plugin is supported on Windows for MySQL client versions 8.0.27 and higher.

### To connect directly

- At the command line interface, use the following `mysql` command to log in to the DB instance endpoint of your DB cluster.

```
mysql -h DB_instance_endpoint -P 3306 -u user_name
```

## Kerberos authentication with Aurora global databases

Kerberos authentication for Aurora MySQL is supported for Aurora global databases. To authenticate users on the secondary DB cluster using the Active Directory of the primary DB cluster, replicate the Active Directory to the secondary Amazon Web Services Region. You turn on Kerberos authentication on the secondary cluster using the same domain ID as for the primary cluster. Amazon Managed Microsoft AD replication is supported only with the Enterprise version of Active Directory. For more information, see [Multi-Region replication](#) in the *Amazon Directory Service Administration Guide*.

## Migrating from RDS for MySQL to Aurora MySQL

After you migrate from RDS for MySQL with Kerberos authentication enabled to Aurora MySQL, modify users created with the `auth_pam` plugin to use the `authentication_kerberos` plugin. For example:

```
ALTER USER user_name IDENTIFIED WITH 'authentication_kerberos' BY 'realm_name';
```

## Preventing ticket caching

If a valid TGT doesn't exist when the MySQL client application starts, the application can obtain and cache the TGT. If you want to prevent the TGT from being cached, set a configuration parameter in the `/etc/krb5.conf` file.

### Note

This configuration only applies to client hosts running Unix, not Windows.

### To prevent TGT caching

- Add an `[appdefaults]` section to `/etc/krb5.conf` as follows:

```
[appdefaults]
mysql = {
    destroy_tickets = true
}
```

## Logging for Kerberos authentication

The `AUTHENTICATION_KERBEROS_CLIENT_LOG` environment variable sets the logging level for Kerberos authentication. You can use the logs for client-side debugging.

The permitted values are 1–5. Log messages are written to the standard error output. The following table describes each logging level.

Logging level	Description
1 or not set	No logging
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages

Logging level	Description
5	Error, warning, information, and debug messages

## Managing a DB cluster in a domain

You can use the Amazon CLI or the RDS API to manage your DB cluster and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to turn off Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt turning on Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To turn off Kerberos authentication on a DB cluster, use the `ModifyDBInstance` API operation and specify `none` as the domain parameter.
- To move a DB cluster from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB cluster, use the `DescribeDBInstances` API operation.

## Understanding domain membership

After you create or modify your DB cluster, it becomes a member of the domain. You can view the status of the domain membership for the DB cluster by running the [describe-db-clusters](#) CLI command. The status of the DB cluster can be one of the following:

- `kerberos-enabled` – The DB cluster has Kerberos authentication turned on.
- `enabling-kerberos` – Amazon is in the process of turning on Kerberos authentication on this DB cluster.
- `pending-enable-kerberos` – Turning on Kerberos authentication is pending on this DB cluster.

- `pending-maintenance-enable-kerberos` – Amazon will attempt to turn on Kerberos authentication on the DB cluster during the next scheduled maintenance window.
- `pending-disable-kerberos` – Turning off Kerberos authentication is pending on this DB cluster.
- `pending-maintenance-disable-kerberos` – Amazon will attempt to turn off Kerberos authentication on the DB cluster during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented Amazon from turning on Kerberos authentication on the DB cluster. Check and fix your configuration before reissuing the DB cluster modify command.
- `disabling-kerberos` – Amazon is in the process of turning off Kerberos authentication on this DB cluster.

A request to turn on Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB cluster or modify an existing DB cluster and the attempt to turn on Kerberos authentication fails. In this case, reissue the modify command or modify the newly created DB cluster to join the domain.

# Migrating data to an Amazon Aurora MySQL DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora MySQL DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

There are two different types of migration: physical and logical. Physical migration means that physical copies of database files are used to migrate the database. Logical migration means that the migration is accomplished by applying logical database changes, such as inserts, updates, and deletes.

Physical migration has the following advantages:

- Physical migration is faster than logical migration, especially for large databases.
- Database performance does not suffer when a backup is taken for physical migration.
- Physical migration can migrate everything in the source database, including complex database components.

Physical migration has the following limitations:

- The `innodb_page_size` parameter must be set to its default value (16KB).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name `"ibdata1:12M:autoextend"`. Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

`"innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend"` and  
`"innodb_data_file_path=ibdata01:50M:autoextend"`.

- The `innodb_log_files_in_group` parameter must be set to its default value (2).

Logical migration has the following advantages:

- You can migrate subsets of the database, such as specific tables or parts of a table.
- The data can be migrated regardless of the physical storage structure.

Logical migration has the following limitations:

- Logical migration is usually slower than physical migration.
- Complex database components can slow down the logical migration process. In some cases, complex database components can even block logical migration.

The following table describes your options and the type of migration for each option.

Migrating from	Migration type	Solution
An RDS for MySQL DB instance	Physical	<p>You can migrate from an RDS for MySQL DB instance by first creating an Aurora MySQL read replica of a MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora MySQL read replica is 0, you can direct your client applications to read from the Aurora read replica and then stop replication to make the Aurora MySQL read replica a standalone Aurora MySQL DB cluster for reading and writing. For details, see <a href="#">Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica</a>.</p>
An RDS for MySQL DB snapshot	Physical	<p>You can migrate data directly from an RDS for MySQL DB snapshot to an Amazon Aurora MySQL DB cluster. For details, see <a href="#">Migrating an RDS for MySQL snapshot to Aurora</a>.</p>
A MySQL database external to Amazon RDS	Logical	<p>You can create a dump of your data using the <code>mysqldump</code> utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For details, see <a href="#">Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump</a>.</p> <p>To export metadata for database users during the migration from an external MySQL database, you can also use</p>

Migrating from	Migration type	Solution
		<p>a MySQL Shell command instead of <code>mysqldump</code> . For more information, see <a href="#">Instance Dump Utility, Schema Dump Utility, and Table Dump Utility</a>.</p> <div data-bbox="932 432 1508 653" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p> <b>Note</b></p> <p>The <a href="#">mysqlpump</a> utility is deprecated as of MySQL 8.0.34.</p> </div>
A MySQL database external to Amazon RDS	Physical	<p>You can copy the backup files from your database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using <code>mysqldump</code> . For details, see <a href="#">Physical migration from MySQL by using Percona XtraBackup and Amazon S3</a>.</p>
A MySQL database external to Amazon RDS	Logical	<p>You can save data from your database as text files and copy those files to an Amazon S3 bucket. You can then load that data into an existing Aurora MySQL DB cluster using the <code>LOAD DATA FROM S3</code> MySQL command. For more information, see <a href="#">Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket</a>.</p>

Migrating from	Migration type	Solution
A database that isn't MySQL-compatible	Logical	You can use Amazon Database Migration Service (Amazon DMS) to migrate data from a database that isn't MySQL-compatible. For more information on Amazon DMS, see <a href="#">What is Amazon database migration service?</a>

**Note**

If you're migrating a MySQL database external to Amazon RDS, the migration options described in the table are supported only if your database supports the InnoDB or MyISAM tablespaces.

If the MySQL database you're migrating to Aurora MySQL uses memcached, remove memcached before migrating it.

You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.

## Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

If your database supports the InnoDB or MyISAM tablespaces, you have these options for migrating your data to an Amazon Aurora MySQL DB cluster:

- You can create a dump of your data using the `mysqldump` utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For more information, see [Logical migration from MySQL to Amazon Aurora MySQL by using `mysqldump`](#).
- You can copy the full and incremental backup files from your database to an Amazon S3 bucket, and then restore to an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using `mysqldump`. For more information, see [Physical migration from MySQL by using Percona XtraBackup and Amazon S3](#).

### Topics

- [Physical migration from MySQL by using Percona XtraBackup and Amazon S3](#)
- [Logical migration from MySQL to Amazon Aurora MySQL by using `mysqldump`](#)

### Physical migration from MySQL by using Percona XtraBackup and Amazon S3

You can copy the full and incremental backup files from your source MySQL version 5.7 or 8.0 database to an Amazon S3 bucket. Then you can restore to an Amazon Aurora MySQL DB cluster with the same major DB engine version from those files.

This option can be considerably faster than migrating data using `mysqldump`, because using `mysqldump` replays all of the commands to recreate the schema and data from your source database in your new Aurora MySQL DB cluster. By copying your source MySQL data files, Aurora MySQL can immediately use those files as the data for an Aurora MySQL DB cluster.

You can also minimize downtime by using binary log replication during the migration process. If you use binary log replication, the external MySQL database remains open to transactions while the data is being migrated to the Aurora MySQL DB cluster. After the Aurora MySQL DB cluster has been created, you use binary log replication to synchronize the Aurora MySQL DB cluster with the transactions that happened after the backup. When the Aurora MySQL DB cluster is caught up with the MySQL database, you finish the migration by completely switching to the Aurora MySQL DB cluster for new transactions. For more information, see [Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication](#).

  - [Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication](#)
  - [Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database](#)
- [Reducing the time for physical migration to Amazon Aurora MySQL](#)
  - [Unsupported table types](#)
  - [User accounts with unsupported privileges](#)
  - [Dynamic privileges in Aurora MySQL version 3](#)
  - [Stored objects with 'rdsadmin'@'localhost' as the definer](#)

## Limitations and considerations

The following limitations and considerations apply to restoring to an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket:

- You can migrate your data only to a new DB cluster, not an existing DB cluster.
- You must use Percona XtraBackup to back up your data to S3. For more information, see [Installing Percona XtraBackup](#).
- The Amazon S3 bucket and the Aurora MySQL DB cluster must be in the same Amazon Region.
- You can't restore from the following:
  - A DB cluster snapshot export to Amazon S3. You also can't migrate data from a DB cluster snapshot export to your S3 bucket.

- An encrypted source database, but you can encrypt the data being migrated. You can also leave the data unencrypted during the migration process.
- A MySQL 5.5 or 5.6 database
- Percona Server for MySQL isn't supported as a source database, because it can contain `compression_dictionary*` tables in the `mysql` schema.
- You can't restore to an Aurora Serverless DB cluster.
- Backward migration isn't supported for either major versions or minor versions. For example, you can't migrate from MySQL version 8.0 to Aurora MySQL version 2 (compatible with MySQL 5.7), and you can't migrate from MySQL version 8.0.32 to Aurora MySQL version 3.03, which is compatible with MySQL community version 8.0.26.
- You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.
- Importing from Amazon S3 isn't supported on the `db.t2.micro` DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about DB instance classes, see [Amazon Aurora DB instance classes](#).
- Amazon S3 limits the size of a file uploaded to an S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- Amazon RDS limits the number of files uploaded to an S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xstream (.xstream) file to store full and incremental backup files in the S3 bucket. Percona XtraBackup 8.0 only supports Percona xstream for compression.
- To provide management services for each DB cluster, the `rdsadmin` user is created when the DB cluster is created. As this is a reserved user in RDS, the following limitations apply:
  - Functions, procedures, views, events, and triggers with the `'rdsadmin'@'localhost'` definer aren't imported. For more information, see [Stored objects with 'rdsadmin'@'localhost' as the definer](#) and [Master user privileges with Amazon Aurora MySQL](#).
  - When the Aurora MySQL DB cluster is created, a master user is created with the maximum privileges supported. While restoring from backup, any unsupported privileges assigned to users being imported are removed automatically during import.

To identify users that might be affected by this, see [User accounts with unsupported privileges](#). For more information on supported privileges in Aurora MySQL, see [Role-based privilege model](#).

- For Aurora MySQL version 3, dynamic privileges aren't imported. Aurora-supported dynamic privileges can be imported after migration. For more information, see [Dynamic privileges in Aurora MySQL version 3](#).
- User-created tables in the `mysql` schema aren't migrated.
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name `ibdata1:12M:autoextend`. Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that aren't allowed:

`innodb_data_file_path=ibdata1:50M,ibdata2:50M:autoextend`, and  
`innodb_data_file_path=ibdata01:50M:autoextend`.

- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- The maximum supported size for uncompressed backups using this method is currently limited to 64 TiB. For compressed backups, this limit goes lower to account for the uncompression space requirements. In such cases, the maximum supported backup size would be  $(64 \text{ TiB} - \text{compressed backup size})$ .
- Aurora MySQL doesn't support the importing of MySQL and other external components and plugins.
- Aurora MySQL doesn't restore everything from your database. We recommend that you save the database schema and values for the following items from your source MySQL database, then add them to your restored Aurora MySQL DB cluster after it has been created:
  - User accounts
  - Functions
  - Stored procedures
  - Time zone information. Time zone information is loaded from the local operating system of your Aurora MySQL DB cluster. For more information, see [Local time zone for Amazon Aurora DB clusters](#).

## Before you begin

Before you can copy your data to an Amazon S3 bucket and restore to a DB cluster from those files, you must do the following:

- Install Percona XtraBackup on your local server.

- Permit Aurora MySQL to access your Amazon S3 bucket on your behalf.

## Installing Percona XtraBackup

Amazon Aurora can restore a DB cluster from files that were created using Percona XtraBackup. You can install Percona XtraBackup from [Software Downloads - Percona](#).

For MySQL 5.7 migration, use Percona XtraBackup 2.4.

For MySQL 8.0 migration, use Percona XtraBackup 8.0. Make sure that the Percona XtraBackup version is compatible with the engine version of your source database.

## Required permissions

To migrate your MySQL data to an Amazon Aurora MySQL DB cluster, several permissions are required:

- The user that is requesting that Aurora create a new cluster from an Amazon S3 bucket must have permission to list the buckets for your Amazon account. You grant the user this permission using an Amazon Identity and Access Management (IAM) policy.
- Aurora requires permission to act on your behalf to access the Amazon S3 bucket where you store the files used to create your Amazon Aurora MySQL DB cluster. You grant Aurora the required permissions using an IAM service role.
- The user making the request must also have permission to list the IAM roles for your Amazon account.
- If the user making the request is to create the IAM service role or request that Aurora create the IAM service role (by using the console), then the user must have permission to create an IAM role for your Amazon account.
- If you plan to encrypt the data during the migration process, update the IAM policy of the user who will perform the migration to grant RDS access to the Amazon KMS keys used for encrypting the backups. For instructions, see [Creating an IAM policy to access Amazon KMS resources](#).

For example, the following IAM policy grants a user the minimum required permissions to use the console to list IAM roles, create an IAM role, list the Amazon S3 buckets for your account, and list the KMS keys.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:ListRoles",
        "iam:CreateRole",
        "iam:CreatePolicy",
        "iam:AttachRolePolicy",
        "s3:ListBucket",
        "kms:ListKeys"
      ],
      "Resource": "*"
    }
  ]
}
```

Additionally, for a user to associate an IAM role with an Amazon S3 bucket, the IAM user must have the `iam:PassRole` permission for that IAM role. This permission allows an administrator to restrict which IAM roles a user can associate with Amazon S3 buckets.

For example, the following IAM policy allows a user to associate the role named `S3Access` with an Amazon S3 bucket.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowS3AccessRole",
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws-cn:iam::123456789012:role/S3Access"
    }
  ]
}
```

For more information on IAM user permissions, see [Managing access using policies](#).

## Creating the IAM service role

You can have the Amazon Web Services Management Console create a role for you by choosing the **Create a New Role** option (shown later in this topic). If you select this option and specify a name for the new role, then Aurora creates the IAM service role required for Aurora to access your Amazon S3 bucket with the name that you supply.

As an alternative, you can manually create the role using the following procedure.

### To create an IAM role for Aurora to access Amazon S3

1. Complete the steps in [Creating an IAM policy to access Amazon S3 resources](#).
2. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).
3. Complete the steps in [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

## Backing up files to be restored as an Amazon Aurora MySQL DB cluster

You can create a full backup of your MySQL database files using Percona XtraBackup and upload the backup files to an Amazon S3 bucket. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files to an Amazon S3 bucket.

### Topics

- [Creating a full backup with Percona XtraBackup](#)
- [Using incremental backups with Percona XtraBackup](#)
- [Backup considerations](#)

## Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3 to create an Aurora MySQL DB cluster, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the `/on-premises/s3-restore/backup` folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=</on-premises/s3-restore/backup>
```

If you want to compress your backup into a single file (which can be split, if needed), you can use the `--stream` option to save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xstream (.xstream)

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | gzip - | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar
```

The following command creates a backup of your MySQL database split into multiple xstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xstream \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.xstream
```

### Note

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

Once you have backed up your MySQL database using the Percona XtraBackup utility, you can copy your backup directories and files to an Amazon S3 bucket.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](#) in the *Amazon S3 Getting Started Guide*.

### Using incremental backups with Percona XtraBackup

Amazon Aurora MySQL supports both full and incremental backups created using Percona XtraBackup. If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files for your full and incremental backups to an Amazon S3 bucket. For more information, see [Create an incremental backup](#) on the Percona website.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Aurora iterates through all files and directories. Aurora uses the `xtrabackup-checkpoints` file included with each incremental backup to identify the base directory and to order incremental backups by log sequence number (LSN) range.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](#) in the *Amazon S3 Getting Started Guide*.

### Backup considerations

Aurora doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

For more information about backing up your database with Percona XtraBackup, see [Percona XtraBackup - Documentation](#) and [Work with binary logs](#) on the Percona website.

Aurora supports incremental backups created using Percona XtraBackup. For more information, see [Create an incremental backup](#) on the Percona website.

Aurora consumes your backup files based on the file name. Be sure to name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xstream format.

Aurora consumes your backup files in alphabetical order and also in natural number order. Always use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If the backup data for your database exceeds 5 TB, use the `split` command to split the backup files into multiple files that are each less than 5 TB.

Aurora limits the number of source files uploaded to an Amazon S3 bucket to 1 million files. In some cases, backup data for your database, including all full and incremental backups, can come to a large number of files. In these cases, use a tarball (.tar.gz) file to store full and incremental backup files in the Amazon S3 bucket.

When you upload a file to an Amazon S3 bucket, you can use server-side encryption to encrypt the data. You can then restore an Amazon Aurora MySQL DB cluster from those encrypted files. Amazon Aurora MySQL can restore a DB cluster with files encrypted using the following types of server-side encryption:

- Server-side encryption with Amazon S3–managed keys (SSE-S3) – Each object is encrypted with a unique key employing strong multifactor encryption.
- Server-side encryption with Amazon KMS–managed keys (SSE-KMS) – Similar to SSE-S3, but you have the option to create and manage encryption keys yourself, and also other differences.

For information about using server-side encryption when uploading files to an Amazon S3 bucket, see [Protecting data using server-side encryption](#) in the *Amazon S3 Developer Guide*.

## Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket

You can restore your backup files from your Amazon S3 bucket to create a new Amazon Aurora MySQL DB cluster by using the Amazon RDS console.

### To restore an Amazon Aurora MySQL DB cluster from files on an Amazon S3 bucket

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the top right corner of the Amazon RDS console, choose the Amazon Region in which to create your DB cluster. Choose the same Amazon Region as the Amazon S3 bucket that contains your database backup.

3. In the navigation pane, choose **Databases**, and then choose **Restore from S3**.
4. Choose **Restore from S3**.

The **Create database by restoring from S3** page appears.

RDS > Create database

# Create database by restoring from S3

## S3 destination

### Write audit logs to S3

Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage build to store and retrieve any amount of data from anywhere

### S3 bucket

### S3 prefix (optional) [Info](#)

## Engine options

### Engine type [Info](#)

Amazon Aurora

MySQL

### Edition

- Amazon Aurora with MySQL compatibility

### Version [Info](#)

## IAM role

### IAM role

Choose or create an IAM role to grant write access to your S3 bucket.

## Settings

### DB cluster identifier [Info](#)

Type a name for your DB cluster. The name must be unique across all DB clusters owned by your  account in the current  Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

## 5. Under **S3 destination**:

- a. Choose the **S3 bucket** that contains the backup files.
- b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named `backups`, and you have multiple sets of backup files, each in its own directory (`gzip_backup1`, `gzip_backup2`, and so on). In this case, you specify a prefix of `backups/gzip_backup1` to restore from the files in the `gzip_backup1` folder.

## 6. Under **Engine options**:

- a. For **Engine type**, choose **Amazon Aurora**.
- b. For **Version**, choose the Aurora MySQL engine version for your restored DB instance.

## 7. For **IAM role**, you can choose an existing IAM role.

## 8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role**. If so:

- a. Enter the **IAM role name**.
- b. Choose whether to **Allow access to KMS key**:
  - If you didn't encrypt the backup files, choose **No**.
  - If you encrypted the backup files with AES-256 (SSE-S3) when you uploaded them to Amazon S3, choose **No**. In this case, the data is decrypted automatically.
  - If you encrypted the backup files with Amazon KMS (SSE-KMS) server-side encryption when you uploaded them to Amazon S3, choose **Yes**. Next, choose the correct KMS key for **Amazon KMS key**.

The Amazon Web Services Management Console creates an IAM policy that enables Aurora to decrypt the data.

For more information, see [Protecting data using server-side encryption](#) in the *Amazon S3 Developer Guide*.

9. Choose settings for your DB cluster, such as the DB cluster storage configuration, DB instance class, DB cluster identifier, and login credentials. For information about each setting, see [Settings for Aurora DB clusters](#).
10. Customize additional settings for your Aurora MySQL DB cluster as needed.
11. Choose **Create database** to launch your Aurora DB instance.

On the Amazon RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of **creating** until the DB instance is created and ready for use. When the state changes to **available**, you can connect to the primary instance for your DB cluster. Depending on the DB instance class and store allocated, it can take several minutes for the new instance to be available.

To view the newly created cluster, choose the **Databases** view in the Amazon RDS console and choose the DB cluster. For more information, see [Viewing an Amazon Aurora DB cluster](#).

RDS > Databases > database-test1

## database-test1

Modify Actions

**Related**

Filter by databases

DB identifier	Role	Engine	Region & AZ	Size
database-test1	Regional cluster	Aurora MySQL	us-west-1	1 instance
database-test1-instance-1	Writer instance	Aurora MySQL	us-west-1b	db.r6g.large

Connectivity & security | Monitoring | Logs & events | Configuration | Maintenance & backups | Tags

**Endpoints (2)** Actions Create custom endpoint

Filter by endpoint < 1 >

Endpoint name	Status	Type	Port
database-test1.cluster-ro-123456789012.us-west-1.rds.amazonaws.com	Available	Reader instance	3306
database-test1.cluster-123456789012.us-west-1.rds.amazonaws.com	Available	Writer instance	3306

Note the port and the writer endpoint of the DB cluster. Use the writer endpoint and port of the DB cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

## Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication

To achieve little or no downtime during the migration, you can replicate transactions that were committed on your MySQL database to your Aurora MySQL DB cluster. Replication enables the DB cluster to catch up with the transactions on the MySQL database that happened during the migration. When the DB cluster is completely caught up, you can stop the replication and finish the migration to Aurora MySQL.

## Topics

- [Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication](#)
- [Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database](#)

## Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

To replicate data securely, you can use encrypted replication.

### Note

If you don't need to use encrypted replication, you can skip these steps and move on to the instructions in [Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database](#).

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL primary database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

## To configure your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

1. Ensure that you are prepared for encrypted replication:
  - If you don't have SSL enabled on the external MySQL primary database and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
  - If SSL is enabled on the external primary, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL primary database.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the primary user using SSL.

For information about connecting to an Aurora MySQL DB cluster with SSL, see [TLS connections to Aurora MySQL DB clusters](#).

3. Run the [mysql.rds\\_import\\_binlog\\_ssl\\_material](#) stored procedure to import the SSL information into the Aurora MySQL DB cluster.

For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

```
call mysql.rds_import_binlog_ssl_material(
  '{"ssl_ca":"-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAQAClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706V

BQoQzd8v7yeb70z1PnW0yN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
-----END RSA PRIVATE KEY-----\n"}');
```

For more information, see [mysql.rds\\_import\\_binlog\\_ssl\\_material](#) and [TLS connections to Aurora MySQL DB clusters](#).

**Note**

After running the procedure, the secrets are stored in files. To erase the files later, you can run the [mysql.rds\\_remove\\_binlog\\_ssl\\_material](#) stored procedure.

## Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database

You can synchronize your Amazon Aurora MySQL DB cluster with the MySQL database using replication.

### To synchronize your Aurora MySQL DB cluster with the MySQL database using replication

1. Ensure that the `/etc/my.cnf` file for the external MySQL database has the relevant entries.

If encrypted replication is not required, ensure that the external MySQL database is started with binary logs (binlogs) enabled and SSL disabled. The following are the relevant entries in the `/etc/my.cnf` file for unencrypted data.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1
```

If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled. The entries in the `/etc/my.cnf` file include the `.pem` file locations for the MySQL database server.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1

# Setup SSL.
ssl-ca=/home/sslcerts/ca.pem
```

```
ssl-cert=/home/sslcerts/server-cert.pem
ssl-key=/home/sslcerts/server-key.pem
```

You can verify that SSL is enabled with the following command.

```
mysql> show variables like 'have_ssl';
```

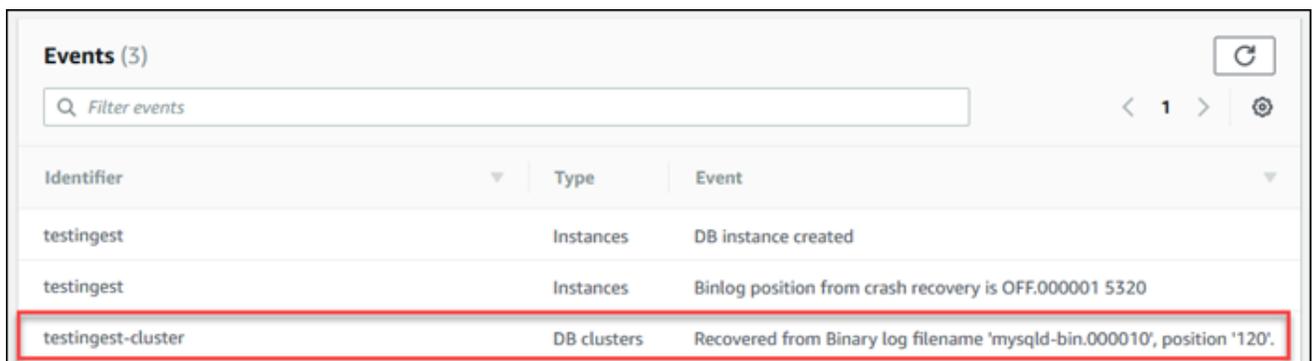

Your output should be similar the following.

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl      | YES   |
+-----+-----+
1 row in set (0.00 sec)
```

2. Determine the starting binary log position for replication. You specify the position to start replication in a later step.

### Using the Amazon Web Services Management Console

- a. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
- b. In the navigation pane, choose **Events**.
- c. In the **Events** list, note the position in the **Recovered from Binary log filename** event.

Identifier	Type	Event
testingest	Instances	DB instance created
testingest	Instances	Binlog position from crash recovery is OFF.000001 5320
testingest-cluster	DB clusters	Recovered from Binary log filename 'mysql-bin.000010', position '120'.

### Using the Amazon CLI

You can also get the binlog file name and position by using the [describe-events](#) Amazon CLI command. The following shows an example describe-events command.

```
PROMPT> aws rds describe-events
```

In the output, identify the event that shows the binlog position.

3. While connected to the external MySQL database, create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
mysql> CREATE USER '<user_name>'@'<domain_name>' IDENTIFIED BY '<password>';
```

The user requires the REPLICATION CLIENT and REPLICATION SLAVE privileges. Grant these privileges to the user.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO  
'<user_name>'@'<domain_name>';
```

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use the following statement to require SSL connections on the user account `<user_name>`.

```
GRANT USAGE ON *.* TO '<user_name>'@'<domain_name>' REQUIRE SSL;
```

#### Note

If REQUIRE SSL is not included, the replication connection might silently fall back to an unencrypted connection.

4. In the Amazon RDS console, add the IP address of the server that hosts the external MySQL database to the VPC security group for the Aurora MySQL DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Aurora MySQL DB cluster, so that it can communicate with your external MySQL database. To find the IP address of the Aurora MySQL DB cluster, use the `host` command.

```
host <db_cluster_endpoint>
```

The host name is the DNS name from the Aurora MySQL DB cluster endpoint.

5. Enable binary log replication by running the [mysql.rds\\_reset\\_external\\_master \(Aurora MySQL version 2\)](#) or [mysql.rds\\_reset\\_external\\_source \(Aurora MySQL version 3\)](#) stored procedure. This stored procedure has the following syntax.

```
CALL mysql.rds_set_external_master (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , mysql_binary_log_file_name  
    , mysql_binary_log_file_location  
    , ssl_encryption  
);  
  
CALL mysql.rds_set_external_source (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , mysql_binary_log_file_name  
    , mysql_binary_log_file_location  
    , ssl_encryption  
);
```

For information about the parameters, see [mysql.rds\\_reset\\_external\\_master \(Aurora MySQL version 2\)](#) and [mysql.rds\\_reset\\_external\\_source \(Aurora MySQL version 3\)](#).

For `mysql_binary_log_file_name` and `mysql_binary_log_file_location`, use the position in the **Recovered from Binary log filename** event you noted earlier.

If the data in the Aurora MySQL DB cluster is not encrypted, the `ssl_encryption` parameter must be set to 0. If the data is encrypted, the `ssl_encryption` parameter must be set to 1.

The following example runs the procedure for an Aurora MySQL DB cluster that has encrypted data.

```
CALL mysql.rds_set_external_master(  
  'Externaldb.some.com',  
  3306,  
  'repl_user'@'mydomain.com',  
  'password',  
  'mysql-bin.000010',  
  120,  
  1);  
  
CALL mysql.rds_set_external_source(  
  'Externaldb.some.com',  
  3306,  
  'repl_user'@'mydomain.com',  
  'password',  
  'mysql-bin.000010',  
  120,  
  1);
```

This stored procedure sets the parameters that the Aurora MySQL DB cluster uses for connecting to the external MySQL database and reading its binary log. If the data is encrypted, it also downloads the SSL certificate authority certificate, client certificate, and client key to the local disk.

6. Start binary log replication by running the [mysql.rds\\_start\\_replication](#) stored procedure.

```
CALL mysql.rds_start_replication;
```

7. Monitor how far the Aurora MySQL DB cluster is behind the MySQL replication primary database. To do so, connect to the Aurora MySQL DB cluster and run the following command.

```
Aurora MySQL version 2:  
SHOW SLAVE STATUS;
```

```
Aurora MySQL version 3:  
SHOW REPLICA STATUS;
```

In the command output, the `Seconds Behind Master` field shows how far the Aurora MySQL DB cluster is behind the MySQL primary. When this value is 0 (zero), the Aurora MySQL DB cluster has caught up to the primary, and you can move on to the next step to stop replication.

8. Connect to the MySQL replication primary database and stop replication. To do so, run the [mysql.rds\\_stop\\_replication](#) stored procedure.

```
CALL mysql.rds_stop_replication;
```

## Reducing the time for physical migration to Amazon Aurora MySQL

You can make the following database modifications to speed up the process of migrating a database to Amazon Aurora MySQL.

### Important

Make sure to perform these updates on a copy of a production database, rather than on a production database. You can then back up the copy and restore it to your Aurora MySQL DB cluster to avoid any service interruptions on your production database.

## Unsupported table types

Aurora MySQL supports only the InnoDB engine for database tables. If you have MyISAM tables in your database, then those tables must be converted before migrating to Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure.

To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command:

```
ALTER TABLE schema.table_name engine=innodb, algorithm=copy;
```

Aurora MySQL doesn't support compressed tables or pages, that is, tables created with `ROW_FORMAT=COMPRESSED` or `COMPRESSION = {"zlib"|"lz4"}`.

To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting `ROW_FORMAT` to `DEFAULT`, `COMPACT`, `DYNAMIC`, or `REDUNDANT`. For compressed pages, set `COMPRESSION="none"`.

For more information, see [InnoDB row formats](#) and [InnoDB table and page compression](#) in the MySQL documentation.

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.

```
-- This script examines a MySQL database for conditions that block
-- migrating the database into Aurora MySQL.
-- It must be run from an account that has read permission for the
-- INFORMATION_SCHEMA database.

-- Verify that this is a supported version of MySQL.

select msg as `==> Checking current version of MySQL.`
from
(
  select
    'This script should be run on MySQL version 5.6 or higher. ' +
    'Earlier versions are not supported.' as msg,
    cast(substring_index(version(), '.', 1) as unsigned) * 100 +
      cast(substring_index(substring_index(version(), '.', 2), '.', -1)
        as unsigned)
      as major_minor
  ) as T
where major_minor <> 506;

-- List MyISAM and compressed tables. Include the table size.

select concat(TABLE_SCHEMA, '.', TABLE_NAME) as `==> MyISAM or Compressed Tables`,
round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where
```

```
ENGINE <> 'InnoDB'
and
(
  -- User tables
  TABLE_SCHEMA not in ('mysql', 'performance_schema',
                        'information_schema')
or
  -- Non-standard system tables
  (
    TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
    (
      'columns_priv', 'db', 'event', 'func', 'general_log',
      'help_category', 'help_keyword', 'help_relation',
      'help_topic', 'host', 'ndb_binlog_index', 'plugin',
      'proc', 'procs_priv', 'proxies_priv', 'servers', 'slow_log',
      'tables_priv', 'time_zone', 'time_zone_leap_second',
      'time_zone_name', 'time_zone_transition',
      'time_zone_transition_type', 'user'
    )
  )
)
or
(
  -- Compressed tables
  ROW_FORMAT = 'Compressed'
);
```

## User accounts with unsupported privileges

User accounts with privileges that aren't supported by Aurora MySQL are imported without the unsupported privileges. For the list of supported privileges, see [Role-based privilege model](#).

You can run the following SQL query on your source database to list the user accounts that have unsupported privileges.

```
SELECT
  user,
  host
FROM
  mysql.user
WHERE
  Shutdown_priv = 'y'
OR File_priv = 'y'
```

```
OR Super_priv = 'y'
OR Create_tablespace_priv = 'y';
```

## Dynamic privileges in Aurora MySQL version 3

Dynamic privileges aren't imported. Aurora MySQL version 3 supports the following dynamic privileges.

```
'APPLICATION_PASSWORD_ADMIN',
'CONNECTION_ADMIN',
'REPLICATION_APPLIER',
'ROLE_ADMIN',
'SESSION_VARIABLES_ADMIN',
'SET_USER_ID',
'XA_RECOVER_ADMIN'
```

The following example script grants the supported dynamic privileges to the user accounts in the Aurora MySQL DB cluster.

```
-- This script finds the user accounts that have Aurora MySQL supported dynamic
privileges
-- and grants them to corresponding user accounts in the Aurora MySQL DB cluster.

/home/ec2-user/opt/mysql/8.0.26/bin/mysql -uusername -pxxxxxx -P8026 -h127.0.0.1 -BNe
"SELECT
CONCAT('GRANT ', GRANTS, ' ON *.* TO ', GRANTEE, ';') AS grant_statement
FROM (select GRANTEE, group_concat(privilege_type) AS GRANTS FROM
information_schema.user_privileges
WHERE privilege_type IN (
'APPLICATION_PASSWORD_ADMIN',
'CONNECTION_ADMIN',
'REPLICATION_APPLIER',
'ROLE_ADMIN',
'SESSION_VARIABLES_ADMIN',
'SET_USER_ID',
'XA_RECOVER_ADMIN')
AND GRANTEE NOT IN (\''mysql.session'@'localhost'\',
\'mysql.infoschema'@'localhost'\',\'mysql.sys'@'localhost'\')) GROUP BY GRANTEE)
AS PRIVGRANTS; " | /home/ec2-user/opt/mysql/8.0.26/bin/mysql -u master_username -
p master_password -h DB_cluster_endpoint
```

## Stored objects with 'rdsadmin'@'localhost' as the definer

Functions, procedures, views, events, and triggers with 'rdsadmin'@'localhost' as the definer aren't imported.

You can use the following SQL script on your source MySQL database to list the stored objects that have the unsupported definer.

```
-- This SQL query lists routines with `rdsadmin`@`localhost` as the definer.

SELECT
    ROUTINE_SCHEMA,
    ROUTINE_NAME
FROM
    information_schema.routines
WHERE
    definer = 'rdsadmin@localhost';

-- This SQL query lists triggers with `rdsadmin`@`localhost` as the definer.

SELECT
    TRIGGER_SCHEMA,
    TRIGGER_NAME,
    DEFINER
FROM
    information_schema.triggers
WHERE
    DEFINER = 'rdsadmin@localhost';

-- This SQL query lists events with `rdsadmin`@`localhost` as the definer.

SELECT
    EVENT_SCHEMA,
    EVENT_NAME
FROM
    information_schema.events
WHERE
    DEFINER = 'rdsadmin@localhost';

-- This SQL query lists views with `rdsadmin`@`localhost` as the definer.
SELECT
    TABLE_SCHEMA,
    TABLE_NAME
```

```
FROM
  information_schema.views
WHERE
  DEFINER = 'rdsadmin@localhost';
```

## Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump

Because Amazon Aurora MySQL is a MySQL-compatible database, you can use the `mysqldump` utility to copy data from your MySQL database or the `mysqldb-dump` utility to copy your data from your MariaDB database to an existing Aurora MySQL DB cluster.

For a discussion of how to do so with MySQL or MariaDB databases that are very large, see the following topics in the *Amazon Relational Database Service User Guide*:

- MySQL – [Importing data to an Amazon RDS for MySQL database with reduced downtime](#)
- MariaDB – [Importing data to an Amazon RDS for MariaDB database with reduced downtime](#)

For MySQL or MariaDB databases that have smaller amounts of data, see the following topics in the *Amazon Relational Database Service User Guide*:

- MySQL – [Importing data from an external MySQL database to an Amazon RDS for MySQL DB instance](#)
- MariaDB – [Importing data from an external MariaDB database to an Amazon RDS for MariaDB DB instance](#)

# Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster

You can migrate (copy) data to an Amazon Aurora MySQL DB cluster from an RDS for MySQL DB instance.

## Topics

- [Migrating an RDS for MySQL snapshot to Aurora](#)
- [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#)

### Note

Because Amazon Aurora MySQL is compatible with MySQL, you can migrate data from your MySQL database by setting up replication between your MySQL database and an Amazon Aurora MySQL DB cluster. For more information, see [Replication with Amazon Aurora](#).

## Migrating an RDS for MySQL snapshot to Aurora

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running a MySQL version that's compatible with Aurora MySQL.

You can migrate either a manual or automated DB snapshot. After the DB cluster is created, you can then create optional Aurora Replicas.

### Note

You can also migrate an RDS for MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source RDS for MySQL DB instance. For more information, see [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#).

You can't migrate to Aurora MySQL version 3.05 and higher from some older MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to MySQL version 8.0.28 before migrating.

The general steps you must take are as follows:

1. Determine the amount of space to provision for your Aurora MySQL DB cluster. For more information, see [How much space do I need?](#)
2. Use the console to create the snapshot in the Amazon Region where the Amazon RDS MySQL instance is located. For information about creating a DB snapshot, see [Creating a DB snapshot](#).
3. If the DB snapshot is not in the same Amazon Region as your DB cluster, use the Amazon RDS console to copy the DB snapshot to that Amazon Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).
4. Use the console to migrate the DB snapshot and create an Aurora MySQL DB cluster with the same databases as the original MySQL DB instance.

#### **Warning**

Amazon RDS limits each Amazon account to one snapshot copy into each Amazon Region at a time.

### **How much space do I need?**

When you migrate a snapshot of a MySQL DB instance into an Aurora MySQL DB cluster, Aurora uses an Amazon Elastic Block Store (Amazon EBS) volume to format the data from the snapshot before migrating it. In some cases, additional space is needed to format the data for migration.

Tables that are not MyISAM tables and are not compressed can be up to 16 TB in size. If you have MyISAM tables, then Aurora must use additional space in the volume to convert the tables to be compatible with Aurora MySQL. If you have compressed tables, then Aurora must use additional space in the volume to expand these tables before storing them on the Aurora cluster volume. Because of this additional space requirement, you should ensure that none of the MyISAM and compressed tables being migrated from your MySQL DB instance exceeds 8 TB in size.

### **Reducing the amount of space required to migrate data into Amazon Aurora MySQL**

You might want to modify your database schema prior to migrating it into Amazon Aurora. Such modification can be helpful in the following cases:

- You want to speed up the migration process.
- You are unsure of how much space you need to provision.

- You have attempted to migrate your data and the migration has failed due to a lack of provisioned space.

You can make the following changes to improve the process of migrating a database into Amazon Aurora.

### Important

Be sure to perform these updates on a new DB instance restored from a snapshot of a production database, rather than on a production instance. You can then migrate the data from the snapshot of your new DB instance into your Aurora DB cluster to avoid any service interruptions on your production database.

Table type	Limitation or guideline
MyISAM tables	<p>Aurora MySQL supports InnoDB tables only. If you have MyISAM tables in your database, then those tables must be converted before being migrated into Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure.</p> <p>To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command:</p> <pre>alter table &lt;schema&gt;.&lt;table_name&gt; engine=inno db, algorithm=copy;</pre>
Compressed tables	<p>Aurora MySQL doesn't support compressed tables (that is, tables created with <code>ROW_FORMAT=COMPRESSED</code> ).</p> <p>To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting <code>ROW_FORMAT</code> to <code>DEFAULT</code>, <code>COMPACT</code>, <code>DYNAMIC</code>, or <code>REDUNDANT</code></p>

Table type	Limitation or guideline
	. For more information, see <a href="#">InnoDB row formats</a> in the MySQL documentation.

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.

```
-- This script examines a MySQL database for conditions that block
-- migrating the database into Amazon Aurora.
-- It needs to be run from an account that has read permission for the
-- INFORMATION_SCHEMA database.

-- Verify that this is a supported version of MySQL.

select msg as `==> Checking current version of MySQL.`
from
(
select
  'This script should be run on MySQL version 5.6 or higher. ' +
  'Earlier versions are not supported.' as msg,
  cast(substring_index(version(), '.', 1) as unsigned) * 100 +
  cast(substring_index(substring_index(version(), '.', 2), '.', -1)
  as unsigned)
  as major_minor
) as T
where major_minor <> 506;

-- List MyISAM and compressed tables. Include the table size.

select concat(TABLE_SCHEMA, '.', TABLE_NAME) as `==> MyISAM or Compressed Tables`,
round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where
  ENGINE <> 'InnoDB'
  and
  (
  -- User tables
  TABLE_SCHEMA not in ('mysql', 'performance_schema',
  'information_schema')

  or
```

```

-- Non-standard system tables
(
  TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
  (
    'columns_priv', 'db', 'event', 'func', 'general_log',
    'help_category', 'help_keyword', 'help_relation',
    'help_topic', 'host', 'ndb_binlog_index', 'plugin',
    'proc', 'procs_priv', 'proxies_priv', 'servers', 'slow_log',
    'tables_priv', 'time_zone', 'time_zone_leap_second',
    'time_zone_name', 'time_zone_transition',
    'time_zone_transition_type', 'user'
  )
)
)
or
(
  -- Compressed tables
  ROW_FORMAT = 'Compressed'
);

```

The script produces output similar to the output in the following example. The example shows two tables that must be converted from MyISAM to InnoDB. The output also includes the approximate size of each table in megabytes (MB).

```

+-----+-----+
| ==> MyISAM or Compressed Tables | Approx size (MB) |
+-----+-----+
| test.name_table                |          2102.25 |
| test.my_table                  |           65.25 |
+-----+-----+
2 rows in set (0.01 sec)

```

## Migrating an RDS for MySQL DB snapshot to an Aurora MySQL DB cluster

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster using the Amazon Web Services Management Console or the Amazon CLI. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

If the DB snapshot is not in the Amazon Region where you want to locate your data, copy the DB snapshot to that Amazon Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

## Console

When you migrate the DB snapshot by using the Amazon Web Services Management Console, the console takes the actions necessary to create only the DB cluster.

You can also choose for your new Aurora MySQL DB cluster to be encrypted at rest using an Amazon KMS key.

### To migrate a MySQL DB snapshot by using the Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Either start the migration from the MySQL DB instance or from the snapshot:

To start the migration from the DB instance:

1. In the navigation pane, choose **Databases**, and then select the MySQL DB instance.
2. For **Actions**, choose **Migrate latest snapshot**.

To start the migration from the snapshot:

1. Choose **Snapshots**.
2. On the **Snapshots** page, choose the snapshot that you want to migrate into an Aurora MySQL DB cluster.
3. Choose **Snapshot Actions**, and then choose **Migrate Snapshot**.

The **Migrate Database** page appears.

3. Set the following values on the **Migrate Database** page:
  - **Migrate to DB Engine:** Select `aurora`.
  - **DB Engine Version:** Select the DB engine version for the Aurora MySQL DB cluster.
  - **DB Instance Class:** Select a DB instance class that has the required storage and capacity for your database, for example `db.r3.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). So you only need to select a DB instance class that meets your current storage requirements. For more information, see [Overview of Amazon Aurora storage](#).

- **DB Instance Identifier:** Type a name for the DB cluster that is unique for your account in the Amazon Region you selected. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the Amazon Region and DB engine you selected, for example **aurora-cluster1**.

The DB instance identifier has the following constraints:

- It must contain from 1 to 63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It cannot end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB instances per Amazon account, per Amazon Region.
- **Virtual Private Cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora MySQL DB cluster by selecting your VPC identifier, for example `vpc-a464d1c1`. For information on creating a VPC, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

Otherwise, you can choose to have Aurora create a VPC for you by selecting **Create a new VPC**.

- **DB subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora MySQL DB cluster by selecting your subnet group identifier, for example `gs-subnet-group1`.

Otherwise, you can choose to have Aurora create a subnet group for you by selecting **Create a new subnet group**.

- **Public accessibility:** Select **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Select **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network. The default is **Yes**.

 **Note**

Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Publicly Accessible** to **No**.

- **Availability Zone:** Select the Availability Zone to host the primary instance for your Aurora MySQL DB cluster. To have Aurora select an Availability Zone for you, select **No Preference**.

- **Database Port:** Type the default port to be used when connecting to instances in the Aurora MySQL DB cluster. The default is 3306.

 **Note**

You might be behind a corporate firewall that doesn't allow access to default ports such as the MySQL default port, 3306. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora MySQL DB cluster.

- **Encryption:** Choose **Enable Encryption** for your new Aurora MySQL DB cluster to be encrypted at rest. If you choose **Enable Encryption**, you must choose a KMS key as the **Amazon KMS key** value.

If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.

If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the DB snapshot or a different key. You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- **Auto Minor Version Upgrade:** This setting doesn't apply to Aurora MySQL DB clusters.

For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](#).

4. Choose **Migrate** to migrate your DB snapshot.
5. Choose **Instances**, and then choose the arrow icon to show the DB cluster details and monitor the progress of the migration. On the details page, you can find the cluster endpoint used to connect to the primary instance of the DB cluster. For more information on connecting to an Aurora MySQL DB cluster, see [Connecting to an Amazon Aurora DB cluster](#).

## Amazon CLI

You can create an Aurora DB cluster from a DB snapshot of an RDS for MySQL DB instance by using the [restore-db-cluster-from-snapshot](#) command with the following parameters:

- `--db-cluster-identifier` – The name of the DB cluster to create.

- `--engine aurora-mysql` – For a MySQL 5.7–compatible or 8.0–compatible DB cluster.
- `--kms-key-id` – The Amazon KMS key to optionally encrypt the DB cluster with, depending on whether your DB snapshot is encrypted.
  - If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster isn't encrypted.
  - If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the DB snapshot.

**Note**

You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

When you migrate the DB snapshot by using the `RestoreDBClusterFromSnapshot` command, the command creates both the DB cluster and the primary instance.

In this example, you create a MySQL 5.7–compatible DB cluster named *mydbcluster* from a DB snapshot with an ARN set to *mydbsnapshotARN*.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier mydbcluster \  
  --snapshot-identifier mydbsnapshotARN \  
  --engine aurora-mysql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^  
  --db-cluster-identifier mydbcluster ^  
  --snapshot-identifier mydbsnapshotARN ^  
  --engine aurora-mysql
```

In this example, you create a MySQL 5.7-compatible DB cluster named *mydbcluster* from a DB snapshot with an ARN set to *mydbsnapshotARN*.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier mydbcluster \  
  --snapshot-identifier mydbsnapshotARN \  
  --engine aurora-mysql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^  
  --db-cluster-identifier mydbcluster ^  
  --snapshot-identifier mydbsnapshotARN ^  
  --engine aurora-mysql
```

## Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

Aurora uses the MySQL DB engines' binary log replication functionality to create a special type of DB cluster called an Aurora read replica for a source RDS for MySQL DB instance. Updates made to the source RDS for MySQL DB instance are asynchronously replicated to the Aurora read replica.

We recommend using this functionality to migrate from a RDS for MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source RDS for MySQL DB instance. When the replica lag between the RDS for MySQL DB instance and the Aurora read replica is 0, you can direct your client applications to the Aurora read replica and then stop replication to make the Aurora read replica a standalone Aurora MySQL DB cluster. Be prepared for migration to take a while, roughly several hours per terabyte (TiB) of data.

For a list of regions where Aurora is available, see [Amazon Aurora](#) in the *Amazon Web Services General Reference*.

When you create an Aurora read replica of an RDS for MySQL DB instance, Amazon RDS creates a DB snapshot of your source RDS for MySQL DB instance (private to Amazon RDS, and incurring no charges). Amazon RDS then migrates the data from the DB snapshot to the Aurora read replica. After the data from the DB snapshot has been migrated to the new Aurora MySQL DB cluster, Amazon RDS starts replication between your RDS for MySQL DB instance and the Aurora MySQL DB cluster. If your RDS for MySQL DB instance contains tables that use storage engines other than InnoDB, or that use compressed row format, you can speed up the process of creating an Aurora read replica by altering those tables to use the InnoDB storage engine and dynamic row format before you create your Aurora read replica. For more information about the process of copying a MySQL DB snapshot to an Aurora MySQL DB cluster, see [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster](#).

You can have only one Aurora read replica for an RDS for MySQL DB instance.

### Note

Replication issues can arise due to feature differences between Aurora MySQL and the MySQL database engine version of your RDS for MySQL DB instance that is the replication primary. If you encounter an error, you can find help in the [Amazon RDS community forum](#) or by contacting Amazon Web Services Support.

You can't create an Aurora read replica if your RDS for MySQL DB instance is already the source for a cross-Region read replica.

You can't migrate to Aurora MySQL version 3.05 and higher from some older RDS for MySQL 8.0 versions, including 8.0.11, 8.0.13, and 8.0.15. We recommend that you upgrade to RDS for MySQL version 8.0.28 before migrating.

For more information on MySQL read replicas, see [Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances](#).

## Creating an Aurora read replica

You can create an Aurora read replica for an RDS for MySQL DB instance by using the console, the Amazon CLI, or the RDS API.

### Console

#### To create an Aurora read replica from a source RDS for MySQL DB instance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the MySQL DB instance that you want to use as the source for your Aurora read replica.
4. For **Actions**, choose **Create Aurora read replica**.
5. Choose the DB cluster specifications you want to use for the Aurora read replica, as described in the following table.

Option	Description
<b>DB instance class</b>	Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see <a href="#">Amazon Aurora DB instance classes</a> .
<b>Multi-AZ deployment</b>	Choose <b>Create Replica in Different Zone</b> to create a standby replica of the new DB cluster in another Availability Zone in the target Amazon Region for failover support. For more information about multiple Availability Zones, see <a href="#">Regions and Availability Zones</a> .

Option	Description
<b>DB instance identifier</b>	<p>Type a name for the primary instance in your Aurora read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</p> <p>The DB instance identifier has the following constraints:</p> <ul style="list-style-type: none"><li>• It must contain from 1 to 63 alphanumeric characters or hyphens.</li><li>• Its first character must be a letter.</li><li>• It cannot end with a hyphen or contain two consecutive hyphens.</li><li>• It must be unique for all DB instances for each Amazon account, for each Amazon Region.</li></ul> <p>Because the Aurora read replica DB cluster is created from a snapshot of the source DB instance, the master user name and master password for the Aurora read replica are the same as the master user name and master password for the source DB instance.</p>
<b>Virtual Private Cloud (VPC)</b>	Select the VPC to host the DB cluster. Select <b>Create new VPC</b> to have Aurora create a VPC for you. For more information, see <a href="#">DB cluster prerequisites</a> .
<b>DB subnet group</b>	Select the DB subnet group to use for the DB cluster. Select <b>Create new DB subnet group</b> to have Aurora create a DB subnet group for you. For more information, see <a href="#">DB cluster prerequisites</a> .

Option	Description
<b>Public accessibility</b>	Select Yes to give the DB cluster a public IP address; otherwise, select No. The instances in your DB cluster can be a mix of both public and private DB instances . For more information about hiding instances from public access, see <a href="#">Hiding a DB cluster in a VPC from the internet</a> .
<b>Availability zone</b>	Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see <a href="#">Regions and Availability Zones</a> .
<b>VPC security group (firewall)</b>	Select <b>Create new VPC security group</b> to have Aurora create a VPC security group for you. Select <b>Select existing VPC security groups</b> to specify one or more VPC security groups to secure network access to the DB cluster. For more information, see <a href="#">DB cluster prerequisites</a> .
<b>Database port</b>	Specify the port for applications and utilities to use to access the database. Aurora MySQL DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.
<b>DB parameter group</b>	Select a DB parameter group for the Aurora MySQL DB cluster. Aurora has a default DB parameter group you can use, or you can create your own DB parameter group. For more information about DB parameter groups, see <a href="#">Parameter groups for Amazon Aurora</a> .

Option	Description
<b>DB cluster parameter group</b>	Select a DB cluster parameter group for the Aurora MySQL DB cluster. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see <a href="#">Parameter groups for Amazon Aurora</a> .
<b>Encryption</b>	<p>Choose <b>Disable encryption</b> if you don't want your new Aurora DB cluster to be encrypted. Choose <b>Enable encryption</b> for your new Aurora DB cluster to be encrypted at rest. If you choose <b>Enable encryption</b>, you must choose a KMS key as the <b>Amazon KMS key</b> value.</p> <p>If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.</p> <p>If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the MySQL DB instance or a different key. You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.</p>
<b>Priority</b>	Choose a failover priority for the DB cluster. If you don't select a value, the default is <b>tier-1</b> . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a> .

Option	Description
<b>Backup retention period</b>	Select the length of time, from 1 to 35 days, that Aurora retains backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.
<b>Enhanced Monitoring</b>	Choose <b>Enable enhanced monitoring</b> to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .
<b>Monitoring Role</b>	Only available if <b>Enhanced Monitoring</b> is set to <b>Enable enhanced monitoring</b> . Choose the IAM role that you created to permit Aurora to communicate with Amazon CloudWatch Logs for you, or choose <b>Default</b> to have Aurora create a role for you named <code>rds-monitoring-role</code> . For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .
<b>Granularity</b>	Only available if <b>Enhanced Monitoring</b> is set to <b>Enable enhanced monitoring</b> . Set the interval, in seconds, between when metrics are collected for your DB cluster.
<b>Auto minor version upgrade</b>	This setting doesn't apply to Aurora MySQL DB clusters.  For more information about engine updates for Aurora MySQL, see <a href="#">Database engine updates for Amazon Aurora MySQL</a> .
<b>Maintenance window</b>	Select <b>Select window</b> and specify the weekly time range during which system maintenance can occur. Or, select <b>No preference</b> for Aurora to assign a period randomly.

## 6. Choose **Create read replica**.

## Amazon CLI

To create an Aurora read replica from a source RDS for MySQL DB instance, use the [create-db-cluster](#) and [create-db-instance](#) Amazon CLI commands to create a new Aurora MySQL DB cluster. When you call the `create-db-cluster` command, include the `--replication-source-identifier` parameter to identify the Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

Don't specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-replica-cluster --engine
aurora \
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2 \
  --replication-source-identifier arn:aws-cn:rds:us-west-2:123456789012:db:primary-
mysql-instance
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-replica-cluster --engine
aurora ^
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2 ^
  --replication-source-identifier arn:aws-cn:rds:us-west-2:123456789012:db:primary-
mysql-instance
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the Amazon CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the [create-db-instance](#) Amazon CLI command with the following parameters.

- `--db-cluster-identifier`

The name of your DB cluster.

- `--db-instance-class`

The name of the DB instance class to use for your primary instance.

- `--db-instance-identifier`

The name of your primary instance.

- `--engine aurora`

In this example, you create a primary instance named *myreadreplicainstance* for the DB cluster named *myreadreplicaccluster*, using the DB instance class specified in *myinstanceclass*.

## Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-cluster-identifier myreadreplicaccluster \  
  --db-instance-class myinstanceclass \  
  --db-instance-identifier myreadreplicainstance \  
  --engine aurora
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier myreadreplicaccluster ^  
  --db-instance-class myinstanceclass ^  
  --db-instance-identifier myreadreplicainstance ^  
  --engine aurora
```

## RDS API

To create an Aurora read replica from a source RDS for MySQL DB instance, use the [CreateDBCluster](#) and [CreateDBInstance](#) Amazon RDS API commands to create a new Aurora DB cluster and primary instance. Do not specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source RDS for MySQL DB instance.

You can create a new Aurora DB cluster for an Aurora read replica from a source RDS for MySQL DB instance by using the [CreateDBCluster](#) Amazon RDS API command with the following parameters:

- `DBClusterIdentifier`

The name of the DB cluster to create.

- `DBSubnetGroupName`

The name of the DB subnet group to associate with this DB cluster.

- `Engine=aurora`

- `KmsKeyId`

The Amazon KMS key to optionally encrypt the DB cluster with, depending on whether your MySQL DB instance is encrypted.

- If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster is encrypted at rest using the default encryption key for your account.
- If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the MySQL DB instance.

 **Note**

You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.

- `ReplicationSourceIdentifier`

The Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

- `VpcSecurityGroupIds`

The list of EC2 VPC security groups to associate with this DB cluster.

In this example, you create a DB cluster named *myreadreplicacluster* from a source MySQL DB instance with an ARN set to *mysqlprimaryARN*, associated with a DB subnet group named *mysubnetgroup* and a VPC security group named *mysecuritygroup*.

## Example

```
https://rds.us-east-1.amazonaws.com/  
?Action=CreateDBCluster
```

```
&DBClusterIdentifier=myreadreplicacluster
&DBSubnetGroupName=mysubnetgroup
&Engine=aurora
&ReplicationSourceIdentifier=mysqlprimaryARN
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&VpcSecurityGroupIds=mysecuritygroup
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150927/us-east-1/rds/aws4_request
&X-Amz-Date=20150927T164851Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=6a8f4bd6a98f649c75ea04a6b3929ecc75ac09739588391cd7250f5280e716db
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the Amazon CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the [CreateDBInstance](#) Amazon RDS API command with the following parameters:

- `DBClusterIdentifier`

The name of your DB cluster.

- `DBInstanceClass`

The name of the DB instance class to use for your primary instance.

- `DBInstanceIdentifier`

The name of your primary instance.

- `Engine=aurora`

In this example, you create a primary instance named *myreadreplicainstance* for the DB cluster named *myreadreplicac*luster, using the DB instance class specified in *myinstanceclass*.

### Example

```
https://rds.us-east-1.amazonaws.com/
```

```
?Action=CreateDBInstance
&DBClusterIdentifier=myreadreplicacluster
&DBInstanceClass=myinstanceclass
&DBInstanceIdentifier=myreadreplicainstance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-09-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140424/us-east-1/rds/aws4_request
&X-Amz-Date=20140424T194844Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=bee4aabc750bf7dad0cd9e22b952bd6089d91e2a16592c2293e532eeaab8bc77
```

## Viewing an Aurora read replica

You can view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the Amazon Web Services Management Console or the Amazon CLI.

### Console

#### To view the primary MySQL DB instance for an Aurora read replica

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica to display its details. The primary MySQL DB instance information is in the **Replication source** field.

## aurora-mysql-db-cluster

### Details

**ARN**

arn:aws:rds: [redacted] :aurora-mysql-db-cluster

**DB cluster**

aurora-mysql-db-cluster ( available )

**DB cluster role****Replica****Replication source**

arn:aws:rds: [redacted] :mydbinstance3

**Cluster endpoint**

aurora-mysql-db-cluster. [redacted] rds.amazonaws.com

**Reader endpoint**

aurora-mysql-db-cluster. [redacted] rds.amazonaws.com

**Port**

3306

### Amazon CLI

To view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the Amazon CLI, use the [describe-db-clusters](#) and [describe-db-instances](#) commands.

To determine which MySQL DB instance is the primary, use the [describe-db-clusters](#) and specify the cluster identifier of the Aurora read replica for the `--db-cluster-identifier` option. Refer to the `ReplicationSourceIdentifier` element in the output for the ARN of the DB instance that is the replication primary.

To determine which DB cluster is the Aurora read replica, use the [describe-db-instances](#) and specify the instance identifier of the MySQL DB instance for the `--db-instance-identifier` option. Refer to the `ReadReplicaDBClusterIdentifiers` element in the output for the DB cluster identifier of the Aurora read replica.

## Example

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters \  
  --db-cluster-identifier myreadreplicacluster
```

```
aws rds describe-db-instances \  
  --db-instance-identifier mysqlprimary
```

For Windows:

```
aws rds describe-db-clusters ^  
  --db-cluster-identifier myreadreplicacluster
```

```
aws rds describe-db-instances ^  
  --db-instance-identifier mysqlprimary
```

## Promoting an Aurora read replica

After migration completes, you can promote the Aurora read replica to a stand-alone DB cluster using the Amazon Web Services Management Console or Amazon CLI.

Then you can direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see [Amazon Aurora endpoint connections](#). Promotion should complete fairly quickly, and you can read from and write to the Aurora read replica during promotion. However, you can't delete the primary MySQL DB instance or unlink the DB Instance and the Aurora read replica during this time.

Before you promote your Aurora read replica, stop any transactions from being written to the source MySQL DB instance, and then wait for the replica lag on the Aurora read replica to reach 0. You can view the replica lag for an Aurora read replica by calling the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your Aurora read replica. Check the **Seconds behind master** value.

You can start writing to the Aurora read replica after write transactions to the primary have stopped and replica lag is 0. If you write to the Aurora read replica before this and you modify tables that are also being modified on the MySQL primary, you risk breaking replication to Aurora. If this happens, you must delete and recreate your Aurora read replica.

## Console

### To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica.
4. For **Actions**, choose **Promote**.
5. Choose **Promote read replica**.

After you promote, confirm that the promotion has completed by using the following procedure.

### To confirm that the Aurora read replica was promoted

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Events**.
3. On the **Events** page, verify that there is a Promoted Read Replica cluster to a stand-alone database cluster event for the cluster that you promoted.

After promotion is complete, the primary MySQL DB instance and the Aurora read replica are unlinked, and you can safely delete the DB instance if you want.

## Amazon CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the [promote-read-replica-db-cluster](#) Amazon CLI command.

## Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \  
  --db-cluster-identifier myreadreplicacluster
```

### For Windows:

```
aws rds promote-read-replica-db-cluster ^  
  --db-cluster-identifier myreadreplicacluster
```

# Managing Amazon Aurora MySQL

The following sections discuss managing an Amazon Aurora MySQL DB cluster.

## Topics

- [Managing performance and scaling for Amazon Aurora MySQL](#)
- [Backtracking an Aurora DB cluster](#)
- [Testing Amazon Aurora MySQL using fault injection queries](#)
- [Altering tables in Amazon Aurora using Fast DDL](#)
- [Displaying volume status for an Aurora MySQL DB cluster](#)

## Managing performance and scaling for Amazon Aurora MySQL

### Scaling Aurora MySQL DB instances

You can scale Aurora MySQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see [Read scaling](#).

You can scale your Aurora MySQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora MySQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 TB. For the specifications of the DB instance classes supported by Aurora MySQL, see [Amazon Aurora DB instance classes](#).

#### Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Using T instance classes for development and testing](#).

### Maximum connections to an Aurora MySQL DB instance

The maximum number of connections allowed to an Aurora MySQL DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance.

The following table lists the resulting default value of `max_connections` for each DB instance class available to Aurora MySQL. You can increase the maximum number of connections to your

Aurora MySQL DB instance by scaling the instance up to a DB instance class with more memory, or by setting a larger value for the `max_connections` parameter in the DB parameter group for your instance, up to 16,000.

**Tip**

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see [Amazon RDS Proxy for Aurora](#).

For details about how Aurora Serverless v2 instances handle this parameter, see [Maximum connections for Aurora Serverless v2](#).

Instance class	max_connections default value		
db.t2.small	45		
db.t2.medium	90		
db.t3.small	45		
db.t3.medium	90		
db.t3.large	135		
db.t4g.medium	90		
db.t4g.large	135		
db.r3.large	1000		
db.r3.xlarge	2000		
db.r3.2xlarge	3000		

Instance class	max_connections default value		
db.r3.4xlarge	4000

db.r8g.8xlarge	5000		
db.r8g.12xlarge	6000		
db.r8g.16xlarge	6000		
db.r8g.24xlarge	7000		
db.r8g.48xlarge	8000		

Instance class	max_connections default value		
db.x2g.large	2000		
db.x2g.xlarge	3000		
db.x2g.2xlarge	4000		
db.x2g.4xlarge	5000		
db.x2g.8xlarge	6000		
db.x2g.12xlarge	7000		
db.x2g.16xlarge	7000		

### Tip

The `max_connections` parameter calculation uses log base 2 (distinct from natural logarithm) and the `DBInstanceClassMemory` value in bytes for the selected Aurora MySQL instance class. The parameter accepts only integer values, with decimal portions truncated from calculations. The formula implements connection limits as follows:

- 1000 connection increment for larger R3, R4, and R5 instances
- 45 connection increment for T2 and T3 instance memory variants

Example: For `db.r6g.large`, while the formula calculates 1069.2, the system implements 1000 to maintain consistent incremental patterns.

If you create a new parameter group to customize your own default for the connection limit, you'll see that the default connection limit is derived using a formula based on the `DBInstanceClassMemory` value. As shown in the preceding table, the formula produces

connection limits that increase by 1000 as the memory doubles between progressively larger R3, R4, and R5 instances, and by 45 for different memory sizes of T2 and T3 instances.

See [Specifying DB parameters](#) for more details on how `DBInstanceClassMemory` is calculated.

Aurora MySQL and RDS for MySQL DB instances have different amounts of memory overhead. Therefore, the `max_connections` value can be different for Aurora MySQL and RDS for MySQL DB instances that use the same instance class. The values in the table only apply to Aurora MySQL DB instances.

### Note

The much lower connectivity limits for T2 and T3 instances are because with Aurora, those instance classes are intended only for development and test scenarios, not for production workloads.

The default connection limits are tuned for systems that use the default values for other major memory consumers, such as the buffer pool and query cache. If you change those other settings for your cluster, consider adjusting the connection limit to account for the increase or decrease in available memory on the DB instances.

## Temporary storage limits for Aurora MySQL

Aurora MySQL stores tables and indexes in the Aurora storage subsystem. Aurora MySQL uses separate temporary or local storage for nonpersistent temporary files and non-InnoDB temporary tables. Local storage also includes files that are used for such purposes as sorting large datasets during query processing or for index build operations. It doesn't include InnoDB temporary tables.

For more information on temporary tables in Aurora MySQL version 3, see [New temporary table behavior in Aurora MySQL version 3](#). For more information on temporary tables in version 2, see [Temporary tablespace behavior in Aurora MySQL version 2](#).

The data and temporary files on these volumes are lost when starting and stopping the DB instance, and during host replacement.

These local storage volumes are backed by Amazon Elastic Block Store (EBS) and can be extended by using a larger DB instance class. For more information about storage, see [Amazon Aurora storage](#).

Local storage is also used for importing data from Amazon S3 using `LOAD DATA FROM S3` or `LOAD XML FROM S3`, and for exporting data to S3 using `SELECT INTO OUTFILE S3`. For more information on importing from and exporting to S3, see the following:

- [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#)
- [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#)

Aurora MySQL uses separate permanent storage for error logs, general logs, slow query logs, and audit logs for most of the Aurora MySQL DB instance classes (not including burstable-performance instance class types such as `db.t2`, `db.t3`, and `db.t4g`). The data on this volume is retained when starting and stopping the DB instance, and during host replacement.

This permanent storage volume is also backed by Amazon EBS and has a fixed size according to the DB instance class. It can't be extended by using a larger DB instance class.

The following table shows the maximum amount of temporary and permanent storage available for each Aurora MySQL DB instance class. For more information on DB instance class support for Aurora, see [Amazon Aurora DB instance classes](#).

DB instance class	Maximum temporary/local storage available (GiB)	Additional maximum storage available for log files (GiB)
db.x2g.16xlarge	1280	500
db.x2g.12xlarge	960	500

db.t3.medium	32	–
db.t3.small	32	–
db.t2.medium	32	–
db.t2.small	32	–

**⚠ Important**

These values represent the theoretical maximum amount of free storage on each DB instance. The actual local storage available to you might be lower. Aurora uses some local storage for its management processes, and the DB instance uses some local storage even before you load any data. You can monitor the temporary storage available for a specific DB instance with the `FreeLocalStorage` CloudWatch metric, described in [Amazon CloudWatch metrics for Amazon Aurora](#). You can check the amount of free storage at the present time. You can also chart the amount of free storage over time. Monitoring the free storage over time helps you to determine whether the value is increasing or decreasing, or to find the minimum, maximum, or average values.

(This doesn't apply to Aurora Serverless v2.)

## Backtracking an Aurora DB cluster

With Amazon Aurora MySQL-Compatible Edition, you can backtrack a DB cluster to a specific time, without restoring data from a backup.

### Contents

- [Overview of backtracking](#)
  - [Backtrack window](#)
  - [Backtracking time](#)
  - [Backtracking limitations](#)
- [Region and version availability](#)
- [Upgrade considerations for backtrack-enabled clusters](#)
- [Configuring backtracking a Aurora MySQL DB cluster](#)
- [Performing a backtrack for an Aurora MySQL DB cluster](#)
- [Monitoring backtracking for an Aurora MySQL DB cluster](#)
- [Subscribing to a backtrack event with the console](#)
- [Retrieving existing backtracks](#)
- [Disabling backtracking for an Aurora MySQL DB cluster](#)

## Overview of backtracking

Backtracking "rewinds" the DB cluster to the time you specify. Backtracking is not a replacement for backing up your DB cluster so that you can restore it to a point in time. However, backtracking provides the following advantages over traditional backup and restore:

- You can easily undo mistakes. If you mistakenly perform a destructive action, such as a DELETE without a WHERE clause, you can backtrack the DB cluster to a time before the destructive action with minimal interruption of service.
- You can backtrack a DB cluster quickly. Restoring a DB cluster to a point in time launches a new DB cluster and restores it from backup data or a DB cluster snapshot, which can take hours. Backtracking a DB cluster doesn't require a new DB cluster and rewinds the DB cluster in minutes.
- You can explore earlier data changes. You can repeatedly backtrack a DB cluster back and forth in time to help determine when a particular data change occurred. For example, you can backtrack a DB cluster three hours and then backtrack forward in time one hour. In this case, the backtrack time is two hours before the original time.

### Note

For information about restoring a DB cluster to a point in time, see [Overview of backing up and restoring an Aurora DB cluster](#).

## Backtrack window

With backtracking, there is a target backtrack window and an actual backtrack window:

- The *target backtrack window* is the amount of time you want to be able to backtrack your DB cluster. When you enable backtracking, you specify a *target backtrack window*. For example, you might specify a target backtrack window of 24 hours if you want to be able to backtrack the DB cluster one day.
- The *actual backtrack window* is the actual amount of time you can backtrack your DB cluster, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for storing information about database changes, called *change records*.

As you make updates to your Aurora DB cluster with backtracking enabled, you generate change records. Aurora retains change records for the target backtrack window, and you pay an hourly rate for storing them. Both the target backtrack window and the workload on your DB cluster determine the number of change records you store. The workload is the number of changes you make to your DB cluster in a given amount of time. If your workload is heavy, you store more change records in your backtrack window than you do if your workload is light.

You can think of your target backtrack window as the goal for the maximum amount of time you want to be able to backtrack your DB cluster. In most cases, you can backtrack the maximum amount of time that you specified. However, in some cases, the DB cluster can't store enough change records to backtrack the maximum amount of time, and your actual backtrack window is smaller than your target. Typically, the actual backtrack window is smaller than the target when you have extremely heavy workload on your DB cluster. When your actual backtrack window is smaller than your target, we send you a notification.

When backtracking is enabled for a DB cluster, and you delete a table stored in the DB cluster, Aurora keeps that table in the backtrack change records. It does this so that you can revert back to a time before you deleted the table. If you don't have enough space in your backtrack window to store the table, the table might be removed from the backtrack change records eventually.

## Backtracking time

Aurora always backtracks to a time that is consistent for the DB cluster. Doing so eliminates the possibility of uncommitted transactions when the backtrack is complete. When you specify a time for a backtrack, Aurora automatically chooses the nearest possible consistent time. This approach means that the completed backtrack might not exactly match the time you specify, but you can determine the exact time for a backtrack by using the [describe-db-cluster-backtracks](#) Amazon CLI command. For more information, see [Retrieving existing backtracks](#).

## Backtracking limitations

The following limitations apply to backtracking:

- Backtracking is only available for DB clusters that were created with the Backtrack feature enabled. You can't modify a DB cluster to enable the Backtrack feature. You can enable the Backtrack feature when you create a new DB cluster or restore a snapshot of a DB cluster.
- The limit for a backtrack window is 72 hours.
- Backtracking affects the entire DB cluster. For example, you can't selectively backtrack a single table or a single data update.

- You can't create cross-Region read replicas from a backtrack-enabled cluster, but you can still enable binary log (binlog) replication on the cluster. If you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you choose to force the backtrack. Any attempts to force a backtrack will break downstream read replicas and interfere with other operations such as blue/green deployments.
- You can't backtrack a database clone to a time before that database clone was created. However, you can use the original database to backtrack to a time before the clone was created. For more information about database cloning, see [Cloning a volume for an Amazon Aurora DB cluster](#).
- Backtracking causes a brief DB instance disruption. You must stop or pause your applications before starting a backtrack operation to ensure that there are no new read or write requests. During the backtrack operation, Aurora pauses the database, closes any open connections, and drops any uncommitted reads and writes. It then waits for the backtrack operation to complete.
- You can't restore a cross-Region snapshot of a backtrack-enabled cluster in an Amazon Region that doesn't support backtracking.
- If you perform an in-place upgrade for a backtrack-enabled cluster from Aurora MySQL version 2 to version 3, you can't backtrack to a point in time before the upgrade happened.

## Region and version availability

Backtrack is not available for Aurora PostgreSQL.

Following are the supported engines and Region availability for Backtrack with Aurora MySQL.

Region	Aurora MySQL version 3	Aurora MySQL version 2
US East (N. Virginia)	All versions	All versions
US East (Ohio)	All versions	All versions
US West (N. California)	All versions	All versions
US West (Oregon)	All versions	All versions

Region	Aurora MySQL version 3	Aurora MySQL version 2
Africa (Cape Town)	–	–
Asia Pacific (Hong Kong)	–	–
Asia Pacific (Jakarta)	–	–
Asia Pacific (Malaysia)	–	–
Asia Pacific (Melbourne)	–	–
Asia Pacific (Mumbai)	All versions	All versions
Asia Pacific (New Zealand)	–	–
Asia Pacific (Osaka)	All versions	Version 2.07.3 and higher
Asia Pacific (Seoul)	All versions	All versions
Asia Pacific (Singapore)	All versions	All versions
Asia Pacific (Sydney)	All versions	All versions
Asia Pacific (Taipei)	–	–
Asia Pacific (Thailand)	–	–

Region	Aurora MySQL version 3	Aurora MySQL version 2
Asia Pacific (Tokyo)	All versions	All versions
Canada (Central)	All versions	All versions
Canada West (Calgary)	–	–
China (Beijing)	–	–
China (Ningxia)	–	–
Europe (Frankfurt)	All versions	All versions
Europe (Ireland)	All versions	All versions
Europe (London)	All versions	All versions
Europe (Milan)	–	–
Europe (Paris)	All versions	All versions
Europe (Spain)	–	–
Europe (Stockholm)	–	–
Europe (Zurich)	–	–
Israel (Tel Aviv)	–	–
Mexico (Central)	–	–
Middle East (Bahrain)	–	–
Middle East (UAE)	–	–

Region	Aurora MySQL version 3	Aurora MySQL version 2
South America (São Paulo)	–	–
Amazon GovCloud (US- East)	–	–
Amazon GovCloud (US- West)	–	–

## Upgrade considerations for backtrack-enabled clusters

You can upgrade a backtrack-enabled DB cluster from Aurora MySQL version 2 to version 3, because all minor versions of Aurora MySQL version 3 are supported for Backtrack.

## Configuring backtracking a Aurora MySQL DB cluster

To use the Backtrack feature, you must enable backtracking and specify a target backtrack window. Otherwise, backtracking is disabled.

For the target backtrack window, specify the amount of time that you want to be able to rewind your database using Backtrack. Aurora tries to retain enough change records to support that window of time.

### Console

You can use the console to configure backtracking when you create a new DB cluster. You can also modify a DB cluster to change the backtrack window for a backtrack-enabled cluster. If you turn off backtracking entirely for a cluster by setting the backtrack window to 0, you can't enable backtrack again for that cluster.

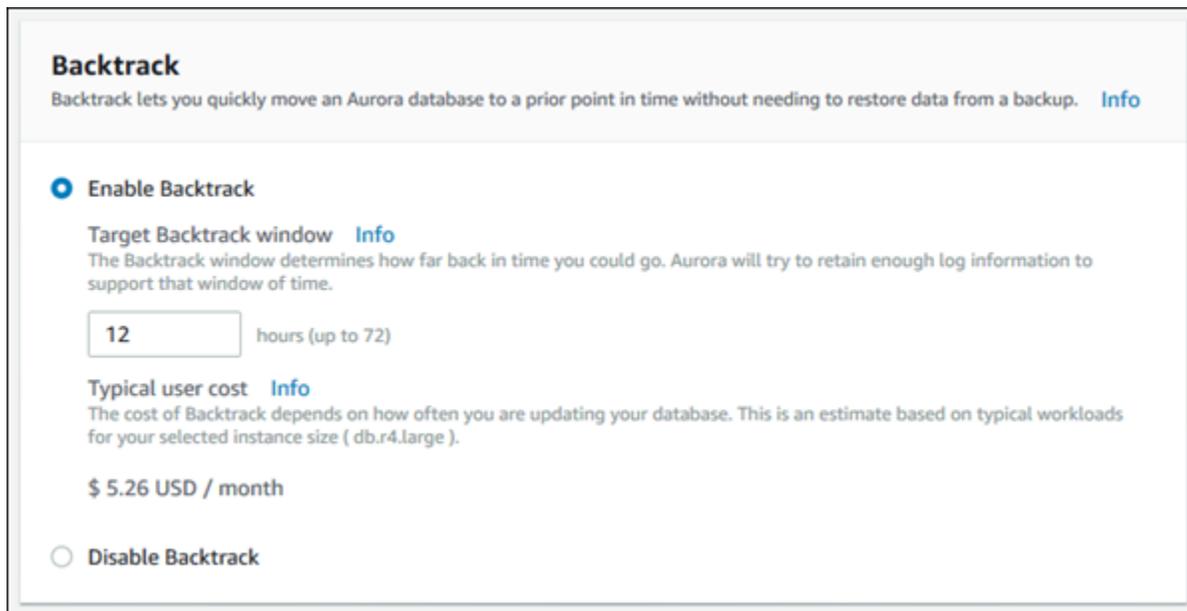

### Topics

- [Configuring backtracking with the console when creating a DB cluster](#)
- [Configuring backtrack with the console when modifying a DB cluster](#)

## Configuring backtracking with the console when creating a DB cluster

When you create a new Aurora MySQL DB cluster, backtracking is configured when you choose **Enable Backtrack** and specify a **Target Backtrack window** value that is greater than zero in the **Backtrack** section.

To create a DB cluster, follow the instructions in [Creating an Amazon Aurora DB cluster](#). The following image shows the **Backtrack** section.

The screenshot shows the 'Backtrack' configuration section in the Amazon Aurora console. At the top, there is a title 'Backtrack' and a description: 'Backtrack lets you quickly move an Aurora database to a prior point in time without needing to restore data from a backup.' followed by an 'Info' link. Below this, there are two radio buttons: 'Enable Backtrack' (which is selected) and 'Disable Backtrack'. Under 'Enable Backtrack', there is a 'Target Backtrack window' field with a value of '12' and the text 'hours (up to 72)'. Below that is a 'Typical user cost' section with a value of '\$ 5.26 USD / month'. There are also 'Info' links for both the 'Target Backtrack window' and 'Typical user cost' sections.

When you create a new DB cluster, Aurora has no data for the DB cluster's workload. So it can't estimate a cost specifically for the new DB cluster. Instead, the console presents a typical user cost for the specified target backtrack window based on a typical workload. The typical cost is meant to provide a general reference for the cost of the Backtrack feature.

### **⚠ Important**

Your actual cost might not match the typical cost, because your actual cost is based on your DB cluster's workload.

## Configuring backtrack with the console when modifying a DB cluster

You can modify backtracking for a DB cluster using the console.

**Note**

Currently, you can modify backtracking only for a DB cluster that has the Backtrack feature enabled. The **Backtrack** section doesn't appear for a DB cluster that was created with the Backtrack feature disabled or if the Backtrack feature has been disabled for the DB cluster.

**To modify backtracking for a DB cluster using the console**

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose the cluster that you want to modify, and choose **Modify**.
4. For **Target Backtrack window**, modify the amount of time that you want to be able to backtrack. The limit is 72 hours.

**Backtrack**  
Backtrack lets you quickly move an Aurora database to a prior point in time without needing to restore data from a backup. [Info](#)

**Enable Backtrack**

**Target Backtrack window** [Info](#)  
The Backtrack window determines how far back in time you could go. Aurora will try to retain enough log information to support that window of time.

hours (up to 72)

**Estimated Cost** [Info](#)  
This is an estimate based on your current workload and can change if your workload changes.

\$ 28.76 USD / month

**Disable Backtrack**

The console shows the estimated cost for the amount of time you specified based on the DB cluster's past workload:

- If backtracking was disabled on the DB cluster, the cost estimate is based on the `VolumeWriteIOPS` metric for the DB cluster in Amazon CloudWatch.
- If backtracking was enabled previously on the DB cluster, the cost estimate is based on the `BacktrackChangeRecordsCreationRate` metric for the DB cluster in Amazon CloudWatch.

5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose one of the following:
  - **Apply during the next scheduled maintenance window** – Wait to apply the **Target Backtrack window** modification until the next maintenance window.
  - **Apply immediately** – Apply the **Target Backtrack window** modification as soon as possible.
7. Choose **Modify cluster**.

## Amazon CLI

When you create a new Aurora MySQL DB cluster using the [create-db-cluster](#) Amazon CLI command, backtracking is configured when you specify a `--backtrack-window` value that is greater than zero. The `--backtrack-window` value specifies the target backtrack window. For more information, see [Creating an Amazon Aurora DB cluster](#).

You can also specify the `--backtrack-window` value using the following Amazon CLI commands:

- [modify-db-cluster](#)
- [restore-db-cluster-from-s3](#)
- [restore-db-cluster-from-snapshot](#)
- [restore-db-cluster-to-point-in-time](#)

The following procedure describes how to modify the target backtrack window for a DB cluster using the Amazon CLI.

### To modify the target backtrack window for a DB cluster using the Amazon CLI

- Call the [modify-db-cluster](#) Amazon CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – The maximum number of seconds that you want to be able to backtrack the DB cluster.

The following example sets the target backtrack window for `sample-cluster` to one day (86,400 seconds).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --backtrack-window 86400
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --backtrack-window 86400
```

### Note

Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

## RDS API

When you create a new Aurora MySQL DB cluster using the [CreateDBCluster](#) Amazon RDS API operation, backtracking is configured when you specify a `BacktrackWindow` value that is greater than zero. The `BacktrackWindow` value specifies the target backtrack window for the DB cluster specified in the `DBClusterIdentifier` value. For more information, see [Creating an Amazon Aurora DB cluster](#).

You can also specify the `BacktrackWindow` value using the following API operations:

- [ModifyDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

**Note**

Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

## Performing a backtrack for an Aurora MySQL DB cluster

You can backtrack a DB cluster to a specified backtrack time stamp. If the backtrack time stamp isn't earlier than the earliest possible backtrack time, and isn't in the future, the DB cluster is backtracked to that time stamp.

Otherwise, an error typically occurs. Also, if you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you've chosen to force the backtrack to occur. Forcing a backtrack to occur can interfere with other operations that use binary logging.

**Important**

Backtracking doesn't generate binlog entries for the changes that it makes. If you have binary logging enabled for the DB cluster, backtracking might not be compatible with your binlog implementation.

**Note**

For database clones, you can't backtrack the DB cluster earlier than the date and time when the clone was created. For more information about database cloning, see [Cloning a volume for an Amazon Aurora DB cluster](#).

### Console

The following procedure describes how to perform a backtrack operation for a DB cluster using the console.

#### To perform a backtrack operation using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

2. In the navigation pane, choose **Instances**.
3. Choose the primary instance for the DB cluster that you want to backtrack.
4. For **Actions**, choose **Backtrack DB cluster**.
5. On the **Backtrack DB cluster** page, enter the backtrack time stamp to backtrack the DB cluster to.

### Backtrack DB cluster

Rewinds the DB cluster to a previous point in time without creating a new DB cluster.

Earliest restorable time is May 7, 2018 at 4:30:59 PM UTC-7 (Local) ⓘ

Date:  Time:  :  :  UTC-7

The next available time will be used if the specified time is not available.

⚠ Your DB cluster is unavailable during the Backtrack process, which typically takes a few minutes.

Cancel Backtrack DB cluster

6. Choose **Backtrack DB cluster**.

## Amazon CLI

The following procedure describes how to backtrack a DB cluster using the Amazon CLI.

### To backtrack a DB cluster using the Amazon CLI

- Call the [backtrack-db-cluster](#) Amazon CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-to` – The backtrack time stamp to backtrack the DB cluster to, specified in ISO 8601 format.

The following example backtracks the DB cluster `sample-cluster` to March 19, 2018, at 10 a.m.

For Linux, macOS, or Unix:

```
aws rds backtrack-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --backtrack-to 2018-03-19T10:00:00+00:00
```

For Windows:

```
aws rds backtrack-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --backtrack-to 2018-03-19T10:00:00+00:00
```

## RDS API

To backtrack a DB cluster using the Amazon RDS API, use the [BacktrackDBCluster](#) operation. This operation backtracks the DB cluster specified in the `DBClusterIdentifier` value to the specified time.

## Monitoring backtracking for an Aurora MySQL DB cluster

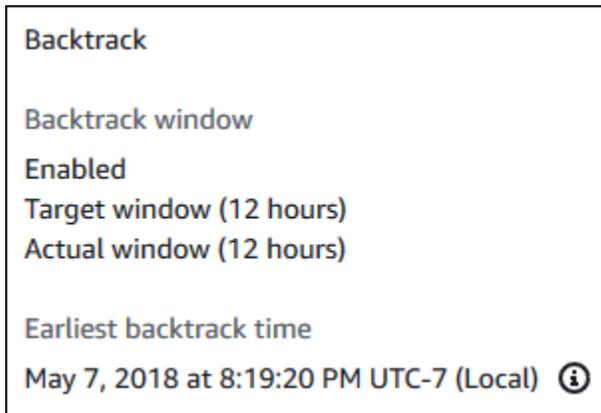

You can view backtracking information and monitor backtracking metrics for a DB cluster.

### Console

#### To view backtracking information and monitor backtracking metrics using the console

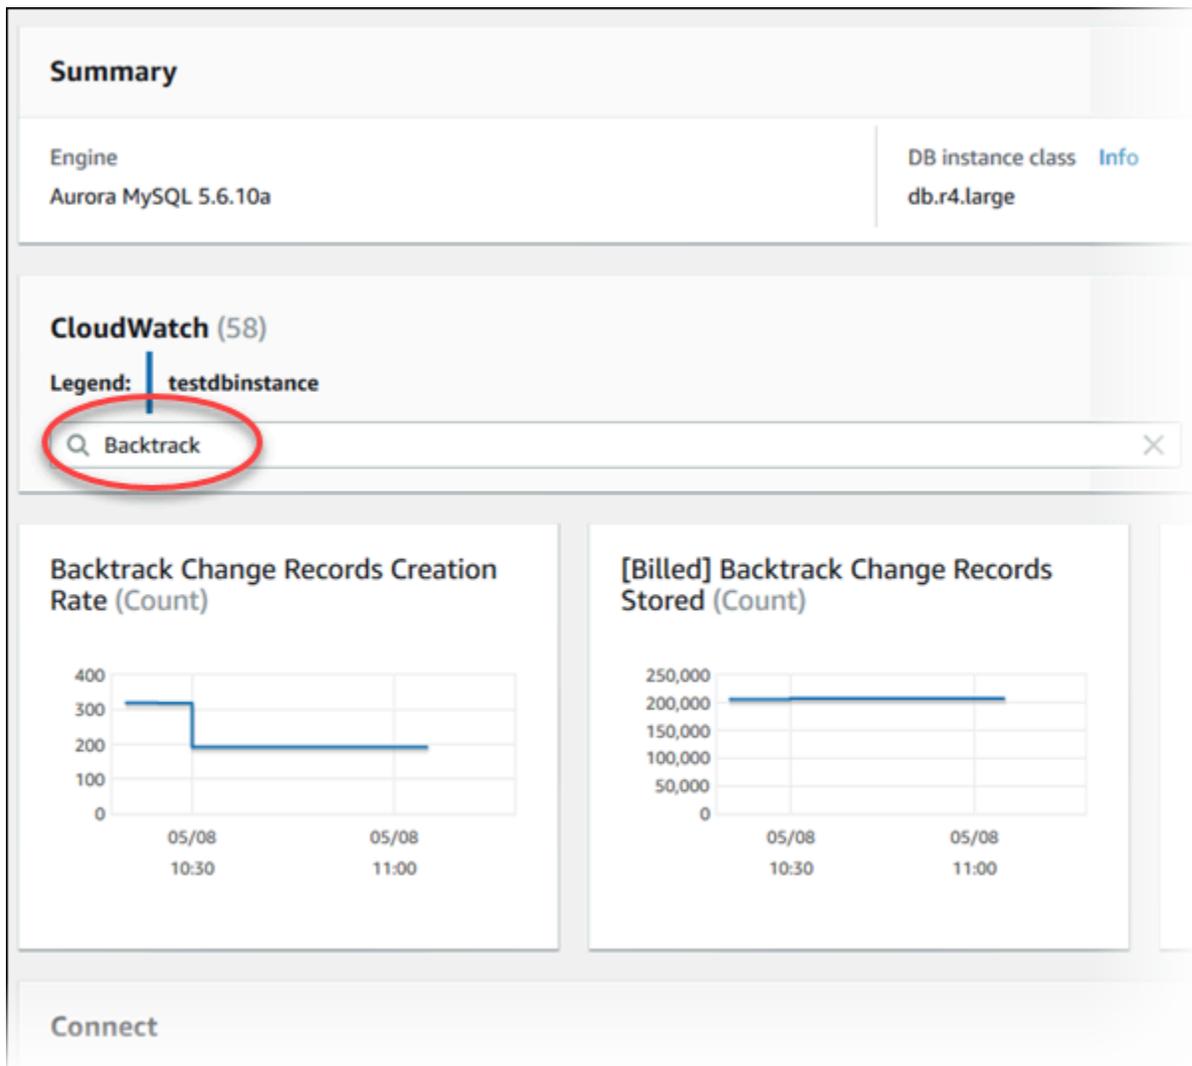

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose the DB cluster name to open information about it.

The backtrack information is in the **Backtrack** section.

When backtracking is enabled, the following information is available:

- **Target window** – The current amount of time specified for the target backtrack window. The target is the maximum amount of time that you can backtrack if there is sufficient storage.
  - **Actual window** – The actual amount of time you can backtrack, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for retaining backtrack change records.
  - **Earliest backtrack time** – The earliest possible backtrack time for the DB cluster. You can't backtrack the DB cluster to a time before the displayed time.
4. Do the following to view backtracking metrics for the DB cluster:
- a. In the navigation pane, choose **Instances**.
  - b. Choose the name of the primary instance for the DB cluster to display its details.
  - c. In the **CloudWatch** section, type **Backtrack** into the **CloudWatch** box to show only the Backtrack metrics.

The following metrics are displayed:

- **Backtrack Change Records Creation Rate (Count)** – This metric shows the number of backtrack change records created over five minutes for your DB cluster. You can use this metric to estimate the backtrack cost for your target backtrack window.
- **[Billed] Backtrack Change Records Stored (Count)** – This metric shows the actual number of backtrack change records used by your DB cluster.
- **Backtrack Window Actual (Minutes)** – This metric shows whether there is a difference between the target backtrack window and the actual backtrack window. For example, if your target backtrack window is 2 hours (120 minutes), and this metric shows that the actual backtrack window is 100 minutes, then the actual backtrack window is smaller than the target.

- **Backtrack Window Alert (Count)** – This metric shows how often the actual backtrack window is smaller than the target backtrack window for a given period of time.

**Note**

The following metrics might lag behind the current time:

- **Backtrack Change Records Creation Rate (Count)**
- **[Billed] Backtrack Change Records Stored (Count)**

## Amazon CLI

The following procedure describes how to view backtrack information for a DB cluster using the Amazon CLI.

### To view backtrack information for a DB cluster using the Amazon CLI

- Call the [describe-db-clusters](#) Amazon CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example lists backtrack information for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters \  
  --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-clusters ^  
  --db-cluster-identifier sample-cluster
```

## RDS API

To view backtrack information for a DB cluster using the Amazon RDS API, use the [DescribeDBClusters](#) operation. This operation returns backtrack information for the DB cluster specified in the `DBClusterIdentifier` value.

## Subscribing to a backtrack event with the console

The following procedure describes how to subscribe to a backtrack event using the console. The event sends you an email or text notification when your actual backtrack window is smaller than your target backtrack window.

### To view backtrack information using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Event subscriptions**.
3. Choose **Create event subscription**.
4. In the **Name** box, type a name for the event subscription, and ensure that **Yes** is selected for **Enabled**.
5. In the **Target** section, choose **New email topic**.
6. For **Topic name**, type a name for the topic, and for **With these recipients**, enter the email addresses or phone numbers to receive the notifications.
7. In the **Source** section, choose **Instances** for **Source type**.
8. For **Instances to include**, choose **Select specific instances**, and choose your DB instance.
9. For **Event categories to include**, choose **Select specific event categories**, and choose **backtrack**.

Your page should look similar to the following page.

# Create event subscription

## Details

**Name**

Name of the Subscription.

BacktrackEventSubscription

**Enabled**

## 10. Choose **Create**.

### Retrieving existing backtracks

You can retrieve information about existing backtracks for a DB cluster. This information includes the unique identifier of the backtrack, the date and time backtracked to and from, the date and time the backtrack was requested, and the current status of the backtrack.

#### **Note**

Currently, you can't retrieve existing backtracks using the console.

### Amazon CLI

The following procedure describes how to retrieve existing backtracks for a DB cluster using the Amazon CLI.

#### To retrieve existing backtracks using the Amazon CLI

- Call the [describe-db-cluster-backtracks](#) Amazon CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example retrieves existing backtracks for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-backtracks \  
  --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-cluster-backtracks ^  
  --db-cluster-identifier sample-cluster
```

## RDS API

To retrieve information about the backtracks for a DB cluster using the Amazon RDS API, use the [DescribeDBClusterBacktracks](#) operation. This operation returns information about backtracks for the DB cluster specified in the `DBClusterIdentifier` value.

## Disabling backtracking for an Aurora MySQL DB cluster

You can disable the Backtrack feature for a DB cluster.

### Console

You can disable backtracking for a DB cluster using the console. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

### To disable the Backtrack feature for a DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose the cluster you want to modify, and choose **Modify**.
4. In the **Backtrack** section, choose **Disable Backtrack**.
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose one of the following:
  - **Apply during the next scheduled maintenance window** – Wait to apply the modification until the next maintenance window.
  - **Apply immediately** – Apply the modification as soon as possible.
7. Choose **Modify Cluster**.

### Amazon CLI

You can disable the Backtrack feature for a DB cluster using the Amazon CLI by setting the target backtrack window to 0 (zero). After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

### To modify the target backtrack window for a DB cluster using the Amazon CLI

- Call the [modify-db-cluster](#) Amazon CLI command and supply the following values:

- `--db-cluster-identifier` – The name of the DB cluster.
- `--backtrack-window` – specify `0` to turn off backtracking.

The following example disables the Backtrack feature for the `sample-cluster` by setting `--backtrack-window` to `0`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --backtrack-window 0
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --backtrack-window 0
```

## RDS API

To disable the Backtrack feature for a DB cluster using the Amazon RDS API, use the [ModifyDBCluster](#) operation. Set the `BacktrackWindow` value to `0` (zero), and specify the DB cluster in the `DBClusterIdentifier` value. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

## Testing Amazon Aurora MySQL using fault injection queries

You can test the fault tolerance of your Aurora MySQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. They let you schedule a simulated occurrence of one of the following events:

- A crash of a writer or reader DB instance
- A failure of an Aurora Replica
- A disk failure
- Disk congestion

When a fault injection query specifies a crash, it forces a crash of the Aurora MySQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur for.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see [Amazon Aurora endpoint connections](#).

Running fault injection queries requires all of the master user privileges. For more information, see [Master user account privileges](#).

## Testing an instance crash

You can force a crash of an Amazon Aurora instance using the `ALTER SYSTEM CRASH` fault injection query.

For this fault injection query, a failover will not occur. If you want to test a failover, then you can choose the **Failover** instance action for your DB cluster in the RDS console, or use the [failover-db-cluster](#) Amazon CLI command or the [FailoverDBCluster](#) RDS API operation.

### Syntax

```
ALTER SYSTEM CRASH [ INSTANCE | DISPATCHER | NODE ];
```

### Options

This fault injection query takes one of the following crash types:

- **INSTANCE** — A crash of the MySQL-compatible database for the Amazon Aurora instance is simulated.
- **DISPATCHER** — A crash of the dispatcher on the writer instance for the Aurora DB cluster is simulated. The *dispatcher* writes updates to the cluster volume for an Amazon Aurora DB cluster.
- **NODE** — A crash of both the MySQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated. For this fault injection simulation, the cache is also deleted.

The default crash type is `INSTANCE`.

## Testing an Aurora replica failure

You can simulate the failure of an Aurora Replica using the `ALTER SYSTEM SIMULATE READ REPLICA FAILURE` fault injection query.

An Aurora Replica failure blocks all requests from the writer instance to an Aurora Replica or all Aurora Replicas in the DB cluster for a specified time interval. When the time interval completes, the affected Aurora Replicas will be automatically synced up with the writer instance.

### Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT READ REPLICA FAILURE
  [ TO ALL | TO "replica name" ]
  FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE |
  SECOND };
```

### Options

This fault injection query takes the following parameters:

- **percentage\_of\_failure** — The percentage of requests to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no requests are blocked. If you specify 100, then all requests are blocked.
- **Failure type** — The type of failure to simulate. Specify `TO ALL` to simulate failures for all Aurora Replicas in the DB cluster. Specify `TO` and the name of the Aurora Replica to simulate a failure of a single Aurora Replica. The default failure type is `TO ALL`.
- **quantity** — The amount of time for which to simulate the Aurora Replica failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

#### Note

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long of a time interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

## Testing a disk failure

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection query.

During a disk failure simulation, the Aurora DB cluster randomly marks disk segments as faulting. Requests to those segments will be blocked for the duration of the simulation.

### Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK FAILURE
  [ IN DISK index | NODE index ]
  FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE |
  SECOND };
```

### Options

This fault injection query takes the following parameters:

- **percentage\_of\_failure** — The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.
- **DISK index** — A specific logical block of data to simulate the failure event for. If you exceed the range of available logical blocks of data, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster](#).
- **NODE index** — A specific storage node to simulate the failure event for. If you exceed the range of available storage nodes, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster](#).
- **quantity** — The amount of time for which to simulate the disk failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

## Testing disk congestion

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK CONGESTION` fault injection query.

During a disk congestion simulation, the Aurora DB cluster randomly marks disk segments as congested. Requests to those segments will be delayed between the specified minimum and maximum delay time for the duration of the simulation.

## Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK CONGESTION
  BETWEEN minimum AND maximum MILLISECONDS
  [ IN DISK index | NODE index ]
  FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE |
  SECOND };
```

## Options

This fault injection query takes the following parameters:

- **percentage\_of\_failure** — The percentage of the disk to mark as congested during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.
- **DISK index Or NODE index** — A specific disk or node to simulate the failure event for. If you exceed the range of indexes for the disk or node, you will receive an error that tells you the maximum index value that you can specify.
- **minimum And maximum** — The minimum and maximum amount of congestion delay, in milliseconds. Disk segments marked as congested will be delayed for a random amount of time within the range of the minimum and maximum amount of milliseconds for the duration of the simulation.
- **quantity** — The amount of time for which to simulate the disk congestion. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified time unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

## Altering tables in Amazon Aurora using Fast DDL

Amazon Aurora includes optimizations to run an ALTER TABLE operation in place, nearly instantaneously. The operation completes without requiring the table to be copied and without having a material impact on other DML statements. Because the operation doesn't consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.

Aurora MySQL version 3 is compatible with the MySQL 8.0 feature called instant DDL. Aurora MySQL version 2 uses a different implementation called Fast DDL.

## Topics

- [Instant DDL \(Aurora MySQL version 3\)](#)
- [Fast DDL \(Aurora MySQL version 2\)](#)

## Instant DDL (Aurora MySQL version 3)

The optimization performed by Aurora MySQL version 3 to improve the efficiency of some DDL operations is called instant DDL.

Aurora MySQL version 3 is compatible with the instant DDL from community MySQL 8.0. You perform an instant DDL operation by using the clause `ALGORITHM=INSTANT` with the `ALTER TABLE` statement. For syntax and usage details about instant DDL, see [ALTER TABLE](#) and [Online DDL Operations](#) in the MySQL documentation.

The following examples demonstrate the instant DDL feature. The `ALTER TABLE` statements add columns and change default column values. The examples include both regular and virtual columns, and both regular and partitioned tables. At each step, you can see the results by issuing `SHOW CREATE TABLE` and `DESCRIBE` statements.

```
mysql> CREATE TABLE t1 (a INT, b INT, KEY(b)) PARTITION BY KEY(b) PARTITIONS 6;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t1 RENAME TO t2, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b SET DEFAULT 100, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b DROP DEFAULT, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN c ENUM('a', 'b', 'c'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 MODIFY COLUMN c ENUM('a', 'b', 'c', 'd', 'e'), ALGORITHM =
INSTANT;
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> ALTER TABLE t2 ADD COLUMN (d INT GENERATED ALWAYS AS (a + 1) VIRTUAL), ALGORITHM
= INSTANT;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t2 ALTER COLUMN a SET DEFAULT 20,
-> ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t3 (a INT, b INT) PARTITION BY LIST(a)(
-> PARTITION mypart1 VALUES IN (1,3,5),
-> PARTITION MyPart2 VALUES IN (2,4,6)
-> );
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE t3 ALTER COLUMN a SET DEFAULT 20, ALTER COLUMN b SET DEFAULT 200,
ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (a INT, b INT) PARTITION BY RANGE(a)
-> (PARTITION p0 VALUES LESS THAN(100), PARTITION p1 VALUES LESS THAN(1000),
-> PARTITION p2 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE t4 ALTER COLUMN a SET DEFAULT 20,
-> ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

/* Sub-partitioning example */
mysql> CREATE TABLE ts (id INT, purchased DATE, a INT, b INT)
-> PARTITION BY RANGE( YEAR(purchased) )
-> SUBPARTITION BY HASH( TO_DAYS(purchased) )
-> SUBPARTITIONS 2 (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (2000),
-> PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.10 sec)

mysql> ALTER TABLE ts ALTER COLUMN a SET DEFAULT 20,
-> ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)
```

## Fast DDL (Aurora MySQL version 2)

Fast DDL in Aurora MySQL is an optimization designed to improve the performance of certain schema changes, such as adding or dropping columns, by reducing downtime and resource usage. It allows these operations to be completed more efficiently compared to traditional DDL methods.

### **Important**

Currently, you must enable Aurora lab mode to use Fast DDL. For information about enabling lab mode, see [Amazon Aurora MySQL lab mode](#).

The Fast DDL optimization was initially introduced in lab mode on Aurora MySQL version 2 to enhance the efficiency of certain DDL operations. In Aurora MySQL version 3, lab mode has been discontinued, and Fast DDL has been replaced by the MySQL 8.0 Instant DDL feature.

In MySQL, many data definition language (DDL) operations have a significant performance impact.

For example, suppose that you use an ALTER TABLE operation to add a column to a table. Depending on the algorithm specified for the operation, this operation can involve the following:

- Creating a full copy of the table
- Creating a temporary table to process concurrent data manipulation language (DML) operations
- Rebuilding all indexes for the table
- Applying table locks while applying concurrent DML changes
- Slowing concurrent DML throughput

This performance impact can be particularly challenging in environments with large tables or high transaction volumes. Fast DDL helps mitigate these challenges by optimizing schema changes, which enables quicker and less resource-intensive operations.

### **Fast DDL limitations**

Currently, Fast DDL has the following limitations:

- Fast DDL only supports adding nullable columns, without default values, to the end of an existing table.
- Fast DDL doesn't work for partitioned tables.
- Fast DDL doesn't work for InnoDB tables that use the REDUNDANT row format.

- Fast DDL doesn't work for tables with full-text search indexes.
- If the maximum possible record size for the DDL operation is too large, Fast DDL is not used. A record size is too large if it is greater than half the page size. The maximum size of a record is computed by adding the maximum sizes of all columns. For variable sized columns, according to InnoDB standards, extern bytes are not included for computation.

## Fast DDL syntax

```
ALTER TABLE tbl_name ADD COLUMN col_name column_definition
```

This statement takes the following options:

- **tbl\_name** — The name of the table to be modified.
- **col\_name** — The name of the column to be added.
- **col\_definition** — The definition of the column to be added.

### Note

You must specify a nullable column definition without a default value. Otherwise, Fast DDL isn't used.

## Fast DDL examples

The following examples demonstrate the speedup from Fast DDL operations. The first SQL example runs ALTER TABLE statements on a large table without using Fast DDL. This operation takes substantial time. A CLI example shows how to enable Fast DDL for the cluster. Then another SQL example runs the same ALTER TABLE statements on an identical table. With Fast DDL enabled, the operation is very fast.

This example uses the ORDERS table from the TPC-H benchmark, containing 150 million rows. This cluster intentionally uses a relatively small instance class, to demonstrate how long ALTER TABLE statements can take when you can't use Fast DDL. The example creates a clone of the original table containing identical data. Checking the `aurora_lab_mode` setting confirms that the cluster can't use Fast DDL, because lab mode isn't enabled. Then ALTER TABLE ADD COLUMN statements take substantial time to add new columns at the end of the table.

```
mysql> create table orders_regular_ddl like orders;
```

```

Query OK, 0 rows affected (0.06 sec)

mysql> insert into orders_regular_ddl select * from orders;
Query OK, 150000000 rows affected (1 hour 1 min 25.46 sec)

mysql> select @@aurora_lab_mode;
+-----+
| @@aurora_lab_mode |
+-----+
|                   0 |
+-----+

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (40 min 31.41 sec)

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (40 min 44.45 sec)

```

This example does the same preparation of a large table as the previous example. However, you can't simply enable lab mode within an interactive SQL session. That setting must be enabled in a custom parameter group. Doing so requires switching out of the `mysql` session and running some Amazon CLI commands or using the Amazon Web Services Management Console.

```

mysql> create table orders_fast_ddl like orders;
Query OK, 0 rows affected (0.02 sec)

mysql> insert into orders_fast_ddl select * from orders;
Query OK, 150000000 rows affected (58 min 3.25 sec)

mysql> set aurora_lab_mode=1;
ERROR 1238 (HY000): Variable 'aurora_lab_mode' is a read only variable

```

Enabling lab mode for the cluster requires some work with a parameter group. This Amazon CLI example uses a cluster parameter group, to ensure that all DB instances in the cluster use the same value for the lab mode setting.

```

$ aws rds create-db-cluster-parameter-group \
  --db-parameter-group-family aurora5.7 \
  --db-cluster-parameter-group-name lab-mode-enabled-57 --description 'TBD'
$ aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name lab-mode-enabled-57 \
  --query '*[*].[ParameterName,ParameterValue]' \

```

```

    --output text | grep aurora_lab_mode
aurora_lab_mode 0
$ aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name lab-mode-enabled-57 \
  --parameters ParameterName=aurora_lab_mode,ParameterValue=1,ApplyMethod=pending-
reboot
{
  "DBClusterParameterGroupName": "lab-mode-enabled-57"
}

# Assign the custom parameter group to the cluster that's going to use Fast DDL.
$ aws rds modify-db-cluster --db-cluster-identifier tpch100g \
  --db-cluster-parameter-group-name lab-mode-enabled-57
{
  "DBClusterIdentifier": "tpch100g",
  "DBClusterParameterGroup": "lab-mode-enabled-57",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.10.2",
  "Status": "available"
}

# Reboot the primary instance for the cluster tpch100g:
$ aws rds reboot-db-instance --db-instance-identifier instance-2020-12-22-5208
{
  "DBInstanceIdentifier": "instance-2020-12-22-5208",
  "DBInstanceStatus": "rebooting"
}

$ aws rds describe-db-clusters --db-cluster-identifier tpch100g \
  --query '*[].[DBClusterParameterGroup]' --output text
lab-mode-enabled-57

$ aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name lab-mode-enabled-57 \
  --query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep aurora_lab_mode
aurora_lab_mode 1

```

The following example shows the remaining steps after the parameter group change takes effect. It tests the `aurora_lab_mode` setting to make sure that the cluster can use Fast DDL. Then it runs `ALTER TABLE` statements to add columns to the end of another large table. This time, the statements finish very quickly.

```
mysql> select @@aurora_lab_mode;
+-----+
| @@aurora_lab_mode |
+-----+
|                1 |
+-----+

mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (1.51 sec)

mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (0.40 sec)
```

## Displaying volume status for an Aurora MySQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the Amazon Region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](#) on the Amazon Database Blog.

You can simulate the failure of an entire storage node, or a single logical block of data within a storage node. To do so, you use the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection statement. For the statement, you specify the index value of a specific logical block of data or storage node. However, if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume, the statement returns an error. For more information about fault injection queries, see [Testing Amazon Aurora MySQL using fault injection queries](#).

You can avoid that error by using the `SHOW VOLUME STATUS` statement. The statement returns two server status variables, `Disks` and `Nodes`. These variables represent the total number of logical blocks of data and storage nodes, respectively, for the DB cluster volume.

### Syntax

```
SHOW VOLUME STATUS
```

## Example

The following example illustrates a typical `SHOW VOLUME STATUS` result.

```
mysql> SHOW VOLUME STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Disks         | 96    |
| Nodes         | 74    |
+-----+-----+
```

# Tuning Aurora MySQL

Wait events and thread states are important tuning tools for Aurora MySQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.

Amazon DevOps Guru for RDS can proactively determine whether your Aurora MySQL databases are experiencing problematic conditions that might cause bigger problems later. Amazon DevOps Guru for RDS publishes an explanation and recommendations for corrective actions in a proactive insight. This section contains insights for common problems.

## Important

The wait events and thread states in this section are specific to Aurora MySQL. Use the information in this section to tune only Amazon Aurora, not Amazon RDS for MySQL. Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works different from open source storage, so storage-related wait events indicate different resource conditions.

## Topics

- [Essential concepts for Aurora MySQL tuning](#)
- [Tuning Aurora MySQL with wait events](#)
- [Tuning Aurora MySQL with thread states](#)
- [Tuning Aurora MySQL with Amazon DevOps Guru proactive insights](#)

## Essential concepts for Aurora MySQL tuning

Before you tune your Aurora MySQL database, make sure to learn what wait events and thread states are and why they occur. Also review the basic memory and disk architecture of Aurora MySQL when using the InnoDB storage engine. For a helpful architecture diagram, see the [MySQL Reference Manual](#).

## Topics

- [Aurora MySQL wait events](#)
- [Aurora MySQL thread states](#)
- [Aurora MySQL memory](#)
- [Aurora MySQL processes](#)

## Aurora MySQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `io/socket/sql/client_connection` indicates that a thread is in the process of handling a new connection. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

## Aurora MySQL thread states

A *general thread state* is a `State` value that is associated with general query processing. For example, the thread state `sending_data` indicates that a thread is reading and filtering rows for a query to determine the correct result set.

You can use thread states to tune Aurora MySQL in a similar fashion to how you use wait events. For example, frequent occurrences of `sending_data` usually indicate that a query isn't using an index. For more information about thread states, see [General Thread States](#) in the *MySQL Reference Manual*.

When you use Performance Insights, one of the following conditions is true:

- Performance Schema is turned on – Aurora MySQL shows wait events rather than the thread state.
- Performance Schema isn't turned on – Aurora MySQL shows the thread state.

We recommend that you configure the Performance Schema for automatic management. The Performance Schema provides additional insights and better tools to investigate potential performance problems. For more information, see [Overview of the Performance Schema for Performance Insights on Aurora MySQL](#).

## Aurora MySQL memory

In Aurora MySQL, the most important memory areas are the buffer pool and log buffer.

### Topics

- [Buffer pool](#)

### Buffer pool

The *buffer pool* is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk.

The buffer pool is structured as a linked list of pages. A *page* can hold multiple rows. Aurora MySQL uses a least recently used (LRU) algorithm to age pages out of the pool.

For more information, see [Buffer Pool](#) in the *MySQL Reference Manual*.

## Aurora MySQL processes

Aurora MySQL uses a process model that is very different from Aurora PostgreSQL.

### Topics

- [MySQL server \(mysqld\)](#)
- [Threads](#)
- [Thread pool](#)

### MySQL server (mysqld)

The MySQL server is a single operating-system process named `mysqld`. The MySQL server doesn't spawn additional processes. Thus, an Aurora MySQL database uses `mysqld` to perform most of its work.

When the MySQL server starts, it listens for network connections from MySQL clients. When a client connects to the database, `mysqld` opens a thread.

### Threads

Connection manager threads associate each client connection with a dedicated thread. This thread manages authentication, runs statements, and returns results to the client. Connection manager creates new threads when necessary.

The *thread cache* is the set of available threads. When a connection ends, MySQL returns the thread to the thread cache if the cache isn't full. The `thread_cache_size` system variable determines the thread cache size.

### Thread pool

The *thread pool* consists of a number of thread groups. Each group manages a set of client connections. When a client connects to the database, the thread pool assigns the connections to thread groups in round-robin fashion. The thread pool separates connections and threads. There is no fixed relationship between connections and the threads that run statements received from those connections.

## Tuning Aurora MySQL with wait events

The following table summarizes the Aurora MySQL wait events that most commonly indicate performance problems. The following wait events are a subset of the list in [Aurora MySQL wait events](#).

Wait event	Description
<a href="#">cpu</a>	This event occurs when a thread is active in CPU or is waiting for CPU.
<a href="#">io/aurora_redo_log_flush</a>	This event occurs when a session is writing persistent data to Aurora storage.
<a href="#">io/aurora_respond_to_client</a>	This event occurs when a thread is waiting to return a result set to a client.
<a href="#">io/redo_log_flush</a>	This event occurs when a session is writing persistent data to Aurora storage.
<a href="#">io/socket/sql/client_connection</a>	This event occurs when a thread is in the process of handling a new connection.
<a href="#">io/table/sql/handler</a>	This event occurs when work has been delegated to a storage engine.
<a href="#">synch/cond/innodb/row_lock_wait</a>	This event occurs when one session has locked a row for an update, and another session tries to update the same row.
<a href="#">synch/cond/innodb/row_lock_wait_cond</a>	This event occurs when one session has locked a row for an update, and another session tries to update the same row.
<a href="#">synch/cond/sql/MDL_context::COND_wai t_status</a>	This event occurs when there are threads waiting on a table metadata lock.

Wait event	Description
<a href="#">synch/mutex/innodb/aurora_lock_thread_slot_futex</a>	This event occurs when one session has locked a row for an update, and another session tries to update the same row.
<a href="#">synch/mutex/innodb/buf_pool_mutex</a>	This event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.
<a href="#">synch/mutex/innodb/fil_system_mutex</a>	This event occurs when a session is waiting to access the tablespace memory cache.
<a href="#">synch/mutex/innodb/trx_sys_mutex</a>	This event occurs when there is high database activity with a large number of transactions.
<a href="#">synch/sxlock/innodb/hash_table_locks</a>	This event occurs when pages not found in the buffer pool must be read from a file.
<a href="#">synch/mutex/innodb/temp_pool_manager_mutex</a>	This event occurs when a session is waiting to acquire a mutex for managing the pool of session temporary tablespaces.

## cpu

The cpu wait event occurs when a thread is active in CPU or is waiting for CPU.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

## Context

For every vCPU, a connection can run work on this CPU. In some situations, the number of active connections that are ready to run is higher than the number of vCPUs. This imbalance results in connections waiting for CPU resources. If the number of active connections stays consistently higher than the number of vCPUs, then your instance experiences CPU contention. The contention causes the `cpu wait` event to occur.

### Note

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the CloudWatch metric `CPUUtilization`. The latter metric is collected from the HyperVisor for a database instance.

Performance Insights OS metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

### Likely causes of increased waits

When this event occurs more than normal, possibly indicating a performance problem, typical causes include the following:

- Analytic queries
- Highly concurrent transactions
- Long-running transactions
- A sudden increase in the number of connections, known as a *login storm*
- An increase in context switching

## Actions

If the `cpu wait` event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Depending on the cause of the increase in CPU utilization, consider the following strategies:

- Increase the CPU capacity of the host. This approach typically gives only temporary relief.
- Identify top queries for potential optimization.
- Redirect some read-only workload to reader nodes, if applicable.

## Topics

- [Identify the sessions or queries that are causing the problem](#)
- [Analyze and optimize the high CPU workload](#)

### Identify the sessions or queries that are causing the problem

To find the sessions and queries, look at the **Top SQL** table in Performance Insights for the SQL statements that have the highest CPU load. For more information, see [Analyzing metrics with the Performance Insights dashboard](#).

Typically, one or two SQL statements consume the majority of CPU cycles. Concentrate your efforts on these statements. Suppose that your DB instance has 2 vCPUs with a DB load of 3.1 average active sessions (AAS), all in the CPU state. In this case, your instance is CPU bound. Consider the following strategies:

- Upgrade to a larger instance class with more vCPUs.
- Tune your queries to have lower CPU load.

In this example, the top SQL queries have a DB load of 1.5 AAS, all in the CPU state. Another SQL statement has a load of 0.1 in the CPU state. In this example, if you stopped the lowest-load SQL statement, you don't significantly reduce database load. However, if you optimize the two high-load queries to be twice as efficient, you eliminate the CPU bottleneck. If you reduce the CPU load of 1.5 AAS by 50 percent, the AAS for each statement decreases to 0.75. The total DB load spent on CPU is now 1.6 AAS. This value is below the maximum vCPU line of 2.0.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#). Also see the Amazon Support article [How can I troubleshoot and resolve high CPU utilization on my Amazon RDS for MySQL instances?](#).

## Analyze and optimize the high CPU workload

After you identify the query or queries increasing CPU usage, you can either optimize them or end the connection. The following example shows how to end a connection.

```
CALL mysql.rds_kill(processID);
```

For more information, see [mysql.rds\\_kill](#).

If you end a session, the action might trigger a long rollback.

## Follow the guidelines for optimizing queries

To optimize queries, consider the following guidelines:

- Run the EXPLAIN statement.

This command shows the individual steps involved in running a query. For more information, see [Optimizing Queries with EXPLAIN](#) in the MySQL documentation.

- Run the SHOW PROFILE statement.

Use this statement to review profile details that can indicate resource usage for statements that are run during the current session. For more information, see [SHOW PROFILE Statement](#) in the MySQL documentation.

- Run the ANALYZE TABLE statement.

Use this statement to refresh the index statistics for the tables accessed by the high-CPU consuming query. By analyzing the statement, you can help the optimizer choose an appropriate execution plan. For more information, see [ANALYZE TABLE Statement](#) in the MySQL documentation.

## Follow the guidelines for improving CPU usage

To improve CPU usage in a database instance, follow these guidelines:

- Ensure that all queries are using proper indexes.

- Find out whether you can use Aurora parallel queries. You can use this technique to reduce CPU usage on the head node by pushing down function processing, row filtering, and column projection for the WHERE clause.
- Find out whether the number of SQL executions per second meets the expected thresholds.
- Find out whether index maintenance or new index creation takes up CPU cycles needed by your production workload. Schedule maintenance activities outside of peak activity times.
- Find out whether you can use partitioning to help reduce the query data set. For more information, see the blog post [How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads](#).

### Check for connection storms

If the DBLoadCPU metric is not very high, but the CPUUtilization metric is high, the cause of the high CPU utilization lies outside of the database engine. A classic example is a connection storm.

Check whether the following conditions are true:

- There is an increase in both the Performance Insights CPUUtilization metric and the Amazon CloudWatch DatabaseConnections metric.
- The number of threads in the CPU is greater than the number of vCPUs.

If the preceding conditions are true, consider decreasing the number of database connections. For example, you can use a connection pool such as RDS Proxy. To learn the best practices for effective connection management and scaling, see the whitepaper [Amazon Aurora MySQL DBA Handbook for Connection Management](#).

### io/aurora\_redo\_log\_flush

The io/aurora\_redo\_log\_flush event occurs when a session is writing persistent data to Amazon Aurora storage.

#### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

## Context

The `io/aurora_redo_log_flush` event is for a write input/output (I/O) operation in Aurora MySQL.

### Note

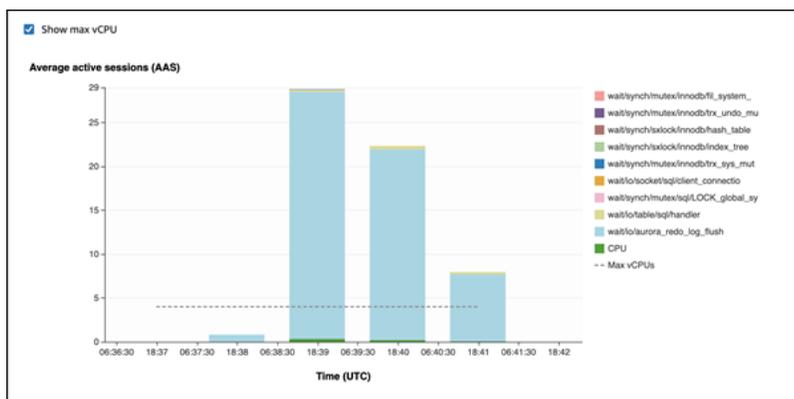

In Aurora MySQL version 3, this wait event is named [io/redo\\_log\\_flush](#).

## Likely causes of increased waits

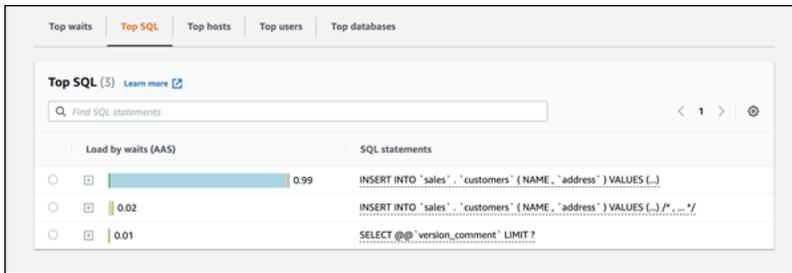

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/aurora_redo_log_flush` wait event.

In the following examples, 50,000 records are inserted into an Aurora MySQL DB cluster using the `db.r5.xlarge` DB instance class:

- In the first example, each session inserts 10,000 records row by row. By default, if a data manipulation language (DML) command isn't within a transaction, Aurora MySQL uses implicit commits. Autocommit is turned on. This means that for each row insertion there is a commit. Performance Insights shows that the connections spend most of their time waiting on the `io/aurora_redo_log_flush` wait event.

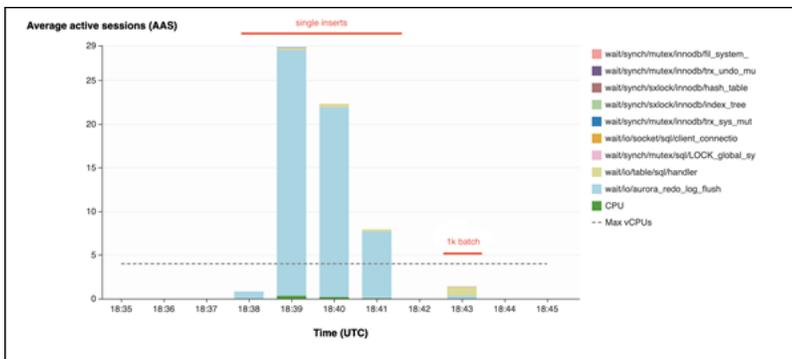

This is caused by the simple insert statements used.

The 50,000 records take 3.5 minutes to be inserted.

- In the second example, inserts are made in 1,000 batches, that is each connection performs 10 commits instead of 10,000. Performance Insights shows that the connections don't spend most of their time on the `io/aurora_redo_log_flush` wait event.

The 50,000 records take 4 seconds to be inserted.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the problematic sessions and queries](#)
- [Group your write operations](#)
- [Turn off autocommit](#)
- [Use transactions](#)
- [Use batches](#)

## Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful Amazon Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### To identify sessions and queries causing a bottleneck

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose your DB instance.
4. In **Database load**, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The queries at the top of the list are causing the highest load on the database.

### Group your write operations

The following examples trigger the `io/aurora_redo_log_flush` wait event. (Autocommit is turned on.)

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```

To reduce the time spent waiting on the `io/aurora_redo_log_flush` wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

## Turn off autocommit

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
-- Other DML statements here
COMMIT;

SET SESSION AUTOCOMMIT=ON;
```

## Use transactions

You can use transactions, as shown in the following example.

```
BEGIN
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

-- Other DML statements here
END
```

## Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES
('xxxx', 'xxxxx'), ('xxxx', 'xxxxx'), ..., ('xxxx', 'xxxxx'), ('xxxx', 'xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND
xxx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1<xx;
```

## io/aurora\_respond\_to\_client

The `io/aurora_respond_to_client` event occurs when a thread is waiting to return a result set to a client.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

### Context

The event `io/aurora_respond_to_client` indicates that a thread is waiting to return a result set to a client.

The query processing is complete, and the results are being returned back to the application client. However, because there isn't enough network bandwidth on the DB cluster, a thread is waiting to return the result set.

## Likely causes of increased waits

When the `io/aurora_respond_to_client` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### DB instance class insufficient for the workload

The DB instance class used by the DB cluster doesn't have the necessary network bandwidth to process the workload efficiently.

### Large result sets

There was an increase in size of the result set being returned, because the query returns higher numbers of rows. The larger result set consumes more network bandwidth.

### Increased load on the client

There might be CPU pressure, memory pressure, or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora MySQL DB cluster.

### Increased network latency

There might be increased network latency between the Aurora MySQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the sessions and queries causing the events](#)
- [Scale the DB instance class](#)
- [Check workload for unexpected results](#)
- [Distribute workload with reader instances](#)
- [Use the `SQL\_BUFFER\_RESULT` modifier](#)

## Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `io/aurora_respond_to_client` wait event. Typically, databases with moderate to significant load

have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

### To find SQL queries that are responsible for high load

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the Amazon Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### Scale the DB instance class

Check for the increase in the value of the Amazon CloudWatch metrics related to network throughput, such as `NetworkReceiveThroughput` and `NetworkTransmitThroughput`. If the DB instance class network bandwidth is being reached, you can scale the DB instance class used by the DB cluster by modifying the DB cluster. A DB instance class with larger network bandwidth returns data to clients more efficiently.

For information about monitoring Amazon CloudWatch metrics, see [Viewing metrics in the Amazon RDS console](#). For information about DB instance classes, see [Amazon Aurora DB instance classes](#).

For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

### Check workload for unexpected results

Check the workload on the DB cluster and make sure that it isn't producing unexpected results. For example, there might be queries that are returning a higher number of rows than expected. In this case, you can use Performance Insights counter metrics such as `InnoDB_rows_read`. For more information, see [Performance Insights counter metrics](#).

## Distribute workload with reader instances

You can distribute read-only workload with Aurora replicas. You can scale horizontally by adding more Aurora replicas. Doing so can result in an increase in the throttling limits for network bandwidth. For more information, see [Amazon Aurora DB clusters](#).

## Use the SQL\_BUFFER\_RESULT modifier

You can add the SQL\_BUFFER\_RESULT modifier to SELECT statements to force the result into a temporary table before they are returned to the client. This modifier can help with performance issues when InnoDB locks aren't being freed because queries are in the io/aurora\_respond\_to\_client wait state. For more information, see [SELECT Statement](#) in the MySQL documentation.

## io/redo\_log\_flush

The io/redo\_log\_flush event occurs when a session is writing persistent data to Amazon Aurora storage.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3

### Context

The io/redo\_log\_flush event is for a write input/output (I/O) operation in Aurora MySQL.

#### Note

In Aurora MySQL version 2, this wait event is named [io/aurora\\_redo\\_log\\_flush](#).

## Likely causes of increased waits

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/redo_log_flush` wait event.

For examples of the behavior of this wait event, see [io/aurora\\_redo\\_log\\_flush](#).

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the problematic sessions and queries](#)
- [Group your write operations](#)
- [Turn off autocommit](#)
- [Use transactions](#)
- [Use batches](#)

## Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful Amazon Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### To identify sessions and queries causing a bottleneck

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose your DB instance.
4. In **Database load**, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The queries at the top of the list are causing the highest load on the database.

## Group your write operations

The following examples trigger the `io/redo_log_flush` wait event. (Autocommit is turned on.)

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```

To reduce the time spent waiting on the `io/redo_log_flush` wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

## Turn off autocommit

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
-- Other DML statements here
COMMIT;

SET SESSION AUTOCOMMIT=ON;
```

## Use transactions

You can use transactions, as shown in the following example.

```
BEGIN
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

-- Other DML statements here
END
```

## Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES
('xxxx','xxxxx'),('xxxx','xxxxx'),...,'xxxx','xxxxx'),('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND
xxx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1<xx;
```

## io/socket/sql/client\_connection

The `io/socket/sql/client_connection` event occurs when a thread is in the process of handling a new connection.

### Topics

- [Supported engine versions](#)

- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

## Context

The event `io/socket/sql/client_connection` indicates that `mysqld` is busy creating threads to handle incoming new client connections. In this scenario, the processing of servicing new client connection requests slows down while connections wait for the thread to be assigned. For more information, see [MySQL server \(mysqld\)](#).

## Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- There is a sudden increase in new user connections from the application to your Amazon RDS instance.
- Your DB instance can't process new connections because the network, CPU, or memory is being throttled.

## Actions

If `io/socket/sql/client_connection` dominates database activity, it doesn't necessarily indicate a performance problem. In a database that isn't idle, a wait event is always on top. Act only when performance degrades. We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the problematic sessions and queries](#)
- [Follow best practices for connection management](#)

- [Scale up your instance if resources are being throttled](#)
- [Check the top hosts and top users](#)
- [Query the performance\\_schema tables](#)
- [Check the thread states of your queries](#)
- [Audit your requests and queries](#)
- [Pool your database connections](#)

## Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### To identify sessions and queries causing a bottleneck

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose your DB instance.
4. In **Database load**, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The queries at the top of the list are causing the highest load on the database.

## Follow best practices for connection management

To manage your connections, consider the following strategies:

- Use connection pooling.

You can gradually increase the number of connections as required. For more information, see the whitepaper [Amazon Aurora MySQL Database Administrator's Handbook](#).

- Use a reader node to redistribute read-only traffic.

For more information, see [Aurora Replicas](#) and [Amazon Aurora endpoint connections](#).

## Scale up your instance if resources are being throttled

Look for examples of throttling in the following resources:

- CPU

Check your Amazon CloudWatch metrics for high CPU usage.

- Network

Check for an increase in the value of the CloudWatch metrics `network_receive_throughput` and `network_transmit_throughput`. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see [Amazon Aurora DB instance classes](#).

- Freeable memory

Check for a drop in the CloudWatch metric `FreeableMemory`. Also, consider turning on Enhanced Monitoring. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

## Check the top hosts and top users

Use Performance Insights to check the top hosts and top users. For more information, see [Analyzing metrics with the Performance Insights dashboard](#).

## Query the performance\_schema tables

To get an accurate count of the current and total connections, query the `performance_schema` tables. With this technique, you identify the source user or host that is responsible for creating a high number of connections. For example, query the `performance_schema` tables as follows.

```
SELECT * FROM performance_schema.accounts;
SELECT * FROM performance_schema.users;
SELECT * FROM performance_schema.hosts;
```

## Check the thread states of your queries

If your performance issue is ongoing, check the thread states of your queries. In the `mysql` client, issue the following command.

```
show processlist;
```

## Audit your requests and queries

To check the nature of the requests and queries from user accounts, use Aurora MySQL Advanced Auditing. To learn how to turn on auditing, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

## Pool your database connections

Consider using Amazon RDS Proxy for connection management. By using RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. For more information, see [Amazon RDS Proxy for Aurora](#).

## io/table/sql/handler

The `io/table/sql/handler` event occurs when work has been delegated to a storage engine.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

### Context

The event `io/table` indicates a wait for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. The `io/table/sql/handler` event indicates an increase in workload activity.

A *handler* is a routine specialized in a certain type of data or focused on certain special tasks. For example, an event handler receives and digests events and signals from the operating system or

from a user interface. A memory handler performs tasks related to memory. A file input handler is a function that receives file input and performs special tasks on the data, according to context.

Views such as `performance_schema.events_waits_current` often show `io/table/sql/handler` when the actual wait is a nested wait event such as a lock. When the actual wait isn't `io/table/sql/handler`, Performance Insights reports the nested wait event. When Performance Insights reports `io/table/sql/handler`, it represents InnoDB processing of the I/O request and not a hidden nested wait event. For more information, see [Performance Schema Atom and Molecule Events](#) in the *MySQL Reference Manual*.

The `io/table/sql/handler` event often appears in top wait events with I/O waits such as `io/aurora_redo_log_flush`.

### Likely causes of increased waits

In Performance Insights, sudden spikes in the `io/table/sql/handler` event indicate an increase in workload activity. Increased activity means increased I/O.

Performance Insights filters the nesting event IDs and doesn't report a `io/table/sql/handler` wait when the underlying nested event is a lock wait. For example, if the root cause event is [synch/mutex/innodb/aurora\\_lock\\_thread\\_slot\\_futex](#), Performance Insights displays this wait in top wait events and not `io/table/sql/handler`.

In views such as `performance_schema.events_waits_current`, waits for `io/table/sql/handler` often appear when the actual wait is a nested wait event such as a lock. When the actual wait differs from `io/table/sql/handler`, Performance Insights looks up the nested wait and reports the actual wait instead of `io/table/sql/handler`. When Performance Insights reports `io/table/sql/handler`, the real wait is `io/table/sql/handler` and not a hidden nested wait event. For more information, see [Performance Schema Atom and Molecule Events](#) in the *MySQL 5.7 Reference Manual*.

### Actions

If this wait event dominates database activity, it doesn't necessarily indicate a performance problem. A wait event is always on top when the database is active. You need to act only when performance degrades.

We recommend different actions depending on the other wait events that you see.

### Topics

- [Identify the sessions and queries causing the events](#)
- [Check for a correlation with Performance Insights counter metrics](#)
- [Check for other correlated wait events](#)

## Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance is isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

### To find SQL queries that are responsible for high load

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### Check for a correlation with Performance Insights counter metrics

Check for Performance Insights counter metrics such as `Innodb_rows_changed`. If counter metrics are correlated with `io/table/sql/handler`, follow these steps:

1. In Performance Insights, look for the SQL statements accounting for the `io/table/sql/handler` top wait event. If possible, optimize this statement so that it returns fewer rows.
2. Retrieve the top tables from the `schema_table_statistics` and `x$schema_table_statistics` views. These views show the amount of time spent per table. For more information, see [The schema\\_table\\_statistics and x\\$schema\\_table\\_statistics Views](#) in the *MySQL Reference Manual*.

By default, rows are sorted by descending total wait time. Tables with the most contention appear first. The output indicates whether time is spent on reads, writes, fetches, inserts, updates, or deletes.

```
mysql> select * from sys.schema_table_statistics limit 1\G

***** 1. row *****
  table_schema: read_only_db
    table_name: sbtest41
  total_latency: 54.11 m
    rows_fetched: 6001557
  fetch_latency: 39.14 m
    rows_inserted: 14833
  insert_latency: 5.78 m
    rows_updated: 30470
  update_latency: 5.39 m
    rows_deleted: 14833
  delete_latency: 3.81 m
io_read_requests: NULL
    io_read: NULL
  io_read_latency: NULL
io_write_requests: NULL
    io_write: NULL
  io_write_latency: NULL
io_misc_requests: NULL
  io_misc_latency: NULL
1 row in set (0.11 sec)
```

## Check for other correlated wait events

If `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` contribute most to the DB load anomaly together, check whether the `innodb_adaptive_hash_index` variable is turned on. If it is, consider increasing the `innodb_adaptive_hash_index_parts` parameter value.

If the Adaptive Hash Index is turned off, consider turning it on. To learn more about the MySQL Adaptive Hash Index, see the following resources:

- The article [Is Adaptive Hash Index in InnoDB right for my workload?](#) on the Percona website
- [Adaptive Hash Index](#) in the *MySQL Reference Manual*

- The article [Contention in MySQL InnoDB: Useful Info From the Semaphores Section](#) on the Percona website

### Note

The Adaptive Hash Index isn't supported on Aurora reader DB instances. In some cases, performance might be poor on a reader instance when `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` are dominant. If so, consider redirecting the workload temporarily to the writer DB instance and turning on the Adaptive Hash Index.

## **synch/cond/innodb/row\_lock\_wait**

The `synch/cond/innodb/row_lock_wait` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](#) in the MySQL documentation.

### **Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3

### **Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

### **Actions**

We recommend different actions depending on the other wait events that you see.

### **Topics**

- [Find and respond to the SQL statements responsible for this wait event](#)
- [Find and respond to the blocking session](#)

## Find and respond to the SQL statements responsible for this wait event

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

## Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;

---TRANSACTION 1688153, ACTIVE 82 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 2 row lock(s)
MySQL thread id 4244, OS thread handle 70369524330224, query id 4020834 172.31.14.179
  reinvent executing
select id1 from test.t1 where id1=1 for update
----- TRX HAS BEEN WAITING 24 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 4 n bits 72 index GEN_CLUST_INDEX of table test.t1 trx
  id 1688153 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread,
           p1.user waiting_user,
           p1.host waiting_host,
```

```

it1.trx_query waiting_query,
ilw.requesting_engine_transaction_id waiting_transaction,
ilw.blocking_engine_lock_id blocking_lock,
il.lock_mode blocking_mode,
il.lock_type blocking_type,
ilw.blocking_engine_transaction_id blocking_transaction,
CASE it.trx_state
  WHEN 'LOCK WAIT'
  THEN it.trx_state
  ELSE p.state end blocker_state,
concat(il.object_schema, '.', il.object_name) as locked_table,
it.trx_mysql_thread_id blocker_thread,
p.user blocker_user,
p.host blocker_host
FROM performance_schema.data_lock_waits ilw
JOIN performance_schema.data_locks il
ON ilw.blocking_engine_lock_id = il.engine_lock_id
AND ilw.blocking_engine_transaction_id = il.engine_transaction_id
JOIN information_schema.innodb_trx it
ON ilw.blocking_engine_transaction_id = it.trx_id join information_schema.processlist p
ON it.trx_mysql_thread_id = p.id join information_schema.innodb_trx it1
ON ilw.requesting_engine_transaction_id = it1.trx_id join
  information_schema.processlist p1
ON it1.trx_mysql_thread_id = p1.id\G

***** 1. row *****
waiting_thread: 4244
waiting_user: reinvent
waiting_host: 123.456.789.012:18158
waiting_query: select id1 from test.t1 where id1=1 for update
waiting_transaction: 1688153
blocking_lock: 70369562074216:11:4:2:70369549808672
blocking_mode: X
blocking_type: RECORD
blocking_transaction: 1688142
blocker_state: User sleep
locked_table: test.t1
blocker_thread: 4243
blocker_user: reinvent
blocker_host: 123.456.789.012:18156
1 row in set (0.00 sec)

```

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB transaction and locking information](#) in the MySQL documentation.

## **synch/cond/innodb/row\_lock\_wait\_cond**

The `synch/cond/innodb/row_lock_wait_cond` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](#) in the MySQL documentation.

### **Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

### **Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

### **Actions**

We recommend different actions depending on the other wait events that you see.

### **Topics**

- [Find and respond to the SQL statements responsible for this wait event](#)
- [Find and respond to the blocking session](#)

### **Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.

- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

## Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;

---TRANSACTION 2771110, ACTIVE 112 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 1 row lock(s)
MySQL thread id 24, OS thread handle 70369573642160, query id 13271336 172.31.14.179
  reinvent Sending data
select id1 from test.t1 where id1=1 for update
----- TRX HAS BEEN WAITING 43 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 3 n bits 0 index GEN_CLUST_INDEX of table test.t1 trx
  id 2771110 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread,
             p1.user waiting_user,
             p1.host waiting_host,
             it1.trx_query waiting_query,
             ilw.requesting_trx_id waiting_transaction,
             ilw.blocking_lock_id blocking_lock,
             il.lock_mode blocking_mode,
             il.lock_type blocking_type,
             ilw.blocking_trx_id blocking_transaction,
             CASE it.trx_state
```

```

        WHEN 'LOCK WAIT'
        THEN it.trx_state
        ELSE p.state
    END blocker_state,
    il.lock_table locked_table,
    it.trx_mysql_thread_id blocker_thread,
    p.user blocker_user,

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB transaction and locking information](#) in the MySQL documentation.

## **synch/cond/sql/MDL\_context::COND\_wait\_status**

The `synch/cond/sql/MDL_context::COND_wait_status` event occurs when there are threads waiting on a table metadata lock.

### **Topics**

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### **Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

### **Context**

The event `synch/cond/sql/MDL_context::COND_wait_status` indicates that there are threads waiting on a table metadata lock. In some cases, one session holds a metadata lock on a table and another session tries to get the same lock on the same table. In such a case, the second session waits on the `synch/cond/sql/MDL_context::COND_wait_status` wait event.

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies to tables, schemas, scheduled events, tablespaces, and user locks acquired with the `get_lock` function, and stored programs. Stored programs include procedures, functions, and triggers. For more information, see [Metadata locking](#) in the MySQL documentation.

The MySQL process list shows this session in the state `waiting for metadata lock`. In Performance Insights, if `Performance_schema` is turned on, the event `synch/cond/sql/MDL_context::COND_wait_status` appears.

The default timeout for a query waiting on a metadata lock is based on the value of the `lock_wait_timeout` parameter, which defaults to 31,536,000 seconds (365 days).

For more details on different InnoDB locks and the types of locks that can cause conflicts, see [InnoDB Locking](#) in the MySQL documentation.

### Likely causes of increased waits

When the `synch/cond/sql/MDL_context::COND_wait_status` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

#### Long-running transactions

One or more transactions are modifying a large amount of data and holding locks on tables for a very long time.

#### Idle transactions

One or more transactions remain open for a long time, without being committed or rolled back.

#### DDL statements on large tables

One or more data definition statements (DDL) statements, such as `ALTER TABLE` commands, were run on very large tables.

#### Explicit table locks

There are explicit locks on tables that aren't being released in a timely manner. For example, an application might run `LOCK TABLE` statements improperly.

### Actions

We recommend different actions depending on the causes of your wait event and on the version of the Aurora MySQL DB cluster.

### Topics

- [Identify the sessions and queries causing the events](#)
- [Check for past events](#)
- [Run queries on Aurora MySQL version 2](#)
- [Respond to the blocking session](#)

## Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `synch/cond/sql/MDL_context::COND_wait_status` wait event. However, to identify the blocking session, query metadata tables from `performance_schema` and `information_schema` on the DB cluster.

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

### To find SQL queries that are responsible for high load

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard for that DB instance appears.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the Amazon Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### Check for past events

You can gain insight into this wait event to check for past occurrences of it. To do so, complete the following actions:

- Check the data manipulation language (DML) and DDL throughput and latency to see if there were any changes in workload.

You can use Performance Insights to find queries waiting on this event at the time of the issue. Also, you can view the digest of the queries run near the time of issue.

- If audit logs or general logs are turned on for the DB cluster, you can check for all queries run on the objects (`schema.table`) involved in the waiting transaction. You can also check for the queries that completed running before the transaction.

The information available to troubleshoot past events is limited. Performing these checks doesn't show which object is waiting for information. However, you can identify tables with heavy load at the time of the event and the set of frequently operated rows causing conflict at the time of issue. You can then use this information to reproduce the issue in a test environment and provide insights about its cause.

## Run queries on Aurora MySQL version 2

In Aurora MySQL version 2, you can identify the blocked session directly by querying `performance_schema` tables or `sys` schema views. An example can illustrate how to query tables to identify blocking queries and sessions.

In the following process list output, the connection ID 89 is waiting on a metadata lock, and it's running a `TRUNCATE TABLE` command. In a query on the `performance_schema` tables or `sys` schema views, the output shows that the blocking session is 76.

```
MySQL [(none)]> select @@version, @@aurora_version;
+-----+-----+
| @@version | @@aurora_version |
+-----+-----+
| 5.7.12    | 2.11.5           |
+-----+-----+
1 row in set (0.01 sec)
```

```
MySQL [(none)]> show processlist;

```

## Respond to the blocking session

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the MySQL documentation.

## synch/mutex/innodb/aurora\_lock\_thread\_slot\_futex

The synch/mutex/innodb/aurora\_lock\_thread\_slot\_futex event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](#) in the *MySQL Reference*.

## Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

## Likely causes of increased waits

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

## Actions

We recommend different actions depending on the other wait events that you see.

## Topics

- [Find and respond to the SQL statements responsible for this wait event](#)
- [Find and respond to the blocking session](#)

## Find and respond to the SQL statements responsible for this wait event

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

## Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;

-----TRANSACTION 302631452, ACTIVE 2 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 376, 1 row lock(s)
MySQL thread id 80109, OS thread handle 0x2ae915060700, query id 938819 10.0.4.12
  reinvent updating
UPDATE sbtest1 SET k=k+1 WHERE id=503
----- TRX HAS BEEN WAITING 2 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 148 page no 11 n bits 30 index `PRIMARY` of table
`sysbench2`.`sbtest1` trx id 302631452 lock_mode X locks rec but not gap waiting
Record lock, heap no 30 PHYSICAL RECORD: n_fields 6; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread,
             p1.user waiting_user,
             p1.host waiting_host,
             it1.trx_query waiting_query,
             ilw.requesting_trx_id waiting_transaction,
             ilw.blocking_lock_id blocking_lock,
             il.lock_mode blocking_mode,
             il.lock_type blocking_type,
             ilw.blocking_trx_id blocking_transaction,
             CASE it.trx_state
               WHEN 'LOCK WAIT'
               THEN it.trx_state
               ELSE p.state
             END blocker_state,
             il.lock_table locked_table,
             it.trx_mysql_thread_id blocker_thread,
             p.user blocker_user,
             p.host blocker_host
FROM information_schema.innodb_lock_waits ilw
JOIN information_schema.innodb_locks il
  ON ilw.blocking_lock_id = il.lock_id
 AND ilw.blocking_trx_id = il.lock_trx_id
JOIN information_schema.innodb_trx it
  ON ilw.blocking_trx_id = it.trx_id
JOIN information_schema.processlist p
```

```

        ON it.trx_mysql_thread_id = p.id
    JOIN information_schema.innodb_trx it1
        ON ilw.requesting_trx_id = it1.trx_id
    JOIN information_schema.processlist p1
        ON it1.trx_mysql_thread_id = p1.id\G

***** 1. row *****
waiting_thread: 3561959471

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the *MySQL Reference Manual*.

## **synch/mutex/innodb/buf\_pool\_mutex**

The `synch/mutex/innodb/buf_pool_mutex` event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.

### **Topics**

- [Relevant engine versions](#)
- [Context](#)

- [Likely causes of increased waits](#)
- [Actions](#)

## Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

## Context

The `buf_pool` mutex is a single mutex that protects the control data structures of the buffer pool.

For more information, see [Monitoring InnoDB Mutex Waits Using Performance Schema](#) in the MySQL documentation.

## Likely causes of increased waits

This is a workload-specific wait event. Common causes for `synch/mutex/innodb/buf_pool_mutex` to appear among the top wait events include the following:

- The buffer pool size isn't large enough to hold the working set of data.
- The workload is more specific to certain pages from a specific table in the database, leading to contention in the buffer pool.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the sessions and queries causing the events](#)
- [Use Performance Insights](#)
- [Create Aurora Replicas](#)
- [Examine the buffer pool size](#)
- [Monitor the global status history](#)

## Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

### To view the Top SQL chart in the Amazon Management Console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Underneath the **Database load** chart, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

## Use Performance Insights

This event is related to workload. You can use Performance Insights to do the following:

- Identify when wait events start, and whether there's any change in the workload around that time from the application logs or related sources.
- Identify the SQL statements responsible for this wait event. Examine the execution plan of the queries to make sure that these queries are optimized and using appropriate indexes.

If the top queries responsible for the wait event are related to the same database object or table, then consider partitioning that object or table.

## Create Aurora Replicas

You can create Aurora Replicas to serve read-only traffic. You can also use Aurora Auto Scaling to handle surges in read traffic. Make sure to run scheduled read-only tasks and logical backups on Aurora Replicas.

For more information, see [Amazon Aurora Auto Scaling with Aurora Replicas](#).

## Examine the buffer pool size

Check whether the buffer pool size is sufficient for the workload by looking at the metric `innodb_buffer_pool_wait_free`. If the value of this metric is high and increasing continuously, that indicates that the size of the buffer pool isn't sufficient to handle the workload. If `innodb_buffer_pool_size` has been set properly, the value of `innodb_buffer_pool_wait_free` should be small. For more information, see [Innodb\\_buffer\\_pool\\_wait\\_free](#) in the MySQL documentation.

Increase the buffer pool size if the DB instance has enough memory for session buffers and operating-system tasks. If it doesn't, change the DB instance to a larger DB instance class to get additional memory that can be allocated to the buffer pool.

### Note

Aurora MySQL automatically adjusts the value of `innodb_buffer_pool_instances` based on the configured `innodb_buffer_pool_size`.

## Monitor the global status history

By monitoring the change rates of status variables, you can detect locking or memory issues on your DB instance. Turn on Global Status History (GoSH) if it isn't already turned on. For more information on GoSH, see [Managing the global status history](#).

You can also create custom Amazon CloudWatch metrics to monitor status variables. For more information, see [Publishing custom metrics](#).

## `synch/mutex/innodb/fil_system_mutex`

The `synch/mutex/innodb/fil_system_mutex` event occurs when a session is waiting to access the tablespace memory cache.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)

- [Actions](#)

## Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

## Context

InnoDB uses tablespaces to manage the storage area for tables and log files. The *tablespace memory cache* is a global memory structure that maintains information about tablespaces. MySQL uses `synch/mutex/innodb/fil_system_mutex` waits to control concurrent access to the tablespace memory cache.

The event `synch/mutex/innodb/fil_system_mutex` indicates that there is currently more than one operation that needs to retrieve and manipulate information in the tablespace memory cache for the same tablespace.

## Likely causes of increased waits

When the `synch/mutex/innodb/fil_system_mutex` event appears more than normal, possibly indicating a performance problem, this typically occurs when all of the following conditions are present:

- An increase in concurrent data manipulation language (DML) operations that update or delete data in the same table.
- The tablespace for this table is very large and has a lot of data pages.
- The fill factor for these data pages is low.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the sessions and queries causing the events](#)
- [Reorganize large tables during off-peak hours](#)

## Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

### To find SQL queries that are responsible for high load

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard appears for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Another way to find out which queries are causing high numbers of `synch/mutex/innodb/fil_system_mutex` waits is to check `performance_schema`, as in the following example.

```
mysql> select * from performance_schema.events_waits_current where EVENT_NAME='wait/
synch/mutex/innodb/fil_system_mutex'\G
***** 1. row *****
      THREAD_ID: 19

## Reorganize large tables during off-peak hours

Reorganize large tables that you identify as the source of high numbers of `synch/mutex/innodb/fil_system_mutex` wait events during a maintenance window outside of production hours. Doing so ensures that the internal tablespaces map cleanup doesn't occur when quick access to the table is critical. For information about reorganizing tables, see [OPTIMIZE TABLE Statement](#) in the *MySQL Reference*.

## `synch/mutex/innodb/trx_sys_mutex`

The `synch/mutex/innodb/trx_sys_mutex` event occurs when there is high database activity with a large number of transactions.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

### Context

Internally, the InnoDB database engine uses the repeatable read isolation level with snapshots to provide read consistency. This gives you a point-in-time view of the database at the time the snapshot was created.

In InnoDB, all changes are applied to the database as soon as they arrive, regardless of whether they're committed. This approach means that without multiversion concurrency control (MVCC),

all users connected to the database see all of the changes and the latest rows. Therefore, InnoDB requires a way to track the changes to understand what to roll back when necessary.

To do this, InnoDB uses a transaction system (`trx_sys`) to track snapshots. The transaction system does the following:

- Tracks the transaction ID for each row in the undo logs.
- Uses an internal InnoDB structure called `ReadView` that helps to identify which transaction IDs are visible for a snapshot.

### Likely causes of increased waits

Any database operation that requires the consistent and controlled handling (creating, reading, updating, and deleting) of transactions IDs generates a call from `trx_sys` to the mutex.

These calls happen inside three functions:

- `trx_sys_mutex_enter` – Creates the mutex.
- `trx_sys_mutex_exit` – Releases the mutex.
- `trx_sys_mutex_own` – Tests whether the mutex is owned.

The InnoDB Performance Schema instrumentation tracks all `trx_sys` mutex calls. Tracking includes, but isn't limited to, management of `trx_sys` on database startup or shutdown, rollback operations, undo cleanups, row read access, and buffer pool loads. High database activity with a large number of transactions results in `synch/mutex/innodb/trx_sys_mutex` appearing among the top wait events.

For more information, see [Monitoring InnoDB Mutex Waits Using Performance Schema](#) in the MySQL documentation.

### Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Identify the sessions and queries causing the events](#)
- [Examine other wait events](#)

## Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load. Find out whether you can optimize the database and application to reduce those events.

### To view the Top SQL chart in the Amazon Web Services Management Console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Under the **Database load** chart, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### Examine other wait events

Examine the other wait events associated with the `synch/mutex/innodb/trx_sys_mutex` wait event. Doing this can provide more information about the nature of the workload. A large number of transactions might reduce throughput, but the workload might also make this necessary.

For more information on how to optimize transactions, see [Optimizing InnoDB Transaction Management](#) in the MySQL documentation.

### `synch/sxlock/innodb/hash_table_locks`

The `synch/sxlock/innodb/hash_table_locks` event occurs when pages not found in the buffer pool must be read from storage.

### Topics

- [Supported engine versions](#)
- [Context](#)

- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for the following versions:

- Aurora MySQL versions 2 and 3

## Context

The event `synch/sxlock/innodb/hash_table_locks` indicates that a workload is frequently accessing data that isn't stored in the buffer pool. This wait event is associated with new page additions and old data evictions from the buffer pool. The data stored in the buffer pool aged and new data must be cached, so the aged pages are evicted to allow caching of the new pages. MySQL uses a least recently used (LRU) algorithm to evict pages from the buffer pool. The workload is trying to access data that hasn't been loaded into the buffer pool or data that has been evicted from the buffer pool.

This wait event occurs when the workload must access the data in files on disk or when blocks are freed from or added to the buffer pool's LRU list. These operations wait to obtain a shared excluded lock (SX-lock). This SX-lock is used for the synchronization over the *hash table*, which is a table in memory designed to improve buffer pool access performance.

For more information, see [Buffer Pool](#) in the MySQL documentation.

## Likely causes of increased waits

When the `synch/sxlock/innodb/hash_table_locks` wait event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

### Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

### Errors reading the pages

There are errors reading pages in the buffer pool, which might indicate data corruption.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Increase the size of the buffer pool](#)
- [Improve data access patterns](#)
- [Reduce or avoid full-table scans](#)
- [Check the error logs for page corruption](#)

### Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer. To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see [Best practices for Amazon Aurora MySQL database configuration](#).

### Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysqli_result::fetch_array`, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the `synch/sxlock/innodb/hash_table_locks` wait event.

### To find SQL queries that are responsible for high load

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the Amazon Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

### Reduce or avoid full-table scans

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as `Handler_read_rnd_next`. For more information, see [Server Status Variables](#) in the MySQL documentation.

### Check the error logs for page corruption

You can check the `mysql-error.log` for corruption-related messages that were detected near the time of the issue. Messages that you can work with to resolve the issue are in the error log. You might need to recreate objects that were reported as corrupted.

### `synch/mutex/innodb/temp_pool_manager_mutex`

The `synch/mutex/innodb/temp_pool_manager_mutex` wait event occurs when a session is waiting to acquire a mutex for managing the pool of session temporary tablespaces.

#### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

#### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3

## Context

Aurora MySQL version 3.x and higher uses `temp_pool_manager_mutex` to control multiple sessions accessing the temporary tablespace pool at the same time. Aurora MySQL manages storage through an Aurora cluster volume for persistent data and local storage for temporary files. A temporary tablespace is needed when a session creates a temporary table on the Aurora cluster volume.

When a session first requests a temporary tablespace, MySQL allocates session temporary tablespaces from the shared pool. A session can hold up to 2 temporary tablespaces at a time for the following table types:

- User-created temporary tables
- Optimizer-generated internal temporary tables

The default `TempTable` engine uses the following overflow mechanism to handle temporary tables:

- Stores tables in RAM up to the [temptable\\_max\\_ram](#) limit.
- Moves to memory-mapped files on local storage when RAM is full.
- Uses the shared cluster volume when memory-mapped files reach their [temptable\\_max\\_mmap](#) limit.

After temporary tables exceed both RAM and local storage limits, MySQL manages them using on-disk tablespace.

When a session requires an on-disk temporary table, MySQL:

- Looks for available `INACTIVE` tablespaces in the pool to reuse.
- Creates 10 new tablespaces if no `INACTIVE` spaces exist.

When a session disconnects, MySQL:

- Truncates the session's temporary tablespaces.
- Marks them as `INACTIVE` in the pool for reuse.
- Maintains the current pool size until server restart.
- Returns to the default pool size (10 tablespaces) after restart.

## Likely causes of increased waits

Common situations that cause this wait event:

- Concurrent sessions creating internal temporary tables on the cluster volume.
- Concurrent sessions creating user temporary tables on the cluster volume.
- Sudden termination of sessions using active tablespaces.
- Tablespace pool expansion during heavy write workloads.
- Concurrent queries accessing INFORMATION\_SCHEMA .

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Monitor and optimize temporary table usage](#)
- [Review queries using INFORMATION\\_SCHEMA](#)
- [Increase innodb\\_sync\\_array\\_size parameter](#)
- [Implement connection pooling](#)

## Monitor and optimize temporary table usage

To monitor and optimize temporary table usage, use one of these methods:

- Check the Created\_tmp\_disk\_tables counter in Performance Insights to track on-disk temporary table creation across your Aurora cluster.
- Run this command in your database to directly monitor temporary table creation: `mysql> show status like '%created_tmp_disk%'`.

### Note

Temporary table behavior differs between Aurora MySQL reader nodes and writer nodes. For more information, see [New temporary table behavior in Aurora MySQL version 3](#).

After identifying queries creating temporary tables, take these optimization steps:

- Use EXPLAIN to examine query execution plans and identify where and why temporary tables are being created.
- Modify queries to reduce temporary table usage where possible.

If query optimization alone doesn't resolve performance issues, consider adjusting these configuration parameters:

- [temptable\\_max\\_ram](#)- Controls maximum RAM usage for temporary tables.
- [temptable\\_max\\_mmap](#) - Sets the limit for memory-mapped file storage.
- [tmp\\_table\\_size](#)- Applies when `aurora_tmptable_enable_per_table_limit` is enabled (disabled by default).

### Important

Note that certain query conditions will always require on-disk temporary tables, regardless of configuration settings. For more information TempTable storage engine, see [Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL](#).

## Review queries using INFORMATION\_SCHEMA

When you query INFORMATION\_SCHEMA tables, MySQL creates InnoDB temporary tables on the cluster volume. Each session needs a temporary tablespace for these tables, which can lead to performance issues during high concurrent access.

To improve performance:

- Use PERFORMANCE\_SCHEMA instead of INFORMATION\_SCHEMA where possible.
- If you must use INFORMATION\_SCHEMA, reduce how often you run these queries.

## Increase innodb\_sync\_array\_size parameter

The `innodb_sync_array_size` parameter controls the size of the mutex/lock wait array in MySQL. The default value of 1 works for general workloads, but increasing it can reduce thread contention during high concurrency.

When your workload shows increasing numbers of waiting threads:

- Monitor the number of waiting threads in your workload.
- Set `innodb_sync_array_size` equal to or higher than your instance's vCPU count to split the thread coordination structure and reduce contention.

**Note**

To determine the number of vCPUs available on your RDS instance, see the vCPU specifications in [Amazon RDS instance types](#).

**Implement connection pooling**

MySQL assigns a dedicated tablespace to each session that creates a temporary table. This tablespace remains active until the database connection ends. To manage your resources more efficiently:

- Implement connection pooling to limit the number of active temporary tablespaces.
- Reuse existing connections instead of creating new ones for each operation.

## Tuning Aurora MySQL with thread states

The following table summarizes the most common general thread states for Aurora MySQL.

General thread state	Description
<a href="#">???</a>	This thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.
<a href="#">???</a>	This thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set.

### creating sort index

The `creating sort index` thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.

#### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

#### Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2

#### Context

The `creating sort index` state appears when a query with an `ORDER BY` or `GROUP BY` clause can't use an existing index to perform the operation. In this case, MySQL needs to perform a more

expensive `filesort` operation. This operation is typically performed in memory if the result set isn't too large. Otherwise, it involves creating a file on disk.

### Likely causes of increased waits

The appearance of `creating sort index` doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of `creating sort index`, the most likely cause is slow queries with `ORDER BY` or `GROUP BY` operators.

### Actions

The general guideline is to find queries with `ORDER BY` or `GROUP BY` clauses that are associated with the increases in the `creating sort index` state. Then see whether adding an index or increasing the sort buffer size solves the problem.

### Topics

- [Turn on the Performance Schema if it isn't turned on](#)
- [Identify the problem queries](#)
- [Examine the explain plans for filesort usage](#)
- [Increase the sort buffer size](#)

### Turn on the Performance Schema if it isn't turned on

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Overview of the Performance Schema for Performance Insights on Aurora MySQL](#).

### Identify the problem queries

To identify current queries that are causing increases in the `creating sort index` state, run `show processlist` and see if any of the queries have `ORDER BY` or `GROUP BY`. Optionally, run `explain for connection N`, where N is the process list ID of the query with `filesort`.

To identify past queries that are causing these increases, turn on the slow query log and find the queries with `ORDER BY`. Run `EXPLAIN` on the slow queries and look for "using filesort." For more information, see [Examine the explain plans for filesort usage](#).

## Examine the explain plans for filesort usage

Identify the statements with ORDER BY or GROUP BY clauses that result in the creating sort index state.

The following example shows how to run explain on a query. The Extra column shows that this query uses filesort.

```
mysql> explain select * from mytable order by c1 limit 10\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: mytable
  partitions: NULL
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
         ref: NULL
         rows: 2064548
   filtered: 100.00
      Extra: Using filesort
1 row in set, 1 warning (0.01 sec)
```

The following example shows the result of running EXPLAIN on the same query after an index is created on column c1.

```
mysql> alter table mytable add index (c1);
```

```
mysql> explain select * from mytable order by c1 limit 10\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: mytable
  partitions: NULL
         type: index
possible_keys: NULL
          key: c1
      key_len: 1023
         ref: NULL
         rows: 10
```

```

filtered: 100.00
  Extra: Using index
1 row in set, 1 warning (0.01 sec)

```

For information on using indexes for sort order optimization, see [ORDER BY Optimization](#) in the MySQL documentation.

### Increase the sort buffer size

To see whether a specific query required a `filesort` process that created a file on disk, check the `sort_merge_passes` variable value after running the query. The following shows an example.

```

mysql> show session status like 'sort_merge_passes';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Sort_merge_passes | 0     |
+-----+-----+
1 row in set (0.01 sec)

--- run query
mysql> select * from mytable order by u limit 10;
--- run status again:

mysql> show session status like 'sort_merge_passes';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Sort_merge_passes | 0     |
+-----+-----+
1 row in set (0.01 sec)

```

If the value of `sort_merge_passes` is high, consider increasing the sort buffer size. Apply the increase at the session level, because increasing it globally can significantly increase the amount of RAM MySQL uses. The following example shows how to change the sort buffer size before running a query.

```

mysql> set session sort_buffer_size=10*1024*1024;
Query OK, 0 rows affected (0.00 sec)
-- run query

```

## sending data

The `sending data` thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set. The name is misleading because it implies the state is transferring data, not collecting and preparing data to be sent later.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2

### Context

Many thread states are short-lasting. Operations occurring during `sending data` tend to perform large numbers of disk or cache reads. Therefore, `sending data` is often the longest-running state over the lifetime of a given query. This state appears when Aurora MySQL is doing the following:

- Reading and processing rows for a SELECT statement
- Performing a large number of reads from either disk or memory
- Completing a full read of all data from a specific query
- Reading data from a table, an index, or the work of a stored procedure
- Sorting, grouping, or ordering data

After the `sending data` state finishes preparing the data, the thread state `writing to net` indicates the return of data to the client. Typically, `writing to net` is captured only when the result set is very large or severe network latency is slowing the transfer.

## Likely causes of increased waits

The appearance of sending data doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of sending data, the most likely causes are as follows.

### Topics

- [Inefficient query](#)
- [Suboptimal server configuration](#)

### Inefficient query

In most cases, what's responsible for this state is a query that isn't using an appropriate index to find the result set of a specific query. For example, consider a query reading a 10 million record table for all orders placed in California, where the state column isn't indexed or is poorly indexed. In the latter case, the index might exist, but the optimizer ignores it because of low cardinality.

### Suboptimal server configuration

If several queries appear in the sending data state, the database server might be configured poorly. Specifically, the server might have the following issues:

- The database server doesn't have enough computing capacity: disk I/O, disk type and speed, CPU, or number of CPUs.
- The server is starved for allocated resources, such as the InnoDB buffer pool for InnoDB tables or the key buffer for MyISAM tables.
- Per-thread memory settings such as `sort_buffer`, `read_buffer`, and `join_buffer` consume more RAM than required, starving the physical server for memory resources.

### Actions

The general guideline is to find queries that return large numbers of rows by checking the Performance Schema. If logging queries that don't use indexes is turned on, you can also examine the results from the slow logs.

### Topics

- [Turn on the Performance Schema if it isn't turned on](#)
- [Examine memory settings](#)

- [Examine the explain plans for index usage](#)
- [Check the volume of data returned](#)
- [Check for concurrency issues](#)
- [Check the structure of your queries](#)

## Turn on the Performance Schema if it isn't turned on

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Overview of the Performance Schema for Performance Insights on Aurora MySQL](#).

## Examine memory settings

Examine the memory settings for the primary buffer pools. Make sure that these pools are appropriately sized for the workload. If your database uses multiple buffer pool instances, make sure that they aren't divided into many small buffer pools. Threads can only use one buffer pool at a time.

Make sure that the following memory settings used for each thread are properly sized:

- `read_buffer`
- `read_rnd_buffer`
- `sort_buffer`
- `join_buffer`
- `binlog_cache`

Unless you have a specific reason to modify the settings, use the default values.

## Examine the explain plans for index usage

For queries in the `sending_data` thread state, examine the plan to determine whether appropriate indexes are used. If a query isn't using a useful index, consider adding hints like `USE INDEX` or `FORCE INDEX`. Hints can greatly increase or decrease the time it takes to run a query, so use care before adding them.

## Check the volume of data returned

Check the tables that are being queried and the amount of data that they contain. Can any of this data be archived? In many cases, the cause of poor query execution times isn't the result of the query plan, but the volume of data to be processed. Many developers are very efficient in adding data to a database but seldom consider dataset life cycle in the design and development phases.

Look for queries that perform well in low-volume databases but perform poorly in your current system. Sometimes developers who design specific queries might not realize that these queries are returning 350,000 rows. The developers might have developed the queries in a lower-volume environment with smaller datasets than production environments have.

## Check for concurrency issues

Check whether multiple queries of the same type are running at the same time. Some forms of queries run efficiently when they run alone. However, if similar forms of query run together, or in high volume, they can cause concurrency issues. Often, these issues are caused when the database uses temp tables to render results. A restrictive transaction isolation level can also cause concurrency issues.

If tables are read and written to concurrently, the database might be using locks. To help identify periods of poor performance, examine the use of databases through large-scale batch processes. To see recent locks and rollbacks, examine the output of the `SHOW ENGINE INNODB STATUS` command.

## Check the structure of your queries

Check whether captured queries from these states use subqueries. This type of query often leads to poor performance because the database compiles the results internally and then substitutes them back into the query to render data. This process is an extra step for the database. In many cases, this step can cause poor performance in a highly concurrent loading condition.

Also check whether your queries use large numbers of `ORDER BY` and `GROUP BY` clauses. In such operations, often the database must first form the entire dataset in memory. Then it must order or group it in a specific manner before returning it to the client.

## Tuning Aurora MySQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detect known problematic conditions on your Aurora MySQL DB clusters before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

### Topics

- [The InnoDB history list length increased significantly](#)
- [Database is creating temporary tables on disk](#)

## The InnoDB history list length increased significantly

Starting on *date*, your history list for row changes increased significantly, up to *length* on *db-instance*. This increase affects query and database shutdown performance.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes for this issue](#)
- [Actions](#)
- [Relevant metrics](#)

### Supported engine versions

This insight information is supported for all versions of Aurora MySQL.

### Context

The InnoDB transaction system maintains multiversion concurrency control (MVCC). When a row is modified, the pre-modification version of the data being modified is stored as an undo record in an undo log. Every undo record has a reference to its previous redo record, forming a linked list.

The *InnoDB history list* is a global list of the undo logs for committed transactions. MySQL uses the history list to purge records and log pages when transactions no longer require the history.

The *history list length* is the total number of undo logs that contain modifications in the history list. Each log contains one or more modifications. If the InnoDB history list length grows too large, indicating a large number of old row versions, queries and database shutdowns become slower.

### Likely causes for this issue

Typical causes of a long history list include the following:

- Long-running transactions, either read or write
- A heavy write load

### Actions

We recommend different actions depending on the causes of your insight.

### Topics

- [Don't begin any operation involving a database shutdown until the InnoDB history list decreases](#)
- [Identify and end long-running transactions](#)
- [Identify the top hosts and top users by using Performance Insights.](#)

### Don't begin any operation involving a database shutdown until the InnoDB history list decreases

Because a long InnoDB history list slows database shutdowns, reduce the list size before initiating operations involving a database shutdown. These operations include major version database upgrades.

### Identify and end long-running transactions

You can find long-running transactions by querying `information_schema.innodb_trx`.

#### Note

Make sure also to look for long-running transactions on read replicas.

### To identify and end long-running transactions

1. In your SQL client, run the following query:

```
SELECT a.trx_id,
       a.trx_state,
       a.trx_started,
       TIMESTAMPDIFF(SECOND,a.trx_started, now()) as "Seconds Transaction Has Been
Open",
       a.trx_rows_modified,
       b.USER,
       b.host,
       b.db,
       b.command,
       b.time,
       b.state
FROM   information_schema.innodb_trx a,
       information_schema.processlist b
WHERE  a.trx_mysql_thread_id=b.id
       AND TIMESTAMPDIFF(SECOND,a.trx_started, now()) > 10
ORDER BY trx_started
```

2. End each long-running transaction with the stored procedure [mysql.rds\\_kill](#).

### Identify the top hosts and top users by using Performance Insights.

Optimize transactions so that large numbers of modified rows are immediately committed.

#### Relevant metrics

The following metrics are related to this insight:

- `trx_rseg_history_len` – This counter metric can be viewed in Performance Insights, as well as the `INFORMATION_SCHEMA.INNODB_METRICS` table. For more information, see [InnoDB INFORMATION\\_SCHEMA metrics table](#) in the MySQL documentation.
- `RollbackSegmentHistoryListLength` – This Amazon CloudWatch metric measures the undo logs that record committed transactions with delete-marked records. These records are scheduled to be processed by the InnoDB purge operation. The metric `trx_rseg_history_len` has the same value as `RollbackSegmentHistoryListLength`.
- `PurgeBoundary` – The transaction number up to which InnoDB purging is allowed. If this CloudWatch metric doesn't advance for extended periods of time, it's a good indication that InnoDB purging is blocked by long-running transactions. To investigate, check the active transactions on your Aurora MySQL DB cluster. This metric is available only for Aurora MySQL version 2.11 and higher, and version 3.08 and higher.

- `PurgeFinishedPoint` – The transaction number up to which InnoDB purging is performed. This CloudWatch metric can help you examine how fast InnoDB purging is progressing. This metric is available only for Aurora MySQL version 2.11 and higher, and version 3.08 and higher.
- `TransactionAgeMaximum` – The age of the oldest active running transaction. This CloudWatch metric is available only for Aurora MySQL version 3.08 and higher.
- `TruncateFinishedPoint` – The transaction number up to which undo truncation is performed. This CloudWatch metric is available only for Aurora MySQL version 2.11 and higher, and version 3.08 and higher.

For more information on the CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

## Database is creating temporary tables on disk

Your recent on-disk temporary table usage increased significantly, up to *percentage*. The database is creating around *number* temporary tables per second. This might impact performance and increase disk operations on *db-instance*.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes for this issue](#)
- [Actions](#)
- [Relevant metrics](#)

### Supported engine versions

This insight information is supported for all versions of Aurora MySQL.

### Context

Sometimes it's necessary for the MySQL server to create an internal temporary table while processing a query. Aurora MySQL can hold an internal temporary table in memory, where it can be processed by the TempTable or MEMORY storage engine, or stored on disk by InnoDB. For more information, see [Internal Temporary Table Use in MySQL](#) in the *MySQL Reference Manual*.

## Likely causes for this issue

An increase in on-disk temporary tables indicates the use of complex queries. If the configured memory is insufficient to store temporary tables in memory, Aurora MySQL creates the tables on disk. This can impact performance and increase disk operations.

## Actions

We recommend different actions depending on the causes of your insight.

- For Aurora MySQL version 3, we recommend that you use the TempTable storage engine.
- Optimize your queries to return less data by selecting only necessary columns.

If you turn on the Performance Schema with all statement instruments enabled and timed, you can query `SYS.statements_with_temp_tables` to retrieve the list of queries that use temporary tables. For more information, see [Prerequisites for Using the sys Schema](#) in the MySQL documentation.

- Consider indexing columns that are involved in sorting and grouping operations.
- Rewrite your queries to avoid BLOB and TEXT columns. These columns always use disk.
- Tune the following database parameters: `tmp_table_size` and `max_heap_table_size`.

The default values for these parameters is 16 MiB. When using the MEMORY storage engine for in-memory temporary tables, their maximum size is defined by the `tmp_table_size` or `max_heap_table_size` value, whichever is smaller. When this maximum size is reached, MySQL automatically converts the in-memory internal temporary table to an InnoDB on-disk internal temporary table. For more information, see [Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL](#).

### Note

When explicitly creating MEMORY tables with `CREATE TABLE`, only the `max_heap_table_size` variable determines how large a table can grow. There is also no conversion to an on-disk format.

## Relevant metrics

The following Performance Insights metrics are related to this insight:

- `Created_tmp_disk_tables`
- `Created_tmp_tables`

For more information, see [Created\\_tmp\\_disk\\_tables](#) in the MySQL documentation.

# Parallel query for Amazon Aurora MySQL

This topic describes the parallel query performance optimization for Amazon Aurora MySQL-Compatible Edition. This feature uses a special processing path for certain data-intensive queries, taking advantage of the Aurora shared storage architecture. Parallel query works best with Aurora MySQL DB clusters that have tables with millions of rows and analytic queries that take minutes or hours to complete.

## Topics

- [Overview of parallel query for Aurora MySQL](#)
- [Creating a parallel query DB cluster in Aurora MySQL](#)
- [Turning parallel query on and off in Aurora MySQL](#)
- [Optimizing parallel query in Aurora MySQL](#)
- [Verifying which statements use parallel query for Aurora MySQL](#)
- [Monitoring parallel query for Aurora MySQL](#)
- [SQL constructs for parallel query in Aurora MySQL](#)

## Overview of parallel query for Aurora MySQL

Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the WHERE clause and join clauses. This data-intensive work is delegated (in database optimization terms, *pushed down*) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.

### Tip

The PostgreSQL database engine also has a feature called "parallel query." That feature is unrelated to Aurora parallel query.

When the parallel query feature is turned on, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes. In the

following sections, you can find an explanation of when parallel query is applied to a query. You can also find how to make sure that parallel query is applied where it provides the most benefit.

### Note

The parallel query optimization provides the most benefit for long-running queries that take minutes or hours to complete. Aurora MySQL generally doesn't perform parallel query optimization for inexpensive queries. It also generally doesn't perform parallel query optimization if another optimization technique makes more sense, such as query caching, buffer pool caching, or index lookups. If you find that parallel query isn't being used when you expect it, see [Verifying which statements use parallel query for Aurora MySQL](#).

## Topics

- [Benefits](#)
- [Architecture](#)
- [Prerequisites](#)
- [Limitations](#)
- [I/O costs with parallel query](#)

## Benefits

With parallel query, you can run data-intensive analytic queries on Aurora MySQL tables. In many cases, you can get an order-of-magnitude performance improvement over the traditional division of labor for query processing.

Benefits of parallel query include the following:

- Improved I/O performance, due to parallelizing physical read requests across multiple storage nodes.
- Reduced network traffic. Aurora doesn't transmit entire data pages from storage nodes to the head node and then filter out unnecessary rows and columns afterward. Instead, Aurora transmits compact tuples containing only the column values needed for the result set.
- Reduced CPU usage on the head node, due to pushing down function processing, row filtering, and column projection for the WHERE clause.

- Reduced memory pressure on the buffer pool. The pages processed by the parallel query aren't added to the buffer pool. This approach reduces the chance of a data-intensive scan evicting frequently used data from the buffer pool.
- Potentially reduced data duplication in your extract, transform, load (ETL) pipeline, by making it practical to perform long-running analytic queries on existing data.

## Architecture

The parallel query feature uses the major architectural principles of Aurora MySQL: decoupling the database engine from the storage subsystem, and reducing network traffic by streamlining communication protocols. Aurora MySQL uses these techniques to speed up write-intensive operations such as redo log processing. Parallel query applies the same principles to read operations.

### Note

The architecture of Aurora MySQL parallel query differs from that of similarly named features in other database systems. Aurora MySQL parallel query doesn't involve symmetric multiprocessing (SMP) and so doesn't depend on the CPU capacity of the database server. The parallel processing happens in the storage layer, independent of the Aurora MySQL server that serves as the query coordinator.

By default, without parallel query, the processing for an Aurora query involves transmitting raw data to a single node within the Aurora cluster (the *head node*). Aurora then performs all further processing for that query in a single thread on that single node. With parallel query, much of this I/O-intensive and CPU-intensive work is delegated to nodes in the storage layer. Only the compact rows of the result set are transmitted back to the head node, with rows already filtered, and column values already extracted and transformed. The performance benefit comes from the reduction in network traffic, reduction in CPU usage on the head node, and parallelizing the I/O across the storage nodes. The amount of parallel I/O, filtering, and projection is independent of the number of DB instances in the Aurora cluster that runs the query.

## Prerequisites

Using all features of parallel query requires an Aurora MySQL DB cluster that's running version 2.09 or higher. If you already have a cluster that you want to use with parallel query, you can upgrade it to a compatible version and turn on parallel query afterward. In that case, make sure to follow the

upgrade procedure in [Upgrade considerations for parallel query](#) because the configuration setting names and default values are different in these newer versions.

The DB instances in your cluster must use the `db.r*` instance classes.

Make sure that hash join optimization is turned on for your cluster. To learn how, see [Turning on hash join for parallel query clusters](#).

To customize parameters such as `aurora_parallel_query` and `aurora_disable_hash_join`, you must have a custom parameter group that you use with your cluster. You can specify these parameters individually for each DB instance by using a DB parameter group. However, we recommend that you specify them in a DB cluster parameter group. That way, all DB instances in your cluster inherit the same settings for these parameters.

## Limitations

The following limitations apply to the parallel query feature:

- Parallel query isn't supported with the Aurora I/O-Optimized DB cluster storage configuration.
- You can't use parallel query with the `db.t2` or `db.t3` instance classes. This limitation applies even if you request parallel query using the `aurora_pq_force` session variable.
- Parallel query doesn't apply to tables using the COMPRESSED or REDUNDANT row formats. Use the COMPACT or DYNAMIC row formats for tables you plan to use with parallel query.
- Aurora uses a cost-based algorithm to determine whether to use the parallel query mechanism for each SQL statement. Using certain SQL constructs in a statement can prevent parallel query or make parallel query unlikely for that statement. For information about compatibility of SQL constructs with parallel query, see [SQL constructs for parallel query in Aurora MySQL](#).
- Each Aurora DB instance can run only a certain number of parallel query sessions at one time. If a query has multiple parts that use parallel query, such as subqueries, joins, or UNION operators, those phases run in sequence. The statement only counts as a single parallel query session at any one time. You can monitor the number of active sessions using the [parallel query status variables](#). You can check the limit on concurrent sessions for a given DB instance by querying the status variable `Aurora_pq_max_concurrent_requests`.
- Parallel query is available in all Amazon Web Services Regions that Aurora supports. For most Amazon Web Services Regions, the minimum required Aurora MySQL version to use parallel query is 2.09.
- Parallel query is designed to improve the performance of data-intensive queries. It isn't designed for lightweight queries.

- We recommend that you use reader nodes for SELECT statements, especially data-intensive ones.

## I/O costs with parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

Parallel query I/O costs for your query are metered at the storage layer, and will be the same or larger with parallel query turned on. Your benefit is the improvement in query performance. There are two reasons for potentially higher I/O costs with parallel query:

- Even if some of the data in a table is in the buffer pool, parallel query requires all data to be scanned at the storage layer, incurring I/O costs.
- Running a parallel query doesn't warm up the buffer pool. As a result, consecutive runs of the same parallel query incur the full I/O cost.

## Creating a parallel query DB cluster in Aurora MySQL

To create an Aurora MySQL cluster with parallel query, add new instances to it, or perform other administrative operations, you use the same Amazon Web Services Management Console and Amazon CLI techniques that you do with other Aurora MySQL clusters. You can create a new cluster to work with parallel query. You can also create a DB cluster to work with parallel query by restoring from a snapshot of a MySQL-compatible Aurora DB cluster. If you aren't familiar with the process for creating a new Aurora MySQL cluster, you can find background information and prerequisites in [Creating an Amazon Aurora DB cluster](#).

When you choose an Aurora MySQL engine version, we recommend that you choose the latest one available. Currently, all available Aurora MySQL versions support parallel query. You have more flexibility to turn parallel query on and off, or use parallel query with existing clusters, if you use the latest versions.

Whether you create a new cluster or restore from a snapshot, you use the same techniques to add new DB instances that you do with other Aurora MySQL clusters.

You can create a parallel query cluster using the Amazon RDS console or the Amazon CLI.

### Contents

- [Creating a parallel query cluster using the console](#)
- [Creating a parallel query cluster using the CLI](#)

## Creating a parallel query cluster using the console

You can create a new parallel query cluster with the console as described following.

### To create a parallel query cluster with the Amazon Web Services Management Console

1. Follow the general Amazon Web Services Management Console procedure in [Creating an Amazon Aurora DB cluster](#).
2. For **Engine type**, choose Aurora MySQL.
3. For **Additional configuration**, choose a parameter group that you created for **DB cluster parameter group**. Using such a custom parameter group is required for Aurora MySQL 2.09 and higher. In your DB cluster parameter group, specify the parameter settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Doing so turns on parallel query for the cluster, and turns on the hash join optimization that works in combination with parallel query.

### To verify that a new cluster can use parallel query

1. Create a cluster using the preceding technique.
2. (For Aurora MySQL version 2 or 3) Check that the `aurora_parallel_query` configuration setting is true.

```
mysql> select @@aurora_parallel_query;
+-----+
| @@aurora_parallel_query |
+-----+
|                1 |
+-----+
```

3. (For Aurora MySQL version 2) Check that the `aurora_disable_hash_join` setting is false.

```
mysql> select @@aurora_disable_hash_join;
+-----+
| @@aurora_disable_hash_join |
+-----+
```

```
|                                0 |
+-----+

```

4. With some large tables and data-intensive queries, check the query plans to confirm that some of your queries are using the parallel query optimization. To do so, follow the procedure in [Verifying which statements use parallel query for Aurora MySQL](#).

## Creating a parallel query cluster using the CLI

You can create a new parallel query cluster with the CLI as described following.

### To create a parallel query cluster with the Amazon CLI

1. (Optional) Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see [Checking Aurora MySQL version compatibility for parallel query](#).
2. (Optional) Create a custom DB cluster parameter group with the settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Use commands such as the following.

```
aws rds create-db-cluster-parameter-group --db-parameter-group-family aurora-
mysql8.0 --db-cluster-parameter-group-name pq-enabled-80-compatible
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-
enabled-80-compatible \
  --parameters
  ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-
enabled-80-compatible \
  --parameters
  ParameterName=aurora_disable_hash_join,ParameterValue=OFF,ApplyMethod=pending-
reboot
```

If you perform this step, specify the option `--db-cluster-parameter-group-name my_cluster_parameter_group` in the subsequent `create-db-cluster` statement. Substitute the name of your own parameter group. If you omit this step, you create the parameter group and associate it with the cluster later, as described in [Turning parallel query on and off in Aurora MySQL](#).

3. Follow the general Amazon CLI procedure in [Creating an Amazon Aurora DB cluster](#).

#### 4. Specify the following set of options:

- For the `--engine` option, use `aurora-mysql`. These values produce parallel query clusters that are compatible with MySQL 5.7 or 8.0.
- For the `--db-cluster-parameter-group-name` option, specify the name of a DB cluster parameter group that you created and specified the parameter value `aurora_parallel_query=ON`. If you omit this option, you can create the cluster with a default parameter group and later modify it to use such a custom parameter group.
- For the `--engine-version` option, use an Aurora MySQL version that's compatible with parallel query. Use the procedure from [Optimizing parallel query in Aurora MySQL](#) to get a list of versions if necessary.

The following code example shows how. Substitute your own value for each of the environment variables such as `$CLUSTER_ID`. This example also specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

```
aws rds create-db-cluster --db-cluster-identifier $CLUSTER_ID \
  --engine aurora-mysql --engine-version 8.0.mysql_aurora.3.04.1 \
  --master-username $MASTER_USER_ID --manage-master-user-password \
  --db-cluster-parameter-group-name $CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-instance --db-instance-identifier ${INSTANCE_ID}-1 \
  --engine same_value_as_in_create_cluster_command \
  --db-cluster-identifier $CLUSTER_ID --db-instance-class $INSTANCE_CLASS
```

#### 5. Verify that a cluster you created or restored has the parallel query feature available.

Check that the `aurora_parallel_query` configuration setting exists. If this setting has the value 1, parallel query is ready for you to use. If this setting has the value 0, set it to 1 before you can use parallel query. Either way, the cluster is capable of performing parallel queries.

```
mysql> select @@aurora_parallel_query;
+-----+
| @@aurora_parallel_query|
+-----+
|                1 |
```

```
+-----+
```

## To restore a snapshot to a parallel query cluster with the Amazon CLI

1. Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see [Checking Aurora MySQL version compatibility for parallel query](#). Decide which version to use for the restored cluster.
2. Locate an Aurora MySQL-compatible cluster snapshot.
3. Follow the general Amazon CLI procedure in [Restoring from a DB cluster snapshot](#).

```
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier mynewdbcluster \
  --snapshot-identifier mydbclustersnapshot \
  --engine aurora-mysql
```

4. Verify that a cluster you created or restored has the parallel query feature available. Use the same verification procedure as in [Creating a parallel query cluster using the CLI](#).

## Turning parallel query on and off in Aurora MySQL

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see [Verifying which statements use parallel query for Aurora MySQL](#) and [SQL constructs for parallel query in Aurora MySQL](#).

You can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the `aurora_parallel_query` option. You can change the `aurora_parallel_query` setting in your DB cluster group to turn parallel query on or off by default.

```
mysql> select @@aurora_parallel_query;
+-----+
| @@aurora_parallel_query|
+-----+
|                1 |
+-----+
```

To toggle the `aurora_parallel_query` parameter at the session level, use the standard methods to change a client configuration setting. For example, you can do so through the `mysql` command line or within a JDBC or ODBC application. The command on the standard MySQL client is `set session aurora_parallel_query = {'ON'/'OFF'}`. You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

You can permanently change the setting for the `aurora_parallel_query` parameter, either for a specific DB instance or for your whole cluster. If you specify the parameter value in a DB parameter group, that value only applies to specific DB instance in your cluster. If you specify the parameter value in a DB cluster parameter group, all DB instances in the cluster inherit the same setting. To toggle the `aurora_parallel_query` parameter, use the techniques for working with parameter groups, as described in [Parameter groups for Amazon Aurora](#). Follow these steps:

1. Create a custom cluster parameter group (recommended) or a custom DB parameter group.
2. In this parameter group, update `parallel_query` to the value that you want.
3. Depending on whether you created a DB cluster parameter group or a DB parameter group, attach the parameter group to your Aurora cluster or to the specific DB instances where you plan to use the parallel query feature.

### Tip

Because `aurora_parallel_query` is a dynamic parameter, it doesn't require a cluster restart after changing this setting. However, any connections that were using parallel query before toggling the option will continue to do so until the connection is closed, or the instance is rebooted.

You can modify the parallel query parameter by using the [ModifyDBClusterParameterGroup](#) or [ModifyDBParameterGroup](#) API operation or the Amazon Web Services Management Console.

You can turn on hash join for parallel query clusters, turn parallel query on and off using the Amazon RDS console or the Amazon CLI, and override the parallel query optimizer.

## Contents

- [Turning on hash join for parallel query clusters](#)
- [Turning on and turning off parallel query using the console](#)

- [Turning on and turning off parallel query using the CLI](#)
- [Overriding the parallel query optimizer](#)

## Turning on hash join for parallel query clusters

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. Thus, it's helpful to make sure that hash joins are turned on for clusters where you plan to use parallel query. For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins](#).

## Turning on and turning off parallel query using the console

You can turn on or turn off parallel query at the DB instance level or the DB cluster level by working with parameter groups.

### To turn on or turn off parallel query for a DB cluster with the Amazon Web Services Management Console

1. Create a custom parameter group, as described in [Parameter groups for Amazon Aurora](#).
2. Update **aurora\_parallel\_query** to **1** (turned on) or **0** (turned off). For clusters where the parallel query feature is available, **aurora\_parallel\_query** is turned off by default.
3. If you use a custom cluster parameter group, attach it to the Aurora DB cluster where you plan to use the parallel query feature. If you use a custom DB parameter group, attach it to one or more DB instances in the cluster. We recommend using a cluster parameter group. Doing so makes sure that all DB instances in the cluster have the same settings for parallel query and associated features such as hash join.

## Turning on and turning off parallel query using the CLI

You can modify the parallel query parameter by using the `modify-db-cluster-parameter-group` or `modify-db-parameter-group` command. Choose the appropriate command depending on whether you specify the value of `aurora_parallel_query` through a DB cluster parameter group or a DB parameter group.

### To turn on or turn off parallel query for a DB cluster with the CLI

- Modify the parallel query parameter by using the `modify-db-cluster-parameter-group` command. Use a command such as the following. Substitute the appropriate name for your

own custom parameter group. Substitute either ON or OFF for the ParameterValue portion of the --parameters option.

```
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-  
name cluster_param_group_name \  
  --parameters  
  ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot  
{  
  "DBClusterParameterGroupName": "cluster_param_group_name"  
}  
  
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-  
name cluster_param_group_name \  
  --parameters ParameterName=aurora_pq,ParameterValue=ON,ApplyMethod=pending-reboot
```

You can also turn on or turn off parallel query at the session level, for example through the mysql command line or within a JDBC or ODBC application. To do so, use the standard methods to change a client configuration setting. For example, the command on the standard MySQL client is `set session aurora_parallel_query = {'ON'/'OFF'}` for Aurora MySQL.

You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

## Overriding the parallel query optimizer

You can use the `aurora_pq_force` session variable to override the parallel query optimizer and request parallel query for every query. We recommend that you do this only for testing purposes. The following example shows how to use `aurora_pq_force` in a session.

```
set SESSION aurora_parallel_query = ON;  
set SESSION aurora_pq_force = ON;
```

To turn off the override, do the following:

```
set SESSION aurora_pq_force = OFF;
```

# Optimizing parallel query in Aurora MySQL

To optimize your DB cluster for parallel query, consider which DB clusters would benefit from parallel query and whether to upgrade for parallel query. Then, tune your workload and create schema objects for parallel query.

## Contents

- [Planning for a parallel query cluster](#)
  - [Checking Aurora MySQL version compatibility for parallel query](#)
- [Upgrade considerations for parallel query](#)
  - [Upgrading parallel query clusters to Aurora MySQL version 3](#)
  - [Upgrading to Aurora MySQL 2.09 and higher](#)
- [Performance tuning for parallel query](#)
- [Creating schema objects to take advantage of parallel query](#)

## Planning for a parallel query cluster

Planning for a DB cluster that has parallel query turned on requires making some choices. These include performing setup steps (either creating or restoring a full Aurora MySQL cluster) and deciding how broadly to turn on parallel query across your DB cluster.

Consider the following as part of planning:

- If you use Aurora MySQL that's compatible with MySQL 5.7, you must create a provisioned cluster. Then you turn on parallel query using the `aurora_parallel_query` parameter.

If you have an existing Aurora MySQL cluster, you don't have to create a new cluster to use parallel query. You can associate your cluster, or specific DB instances in the cluster, with a parameter group that has the `aurora_parallel_query` parameter turned on. By doing so, you can reduce the time and effort to set up the relevant data to use with parallel query.

- Plan for any large tables that you need to reorganize so that you can use parallel query when accessing them. You might need to create new versions of some large tables where parallel query is useful. For example, you might need to remove full-text search indexes. For details, see [Creating schema objects to take advantage of parallel query](#).

## Checking Aurora MySQL version compatibility for parallel query

To check which Aurora MySQL versions are compatible with parallel query clusters, use the `describe-db-engine-versions` Amazon CLI command and check the value of the `SupportsParallelQuery` field. The following code example shows how to check which combinations are available for parallel query clusters in a specified Amazon Region. Make sure to specify the full `--query` parameter string on a single line.

```
aws rds describe-db-engine-versions --region us-east-1 --engine aurora-mysql \  
--query '*[[]][?SupportsParallelQuery == `true`].[EngineVersion]' --output text
```

The preceding commands produce output similar to the following. The output might vary depending on which Aurora MySQL versions are available in the specified Amazon Region.

```
5.7.mysql_aurora.2.11.1  
5.7.mysql_aurora.2.11.2  
5.7.mysql_aurora.2.11.3  
5.7.mysql_aurora.2.11.4  
5.7.mysql_aurora.2.11.5  
5.7.mysql_aurora.2.11.6  
5.7.mysql_aurora.2.12.0  
5.7.mysql_aurora.2.12.1  
5.7.mysql_aurora.2.12.2  
5.7.mysql_aurora.2.12.3  
5.7.mysql_aurora.2.12.4  
8.0.mysql_aurora.3.04.0  
8.0.mysql_aurora.3.04.1  
8.0.mysql_aurora.3.04.2  
8.0.mysql_aurora.3.04.3  
8.0.mysql_aurora.3.05.2  
8.0.mysql_aurora.3.06.0  
8.0.mysql_aurora.3.06.1  
8.0.mysql_aurora.3.07.0  
8.0.mysql_aurora.3.07.1
```

After you start using parallel query with a cluster, you can monitor performance and remove obstacles to parallel query usage. For those instructions, see [Performance tuning for parallel query](#).

## Upgrade considerations for parallel query

Depending on the original and destination versions when you upgrade a parallel query cluster, you might find enhancements in the types of queries that parallel query can optimize. You might

also find that you don't need to specify a special engine mode parameter for parallel query. The following sections explain the considerations when you upgrade a cluster that has parallel query turned on.

### Upgrading parallel query clusters to Aurora MySQL version 3

Several SQL statements, clauses, and data types have new or improved parallel query support starting in Aurora MySQL version 3. When you upgrade from a release that's earlier than version 3, check whether additional queries can benefit from parallel query optimizations. For information about these parallel query enhancements, see [Column data types](#), [Partitioned tables](#), and [Aggregate functions, GROUP BY clauses, and HAVING clauses](#).

If you're upgrading a parallel query cluster from Aurora MySQL 2.08 or lower, also learn about changes in how to turn on parallel query. To do so, read [Upgrading to Aurora MySQL 2.09 and higher](#).

In Aurora MySQL version 3, hash join optimization is turned on by default. The `aurora_disable_hash_join` configuration option from earlier versions isn't used.

### Upgrading to Aurora MySQL 2.09 and higher

In Aurora MySQL version 2.09 and higher, parallel query works for provisioned clusters and doesn't require the `parallelquery` engine mode parameter. Thus, you don't need to create a new cluster or restore from an existing snapshot to use parallel query with these versions. You can use the upgrade procedures described in [Upgrading the minor version or patch level of an Aurora MySQL DB cluster](#) to upgrade your cluster to such a version. You can upgrade an older cluster regardless of whether it was a parallel query cluster or a provisioned cluster. To reduce the number of choices in the **Engine version** menu, you can choose **Show versions that support the parallel query feature** to filter the entries in that menu. Then choose Aurora MySQL 2.09 or higher.

After you upgrade an earlier parallel query cluster to Aurora MySQL 2.09 or higher, you turn on parallel query in the upgraded cluster. Parallel query is turned off by default in these versions, and the procedure for enabling it is different. The hash join optimization is also turned off by default and must be turned on separately. Thus, make sure that you turn on these settings again after the upgrade. For instructions on doing so, see [Turning parallel query on and off in Aurora MySQL](#) and [Turning on hash join for parallel query clusters](#).

In particular, you turn on parallel query by using the configuration parameters `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF` instead of

`aurora_pq_supported` and `aurora_pq`. The `aurora_pq_supported` and `aurora_pq` parameters are deprecated in the newer Aurora MySQL versions.

In the upgraded cluster, the `EngineMode` attribute has the value `provisioned` instead of `parallelquery`. To check whether parallel query is available for a specified engine version, now you check the value of the `SupportsParallelQuery` field in the output of the `describe-db-engine-versions` Amazon CLI command. In earlier Aurora MySQL versions, you checked for the presence of `parallelquery` in the `SupportedEngineModes` list.

After you upgrade to Aurora MySQL version 2.09 or higher, you can take advantage of the following features. These features aren't available to parallel query clusters running older Aurora MySQL versions.

- Performance Insights. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).
- Backtracking. For more information, see [Backtracking an Aurora DB cluster](#).
- Stopping and starting the cluster. For more information, see [Stopping and starting an Amazon Aurora DB cluster](#).

## Performance tuning for parallel query

To manage the performance of a workload with parallel query, make sure that parallel query is used for the queries where this optimization helps the most.

To do so, you can do the following:

- Make sure that your biggest tables are compatible with parallel query. You might change table properties or recreate some tables so that queries for those tables can take advantage of the parallel query optimization. To learn how, see [Creating schema objects to take advantage of parallel query](#).
- Monitor which queries use parallel query. To learn how, see [Monitoring parallel query for Aurora MySQL](#).
- Verify that parallel query is being used for the most data-intensive and long-running queries, and with the right level of concurrency for your workload. To learn how, see [Verifying which statements use parallel query for Aurora MySQL](#).
- Fine-tune your SQL code to turn on parallel query to apply to the queries that you expect. To learn how, see [SQL constructs for parallel query in Aurora MySQL](#).

## Creating schema objects to take advantage of parallel query

Before you create or modify tables that you plan to use for parallel query, make sure to familiarize yourself with the requirements described in [Prerequisites](#) and [Limitations](#).

Because parallel query requires tables to use the `ROW_FORMAT=Compact` or `ROW_FORMAT=Dynamic` setting, check your Aurora configuration settings for any changes to the `INNODB_FILE_FORMAT` configuration option. Issue the `SHOW TABLE STATUS` statement to confirm the row format for all the tables in a database.

Before changing your schema to turn on parallel query to work with more tables, make sure to test. Your tests should confirm if parallel query results in a net increase in performance for those tables. Also, make sure that the schema requirements for parallel query are otherwise compatible with your goals.

For example, before switching from `ROW_FORMAT=Compressed` to `ROW_FORMAT=Compact` or `ROW_FORMAT=Dynamic`, test the performance of workloads for the original and new tables. Also, consider other potential effects such as increased data volume.

## Verifying which statements use parallel query for Aurora MySQL

In typical operation, you don't need to perform any special actions to take advantage of parallel query. After a query meets the essential requirements for parallel query, the query optimizer automatically decides whether to use parallel query for each specific query.

If you run experiments in a development or test environment, you might find that parallel query isn't used because your tables are too small in number of rows or overall data volume. The data for the table might also be entirely in the buffer pool, especially for tables that you created recently to perform experiments.

As you monitor or tune cluster performance, make sure to decide whether parallel query is being used in the appropriate contexts. You might adjust the database schema, settings, SQL queries, or even the cluster topology and application connection settings to take advantage of this feature.

To check if a query is using parallel query, check the query plan (also known as the "explain plan") by running the [EXPLAIN](#) statement. For examples of how SQL statements, clauses, and expressions affect EXPLAIN output for parallel query, see [SQL constructs for parallel query in Aurora MySQL](#).

The following example demonstrates the difference between a traditional query plan and a parallel query plan. This explain plan is from Query 3 from the TPC-H benchmark. Many of the sample

queries throughout this section use the tables from the TPC-H dataset. You can get the table definitions, queries, and the dbgen program that generates sample data from [the TPC-h website](#).

```
EXPLAIN SELECT l_orderkey,
  sum(l_extendedprice * (1 - l_discount)) AS revenue,
  o_orderdate,
  o_shippriority
FROM customer,
  orders,
  lineitem
WHERE c_mktsegment = 'AUTOMOBILE'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < date '1995-03-13'
AND l_shipdate > date '1995-03-13'
GROUP BY l_orderkey,
  o_orderdate,
  o_shippriority
ORDER BY revenue DESC,
  o_orderdate LIMIT 10;
```

By default, the query might have a plan like the following. If you don't see hash join used in the query plan, make sure that optimization is turned on first.

```
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table   | partitions | type | possible_keys | key  | key_len |
ref | rows       | filtered | Extra      |      |                |     |         |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1  | SIMPLE     | customer | NULL       | ALL | NULL          | NULL | NULL    |
NULL | 1480234    | 10.00   | Using where; Using temporary; Using filesort |
| 1  | SIMPLE     | orders  | NULL       | ALL | NULL          | NULL | NULL    |
NULL | 14875240   | 3.33    | Using where; Using join buffer (Block Nested Loop) |
| 1  | SIMPLE     | lineitem | NULL       | ALL | NULL          | NULL | NULL    |
NULL | 59270573   | 3.33    | Using where; Using join buffer (Block Nested Loop) |
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
```

For Aurora MySQL version 3, you turn on hash join at the session level by issuing the following statement.

```
SET optimizer_switch='block_nested_loop=on';
```

For Aurora MySQL version 2.09 and higher, you set the `aurora_disable_hash_join` DB parameter or DB cluster parameter to 0 (off). Turning off `aurora_disable_hash_join` sets the value of `optimizer_switch` to `hash_join=on`.

After you turn on hash join, try running the EXPLAIN statement again. For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins](#).

With hash join turned on but parallel query turned off, the query might have a plan like the following, which uses hash join but not parallel query.

```
+----+-----+-----+...+-----+
+-----+
| id | select_type | table  |...| rows      | Extra
|     |             |       |   |           |
+----+-----+-----+...+-----+
+-----+
| 1 | SIMPLE      | customer |...| 5798330 | Using where; Using index; Using
temporary; Using filesort
| 1 | SIMPLE      | orders  |...| 154545408 | Using where; Using join buffer (Hash
Join Outer table orders)
| 1 | SIMPLE      | lineitem |...| 606119300 | Using where; Using join buffer (Hash
Join Outer table lineitem)
+----+-----+-----+...+-----+
+-----+
```

After parallel query is turned on, two steps in this query plan can use the parallel query optimization, as shown under the `Extra` column in the EXPLAIN output. The I/O-intensive and CPU-intensive processing for those steps is pushed down to the storage layer.

```
+----+...
+-----+-----+-----+-----+-----+
+
| id |...| Extra
|     |   |
+----+...
+-----+-----+-----+-----+-----+
+
| 1 |...| Using where; Using index; Using temporary; Using filesort
|     |   |
```

10 rows in set (1 min 49.91 sec)

Many of the sample queries throughout this section use the tables from this TPC-H dataset, particularly the PART table, which has 20 million rows and the following definition.

```
+-----+-----+-----+-----+-----+-----+
| Field          | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| p_partkey      | int(11)       | NO   | PRI | NULL     |       |
| p_name         | varchar(55)   | NO   |     | NULL     |       |
| p_mfgpr        | char(25)      | NO   |     | NULL     |       |
| p_brand        | char(10)      | NO   |     | NULL     |       |
| p_type         | varchar(25)   | NO   |     | NULL     |       |
| p_size         | int(11)       | NO   |     | NULL     |       |
| p_container    | char(10)      | NO   |     | NULL     |       |
| p_retailprice  | decimal(15,2) | NO   |     | NULL     |       |
| p_comment      | varchar(23)   | NO   |     | NULL     |       |
+-----+-----+-----+-----+-----+-----+
```

Experiment with your workload to get a sense of whether individual SQL statements can take advantage of parallel query. Then use the following monitoring techniques to help verify how often parallel query is used in real workloads over time. For real workloads, extra factors such as concurrency limits apply.

## Monitoring parallel query for Aurora MySQL

If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

In addition to the Amazon CloudWatch metrics described in [Viewing metrics in the Amazon RDS console](#), Aurora provides other global status variables. You can use these global status variables to help monitor parallel query execution. They can give you insights into why the optimizer might use or not use parallel query in a given situation. To access these variables, you can use the [SHOW GLOBAL STATUS](#) command. You can also find these variables listed following.

A parallel query session isn't necessarily a one-to-one mapping with the queries performed by the database. For example, suppose that your query plan has two steps that use parallel query. In that case, the query involves two parallel sessions and the counters for requests attempted and requests successful are incremented by two.

When you experiment with parallel query by issuing EXPLAIN statements, expect to see increases in the counters designated as "not chosen" even though the queries aren't actually running.

When you work with parallel query in production, you can check if the "not chosen" counters are increasing faster than you expect. At this point, you can adjust so that parallel query runs for the queries that you expect. To do so, you can change your cluster settings, query mix, DB instances where parallel query is turned on, and so on.

These counters are tracked at the DB instance level. When you connect to a different endpoint, you might see different metrics because each DB instance runs its own set of parallel queries. You might also see different metrics when the reader endpoint connects to a different DB instance for each session.

Name	Description
Aurora_pq_bytes_returned	The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against Aurora_pq_pages_pushed_down .
Aurora_pq_max_concurrent_requests	The maximum number of parallel query sessions that can run concurrently on this Aurora DB instance. This is a fixed number that depends on the Amazon DB instance class.
Aurora_pq_pages_pushed_down	The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.
Aurora_pq_request_attempted	The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.
Aurora_pq_request_executed	The number of parallel query sessions run successfully.
Aurora_pq_request_failed	The number of parallel query sessions that returned an error to the client. In some cases,

Name	Description
	a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism . If the retried query also fails, an error is returned to the client and this counter is incremented.
Aurora_pq_request_in_progress	The number of parallel query sessions currently in progress. This number applies to the particular Aurora DB instance that you are connected to, not the entire Aurora DB cluster. To see if a DB instance is close to its concurrency limit, compare this value to <code>Aurora_pq_max_concurrent_requests</code> .
Aurora_pq_request_not_chosen	The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_below_min_rows	The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_column_bit	The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.

Name	Description
Aurora_pq_request_not_chosen_column_geometry	The number of parallel query requests that use the nonparallel query processing path because the table has columns with the GEOMETRY data type. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a> .
Aurora_pq_request_not_chosen_column_lob	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a> .
Aurora_pq_request_not_chosen_column_virtual	The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.
Aurora_pq_request_not_chosen_custom_charset	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.
Aurora_pq_request_not_chosen_fast_ddl	The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER statement.

Name	Description
Aurora_pq_request_not_chosen_few_pages_outside_buffer_pool	The number of times parallel query wasn't chosen, even though less than 95 percent of the table data was in the buffer pool, because there wasn't enough unbuffered table data to make parallel query worthwhile.
Aurora_pq_request_not_chosen_full_text_index	The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.
Aurora_pq_request_not_chosen_high_buffer_pool_pct	The number of times parallel query wasn't chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_index_hint	The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.
Aurora_pq_request_not_chosen_innodb_table_format	The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.

Name	Description
Aurora_pq_request_not_chosen_long_trx	The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_no_where_clause	The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.
Aurora_pq_request_not_chosen_range_scan	The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.
Aurora_pq_request_not_chosen_row_length_too_long	The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.
Aurora_pq_request_not_chosen_small_table	The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_temporary_table	The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.

Name	Description
Aurora_pq_request_not_chosen_tx_isolation	The number of parallel query requests that use the nonparallel query processing path because query uses an unsupported transaction isolation level. On reader DB instances, parallel query only applies to the REPEATABLE READ and READ COMMITTED isolation levels.
Aurora_pq_request_not_chosen_update_delete_stmts	The number of parallel query requests that use the nonparallel query processing path because the query is part of an UPDATE or DELETE statement.
Aurora_pq_request_not_chosen_unsupported_access	The number of parallel query requests that use the nonparallel query processing path because the WHERE clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a DELETE or UPDATE statement.
Aurora_pq_request_not_chosen_unsupported_storage_type	The number of parallel query requests that use the nonparallel query processing path because the Aurora MySQL DB cluster isn't using a supported Aurora cluster storage configuration. This parameter is available in Aurora MySQL version 3.04 and higher. For more information, see <a href="#">Limitations</a> .
Aurora_pq_request_throttled	The number of times parallel query wasn't chosen due to the maximum number of concurrent parallel queries already running on a particular Aurora DB instance.

## SQL constructs for parallel query in Aurora MySQL

In the following section, you can find more detail about why particular SQL statements use or don't use parallel query. This section also details how Aurora MySQL features interact with parallel query. This information can help you diagnose performance issues for a cluster that uses parallel query or understand how parallel query applies for your particular workload.

The decision to use parallel query relies on many factors that occur at the moment that the statement runs. Thus, parallel query might be used for certain queries always, never, or only under certain conditions.

### Tip

When you view these examples in HTML, you can use the **Copy** widget in the upper-right corner of each code listing to copy the SQL code to try yourself. Using the **Copy** widget avoids copying the extra characters around the `mysql>` prompt and `->` continuation lines.

## EXPLAIN statement

As shown in examples throughout this section, the EXPLAIN statement indicates whether each stage of a query is currently eligible for parallel query. It also indicates which aspects of a query can be pushed down to the storage layer. The most important items in the query plan are the following:

- A value other than NULL for the key column suggests that the query can be performed efficiently using index lookups, and parallel query is unlikely.
- A small value for the rows column (a value not in the millions) suggests that the query isn't accessing enough data to make parallel query worthwhile. This means that parallel query is unlikely.
- The Extra column shows you if parallel query is expected to be used. This output looks like the following example.

```
Using parallel query (A columns, B filters, C exprs; D extra)
```

The columns number represents how many columns are referred to in the query block.

The filters number represents the number of WHERE predicates representing a simple comparison of a column value to a constant. The comparison can be for equality, inequality, or a range. Aurora can parallelize these kinds of predicates most effectively.

The exprs number represents the number of expressions such as function calls, operators, or other expressions that can also be parallelized, though not as effectively as a filter condition.

The extra number represents how many expressions can't be pushed down and are performed by the head node.

For example, consider the following EXPLAIN output.

```
mysql> explain select p_name, p_mfgr from part
-> where p_brand is not null
-> and upper(p_type) is not null
-> and round(p_retailprice) is not null;
+----+-----+-----+...+-----+
+-----+
| id | select_type | table | ... | rows      | Extra
      |
+----+-----+-----+...+-----+
+-----+
| 1 | SIMPLE      | part  | ... | 20427936 | Using where; Using parallel query (5
columns, 1 filters, 2 exprs; 0 extra) |
+----+-----+-----+...+-----+
+-----+
```

The information from the `Extra` column shows that five columns are extracted from each row to evaluate the query conditions and construct the result set. One `WHERE` predicate involves a filter, that is, a column that is directly tested in the `WHERE` clause. Two `WHERE` clauses require evaluating more complicated expressions, in this case involving function calls. The `0 extra` field confirms that all the operations in the `WHERE` clause are pushed down to the storage layer as part of parallel query processing.

In cases where parallel query isn't chosen, you can typically deduce the reason from the other columns of the EXPLAIN output. For example, the `rows` value might be too small, or the `possible_keys` column might indicate that the query can use an index lookup instead of a data-intensive scan. The following example shows a query where the optimizer can estimate that the query will scan only a small number of rows. It does so based on the characteristics of the primary key. In this case, parallel query isn't required.

```
mysql> explain select count(*) from part where p_partkey between 1 and 100;
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
      |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
| 1 | SIMPLE      | part  | range | PRIMARY       | PRIMARY | 4       | NULL | 99  |
Using where; Using index |
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
```

The output showing whether parallel query will be used takes into account all available factors at the moment that the EXPLAIN statement is run. The optimizer might make a different choice when the query is actually run, if the situation changed in the meantime. For example, EXPLAIN might report that a statement will use parallel query. But when the query is actually run later, it might not use parallel query based on the conditions then. Such conditions can include several other parallel queries running concurrently. They can also include rows being deleted from the table, a new index being created, too much time passing within an open transaction, and so on.

## WHERE clause

For a query to use the parallel query optimization, it *must* include a WHERE clause.

The parallel query optimization speeds up many kinds of expressions used in the WHERE clause:

- Simple comparisons of a column value to a constant, known as *filters*. These comparisons benefit the most from being pushed down to the storage layer. The number of filter expressions in a query is reported in the EXPLAIN output.
- Other kinds of expressions in the WHERE clause are also pushed down to the storage layer where possible. The number of such expressions in a query is reported in the EXPLAIN output. These expressions can be function calls, LIKE operators, CASE expressions, and so on.
- Certain functions and operators aren't currently pushed down by parallel query. The number of such expressions in a query is reported as the `extra` counter in the EXPLAIN output. The rest of the query can still use parallel query.
- While expressions in the select list aren't pushed down, queries containing such functions can still benefit from reduced network traffic for the intermediate results of parallel queries. For example, queries that call aggregation functions in the select list can benefit from parallel query, even though the aggregation functions aren't pushed down.

For example, the following query does a full-table scan and processes all the values for the P\_BRAND column. However, it doesn't use parallel query because the query doesn't include any WHERE clause.

```
mysql> explain select count(*), p_brand from part group by p_brand;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
```

```

| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | part | ALL | NULL | NULL | NULL | NULL | 20427936 | Using temporary; Using filesort |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

In contrast, the following query includes WHERE predicates that filter the results, so parallel query can be applied:

```

mysql> explain select count(*), p_brand from part where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000
-> group by p_brand;
+-----+...+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+
| id |...| rows | Extra
+-----+...+-----+
+
| 1 |...| 20427936 | Using where; Using temporary; Using filesort; Using parallel
query (5 columns, 1 filters, 2 exprs; 0 extra) |
+-----+...+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+

```

If the optimizer estimates that the number of returned rows for a query block is small, parallel query isn't used for that query block. The following example shows a case where a greater-than operator on the primary key column applies to millions of rows, which causes parallel query to be used. The converse less-than test is estimated to apply to only a few rows and doesn't use parallel query.

```

mysql> explain select count(*) from part where p_partkey > 10;
+-----+...+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+
| id |...| rows | Extra
+-----+...+-----+
+

```

```

| 1 |...| 20427936 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+-----+
+-----+
mysql> explain select count(*) from part where p_partkey < 10;
+----+...+-----+-----+
| id |...| rows | Extra |
+----+...+-----+-----+
| 1 |...| 9 | Using where; Using index |
+----+...+-----+-----+

```

## Data definition language (DDL)

In Aurora MySQL version 2, parallel query is only available for tables for which no fast data definition language (DDL) operations are pending. In Aurora MySQL version 3, you can use parallel query on a table at the same time as an instant DDL operation.

Instant DDL in Aurora MySQL version 3 replaces the fast DDL feature in Aurora MySQL version 2. For information about instant DDL, see [Instant DDL \(Aurora MySQL version 3\)](#).

## Column data types

In Aurora MySQL version 3, parallel query can work with tables containing columns with data types TEXT, BLOB, JSON, and GEOMETRY. It can also work with VARCHAR and CHAR columns with a maximum declared length longer than 768 bytes. If your query refers to any columns containing such large object types, the additional work to retrieve them does add some overhead to query processing. In that case, check if the query can omit the references to those columns. If not, run benchmarks to confirm if such queries are faster with parallel query turned on or turned off.

In Aurora MySQL version 2, parallel query has these limitations for large object types:

- TEXT, BLOB, JSON, and GEOMETRY data types aren't supported with parallel query. A query that refers to any columns of these types can't use parallel query.
- Variable-length columns (VARCHAR and CHAR data types) are compatible with parallel query up to a maximum declared length of 768 bytes. A query that refers to any columns of the types declared with a longer maximum length can't use parallel query. For columns that use multibyte character sets, the byte limit takes into account the maximum number of bytes in the character set. For example, for the character set utf8mb4 (which has a maximum character length of 4

bytes), a VARCHAR(192) column is compatible with parallel query but a VARCHAR(193) column isn't.

## Partitioned tables

You can use partitioned tables with parallel query in Aurora MySQL version 3. Because partitioned tables are represented internally as multiple smaller tables, a query that uses parallel query on a nonpartitioned table might not use parallel query on an identical partitioned table. Aurora MySQL considers whether each partition is large enough to qualify for the parallel query optimization, instead of evaluating the size of the entire table. Check whether the `Aurora_pq_request_not_chosen_small_table` status variable is incremented if a query on a partitioned table doesn't use parallel query when you expect it to.

For example, consider one table partitioned with `PARTITION BY HASH (column) PARTITIONS 2` and another table partitioned with `PARTITION BY HASH (column) PARTITIONS 10`. In the table with two partitions, the partitions are five times as large as the table with ten partitions. Thus, parallel query is more likely to be used for queries against the table with fewer partitions. In the following example, the table `PART_BIG_PARTITIONS` has two partitions and `PART_SMALL_PARTITIONS` has ten partitions. With identical data, parallel query is more likely to be used for the table with fewer big partitions.

```
mysql> explain select count(*), p_brand from part_big_partitions where p_name is not
null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000
group by p_brand;
+----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+
| id | select_type | table          | partitions | Extra
|
+----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+
| 1 | SIMPLE      | part_big_partitions | p0,p1      | Using where; Using temporary;
Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra; 1 group-bys, 1 aggrs) |
+----+-----+-----+-----+-----+

```

## Aggregate functions, GROUP BY clauses, and HAVING clauses

Queries involving aggregate functions are often good candidates for parallel query, because they involve scanning large numbers of rows within large tables.

In Aurora MySQL 3, parallel query can optimize aggregate function calls in the select list and the HAVING clause.

Before Aurora MySQL 3, aggregate function calls in the select list or the HAVING clause aren't pushed down to the storage layer. However, parallel query can still improve the performance of such queries with aggregate functions. It does so by first extracting column values from the raw data pages in parallel at the storage layer. It then transmits those values back to the head node in a compact tuple format instead of as entire data pages. As always, the query requires at least one WHERE predicate for parallel query to be activated.

The following simple examples illustrate the kinds of aggregate queries that can benefit from parallel query. They do so by returning intermediate results in compact form to the head node, filtering nonmatching rows from the intermediate results, or both.

```
mysql> explain select sql_no_cache count(distinct p_brand) from part where p_mfgr =
'Manufacturer#5';
+----+...+-----+-----+-----+-----+
| id |...| Extra
+----+...+-----+-----+-----+-----+
| 1 |...| Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+-----+-----+-----+-----+
```

```

+----+...
+-----+
+
| 1 |...| Using where; Using temporary; Using parallel query (2 columns, 0 filters, 1
exprs; 0 extra) |
+----+...
+-----+
+

```

The same considerations apply to other expressions, such as CASE expressions or LIKE operators. For example, the following example shows that parallel query evaluates the CASE expression and LIKE operators in the WHERE clause.

```

mysql> explain select p_mfgr, p_retailprice from part
-> where p_retailprice > case p_mfgr
->   when 'Manufacturer#1' then 1000
->   when 'Manufacturer#2' then 1200
->   else 950
-> end
-> and p_name like '%vanilla%'
-> group by p_retailprice;
+----+...
+-----+
+
| id |...| Extra
          |
+----+...
+-----+
+
| 1 |...| Using where; Using temporary; Using filesort; Using parallel query (4
columns, 0 filters, 2 exprs; 0 extra) |
+----+...
+-----+
+

```

## LIMIT clause

Currently, parallel query isn't used for any query block that includes a LIMIT clause. Parallel query might still be used for earlier query phases with GROUP BY, ORDER BY, or joins.

## Comparison operators

The optimizer estimates how many rows to scan to evaluate comparison operators, and determines whether to use parallel query based on that estimate.

The first example following shows that an equality comparison against the primary key column can be performed efficiently without parallel query. The second example following shows that a similar comparison against an unindexed column requires scanning millions of rows and therefore can benefit from parallel query.

```
mysql> explain select * from part where p_partkey = 10;
+----+...+-----+-----+
| id |...| rows | Extra |
+----+...+-----+-----+
|  1 |...|    1 | NULL  |
+----+...+-----+-----+
```

```
mysql> explain select * from part where p_type = 'LARGE BRUSHED BRASS';
+----+...+-----+
+-----+
| id |...| rows      | Extra
      |
+----+...+-----+
+-----+
|  1 |...| 20427936 | Using where; Using parallel query (9 columns, 1 filters, 0 exprs;
0 extra) |
+----+...+-----+
+-----+
```

The same considerations apply for not-equals tests and for range comparisons such as less than, greater than or equal to, or BETWEEN. The optimizer estimates the number of rows to scan, and determines whether parallel query is worthwhile based on the overall volume of I/O.

## Joins

Join queries with large tables typically involve data-intensive operations that benefit from the parallel query optimization. The comparisons of column values between multiple tables (that is, the join predicates themselves) currently aren't parallelized. However, parallel query can push down some of the internal processing for other join phases, such as constructing the Bloom filter during a hash join. Parallel query can apply to join queries even without a WHERE clause. Therefore, a join query is an exception to the rule that a WHERE clause is required to use parallel query.

For a join query that uses the nested loop mechanism, the outermost nested loop block might use parallel query. The use of parallel query depends on the same factors as usual, such as the presence of additional filter conditions in the *WHERE* clause.

```
mysql> -- Nested loop join with extra filter conditions can use parallel query.
mysql> explain select count(*) from part, partsupp where p_partkey != ps_partkey and
  p_name is not null and ps_availqty > 0;
+----+-----+-----+...+-----+
+-----+
| id | select_type | table  |...| rows    | Extra
      |
+----+-----+-----+...+-----+
+-----+
|  1 | SIMPLE      | part   |...| 20427936 | Using where; Using parallel query (2
  columns, 1 filters, 0 exprs; 0 extra) |
|  1 | SIMPLE      | partsupp |...| 78164450 | Using where; Using join buffer (Block
  Nested Loop)
      |
+----+-----+-----+...+-----+
+-----+
```

## Subqueries

The outer query block and inner subquery block might each use parallel query, or not. Whether they do is based on the usual characteristics of the table, *WHERE* clause, and so on, for each block. For example, the following query uses parallel query for the subquery block but not the outer block.

```
mysql> explain select count(*) from part where
  --> p_partkey < (select max(p_partkey) from part where p_name like '%vanilla%');
+----+-----+...+-----+
+-----+
| id | select_type |...| rows    | Extra
      |
+----+-----+...+-----+
+-----+
|  1 | PRIMARY     |...| NULL    | Impossible WHERE noticed after reading const tables
      |
|  2 | SUBQUERY    |...| 20427936 | Using where; Using parallel query (2 columns, 0
  filters, 1 exprs; 0 extra) |
+----+-----+...+-----+
+-----+
```

Currently, correlated subqueries can't use the parallel query optimization.

## UNION

Each query block in a UNION query can use parallel query, or not, based on the usual characteristics of the table, WHERE clause, and so on, for each part of the UNION.

```
mysql> explain select p_partkey from part where p_name like '%choco_ate%'
-> union select p_partkey from part where p_name like '%vanil_a%';
+----+-----+...+-----+
+-----+
| id | select_type | ... | rows | Extra
      |
+----+-----+...+-----+
+-----+
| 1 | PRIMARY | ... | 20427936 | Using where; Using parallel query (2 columns, 0
filters, 1 exprs; 0 extra) |
| 2 | UNION | ... | 20427936 | Using where; Using parallel query (2 columns, 0
filters, 1 exprs; 0 extra) |
| NULL | UNION RESULT | <union1,2> | ... | NULL | Using temporary
      |
+----+-----+...+-----+
+-----+
```

### Note

Each UNION clause within the query is run sequentially. Even if the query includes multiple stages that all use parallel query, it only runs a single parallel query at any one time. Therefore, even a complex multistage query only counts as 1 toward the limit of concurrent parallel queries.

## Views

The optimizer rewrites any query using a view as a longer query using the underlying tables. Thus, parallel query works the same whether table references are views or real tables. All the same considerations about whether to use parallel query for a query, and which parts are pushed down, apply to the final rewritten query.

For example, the following query plan shows a view definition that usually doesn't use parallel query. When the view is queried with additional WHERE clauses, Aurora MySQL uses parallel query.

```
mysql> create view part_view as select * from part;
mysql> explain select count(*) from part_view where p_partkey is not null;
+----+...+-----+
+-----+
| id |...| rows      | Extra
      |
+----+...+-----+
+-----+
|  1 |...| 20427936 | Using where; Using parallel query (1 columns, 0 filters, 0 exprs;
  1 extra) |
+----+...+-----+
+-----+
```

## Data manipulation language (DML) statements

The INSERT statement can use parallel query for the SELECT phase of processing, if the SELECT part meets the other conditions for parallel query.

```
mysql> create table part_subset like part;
mysql> explain insert into part_subset select * from part where p_mfgr =
  'Manufacturer#1';
+----+...+-----+
+-----+
| id |...| rows      | Extra
      |
+----+...+-----+
+-----+
|  1 |...| 20427936 | Using where; Using parallel query (9 columns, 1 filters, 0 exprs;
  0 extra) |
+----+...+-----+
+-----+
```

### Note

Typically, after an INSERT statement, the data for the newly inserted rows is in the buffer pool. Therefore, a table might not be eligible for parallel query immediately after inserting a large number of rows. Later, after the data is evicted from the buffer pool during normal operation, queries against the table might begin using parallel query again.

The `CREATE TABLE AS SELECT` statement doesn't use parallel query, even if the `SELECT` portion of the statement would otherwise be eligible for parallel query. The DDL aspect of this statement makes it incompatible with parallel query processing. In contrast, in the `INSERT ... SELECT` statement, the `SELECT` portion can use parallel query.

Parallel query is never used for `DELETE` or `UPDATE` statements, regardless of the size of the table and predicates in the `WHERE` clause.

```
mysql> explain delete from part where p_name is not null;
+----+-----+...+-----+-----+
| id | select_type |...| rows      | Extra          |
+----+-----+...+-----+-----+
|  1 | SIMPLE      |...| 20427936 | Using where    |
+----+-----+...+-----+-----+
```

## Transactions and locking

You can use all the isolation levels on the Aurora primary instance.

On Aurora reader DB instances, parallel query applies to statements performed under the `REPEATABLE READ` isolation level. Aurora MySQL version 2.09 or higher can also use the `READ COMMITTED` isolation level on reader DB instances. `REPEATABLE READ` is the default isolation level for Aurora reader DB instances. To use `READ COMMITTED` isolation level on reader DB instances requires setting the `aurora_read_replica_read_committed` configuration option at the session level. The `READ COMMITTED` isolation level for reader instances complies with SQL standard behavior. However, the isolation is less strict on reader instances than when queries use `READ COMMITTED` isolation level on the writer instance.

For more information about Aurora isolation levels, especially the differences in `READ COMMITTED` between writer and reader instances, see [Aurora MySQL isolation levels](#).

After a big transaction is finished, the table statistics might be stale. Such stale statistics might require an `ANALYZE TABLE` statement before Aurora can accurately estimate the number of rows. A large-scale DML statement might also bring a substantial portion of the table data into the buffer pool. Having this data in the buffer pool can lead to parallel query being chosen less frequently for that table until the data is evicted from the pool.

When your session is inside a long-running transaction (by default, 10 minutes), further queries inside that session don't use parallel query. A timeout can also occur during a single long-running

query. This type of timeout might happen if the query runs for longer than the maximum interval (currently 10 minutes) before the parallel query processing starts.

You can reduce the chance of starting long-running transactions accidentally by setting `autocommit=1` in `mysql` sessions where you perform ad hoc (one-time) queries. Even a `SELECT` statement against a table begins a transaction by creating a read view. A *read view* is a consistent set of data for subsequent queries that remains until the transaction is committed. Be aware of this restriction also when using JDBC or ODBC applications with Aurora, because such applications might run with the `autocommit` setting turned off.

The following example shows how, with the `autocommit` setting turned off, running a query against a table creates a read view that implicitly begins a transaction. Queries that are run shortly afterward can still use parallel query. However, after a pause of several minutes, queries are no longer eligible for parallel query. Ending the transaction with `COMMIT` or `ROLLBACK` restores parallel query eligibility.

```
mysql> set autocommit=0;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+-----+
+-----+
| id |...| rows    | Extra
      |
+----+...+-----+
+-----+
|  1 |...| 2976129 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs;
0 extra) |
+----+...+-----+
+-----+

mysql> select sleep(720); explain select sql_no_cache count(*) from part where
p_retailprice > 10.0;
+-----+
| sleep(720) |
+-----+
|           0 |
+-----+
1 row in set (12 min 0.00 sec)

+----+...+-----+-----+
| id |...| rows    | Extra      |
+----+...+-----+-----+
```

```

| 1 |...| 2976129 | Using where |
+----+...+-----+-----+

mysql> commit;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+-----+
+-----+
| id |...| rows    | Extra
      |
+----+...+-----+
+-----+
| 1 |...| 2976129 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs;
0 extra) |
+----+...+-----+
+-----+

```

To see how many times queries weren't eligible for parallel query because they were inside long-running transactions, check the status variable `Aurora_pq_request_not_chosen_long_trx`.

```

mysql> show global status like '%pq%trx%';
+-----+
| Variable_name          | Value |
+-----+
| Aurora_pq_request_not_chosen_long_trx | 4     |
+-----+

```

Any `SELECT` statement that acquires locks, such as the `SELECT FOR UPDATE` or `SELECT LOCK IN SHARE MODE` syntax, can't use parallel query.

Parallel query can work for a table that is locked by a `LOCK TABLES` statement.

```

mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk =
'Clerk#000095055';
+----+...+-----+
+-----+
| id |...| rows      | Extra
      |
+----+...+-----+
+-----+
| 1 |...| 154545408 | Using where; Using parallel query (3 columns, 1 filters, 0
exprs; 0 extra) |

```

```
+----+...+-----+
+-----+
mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk =
      'Clerk#000095055' for update;
+----+...+-----+-----+
| id |...| rows      | Extra      |
+----+...+-----+-----+
|  1 |...| 154545408 | Using where |
+----+...+-----+-----+
```

## B-tree indexes

The statistics gathered by the `ANALYZE TABLE` statement help the optimizer to decide when to use parallel query or index lookups, based on the characteristics of the data for each column. Keep statistics current by running `ANALYZE TABLE` after DML operations that make substantial changes to the data within a table.

If index lookups can perform a query efficiently without a data-intensive scan, Aurora might use index lookups. Doing so avoids the overhead of parallel query processing. There are also concurrency limits on the number of parallel queries that can run simultaneously on any Aurora DB cluster. Make sure to use best practices for indexing your tables, so that your most frequent and most highly concurrent queries use index lookups.

## Full-text search (FTS) indexes

Currently, parallel query isn't used for tables that contain a full-text search index, regardless of whether the query refers to such indexed columns or uses the `MATCH` operator.

## Virtual columns

Currently, parallel query isn't used for tables that contain a virtual column, regardless of whether the query refers to any virtual columns.

## Built-in caching mechanisms

Aurora includes built-in caching mechanisms, namely the buffer pool and the query cache. The Aurora optimizer chooses between these caching mechanisms and parallel query depending on which one is most effective for a particular query.

When a parallel query filters rows and transforms and extracts column values, data is transmitted back to the head node as tuples rather than as data pages. Therefore, running a parallel query doesn't add any pages to the buffer pool, or evict pages that are already in the buffer pool.

Aurora checks the number of pages of table data that are present in the buffer pool, and what proportion of the table data that number represents. Aurora uses that information to determine whether it is more efficient to use parallel query (and bypass the data in the buffer pool). Alternatively, Aurora might use the nonparallel query processing path, which uses data cached in the buffer pool. Which pages are cached and how data-intensive queries affect caching and eviction depends on configuration settings related to the buffer pool. Therefore, it can be hard to predict whether any particular query uses parallel query, because the choice depends on the ever-changing data within the buffer pool.

Also, Aurora imposes concurrency limits on parallel queries. Because not every query uses parallel query, tables that are accessed by multiple queries simultaneously typically have a substantial portion of their data in the buffer pool. Therefore, Aurora often doesn't choose these tables for parallel queries.

When you run a sequence of nonparallel queries on the same table, the first query might be slow due to the data not being in the buffer pool. Then the second and subsequent queries are much faster because the buffer pool is now "warmed up". Parallel queries typically show consistent performance from the very first query against the table. When conducting performance tests, benchmark the nonparallel queries with both a cold and a warm buffer pool. In some cases, the results with a warm buffer pool can compare well to parallel query times. In these cases, consider factors such as the frequency of queries against that table. Also consider whether it is worthwhile to keep the data for that table in the buffer pool.

The query cache avoids rerunning a query when an identical query is submitted and the underlying table data hasn't changed. Queries optimized by parallel query feature can go into the query cache, effectively making them instantaneous when run again.

#### Note

When conducting performance comparisons, the query cache can produce artificially low timing numbers. Therefore, in benchmark-like situations, you can use the `sql_no_cache` hint. This hint prevents the result from being served from the query cache, even if the same query had been run previously. The hint comes immediately after the `SELECT` statement in a query. Many parallel query examples in this topic include this hint, to make query times

comparable between versions of the query for which parallel query is turned on and turned off.

Make sure that you remove this hint from your source when you move to production use of parallel query.

## Optimizer hints

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. For example, you can turn on an optimization for one table in a statement, and then turn off the optimization for a different table. For more information about these hints, see [Optimizer Hints](#) in the *MySQL Reference Manual*.

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.

We have extended the SQL hints feature to help you control optimizer choices for your query plans. These hints apply to queries that use parallel query optimization. For more information, see [Aurora MySQL hints](#).

## MyISAM temporary tables

The parallel query optimization only applies to InnoDB tables. Because Aurora MySQL uses MyISAM behind the scenes for temporary tables, internal query phases involving temporary tables never use parallel query. These query phases are indicated by `Using temporary` in the EXPLAIN output.

# Using Advanced Auditing with an Amazon Aurora MySQL DB cluster

You can use the high-performance Advanced Auditing feature in Amazon Aurora MySQL to audit database activity. To do so, you enable the collection of audit logs by setting several DB cluster parameters. When Advanced Auditing is enabled, you can use it to log any combination of supported events.

You can view or download the audit logs to review the audit information for one DB instance at a time. To do so, you can use the procedures in [Monitoring Amazon Aurora log files](#).

## Tip

For an Aurora DB cluster containing multiple DB instances, you might find it more convenient to examine the audit logs for all instances in the cluster. To do so, you can use CloudWatch Logs. You can turn on a setting at the cluster level to publish the Aurora MySQL audit log data to a log group in CloudWatch. Then you can view, filter, and search the audit logs through the CloudWatch interface. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](#).

## Enabling Advanced Auditing

Use the parameters described in this section to enable and configure Advanced Auditing for your DB cluster.

Use the `server_audit_logging` parameter to enable or disable Advanced Auditing.

Use the `server_audit_events` parameter to specify what events to log.

Use the `server_audit_incl_users` and `server_audit_excl_users` parameters to specify who gets audited. By default, all users are audited. For details about how these parameters work when one or both are left empty, or the same user names are specified in both, see [server\\_audit\\_incl\\_users](#) and [server\\_audit\\_excl\\_users](#).

Configure Advanced Auditing by setting these parameters in the parameter group used by your DB cluster. You can use the procedure shown in [Modifying parameters in a DB parameter group in Amazon Aurora](#) to modify DB cluster parameters using the Amazon Web Services Management

Console. You can use the [modify-db-cluster-parameter-group](#) Amazon CLI command or the [ModifyDBClusterParameterGroup](#) Amazon RDS API operation to modify DB cluster parameters programmatically.

Modifying these parameters doesn't require a DB cluster restart when the parameter group is already associated with your cluster. When you associate the parameter group with the cluster for the first time, a cluster restart is required.

## Topics

- [server\\_audit\\_logging](#)
- [server\\_audit\\_events](#)
- [server\\_audit\\_incl\\_users](#)
- [server\\_audit\\_excl\\_users](#)

## server\_audit\_logging

Enables or disables Advanced Auditing. This parameter defaults to OFF; set it to ON to enable Advanced Auditing.

No audit data appears in the logs unless you also define one or more types of events to audit using the `server_audit_events` parameter.

To confirm that audit data is logged for a DB instance, check that some log files for that instance have names of the form `audit/audit.log.other_identifying_information`. To see the names of the log files, follow the procedure in [Viewing and listing database log files](#).

## server\_audit\_events

Contains the comma-delimited list of events to log. Events must be specified in all caps, and there should be no white space between the list elements, for example: `CONNECT,QUERY_DDL`. This parameter defaults to an empty string.

You can log any combination of the following events:

- **CONNECT** – Logs both successful and failed connections and also disconnections. This event includes user information.
- **QUERY** – Logs all queries in plain text, including queries that fail due to syntax or permission errors.

**Tip**

With this event type turned on, the audit data includes information about the continuous monitoring and health-checking information that Aurora does automatically. If you are only interested in particular kinds of operations, you can use the more specific kinds of events. You can also use the CloudWatch interface to search in the logs for events related to specific databases, tables, or users.

- **QUERY\_DCL** – Similar to the **QUERY** event, but returns only data control language (DCL) queries (**GRANT**, **REVOKE**, and so on).
- **QUERY\_DDL** – Similar to the **QUERY** event, but returns only data definition language (DDL) queries (**CREATE**, **ALTER**, and so on).
- **QUERY\_DML** – Similar to the **QUERY** event, but returns only data manipulation language (DML) queries (**INSERT**, **UPDATE**, and so on, and also **SELECT**).
- **TABLE** – Logs the tables that were affected by query execution.

**Note**

There's no filter in Aurora that excludes certain queries from audit logs. To exclude **SELECT** queries, you must exclude all DML statements.

If a certain user is reporting these internal **SELECT** queries in the audit logs, then you can exclude that user by setting the [server\\_audit\\_excl\\_users](#) DB cluster parameter. However, if that user is also used in other activities and can't be omitted, then there is no other option for excluding **SELECT** queries.

## server\_audit\_incl\_users

Contains the comma-delimited list of user names for users whose activity is logged. There should be no white space between the list elements, for example: `user_3,user_4`. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the `User` column of the `mysql.user` table. For more information about user names, see [Account User Names and Passwords](#) in the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.

If you add users to `server_audit_incl_users` and leave `server_audit_excl_users` empty, then only those users are audited.

If you add users to `server_audit_excl_users` and leave `server_audit_incl_users` empty, then all users are audited, except for those listed in `server_audit_excl_users`.

If you add the same users to both `server_audit_excl_users` and `server_audit_incl_users`, then those users are audited. When the same user is listed in both settings, `server_audit_incl_users` is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged even if that user is also specified in the `server_audit_excl_users` parameter, because `server_audit_incl_users` has higher priority.

## **server\_audit\_excl\_users**

Contains the comma-delimited list of user names for users whose activity isn't logged. There should be no white space between the list elements, for example: `rdadmin,user_1,user_2`. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the `User` column of the `mysql.user` table. For more information about user names, see [Account User Names and Passwords](#) in the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.

If you add users to `server_audit_excl_users` and leave `server_audit_incl_users` empty, then only those users that you list in `server_audit_excl_users` are not audited, and all other users are.

If you add the same users to both `server_audit_excl_users` and `server_audit_incl_users`, then those users are audited. When the same user is listed in both settings, `server_audit_incl_users` is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged if that user is also specified in the `server_audit_incl_users` parameter, because that setting has higher priority than `server_audit_excl_users`.

## Viewing audit logs

You can view and download the audit logs by using the console. On the **Databases** page, choose the DB instance to show its details, then scroll to the **Logs** section. The audit logs produced by the Advanced Auditing feature have names of the form `audit/audit.log.other_identifying_information`.

To download a log file, choose that file in the **Logs** section and then choose **Download**.

You can also get a list of the log files by using the [describe-db-log-files](#) Amazon CLI command. You can download the contents of a log file by using the [download-db-log-file-portion](#) Amazon CLI command. For more information, see [Viewing and listing database log files](#) and [Downloading a database log file](#).

## Audit log details

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. Queries are also wrapped in single quotes (').

The audit log is stored separately on the local storage of each Aurora MySQL DB instance. Each instance distributes writes across four log files at a time. The maximum size of a log file is 100 MB. When this non-configurable limit is reached, Aurora rotates the file and generates a new file.

### Tip

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](#).

The audit log files include the following comma-delimited information in rows, in the specified order:

Field	Description
timestamp	The Unix time stamp for the logged event with microsecond precision.
serverhost	The name of the instance that the event is logged for.
username	The connected user name of the user.
host	The host that the user connected from.
connectionid	The connection ID number for the logged operation.
queryid	The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.
operation	The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.
database	The active database, as set by the USE command.
object	For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.
retcode	The return code of the logged operation.

# Replication with Amazon Aurora MySQL

The Aurora MySQL replication features are key to the high availability and performance of your cluster. Aurora makes it easy to create or resize clusters with up to 15 Aurora Replicas.

All the replicas work from the same underlying data. If some database instances go offline, others remain available to continue processing queries or to take over as the writer if needed. Aurora automatically spreads your read-only connections across multiple database instances, helping an Aurora cluster to support query-intensive workloads.

In the following topics, you can find information about how Aurora MySQL replication works and how to fine-tune replication settings for best availability and performance.

## Topics

- [Using Aurora Replicas](#)
- [Replication options for Amazon Aurora MySQL](#)
- [Performance considerations for Amazon Aurora MySQL replication](#)
- [Configuring replication filters with Aurora MySQL](#)
- [Monitoring Amazon Aurora MySQL replication](#)
- [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#)
- [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#)
- [Using GTID-based replication](#)

## Using Aurora Replicas

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an Amazon Web Services Region. Although the DB cluster volume is made up of multiple copies of the data for the DB cluster, the data in the cluster volume is represented as a single, logical volume to the primary instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see [Aurora Replicas](#).

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster

volume is shared among all instances in your Aurora MySQL DB cluster, no additional work is required to replicate a copy of the data for each Aurora Replica. In contrast, MySQL read replicas must replay, on a single thread, all write operations from the source DB instance to their local data store. This limitation can affect the ability of MySQL read replicas to support large volumes of read traffic.

With Aurora MySQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

### Important

Aurora Replicas for Aurora MySQL always use the `REPEATABLE READ` default transaction isolation level for operations on InnoDB tables. You can use the `SET TRANSACTION ISOLATION LEVEL` command to change the transaction level only for the primary instance of an Aurora MySQL DB cluster. This restriction avoids user-level locks on Aurora Replicas, and allows Aurora Replicas to scale to support thousands of active user connections while still keeping replica lag to a minimum.

### Note

DDL statements that run on the primary instance might interrupt database connections on the associated Aurora Replicas. If an Aurora Replica connection is actively using a database object, such as a table, and that object is modified on the primary instance using a DDL statement, the Aurora Replica connection is interrupted.

### Note

The China (Ningxia) Region does not support cross-Region read replicas.

## Replication options for Amazon Aurora MySQL

You can set up replication between any of the following options:

- Two Aurora MySQL DB clusters in different Amazon Web Services Regions, by creating a cross-Region read replica of an Aurora MySQL DB cluster.

For more information, see [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#).

- Two Aurora MySQL DB clusters in the same Amazon Web Services Region, by using MySQL binary log (binlog) replication.

For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

- An RDS for MySQL DB instance as the source and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance.

You can use this approach to bring existing and ongoing data changes into Aurora MySQL during migration to Aurora. For more information, see [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#).

You can also use this approach to increase the scalability of read queries for your data. You do so by querying the data using one or more DB instances within a read-only Aurora MySQL cluster. For more information, see [Scaling reads for your MySQL database with Amazon Aurora](#).

- An Aurora MySQL DB cluster in one Amazon Web Services Region and up to five Aurora read-only Aurora MySQL DB clusters in different Regions, by creating an Aurora global database.

You can use an Aurora global database to support applications with a world-wide footprint. The primary Aurora MySQL DB cluster has a Writer instance and up to 15 Aurora Replicas. The read-only secondary Aurora MySQL DB clusters can each be made up of as many as 16 Aurora Replicas. For more information, see [Using Amazon Aurora Global Database](#).

#### Note

Rebooting the primary instance of an Amazon Aurora DB cluster also automatically reboots the Aurora Replicas for that DB cluster, to re-establish an entry point that guarantees read/write consistency across the DB cluster.

## Performance considerations for Amazon Aurora MySQL replication

The following features help you to fine-tune the performance of Aurora MySQL replication.

The replica log compression feature automatically reduces network bandwidth for replication messages. Because each message is transmitted to all Aurora Replicas, the benefits are greater for larger clusters. This feature involves some CPU overhead on the writer node to perform the compression. It's always enabled in Aurora MySQL version 2 and version 3.

The binlog filtering feature automatically reduces network bandwidth for replication messages. Because the Aurora Replicas don't use the binlog information that is included in the replication messages, that data is omitted from the messages sent to those nodes.

In Aurora MySQL version 2, you can control this feature by changing the `aurora_enable_repl_bin_log_filtering` parameter. This parameter is on by default. Because this optimization is intended to be transparent, you might turn off this setting only during diagnosis or troubleshooting for issues related to replication. For example, you can do so to match the behavior of an older Aurora MySQL cluster where this feature was not available.

Binlog filtering is always enabled in Aurora MySQL version 3.

## Configuring replication filters with Aurora MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB cluster that has read replicas in different Amazon Web Services Regions, to replicate different databases or tables in different Amazon Web Services Regions.
- To specify which databases and tables are replicated with an Aurora MySQL DB cluster that is configured as a replica in an inbound replication topology. For more information about this

configuration, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

## Topics

- [Setting replication filtering parameters for Aurora MySQL](#)
- [Replication filtering limitations for Aurora MySQL](#)
- [Replication filtering examples for Aurora MySQL](#)
- [Viewing the replication filters for a read replica](#)

## Setting replication filtering parameters for Aurora MySQL

To configure replication filters, set the following parameters:

- `binlog-do-db` – Replicate changes to the specified binary logs. When you set this parameter for a binlog source cluster, only the binary logs specified in the parameter are replicated.
- `binlog-ignore-db` – Don't replicate changes to the specified binary logs. When the `binlog-do-db` parameter is set for a binlog source cluster, this parameter isn't evaluated.
- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a binlog replica cluster, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a binlog replica cluster, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the binlog replica cluster.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a binlog replica cluster, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the binlog replica cluster.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-`

`do-table` or `replicate-wild-do-table` parameter is set for a binlog replica cluster, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see [Replica Server Options and Variables](#).
- For information about how database replication filtering parameters are evaluated, see [Evaluation of Database-Level Replication and Binary Logging Options](#).
- For information about how table replication filtering parameters are evaluated, see [Evaluation of Table-Level Replication Options](#).

By default, each of these parameters has an empty value. On each binlog cluster, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and `_` wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the `_` wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see [Configuring Aurora MySQL binary logging for Single-AZ databases](#).

#### Note

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

## Replication filtering limitations for Aurora MySQL

The following limitations apply to replication filtering for Aurora MySQL:

- Replication filters are supported only for Aurora MySQL version 3.
- Each replication filtering parameter has a 2,000-character limit.

- Commas aren't supported in replication filters.
- Replication filtering doesn't support XA transactions.

For more information, see [Restrictions on XA Transactions](#) in the MySQL documentation.

## Replication filtering examples for Aurora MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the DB cluster parameter group associated with the read replica.

### Note

You can't modify a default DB cluster parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB cluster parameter groups, see [Parameter groups for Amazon Aurora](#).

You can set parameters in a DB cluster parameter group using the Amazon Web Services Management Console, Amazon CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon Aurora](#). When you set parameters in a DB cluster parameter group, all of the DB clusters associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a DB cluster parameter group, make sure that the parameter group is associated only with read replica clusters. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the Amazon CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- [Including databases in replication](#)
- [Including tables in replication](#)
- [Including tables in replication with wildcard characters](#)
- [Excluding databases from replication](#)

- [Excluding tables from replication](#)
- [Excluding tables from replication using wildcard characters](#)

## Example Including databases in replication

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-do-  
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-do-  
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

## Example Including tables in replication

The following example includes the table1 and table2 tables in database mydb1 in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-do-  
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-do-  
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

## Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order  
%,mydb.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order  
%,mydb.return%',ApplyMethod=immediate"
```

## Example Excluding databases from replication

The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-ignore-  
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-ignore-  
db,ParameterValue='mydb5,mydb6,ApplyMethod=immediate"
```

## Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

## For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-ignore-  
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

## For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-ignore-  
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

## Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

## For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order  
%,mydb7.return%',ApplyMethod=immediate"
```

## For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order  
%,mydb7.return%',ApplyMethod=immediate"
```

## Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see [Viewing parameter values for a DB parameter group in Amazon Aurora](#).

- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

In the output, the following fields show the replication filters for the read replica:

- `Binlog_Do_DB`
- `Binlog_Ignore_DB`
- `Replicate_Do_DB`
- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

## Monitoring Amazon Aurora MySQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the primary instance of your Aurora MySQL DB cluster by monitoring the Amazon CloudWatch `AuroraReplicaLag` metric. The `AuroraReplicaLag` metric is recorded in each Aurora Replica.

The primary DB instance also records the `AuroraReplicaLagMaximum` and `AuroraReplicaLagMinimum` Amazon CloudWatch metrics. The `AuroraReplicaLagMaximum` metric records the maximum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster. The `AuroraReplicaLagMinimum` metric records the minimum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster.

If you need the most current value for Aurora Replica lag, you can check the `AuroraReplicaLag` metric in Amazon CloudWatch. The Aurora Replica lag is also recorded on each Aurora Replica of your Aurora MySQL DB cluster in the `information_schema.replica_host_status` table. For more information on this table, see [information\\_schema.replica\\_host\\_status](#).

For more information on monitoring RDS instances and CloudWatch metrics, see [Monitoring metrics in an Amazon Aurora cluster](#).

## Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions

You can create an Amazon Aurora MySQL DB cluster as a read replica in a different Amazon Web Services Region than the source DB cluster. Taking this approach can improve your disaster recovery capabilities, let you scale read operations into an Amazon Web Services Region that is closer to your users, and make it easier to migrate from one Amazon Web Services Region to another.

You can create read replicas of both encrypted and unencrypted DB clusters. The read replica must be encrypted if the source DB cluster is encrypted.

For each source DB cluster, you can have up to five cross-Region DB clusters that are read replicas.

### Note

As an alternative to cross-Region read replicas, you can scale read operations with minimal lag time by using an Aurora global database. An Aurora global database has a primary Aurora DB cluster in one Amazon Web Services Region and up to 10 secondary read-only DB clusters in different Regions. Each secondary DB cluster can include up to 16 (rather than 15) Aurora Replicas. Replication from the primary DB cluster to all secondaries is handled by the Aurora storage layer rather than by the database engine, so lag time for replicating changes is minimal—typically, less than 1 second. Keeping the database engine out of the replication process means that the database engine is dedicated to processing workloads. It also means that you don't need to configure or manage the Aurora MySQL binlog (binary logging) replication. To learn more, see [Using Amazon Aurora Global Database](#).

When you create an Aurora MySQL DB cluster read replica in another Amazon Web Services Region, you should be aware of the following:

- Both your source DB cluster and your cross-Region read replica DB cluster can have up to 15 Aurora Replicas, along with the primary instance for the DB cluster. By using this functionality, you can scale read operations for both your source Amazon Web Services Region and your replication target Amazon Web Services Region.
- In a cross-Region scenario, there is more lag time between the source DB cluster and the read replica due to the longer network channels between Amazon Web Services Regions.

- Data transferred for cross-Region replication incurs Amazon RDS data transfer charges. The following cross-Region replication actions generate charges for the data transferred out of the source Amazon Web Services Region:
  - When you create the read replica, Amazon RDS takes a snapshot of the source cluster and transfers the snapshot to the Amazon Web Services Region that holds the read replica.
  - For each data modification made in the source databases, Amazon RDS transfers data from the source region to the Amazon Web Services Region that holds the read replica.

For more information about Amazon RDS data transfer pricing, see [Amazon Aurora pricing](#).

- You can run multiple concurrent create or delete actions for read replicas that reference the same source DB cluster. However, you must stay within the limit of five read replicas for each source DB cluster.
- For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB cluster. If you scale the source DB cluster, you should also scale the read replicas.

## Topics

- [Before you begin](#)
- [Creating a cross-Region read replica DB cluster for Aurora MySQL](#)
- [Promoting a read replica to a DB cluster for Aurora MySQL](#)
- [Troubleshooting cross-Region replicas for Amazon Aurora MySQL](#)

## Before you begin

Before you can create an Aurora MySQL DB cluster that is a cross-Region read replica, you must turn on binary logging on your source Aurora MySQL DB cluster. Cross-region replication for Aurora MySQL uses MySQL binary replication to replay changes on the cross-Region read replica DB cluster.

To turn on binary logging on an Aurora MySQL DB cluster, update the `binlog_format` parameter for your source DB cluster. The `binlog_format` parameter is a cluster-level parameter that is in the default cluster parameter group. If your DB cluster uses the default DB cluster parameter group, create a new DB cluster parameter group to modify `binlog_format` settings. We recommend that you set the `binlog_format` to `MIXED`. However, you can also set

`binlog_format` to ROW or STATEMENT if you need a specific binlog format. Reboot your Aurora DB cluster for the change to take effect.

For more information about using binary logging with Aurora MySQL, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#). For more information about modifying Aurora MySQL configuration parameters, see [Amazon Aurora DB cluster and DB instance parameters](#) and [Parameter groups for Amazon Aurora](#).

## Creating a cross-Region read replica DB cluster for Aurora MySQL

You can create an Aurora DB cluster that is a cross-Region read replica by using the Amazon Web Services Management Console, the Amazon Command Line Interface (Amazon CLI), or the Amazon RDS API. You can create cross-Region read replicas from both encrypted and unencrypted DB clusters.

When you create a cross-Region read replica for Aurora MySQL by using the Amazon Web Services Management Console, Amazon RDS creates a DB cluster in the target Amazon Web Services Region, and then automatically creates a DB instance that is the primary instance for that DB cluster.

When you create a cross-Region read replica using the Amazon CLI or RDS API, you first create the DB cluster in the target Amazon Web Services Region and wait for it to become active. Once it is active, you then create a DB instance that is the primary instance for that DB cluster.

Replication begins when the primary instance of the read replica DB cluster becomes available.

Use the following procedures to create a cross-Region read replica from an Aurora MySQL DB cluster. These procedures work for creating read replicas from either encrypted or unencrypted DB clusters.

### Console

#### To create an Aurora MySQL DB cluster that is a cross-Region read replica with the Amazon Web Services Management Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the top-right corner of the Amazon Web Services Management Console, select the Amazon Web Services Region that hosts your source DB cluster.

3. In the navigation pane, choose **Databases**.
4. Choose the DB cluster for which you want to create a cross-Region read replica.
5. For **Actions**, choose **Create cross-Region read replica**.
6. On the **Create cross region read replica** page, choose the option settings for your cross-Region read replica DB cluster, as described in the following table.

Option	Description
<b>Destination region</b>	Choose the Amazon Web Services Region to host the new cross-Region read replica DB cluster.
<b>Destination DB subnet group</b>	Choose the DB subnet group to use for the cross-Region read replica DB cluster.
<b>Publicly accessible</b>	Choose <b>Yes</b> to give the cross-Region read replica DB cluster a public IP address; otherwise, select <b>No</b> .
<b>Encryption</b>	Select <b>Enable Encryption</b> to turn on encryption at rest for this DB cluster. For more information, see <a href="#">Encrypting Amazon Aurora resources</a> .
<b>Amazon KMS key</b>	Only available if <b>Encryption</b> is set to <b>Enable Encryption</b> . Select the Amazon KMS key to use for encrypting this DB cluster. For more information, see <a href="#">Encrypting Amazon Aurora resources</a> .
<b>DB instance class</b>	Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see <a href="#">Amazon Aurora DB instance classes</a> .
<b>Multi-AZ deployment</b>	Choose <b>Yes</b> to create a read replica of the new DB cluster in another Availability Zone in the target Amazon Web Services Region for failover support. For more information about multiple Availability Zones, see <a href="#">Regions and Availability Zones</a> .

Option	Description
<b>Read replica source</b>	Choose the source DB cluster to create a cross-Region read replica for.
<b>DB instance identifier</b>	<p>Type a name for the primary instance in your cross-Region read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</p> <p>The DB instance identifier has the following constraints:</p> <ul style="list-style-type: none"><li>• It must contain from 1 to 63 alphanumeric characters or hyphens.</li><li>• Its first character must be a letter.</li><li>• It cannot end with a hyphen or contain two consecutive hyphens.</li><li>• It must be unique for all DB instances for each Amazon Web Services account, for each Amazon Web Services Region.</li></ul> <p>Because the cross-Region read replica DB cluster is created from a snapshot of the source DB cluster, the master user name and master password for the read replica are the same as the master user name and master password for the source DB cluster.</p>

Option	Description
<b>DB cluster identifier</b>	<p>Type a name for your cross-Region read replica DB cluster that is unique for your account in the target Amazon Web Services Region for your replica. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see <a href="#">Amazon Aurora endpoint connections</a>.</p> <p>The DB cluster identifier has the following constraints:</p> <ul style="list-style-type: none"><li>• It must contain from 1 to 63 alphanumeric characters or hyphens.</li><li>• Its first character must be a letter.</li><li>• It cannot end with a hyphen or contain two consecutive hyphens.</li><li>• It must be unique for all DB clusters for each Amazon Web Services account, for each Amazon Web Services Region.</li></ul>
<b>Priority</b>	<p>Choose a failover priority for the primary instance of the new DB cluster. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. If you don't select a value, the default is <b>tier-1</b>. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a>.</p>
<b>Database port</b>	<p>Specify the port for applications and utilities to use to access the database. Aurora DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.</p>

Option	Description
<b>Enhanced monitoring</b>	Choose <b>Enable enhanced monitoring</b> to turn on gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .
<b>Monitoring Role</b>	Only available if <b>Enhanced Monitoring</b> is set to <b>Enable enhanced monitoring</b> . Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose <b>Default</b> to have RDS create a role for you named <code>rds-monitoring-role</code> . For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .
<b>Granularity</b>	Only available if <b>Enhanced Monitoring</b> is set to <b>Enable enhanced monitoring</b> . Set the interval, in seconds, between when metrics are collected for your DB cluster.
<b>Auto minor version upgrade</b>	This setting doesn't apply to Aurora MySQL DB clusters.  For more information about engine updates for Aurora MySQL, see <a href="#">Database engine updates for Amazon Aurora MySQL</a> .

7. Choose **Create** to create your cross-Region read replica for Aurora.

## Amazon CLI

### To create an Aurora MySQL DB cluster that is a cross-Region read replica with the CLI

1. Call the Amazon CLI [create-db-cluster](#) command in the Amazon Web Services Region where you want to create the read replica DB cluster. Include the `--replication-source-`

`identifier` option and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

For cross-Region replication where the DB cluster identified by `--replication-source-identifier` is encrypted, specify the `--kms-key-id` option and the `--storage-encrypted` option.

**Note**

You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `--storage-encrypted` and providing a value for `--kms-key-id`.

You can't specify the `--master-username` and `--master-user-password` parameters. Those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region. This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier sample-replica-cluster \  
  --engine aurora-mysql \  
  --engine-version 8.0.mysql_aurora.3.08.0 \  
  --replication-source-identifier arn:aws-cn:rds:us-  
west-2:123456789012:cluster:sample-master-cluster
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier sample-replica-cluster ^  
  --engine aurora-mysql ^  
  --engine-version 8.0.mysql_aurora.3.08.0 ^
```

```
--replication-source-identifier arn:aws-cn:rds:us-west-2:123456789012:cluster:sample-master-cluster
```

The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier sample-replica-cluster \  
  --engine aurora-mysql \  
  --engine-version 8.0.mysql_aurora.3.08.0 \  
  --replication-source-identifier arn:aws-cn:rds:us-west-2:123456789012:cluster:sample-master-cluster \  
  --kms-key-id my-us-east-1-key \  
  --storage-encrypted
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier sample-replica-cluster ^  
  --engine aurora-mysql ^  
  --engine-version 8.0.mysql_aurora.3.08.0 ^  
  --replication-source-identifier arn:aws-cn:rds:us-west-2:123456789012:cluster:sample-master-cluster ^  
  --kms-key-id my-us-east-1-key ^  
  --storage-encrypted
```

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A *presigned URL* is a URL that contains a Signature Version 4 signed request for the `create-db-cluster` command that is called in the source Amazon Web Services Region. To learn more about the `pre-signed-url` option, see [create-db-cluster](#) in the *Amazon CLI Command Reference*.

2. Check that the DB cluster has become available to use by using the Amazon CLI [describe-db-clusters](#) command, as shown in the following example.

```
aws rds describe-db-clusters --db-cluster-identifier sample-replica-cluster
```

When the **describe-db-clusters** results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the Amazon CLI [create-db-instance](#) command as shown in the following example.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-cluster-identifier sample-replica-cluster \  
  --db-instance-class db.r5.large \  
  --db-instance-identifier sample-replica-instance \  
  --engine aurora-mysql
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier sample-replica-cluster ^  
  --db-instance-class db.r5.large ^  
  --db-instance-identifier sample-replica-instance ^  
  --engine aurora-mysql
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the Amazon CLI [describe-db-instances](#) command.

## RDS API

### To create an Aurora MySQL DB cluster that is a cross-Region read replica with the API

1. Call the RDS API [CreateDBCluster](#) operation in the Amazon Web Services Region where you want to create the read replica DB cluster. Include the `ReplicationSourceIdentifier` parameter and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

For cross-Region replication where the DB cluster identified by `ReplicationSourceIdentifier` is encrypted, specify the `KmsKeyId` parameter and set the `StorageEncrypted` parameter to `true`.

**Note**

You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `StorageEncrypted` as **true** and providing a value for `KmsKeyId`. In this case, you don't need to specify `PreSignedUrl`.

You don't need to include the `MasterUsername` and `MasterUserPassword` parameters, because those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&ReplicationSourceIdentifier=arn:aws-cn:rds:us-
west-2:123456789012:cluster:sample-master-cluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora-mysql
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T001547Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=a04c831a0b54b5e4cd236a90dcb9f5fab7185eb3b72b5ebe9a70a4e95790c8b7
```

The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&KmsKeyId=my-us-east-1-key
&StorageEncrypted=true
&PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F
%253FAction%253DCreateDBCluster
%2526DestinationRegion%253Dus-east-1
%2526KmsKeyId%253Dmy-us-east-1-key
```

```

%2526ReplicationSourceIdentifier%253Darn%25253Aaws%25253Ards%25253Aus-
west-2%25253A123456789012%25253Acluster%25253Asample-master-cluster

&ReplicationSourceIdentifier=arn:aws-cn:rds:us-
west-2:123456789012:cluster:sample-master-cluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora-mysql
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T001547Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=a04c831a0b54b5e4cd236a90dcb9f5fab7185eb3b72b5ebe9a70a4e95790c8b7

```

2. Check that the DB cluster has become available to use by using the RDS API [DescribeDBClusters](#) operation, as shown in the following example.

```

https://rds.us-east-1.amazonaws.com/
?Action=DescribeDBClusters
&DBClusterIdentifier=sample-replica-cluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T002223Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=84c2e4f8fba7c577ac5d820711e34c6e45ffcd35be8a6b7c50f329a74f35f426

```

When DescribeDBClusters results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the RDS API [CreateDBInstance](#) action as shown in the following example.

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=sample-replica-cluster
&DBInstanceClass=db.r5.large
&DBInstanceIdentifier=sample-replica-instance
&Engine=aurora-mysql
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T003808Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=125fe575959f5bbcebd53f2365f907179757a08b5d7a16a378dfa59387f58cdb
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the Amazon CLI [DescribeDBInstances](#) command.

## Viewing Amazon Aurora MySQL cross-Region replicas

You can view the cross-Region replication relationships for your Amazon Aurora MySQL DB clusters by calling the [describe-db-clusters](#) Amazon CLI command or the [DescribeDBClusters](#) RDS API operation. In the response, refer to the ReadReplicaIdentifiers field for the DB cluster identifiers of any cross-Region read replica DB clusters. Refer to the ReplicationSourceIdentifier element for the ARN of the source DB cluster that is the replication source.

## Promoting a read replica to a DB cluster for Aurora MySQL

You can promote an Aurora MySQL read replica to a standalone DB cluster. When you promote an Aurora MySQL read replica, its DB instances are rebooted before they become available.

Typically, you promote an Aurora MySQL read replica to a standalone DB cluster as a data recovery scheme if the source DB cluster fails.

To do this, first create a read replica and then monitor the source DB cluster for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB cluster.
3. Create a replacement read replica with the promoted DB cluster as its source.

When you promote a read replica, the read replica becomes a standalone Aurora DB cluster. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB cluster, it's just like any other DB cluster. For example, you can create read replicas from it and perform point-in-time restore operations. You can also create Aurora Replicas for the DB cluster.

Because the promoted DB cluster is no longer a read replica, you can't use it as a replication target.

The following steps show the general process for promoting a read replica to a DB cluster:

1. Stop any transactions from being written to the read replica source DB cluster, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the source DB cluster, and this replication lag can vary significantly. Use the `ReplicaLag` metric to determine when all updates have been made to the read replica. The `ReplicaLag` metric records the amount of time a read replica DB instance lags behind the source DB instance. When the `ReplicaLag` metric reaches 0, the read replica has caught up to the source DB instance.
2. Promote the read replica by using the **Promote** option on the Amazon RDS console, the Amazon CLI command [promote-read-replica-db-cluster](#), or the [PromoteReadReplicaDBCluster](#) Amazon RDS API operation.

You choose an Aurora MySQL DB instance to promote the read replica. After the read replica is promoted, the Aurora MySQL DB cluster is promoted to a standalone DB cluster. The DB instance with the highest failover priority is promoted to the primary DB instance for the DB cluster. The other DB instances become Aurora Replicas.

**Note**

The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the DB instances are rebooted. When the reboot is complete, the read replica is available as a new DB cluster.

**Console****To promote an Aurora MySQL read replica to a DB cluster**

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. On the console, choose **Instances**.

The **Instance** pane appears.

3. In the **Instances** pane, choose the read replica that you want to promote.

The read replicas appear as Aurora MySQL DB instances.

4. For **Actions**, choose **Promote read replica**.
5. On the acknowledgment page, choose **Promote read replica**.

**Amazon CLI**

To promote a read replica to a DB cluster, use the Amazon CLI [promote-read-replica-db-cluster](#) command.

**Example**

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \  
  --db-cluster-identifier mydbcluster
```

For Windows:

```
aws rds promote-read-replica-db-cluster ^
```

```
--db-cluster-identifier mydbcluster
```

## RDS API

To promote a read replica to a DB cluster, call [PromoteReadReplicaDBCluster](#).

## Troubleshooting cross-Region replicas for Amazon Aurora MySQL

Following you can find a list of common error messages that you might encounter when creating an Amazon Aurora cross-Region read replica, and how to resolve the specified errors.

### Source cluster [DB cluster ARN] doesn't have binlogs enabled

To resolve this issue, turn on binary logging on the source DB cluster. For more information, see [Before you begin](#).

### Source cluster [DB cluster ARN] doesn't have cluster parameter group in sync on writer

You receive this error if you have updated the `binlog_format` DB cluster parameter, but have not rebooted the primary instance for the DB cluster. Reboot the primary instance (that is, the writer) for the DB cluster and try again.

### Source cluster [DB cluster ARN] already has a read replica in this region

You can have up to five cross-Region DB clusters that are read replicas for each source DB cluster in any Amazon Web Services Region. If you already have the maximum number of read replicas for a DB cluster in a particular Amazon Web Services Region, you must delete an existing one before you can create a new cross-Region DB cluster in that Region.

### DB cluster [DB cluster ARN] requires a database engine upgrade for cross-Region replication support

To resolve this issue, upgrade the database engine version for all of the instances in the source DB cluster to the most recent database engine version, and then try creating a cross-Region read replica DB again.

## Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

Because Amazon Aurora MySQL is compatible with MySQL, you can set up replication between a MySQL database and an Amazon Aurora MySQL DB cluster. This type of replication uses the MySQL

binary log replication, also referred to as *binlog replication*. If you use binary log replication with Aurora, we recommend that your MySQL database run MySQL version 5.5 or later. You can set up replication where your Aurora MySQL DB cluster is the replication source or the replica. You can replicate with an Amazon RDS MySQL DB instance, a MySQL database external to Amazon RDS, or another Aurora MySQL DB cluster.

 **Note**

You can't use binlog replication to or from certain types of Aurora DB clusters. In particular, binlog replication isn't available for Aurora Serverless v1 clusters. If the `SHOW MASTER STATUS` and `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) statement returns no output, check that the cluster you're using supports binlog replication.

You can also replicate with an RDS for MySQL DB instance or Aurora MySQL DB cluster in another Amazon Web Services Region. When you're performing replication across Amazon Web Services Regions, make sure that your DB clusters and DB instances are publicly accessible. If the Aurora MySQL DB clusters are in private subnets in your VPC, use VPC peering between the Amazon Web Services Regions. For more information, see [A DB cluster in a VPC accessed by an EC2 instance in a different VPC](#).

If you want to configure replication between an Aurora MySQL DB cluster and an Aurora MySQL DB cluster in another Amazon Web Services Region, you can create an Aurora MySQL DB cluster as a read replica in a different Amazon Web Services Region from the source DB cluster. For more information, see [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#).

With Aurora MySQL version 2 and 3, you can replicate between Aurora MySQL and an external source or target that uses global transaction identifiers (GTIDs) for replication. Ensure that the GTID-related parameters in the Aurora MySQL DB cluster have settings that are compatible with the GTID status of the external database. To learn how to do this, see [Using GTID-based replication](#). In Aurora MySQL version 3.01 and higher, you can choose how to assign GTIDs to transactions that are replicated from a source that doesn't use GTIDs. For information about the stored procedure that controls that setting, see [mysql.rds\\_assign\\_gtids\\_to\\_anonymous\\_transactions \(Aurora MySQL version 3\)](#).

**⚠ Warning**

When you replicate between Aurora MySQL and MySQL, make sure that you use only InnoDB tables. If you have MyISAM tables that you want to replicate, you can convert them to InnoDB before setting up replication with the following command.

```
alter table <schema>.<table_name> engine=innodb, algorithm=copy;
```

In the following sections, set up replication, stop replication, scale reads for your database, optimize binlog replication, and set up enhanced binlog.

**Topics**

- [Setting up binary log replication for Aurora MySQL](#)
- [Stopping binary log replication for Aurora MySQL](#)
- [Scaling reads for your MySQL database with Amazon Aurora](#)
- [Optimizing binary log replication for Aurora MySQL](#)

**Setting up binary log replication for Aurora MySQL**

Setting up MySQL replication with Aurora MySQL involves the following steps, which are discussed in detail:

**Contents**

- [1. Turn on binary logging on the replication source](#)
- [2. Retain binary logs on the replication source until no longer needed](#)
- [3. Create a copy or dump of your replication source](#)
- [4. Load the dump into your replica target \(if needed\)](#)
- [5. Create a replication user on your replication source](#)
- [6. Turn on replication on your replica target](#)
  - [Setting a location to stop replication to a read replica](#)
- [7. Monitor your replica](#)
- [Synchronizing passwords between replication source and target](#)

## 1. Turn on binary logging on the replication source

Find instructions on how to turn on binary logging on the replication source for your database engine following.

Database engine	Instructions
Aurora MySQL	<p><b>To turn on binary logging on an Aurora MySQL DB cluster</b></p> <p>Set the <code>binlog_format</code> DB cluster parameter to <code>ROW</code>, <code>STATEMENT</code>, or <code>MIXED</code>. <code>MIXED</code> is recommended unless you have a need for a specific binlog format. (The default value is <code>OFF</code>.)</p> <p>To change the <code>binlog_format</code> parameter, create a custom DB cluster parameter group and associate that custom parameter group with your DB cluster. You can't change parameters in the default DB cluster parameter group.</p> <p>If you're changing the <code>binlog_format</code> parameter from <code>OFF</code> to another value, reboot your Aurora DB cluster for the change to take effect.</p> <p>For more information, see <a href="#">Amazon Aurora DB cluster and DB instance parameters</a> and <a href="#">Parameter groups for Amazon Aurora</a>.</p>
RDS for MySQL	<p><b>To turn on binary logging on an Amazon RDS DB instance</b></p> <p>You can't turn on binary logging directly for an Amazon RDS DB instance, but you can turn it on by doing one of the following:</p> <ul style="list-style-type: none"> <li>• Turn on automated backups for the DB instance. You can turn on automated backups when you create a DB instance, or you can turn on backups by modifying an existing DB instance. For more information, see <a href="#">Creating a DB instance</a> in the <i>Amazon RDS User Guide</i>.</li> <li>• Create a read replica for the DB instance. For more information, see <a href="#">Working with read replicas</a> in the <i>Amazon RDS User Guide</i>.</li> </ul>
MySQL (external)	<p><b>To set up encrypted replication</b></p> <p>To replicate data securely with Aurora MySQL version 2, you can use encrypted replication.</p>

**Database engine****Instructions****Note**

If you don't need to use encrypted replication, you can skip these steps.

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL source database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

1. Ensure that you are prepared for encrypted replication:
  - If you don't have SSL enabled on the external MySQL source database and don't have a client key and client certificate prepared, turn on SSL on the MySQL database server and generate the required client key and client certificate.
  - If SSL is enabled on the external source, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL source database.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the master user using SSL.

**Database engine****Instructions**

For information about connecting to an Aurora MySQL DB cluster with SSL, see [TLS connections to Aurora MySQL DB clusters](#).

3. Run the `mysql.rds_import_binlog_ssl_material` stored procedure to import the SSL information into the Aurora MySQL DB cluster.

For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

```
call mysql.rds_import_binlog_ssl_material(

The <code>log_bin</code> option provides a file name identifier for binary log files. The <code>server_id</code> option provides a unique identifier for the server in source-replica relationships.</p>

**Database engine****Instructions**

If encrypted replication isn't required, ensure that the external MySQL database is started with binlogs enabled and SSL is turned off.

The following are the relevant entries in the `/etc/my.cnf` file for unencrypted data.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1
```

If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled.

The entries in the `/etc/my.cnf` file include the `.pem` file locations for the MySQL database server.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1

# Setup SSL.
ssl-ca=/home/sslcerts/ca.pem
ssl-cert=/home/sslcerts/server-cert.pem
ssl-key=/home/sslcerts/server-key.pem
```

Additionally, the `sql_mode` option for your MySQL DB instance must be set to 0, or must not be included in your `my.cnf` file.

While connected to the external MySQL database, record the external MySQL database's binary log position.

```
mysql> SHOW MASTER STATUS;
```

Your output should be similar to the following:

Database engine	Instructions
	<pre data-bbox="349 283 1388 703"> +-----+-----+-----+-----+ +-----+   File             Position   Binlog_Do_DB   Binlog_Ignore_DB     Executed_Gtid_Set  +-----+-----+-----+-----+ +-----+   mysql-bin.000031        107   +-----+-----+-----+-----+ +-----+ 1 row in set (0.00 sec) </pre> <p data-bbox="332 766 1437 850">For more information, see <a href="#">Setting the replication source configuration</a> in the MySQL documentation.</p> <p data-bbox="292 871 673 913">3. Start the mysql service.</p> <pre data-bbox="349 955 755 1008"> sudo service mysqld start </pre>

## 2. Retain binary logs on the replication source until no longer needed

When you use MySQL binary log replication, Amazon RDS doesn't manage the replication process. As a result, you need to ensure that the binlog files on your replication source are retained until after the changes have been applied to the replica. This maintenance helps you to restore your source database in the event of a failure.

Use the following instructions to retain binary logs for your database engine.

Database engine	Instructions
Aurora MySQL	<p data-bbox="292 1669 1079 1711"><b>To retain binary logs on an Aurora MySQL DB cluster</b></p> <p data-bbox="292 1743 1502 1879">You don't have access to the binlog files for an Aurora MySQL DB cluster. As a result, you must choose a time frame to retain the binlog files on your replication source long enough to ensure that the changes have been applied to your replica before</p>

**Database engine****Instructions**

the binlog file is deleted by Amazon RDS. You can retain binlog files on an Aurora MySQL DB cluster for up to 90 days.

If you're setting up replication with a MySQL database or RDS for MySQL DB instance as the replica, and the database that you are creating a replica for is very large, choose a large time frame to retain binlog files until the initial copy of the database to the replica is complete and the replica lag has reached 0.

To set the binary log retention time frame, use the [mysql.rds\\_set\\_configuration](#) procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The maximum value for Aurora MySQL version 2.11.0 and higher and version 3 is 2160 (90 days).

The following example sets the retention period for binlog files to 6 days:

```
CALL mysql.rds_set_configuration('binlog retention hours', 144);
```

After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the `Seconds behind master` field. If the `Seconds behind master` field is 0, then there is no replica lag. When there is no replica lag, reduce the length of time that binlog files are retained by setting the `binlog retention hours` configuration parameter to a smaller time frame.

If this setting isn't specified, the default for Aurora MySQL is 24 (1 day).

If you specify a value for 'binlog retention hours' that is higher than the maximum value, then Aurora MySQL uses the maximum.

Database engine	Instructions
RDS for MySQL	<p><b>To retain binary logs on an Amazon RDS DB instance</b></p> <p>You can retain binary log files on an Amazon RDS DB instance by setting the binlog retention hours just as with an Aurora MySQL DB cluster, described in the previous row.</p> <p>You can also retain binlog files on an Amazon RDS DB instance by creating a read replica for the DB instance. This read replica is temporary and solely for the purpose of retaining binlog files. After the read replica has been created, call the <a href="#">mysql.rds_stop_replication</a> procedure on the read replica. While replication is stopped, Amazon RDS doesn't delete any of the binlog files on the replication source. After you have set up replication with your permanent replica, you can delete the read replica when the replica lag (Seconds behind master field) between your replication source and your permanent replica reaches 0.</p>
MySQL (external)	<p><b>To retain binary logs on an external MySQL database</b></p> <p>Because binlog files on an external MySQL database are not managed by Amazon RDS, they are retained until you delete them.</p> <p>After replication has been started, you can verify that changes have been applied to your replica by running the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 2) or <code>SHOW REPLICA STATUS</code> (Aurora MySQL version 3) command on your replica and checking the Seconds behind master field. If the Seconds behind master field is 0, then there is no replica lag. When there is no replica lag, you can delete old binlog files.</p>

### 3. Create a copy or dump of your replication source

You use a snapshot, clone, or dump of your replication source to load a baseline copy of your data onto your replica. Then you start replicating from that point.

Use the following instructions to create a copy or dump of the replication source for your database engine.

Database engine	Instructions
Aurora MySQL	<p><b>To create a copy of an Aurora MySQL DB cluster</b></p> <p>Use one of the following methods:</p> <ul style="list-style-type: none"><li>• Restore from a DB cluster snapshot:<ol style="list-style-type: none"><li>1. Create a DB cluster snapshot of your Amazon Aurora DB cluster. For more information, see <a href="#">Creating a DB cluster snapshot</a>.</li><li>2. Create a new Aurora DB cluster by restoring from the DB cluster snapshot that you just created.</li></ol><p>Be sure to retain the same DB parameter group for your restored DB cluster as your original DB cluster. Doing this ensures that the copy of your DB cluster has binary logging enabled. For more information, see <a href="#">Restoring from a DB cluster snapshot</a>.</p></li><li>• Clone your DB cluster. For more information, see <a href="#">Cloning a volume for an Amazon Aurora DB cluster</a>.</li></ul> <p><b>To determine the binlog file name and position</b></p> <p>Use one of the following methods:</p> <ul style="list-style-type: none"><li>• In the Amazon Web Services Management Console:<ol style="list-style-type: none"><li>1. Choose <b>Databases</b>, then choose the primary instance (writer) for your new Aurora DB cluster to show its details.</li><li>2. Scroll to <b>Recent Events</b>. An event message shows that includes the binlog file name and position. The event message is in the following format.</li></ol><div data-bbox="363 1549 1507 1667" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>Binlog position from crash recovery is <i>binlog-file-name binlog-position</i></pre></div><ol style="list-style-type: none"><li>3. Save the binlog file name and position values for when you start replication.</li></ol></li><li>• Call the <a href="#">describe-events</a> Amazon CLI command, as in the following example.</li></ul> <div data-bbox="326 1812 1507 1866" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"><pre>aws rds describe-events</pre></div>

Database engine	Instructions
	<pre data-bbox="342 296 1446 842"> {   "Events": [     {       "EventCategories": [],       "SourceType": "db-instance",       "SourceArn": "arn:aws:rds:us-west-2:123456789012: db:sample-restored-instance",       "Date": "2016-10-28T19:43:46.862Z",       "Message": "Binlog position from crash recovery is mysql- bin-changelog.000003 4278",       "SourceIdentifier": "sample-restored-instance"     }   ] } </pre> <ul data-bbox="293 884 1276 919" style="list-style-type: none"> <li>• Check the MySQL error log for the last MySQL binlog file position.</li> </ul> <p data-bbox="293 995 1024 1031"><b>To create a dump of an Aurora MySQL DB cluster</b></p> <p data-bbox="293 1073 1403 1157">If your replica target is an external MySQL database or an RDS for MySQL DB instance, then you must create a dump file from your Aurora DB cluster.</p> <p data-bbox="293 1199 1479 1430">Be sure to run the <code>mysqldump</code> command against the copy of your source DB cluster that you created. This is to avoid locking considerations when taking the dump. If the dump were taken on the source DB cluster directly, it would be necessary to lock the source tables to prevent concurrent writes to them while the dump is in progress.</p> <ol data-bbox="293 1472 1036 1566" style="list-style-type: none"> <li>1. Connect to your DB cluster using a MySQL client.</li> <li>2. Issue the <code>mysqldump</code> command. For example: <div data-bbox="350 1625 1406 1696" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin: 10px 0;"> <pre>PROMPT&gt; mysqldump --databases <i>database_name</i> --single-transaction --order-by-primary -r backup.sql -u <i>local_user</i> s -p</pre> </div> </li> <li>3. After you create the dump file, you can delete the DB cluster copy.</li> </ol>

Database engine	Instructions
RDS for MySQL	<p><b>To create a snapshot of an Amazon RDS DB instance</b></p> <p>Create a read replica of your Amazon RDS DB instance. For more information, see <a href="#">Creating a read replica</a> in the <i>Amazon Relational Database Service User Guide</i>.</p> <ol style="list-style-type: none"><li>1. Connect to your read replica and stop replication by running the <a href="#">mysql.rds_stop_replication</a> procedure.</li><li>2. While the read replica is <b>Stopped</b>, Connect to the read replica and run the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 2) or <code>SHOW REPLICA STATUS</code> (Aurora MySQL version 3) command. Retrieve the current binary log file name from the <code>Relay_Master_Log_File</code> field and the log file position from the <code>Exec_Master_Log_Pos</code> field. Save these values for when you start replication.</li><li>3. While the read replica remains <b>Stopped</b>, create a DB snapshot of the read replica. For more information, see <a href="#">Creating a DB snapshot</a> in the <i>Amazon Relational Database Service User Guide</i>.</li><li>4. Delete the read replica.</li></ol>

Database engine	Instructions
MySQL (external)	<p><b>To create a dump of an external MySQL database</b></p> <ol style="list-style-type: none"><li>1. Before you create a dump, you need to ensure that the binlog location for the dump is current with the data in your source instance. To do this, you must first stop any write operations to the instance with the following command: <pre>mysql&gt; FLUSH TABLES WITH READ LOCK;</pre></li><li>2. Create a dump of your MySQL database using the <code>mysqldump</code> command as shown following: <pre>PROMPT&gt; sudo mysqldump --databases <i>database_name</i> --master-data=2 --single-transaction \ --order-by-primary -r backup.sql -u <i>local_user</i> -p</pre></li><li>3. After you have created the dump, unlock the tables in your MySQL database with the following command: <pre>mysql&gt; UNLOCK TABLES;</pre></li></ol>

#### 4. Load the dump into your replica target (if needed)

If you plan to load data from a dump of a MySQL database that is external to Amazon RDS, you might want to create an EC2 instance to copy the dump files to. Then you can load the data into your DB cluster or DB instance from that EC2 instance. Using this approach, you can compress the dump file(s) before copying them to the EC2 instance in order to reduce the network costs associated with copying data to Amazon RDS. You can also encrypt the dump file or files to secure the data as it is being transferred across the network.

##### Note

If you create a new Aurora MySQL DB cluster as your replica target, then you don't need to load a dump file:

- You can restore from a DB cluster snapshot to create a new DB cluster. For more information, see [Restoring from a DB cluster snapshot](#).
- You can clone your source DB cluster to create a new DB cluster. For more information, see [Cloning a volume for an Amazon Aurora DB cluster](#).
- You can migrate the data from a DB instance snapshot into a new DB cluster. For more information, see [Migrating data to an Amazon Aurora MySQL DB cluster](#).

Use the following instructions to load the dump of your replication source into your replica target for your database engine.

Database engine	Instructions
Aurora MySQL	<p><b>To load a dump into an Aurora MySQL DB cluster</b></p> <ol style="list-style-type: none"> <li>1. Copy the output of the <code>mysqldump</code> command from your replication source to a location that can also connect to your Aurora MySQL DB cluster.</li> <li>2. Connect to your Aurora MySQL DB cluster using the <code>mysql</code> command. The following is an example. <pre data-bbox="334 1157 1503 1234">PROMPT&gt; mysql -h <i>host_name</i> -port=3306 -u <i>db_master_user</i> -p</pre> </li> <li>3. At the <code>mysql</code> prompt, run the <code>source</code> command and pass it the name of your database dump file to load the data into the Aurora MySQL DB cluster, for example: <pre data-bbox="334 1419 1503 1497">mysql&gt; source backup.sql;</pre> </li> </ol>
RDS for MySQL	<p><b>To load a dump into an Amazon RDS DB instance</b></p> <ol style="list-style-type: none"> <li>1. Copy the output of the <code>mysqldump</code> command from your replication source to a location that can also connect to your MySQL DB instance.</li> <li>2. Connect to your MySQL DB instance using the <code>mysql</code> command. The following is an example.</li> </ol>

Database engine	Instructions
	<pre>PROMPT&gt; mysql -h <i>host_name</i> -port=3306 -u <i>db_master_user</i> -p</pre> <p>3. At the <code>mysql</code> prompt, run the <code>source</code> command and pass it the name of your database dump file to load the data into the MySQL DB instance, for example:</p> <pre>mysql&gt; source backup.sql;</pre>

MySQL  
(external)

### To load a dump into an external MySQL database

You can't load a DB snapshot or a DB cluster snapshot into an external MySQL database. Instead, you must use the output from the `mysqldump` command.

1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your MySQL database.
2. Connect to your MySQL database using the `mysql` command. The following is an example.

```
PROMPT> mysql -h host_name -port=3306 -u db_master_user -p
```

3. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into your MySQL database. The following is an example.

```
mysql> source backup.sql;
```

## 5. Create a replication user on your replication source

Create a user ID on the source that is used solely for replication. The following example is for RDS for MySQL or external MySQL source databases.

```
mysql> CREATE USER 'repl_user'@'domain_name' IDENTIFIED BY 'password';
```

For Aurora MySQL source databases, the `skip_name_resolve` DB cluster parameter is set to 1 (ON) and can't be modified, so you must use an IP address for the host instead of a domain name. For more information, see [skip\\_name\\_resolve](#) in the MySQL documentation.

```
mysql> CREATE USER 'repl_user'@'IP_address' IDENTIFIED BY 'password';
```

The user requires the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges. Grant these privileges to the user.

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use one of the following statements to require SSL connections on the user account `repl_user`.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'IP_address';
```

```
GRANT USAGE ON *.* TO 'repl_user'@'IP_address' REQUIRE SSL;
```

### Note

If `REQUIRE SSL` isn't included, the replication connection might silently fall back to an unencrypted connection.

## 6. Turn on replication on your replica target

Before you turn on replication, we recommend that you take a manual snapshot of the Aurora MySQL DB cluster or RDS for MySQL DB instance replica target. If a problem arises and you need to re-establish replication with the DB cluster or DB instance replica target, you can restore the DB cluster or DB instance from this snapshot instead of having to import the data into your replica target again.

Use the following instructions to turn on replication for your database engine.

Database engine	Instructions
Aurora MySQL	<b>To turn on replication from an Aurora MySQL DB cluster</b>

**Database engine****Instructions**

1. Find the starting place for replication. You need the binlog file name and binlog position.

If your DB cluster replica target was created from the following:

- DB cluster snapshot or clone – Retrieve the binlog file name and position from the recent events for your new DB cluster, as shown in [3. Create a copy or dump of your replication source](#).
- DB snapshot – You retrieved the binlog file name and position from the SHOW SLAVE STATUS (Aurora MySQL version 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) command when you created the snapshot of your replication source.

2. Connect to the DB cluster and call the following procedures to start replication with your replication source using the binary log file name and location from the previous step:

- [mysql.rds\\_set\\_external\\_source \(Aurora MySQL version 3\)](#)
- [mysql.rds\\_set\\_external\\_master \(Aurora MySQL version 2\)](#)
- [mysql.rds\\_start\\_replication](#) (all versions)

The following example is for Aurora MySQL version 3.

```
CALL mysql.rds_set_external_source ('mydbinstance.123456789012
.us-east-1.rds.amazonaws.com', 3306,
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107,
    0);
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.

Database engine	Instructions
RDS for MySQL	<p><b>To turn on replication from an Amazon RDS DB instance</b></p> <ol style="list-style-type: none"><li>1. If your DB instance replica target was created from a DB snapshot, then you need the binlog file and binlog position that are the starting place for replication. You retrieved these values from the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 2) or <code>SHOW REPLICA STATUS</code> (Aurora MySQL version 3) command when you created the snapshot of your replication source.</li><li>2. Connect to the DB instance and call the <a href="#">mysql.rds_set_external_master (Aurora MySQL version 2)</a> or <a href="#">mysql.rds_set_external_source (Aurora MySQL version 3)</a> and <a href="#">mysql.rds_start_replication</a> procedures to start replication with your replication source. Use the binary log file name and location from the previous step. The following is an example.</li></ol> <pre data-bbox="332 867 1507 1104">CALL mysql.rds_set_external_master ('mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0); CALL mysql.rds_start_replication;</pre> <p>To use SSL encryption, set the final value to 1 instead of 0.</p>

Database engine	Instructions
MySQL (external)	<p data-bbox="277 254 1511 310"><b>To turn on replication from an external MySQL database</b></p> <ol data-bbox="277 317 1511 674" style="list-style-type: none"><li data-bbox="277 317 1511 674">1. Retrieve the binlog file and binlog position that are the starting place for replication. You retrieved these values from the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 2) or <code>SHOW REPLICA STATUS</code> (Aurora MySQL version 3) command when you created the snapshot of your replication source. If your external MySQL replica target was populated from the output of the <code>mysqldump</code> command with the <code>--master-data=2</code> option, then the binlog file and binlog position are included in the output. The following is an example.<pre data-bbox="332 716 1505 989">-- -- Position to start replication or point-in-time recovery from -- -- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;</pre></li><li data-bbox="277 995 1511 1178">2. Connect to the external MySQL replica target, and issue <code>CHANGE MASTER TO</code> and <code>START SLAVE</code> (Aurora MySQL version 2) or <code>START REPLICA</code> (Aurora MySQL version 3) to start replication with your replication source using the binary log file name and location from the previous step, for example:<pre data-bbox="332 1220 1505 1682">CHANGE MASTER TO   MASTER_HOST = 'mydbcluster.cluster-123456789012.us-east-1.r ds.amazonaws.com',   MASTER_PORT = 3306,   MASTER_USER = 'repl_user',   MASTER_PASSWORD = 'password',   MASTER_LOG_FILE = 'mysql-bin-changelog.000031',   MASTER_LOG_POS = 107; -- And one of these statements depending on your engine version: START SLAVE; -- Aurora MySQL version 2 START REPLICA; -- Aurora MySQL version 3</pre></li></ol>

If replication fails, it can result in a large increase in unintentional I/O on the replica, which can degrade performance. If replication fails or is no longer needed, you can run the

[mysql.rds\\_reset\\_external\\_master \(Aurora MySQL version 2\)](#) or [mysql.rds\\_reset\\_external\\_source \(Aurora MySQL version 3\)](#) stored procedure to remove the replication configuration.

## Setting a location to stop replication to a read replica

In Aurora MySQL version 3.04 and higher, you can start replication and then stop it at a specified binary log file location using the [mysql.rds\\_start\\_replication\\_until \(Aurora MySQL version 3\)](#) stored procedure.

### To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the replica Aurora MySQL DB cluster as the master user.
2. Run the [mysql.rds\\_start\\_replication\\_until \(Aurora MySQL version 3\)](#) stored procedure.

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```
call mysql.rds_start_replication_until(  
    'mysql-bin-changelog.000777',  
    120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated: Replication has been stopped since the replica reached the stop point specified by the `rds_start_replication_until` stored procedure.

If you use GTID-based replication, use the [mysql.rds\\_start\\_replication\\_until\\_gtid \(Aurora MySQL version 3\)](#) stored procedure instead of the [mysql.rds\\_start\\_replication\\_until \(Aurora MySQL version 3\)](#) stored procedure. For more information about GTID-based replication, see [Using GTID-based replication](#).

## 7. Monitor your replica

When you set up MySQL replication with an Aurora MySQL DB cluster, you must monitor failover events for the Aurora MySQL DB cluster when it is the replica target. If a failover occurs, then the DB cluster that is your replica target might be recreated on a new host with a different network address. For information on how to monitor failover events, see [Working with Amazon RDS event notification](#).

You can also monitor how far the replica target is behind the replication source by connecting to the replica target and running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command. In the command output, the `Seconds Behind Master` field tells you how far the replica target is behind the source.

### Important

If you upgrade your DB cluster and specify a custom parameter group, make sure to manually reboot the cluster after the upgrade finishes. Doing so makes the cluster use your new custom parameter settings, and restarts binlog replication.

## Synchronizing passwords between replication source and target

When you change user accounts and passwords on the replication source using SQL statements, those changes are replicated to the replication target automatically.

If you use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API to change the master password on the replication source, those changes are not automatically replicated to the replication target. If you want to synchronize the master user and master password between the source and target systems, you must make the same change on the replication target yourself.

## Stopping binary log replication for Aurora MySQL

To stop binary log replication with a MySQL DB instance, external MySQL database, or another Aurora DB cluster, follow these steps, discussed in detail following in this topic.

### [1. Stop binary log replication on the replica target](#)

### [2. Turn off binary logging on the replication source](#)

#### 1. Stop binary log replication on the replica target

Use the following instructions to stop binary log replication for your database engine.

Database engine	Instructions
Aurora MySQL	<b>To stop binary log replication on an Aurora MySQL DB cluster replica target</b>

Database engine	Instructions
	Connect to the Aurora DB cluster that is the replica target, and call the <a href="#">mysql.rds_stop_replication</a> procedure.
RDS for MySQL	<p><b>To stop binary log replication on an Amazon RDS DB instance</b></p> <p>Connect to the RDS DB instance that is the replica target and call the <a href="#">mysql.rds_stop_replication</a> procedure.</p>
MySQL (external)	<p><b>To stop binary log replication on an external MySQL database</b></p> <p>Connect to the MySQL database and run the STOP SLAVE (version 5.7) or STOP REPLICICA (version 8.0) command.</p>

## 2. Turn off binary logging on the replication source

Use the instructions in the following table to turn off binary logging on the replication source for your database engine.

Database engine	Instructions
Aurora MySQL	<p><b>To turn off binary logging on an Amazon Aurora DB cluster</b></p> <ol style="list-style-type: none"> <li>1. Connect to the Aurora DB cluster that is the replication source.</li> <li>2. Use the <a href="#">mysql.rds_set_configuration</a> procedure and specify the configuration parameter <code>binlog retention hours</code>, with the value <code>NULL</code>, as shown in the following example.</li> </ol> <pre data-bbox="331 1539 1507 1619">CALL mysql.rds_set_configuration('binlog retention hours', NULL);</pre> <div data-bbox="331 1654 1507 1812"> <p><b>Note</b></p> <p>You can't use the value <code>0</code> for <code>binlog retention hours</code>.</p> </div>

Database engine	Instructions
	<p>3. Set the <code>binlog_format</code> parameter to OFF on the replication source. The <code>binlog_format</code> parameter is in the custom DB cluster parameter group associated with your DB cluster.</p> <p>After you've changed the <code>binlog_format</code> parameter value, reboot your DB cluster for the change to take effect.</p> <p>For more information, see <a href="#">Amazon Aurora DB cluster and DB instance parameters</a> and <a href="#">Modifying parameters in a DB parameter group in Amazon Aurora</a>.</p>
RDS for MySQL	<p><b>To turn off binary logging on an Amazon RDS DB instance</b></p> <p>You can't turn off binary logging directly for an Amazon RDS DB instance, but you can turn it off by doing the following:</p> <ol style="list-style-type: none"><li>1. Turn off automated backups for the DB instance. You can turn off automated backups by modifying an existing DB instance and setting the <b>Backup Retention Period</b> to 0. For more information, see <a href="#">Modifying an Amazon RDS DB instance</a> and <a href="#">Working with backups</a> in the <i>Amazon Relational Database Service User Guide</i>.</li><li>2. Delete all read replicas for the DB instance. For more information, see <a href="#">Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances</a> in the <i>Amazon Relational Database Service User Guide</i>.</li></ol>

Database engine	Instructions
MySQL (external)	<p data-bbox="293 268 1166 310"><b>To turn off binary logging on an external MySQL database</b></p> <p data-bbox="293 352 1430 394">Connect to the MySQL database and call the <code>STOP REPLICATION</code> command.</p> <ol style="list-style-type: none"><li data-bbox="293 436 1036 478">1. From a command shell, stop the <code>mysqld</code> service, <pre data-bbox="331 506 1507 583">sudo service mysqld stop</pre></li><li data-bbox="293 604 1084 646">2. Edit the <code>my.cnf</code> file (this file is usually under <code>/etc</code>). <pre data-bbox="331 674 1507 751">sudo vi /etc/my.cnf</pre><p data-bbox="331 793 1414 835">Delete the <code>log_bin</code> and <code>server_id</code> options from the <code>[mysqld]</code> section.</p><p data-bbox="331 877 1430 961">For more information, see <a href="#">Setting the replication source configuration</a> in the MySQL documentation.</p></li><li data-bbox="293 982 678 1024">3. Start the <code>mysql</code> service. <pre data-bbox="331 1052 1507 1129">sudo service mysqld start</pre></li></ol>

## Scaling reads for your MySQL database with Amazon Aurora

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to scale reads for your MySQL DB instance, create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

For information on creating an Amazon Aurora DB cluster, see [Creating an Amazon Aurora DB cluster](#).

When you set up replication between your MySQL DB instance and your Amazon Aurora DB cluster, be sure to follow these guidelines:

- Use the Amazon Aurora DB cluster endpoint address when you reference your Amazon Aurora MySQL DB cluster. If a failover occurs, then the Aurora Replica that is promoted to the primary instance for the Aurora MySQL DB cluster continues to use the DB cluster endpoint address.
- Maintain the binlogs on your writer instance until you have verified that they have been applied to the Aurora Replica. This maintenance ensures that you can restore your writer instance in the event of a failure.

### Important

When using self-managed replication, you're responsible for monitoring and resolving any replication issues that may occur. For more information, see [Diagnosing and resolving lag between read replicas](#).

### Note

The permissions required to start replication on an Aurora MySQL DB cluster are restricted and not available to your Amazon RDS master user. Therefore, you must use the [mysql.rds\\_set\\_external\\_master \(Aurora MySQL version 2\)](#) or [mysql.rds\\_set\\_external\\_source \(Aurora MySQL version 3\)](#) and [mysql.rds\\_start\\_replication](#) procedures to set up replication between your Aurora MySQL DB cluster and your MySQL DB instance.

## Start replication between an external source instance and an Aurora MySQL DB cluster

1. Make the source MySQL DB instance read-only:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL DB instance to determine the binlog location. You receive output similar to the following example:

```
File                                Position  
-----  
mysql-bin-changelog.000031         107  
-----
```

3. Copy the database from the external MySQL DB instance to the Amazon Aurora MySQL DB cluster using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS for MySQL database with reduced downtime](#) in the *Amazon Relational Database Service User Guide*.

For Linux, macOS, or Unix:

```
mysqldump \  
  --databases <database_name> \  
  --single-transaction \  
  --compress \  
  --order-by-primary \  
  -u local_user \  
  -p local_password | mysql \  
    --host aurora_cluster_endpoint_address \  
    --port 3306 \  
    -u RDS_user_name \  
    -p RDS_password
```

For Windows:

```
mysqldump ^  
  --databases <database_name> ^  
  --single-transaction ^  
  --compress ^  
  --order-by-primary ^  
  -u local_user ^  
  -p local_password | mysql ^  
    --host aurora_cluster_endpoint_address ^  
    --port 3306 ^  
    -u RDS_user_name ^  
    -p RDS_password
```

**Note**

Make sure that there is not a space between the `-p` option and the entered password.

Use the `--host`, `--user` (`-u`), `--port` and `-p` options in the `mysql` command to specify the hostname, user name, port, and password to connect to your Aurora DB cluster. The

host name is the DNS name from the Amazon Aurora DB cluster endpoint, for example, `mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the cluster details in the Amazon RDS Management Console.

4. Make the source MySQL DB instance writeable again:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [Backing up a source or replica by making it read only](#) in the MySQL documentation.

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the source MySQL database to the VPC security group for the Amazon Aurora DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Amazon Aurora DB cluster, so that it can communicate with your source MySQL instance. To find the IP address of the Amazon Aurora DB cluster, use the host command.

```
host aurora_endpoint_address
```

The host name is the DNS name from the Amazon Aurora DB cluster endpoint.

6. Using the client of your choice, connect to the external MySQL instance and create a MySQL user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
```

7. For the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the '`repl_user`' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com'
IDENTIFIED BY 'password';
```

- Take a manual snapshot of the Aurora MySQL DB cluster to be the read replica before setting up replication. If you need to reestablish replication with the DB cluster as a read replica, you can restore the Aurora MySQL DB cluster from this snapshot instead of having to import the data from your MySQL DB instance into a new Aurora MySQL DB cluster.
- Make the Amazon Aurora DB cluster the replica. Connect to the Amazon Aurora DB cluster as the master user and identify the source MySQL database as the replication source by using the [mysql.rds\\_set\\_external\\_master \(Aurora MySQL version 2\)](#) or [mysql.rds\\_set\\_external\\_source \(Aurora MySQL version 3\)](#) and [mysql.rds\\_start\\_replication](#) procedures.

Use the binlog file name and position that you determined in Step 2. The following is an example.

```
For Aurora MySQL version 2:  
CALL mysql.rds_set_external_master ('mymasterserver.example.com', 3306,  
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);  
  
For Aurora MySQL version 3:  
CALL mysql.rds_set_external_source ('mymasterserver.example.com', 3306,  
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

- On the Amazon Aurora DB cluster, call the [mysql.rds\\_start\\_replication](#) procedure to start replication.

```
CALL mysql.rds_start_replication;
```

After you have established replication between your source MySQL DB instance and your Amazon Aurora DB cluster, you can add Aurora Replicas to your Amazon Aurora DB cluster. You can then connect to the Aurora Replicas to read scale your data. For information on creating an Aurora Replica, see [Adding Aurora Replicas to a DB cluster](#).

## Optimizing binary log replication for Aurora MySQL

Following, you can learn how to optimize binary log replication performance and troubleshoot related issues in Aurora MySQL.

**Tip**

This discussion presumes that you are familiar with the MySQL binary log replication mechanism and how it works. For background information, see [Replication Implementation](#) in the MySQL documentation.

## Multithreaded binary log replication

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by the coordinator thread. The binary log events are applied in parallel when possible. The level of parallelism depends on factors including version, parameters, schema design, and workload characteristics.

Multithreaded binary log replication is supported in Aurora MySQL version 3, and in Aurora MySQL version 2.12.1 and higher. For a multithreaded replica to efficiently process binlog events in parallel, you must configure the source for multithreaded binary log replication, and the source must use a version that includes the parallelism information on its binary log files.

When an Aurora MySQL DB instance is configured to use binary log replication, by default the replica instance uses single-threaded replication for Aurora MySQL versions lower than 3.04. To enable multithreaded replication, you update the `replica_parallel_workers` parameter to a value greater than 1 in your custom parameter group.

For Aurora MySQL version 3.04 and higher, replication is multithreaded by default, with `replica_parallel_workers` set to 4. You can modify this parameter in your custom parameter group.

To increase the resilience of your database against unexpected halts, we recommend that you enable GTID replication on the source and allow GTIDs on the replica. To allow GTID replication, set `gtid_mode` to `ON_PERMISSIVE` on both the source and replica. For more information about GTID-based replication, see [Using GTID-based replication](#).

The following configuration options help you to fine-tune multithreaded replication. For usage information, see [Replication and Binary Logging Options and Variables](#) in the *MySQL Reference Manual*. For more information about multithreaded replication, see the MySQL Blog [Improving the Parallel Applier with Writeset-based Dependency Tracking](#).

Optimal parameter values depend on several factors. For example, performance for binary log replication is influenced by your database workload characteristics and the DB instance class the replica is running on. Thus, we recommend that you thoroughly test all changes to these configuration parameters before applying new parameter settings to a production instance:

- `binlog_format` recommended value – set to ROW
- `binlog_group_commit_sync_delay`
- `binlog_group_commit_sync_no_delay_count`
- `binlog_transaction_dependency_history_size`
- `binlog_transaction_dependency_tracking` – recommended value is WRITESET
- `replica_preserve_commit_order`
- `replica_parallel_type` – recommended value is LOGICAL\_CLOCK
- `replica_parallel_workers`
- `replica_pending_jobs_size_max`
- `transaction_write_set_extraction` – recommended value is XXHASH64

Your schema and workload characteristics are factors that affect replication in parallel. The most common factors are the following.

- Absence of primary keys – RDS can't establish writeset dependency for tables without primary keys. With ROW format, a single multi-row statement can be accomplished with a single full table scan on the source, but results in one full table scan per row modified on the replica. The absence of primary keys significantly decreases replication throughput.
- Presence of foreign keys – If foreign keys are present, Amazon RDS can't use writeset dependency for parallelism of the tables with the FK relationship.
- Size of transactions – If a single transaction spans dozens or hundreds of megabytes or gigabytes, the coordinator thread and one of the worker threads might spend a long time processing only that transaction. During that time, all other worker threads might remain idle after they conclude processing their previous transactions.

In Aurora MySQL version 3.06 and higher, you can improve performance for binary log replicas when replicating transactions for large tables with more than one secondary index. This feature introduces a thread pool to apply secondary index changes in parallel on a binlog replica. The feature is controlled by the `aurora_binlog_replication_sec_index_parallel_workers`

DB cluster parameter, which controls the total number of parallel threads available to apply the secondary index changes. The parameter is set to 0 (disabled) by default. Enabling this feature doesn't require an instance restart. To enable this feature, stop ongoing replication, set the desired number of parallel worker threads, and then start replication again.

## Optimizing binlog replication

In Aurora MySQL 2.10 and higher, Aurora automatically applies an optimization known as the binlog I/O cache to binary log replication. By caching the most recently committed binlog events, this optimization is designed to improve binlog dump thread performance while limiting the impact to foreground transactions on the binlog source instance.

### Note

This memory used for this feature is independent of the MySQL `binlog_cache` setting. This feature doesn't apply to Aurora DB instances that use the `db.t2` and `db.t3` instance classes.

You don't need to adjust any configuration parameters to turn on this optimization. In particular, if you had adjusted the configuration parameter `aurora_binlog_replication_max_yield_seconds` to a nonzero value in earlier Aurora MySQL versions, set it back to zero for currently available versions.

The status variables `aurora_binlog_io_cache_reads` and `aurora_binlog_io_cache_read_requests` help you to monitor how often the data is read from the binlog I/O cache.

- `aurora_binlog_io_cache_read_requests` shows the number of binlog I/O read requests from the cache.
- `aurora_binlog_io_cache_reads` shows the number of binlog I/O reads that retrieve information from the cache.

The following SQL query computes the percentage of binlog read requests that take advantage of the cached information. In this case, the closer the ratio is to 100, the better it is.

```
mysql> SELECT  
  (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
```

```

WHERE VARIABLE_NAME='aurora_binlog_io_cache_reads')
/ (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
WHERE VARIABLE_NAME='aurora_binlog_io_cache_read_requests')
* 100
as binlog_io_cache_hit_ratio;
+-----+
| binlog_io_cache_hit_ratio |
+-----+
|          99.99847949080622 |
+-----+

```

The binlog I/O cache feature also includes new metrics related to the binlog dump threads. *Dump threads* are the threads that are created when new binlog replicas are connected to the binlog source instance.

The dump thread metrics are printed to the database log every 60 seconds with the prefix [Dump thread metrics]. The metrics include information for each binlog replica such as `Secondary_id`, `Secondary_uuid`, binlog file name, and the position that each replica is reading. The metrics also include `Bytes_behind_primary` representing the distance in bytes between replication source and replica. This metric measures the lag of the replica I/O thread. That figure is different from the lag of the replica SQL applier thread, which is represented by the `seconds_behind_master` metric on the binlog replica. You can determine whether binlog replicas are catching up to the source or falling behind by checking whether the distance decreases or increases.

## In-memory relay log

In Aurora MySQL version 3.10 and higher, Aurora introduces an optimization known as in-memory relay log to improve replication throughput. This optimization enhances relay log I/O performance by caching all intermediate relay log content in memory. As a result, it reduces commit latency by minimizing storage I/O operations since the relay log content remains readily accessible in memory.

By default, the in-memory relay log feature is automatically enabled for Aurora-managed replication scenarios (including blue-green deployments, Aurora-Aurora replication, and cross-region replicas) when the replica meets any of these configurations:

- Single-threaded replication mode (`replica_parallel_workers = 0`)
- Multi-threaded replication with GTID mode enabled:
  - Auto-position enabled

- GTID mode set to ON on the replica
- File-based replication with `replica_preserve_commit_order = ON`

The in-memory relay log feature is supported on instance classes larger than `t3.large`, but is not available on Aurora Serverless instances. The relay log circular buffer has a fixed size of 128 MB. To monitor the memory consumption of this feature, you can run the following query:

```
SELECT event_name, current_alloc FROM sys.memory_global_by_current_bytes WHERE
event_name = 'memory/sql/relaylog_io_cache';
```

The in-memory relay log feature is controlled by the `aurora_in_memory_relaylog` parameter, which can be set at either the DB cluster or instance level. You can enable or disable this feature dynamically without restarting your instance:

1. Stop the ongoing replication
2. Set `aurora_in_memory_relaylog` to ON (to enable) or OFF (to disable) in parameter group
3. Restart replication

Example:

```
CALL mysql.rds_stop_replication;
set aurora_in_memory_relaylog to ON to enable or OFF to disable in cluster parameter
group
CALL mysql.rds_start_replication;
```

Even when `aurora_in_memory_relaylog` is set to ON, the in-memory relay log feature might still be disabled under certain conditions. To verify the feature's current status, you can use the following command:

```
SHOW GLOBAL STATUS LIKE 'Aurora_in_memory_relaylog_status';
```

If the feature is unexpectedly disabled, you can identify the reason by running:

```
SHOW GLOBAL STATUS LIKE 'Aurora_in_memory_relaylog_disabled_reason';
```

This command returns a message explaining why the feature is currently disabled.

## Setting up enhanced binlog for Aurora MySQL

Enhanced binlog reduces the compute performance overhead caused by turning on binlog, which can reach up to 50% in certain cases. With enhanced binlog, this overhead can be reduced to about 13%. To reduce overhead, enhanced binlog writes the binary and transactions logs to storage in parallel, which minimizes the data written at the transaction commit time.

Using enhanced binlog also improves database recovery time after restarts and failovers by up to 99% compared to community MySQL binlog. The enhanced binlog is compatible with existing binlog-based workloads, and you interact with it the same way you interact with the community MySQL binlog.

Enhanced binlog is available on Aurora MySQL version 3.03.1 and higher.

### Topics

- [Configuring enhanced binlog parameters](#)
- [Other related parameters](#)
- [Differences between enhanced binlog and community MySQL binlog](#)
- [Amazon CloudWatch metrics for enhanced binlog](#)
- [Enhanced binlog limitations](#)

### Configuring enhanced binlog parameters

You can switch between community MySQL binlog and enhanced binlog by turning on/off the enhanced binlog parameters. The existing binlog consumers can continue to read and consume the binlog files without any gaps in the binlog file sequence.

To turn on enhanced binlog, set the following parameters:

Parameter	Default	Description
<code>binlog_format</code>	–	Set the <code>binlog_format</code> parameter to the binary logging format of your choice to turn on enhanced binlog. Make sure the <code>binlog_fo</code>

Parameter	Default	Description
		mat parameter isn't set to OFF. For more information, see <a href="#">Configuring Aurora MySQL binary logging</a> .
aurora_enhanced_binlog	0	Set the value of this parameter to 1 in the DB cluster parameter group associated with the Aurora MySQL cluster. When you change the value of this parameter, you must reboot the writer instance when the DBClusterParameterGroupStatus value is shown as pending-reboot .
binlog_backup	1	Turn off this parameter to turn on enhanced binlog. To do so, set the value of this parameter to 0.
binlog_replication_globaldb	1	Turn off this parameter to turn on enhanced binlog. To do so, set the value of this parameter to 0.

**⚠ Important**

You can turn off the `binlog_backup` and `binlog_replication_globaldb` parameters only when you use enhanced binlog.

To turn off enhanced binlog, set the following parameters:

Parameter	Description
<code>aurora_enhanced_binlog</code>	Set the value of this parameter to 0 in the DB cluster parameter group associated with the Aurora MySQL cluster. Whenever you change the value of this parameter, you must reboot the writer instance when the <code>DBClusterParameterGroupStatus</code> value is shown as <code>pending-reboot</code> .
<code>binlog_backup</code>	Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.
<code>binlog_replication_globaldb</code>	Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.

To check whether enhanced binlog is turned on, use the following command in the MySQL client:

```
mysql>show status like 'aurora_enhanced_binlog';
```

```
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| aurora_enhanced_binlog | ACTIVE |
+-----+-----+
1 row in set (0.00 sec)
```

When enhanced binlog is turned on, the output shows `ACTIVE` for `aurora_enhanced_binlog`.

## Other related parameters

When you turn on the enhanced binlog, the following parameters are affected:

- The `max_binlog_size` parameter is visible but not modifiable. Its default value 134217728 is automatically adjusted to 268435456 when enhanced binlog is turned on.

- Unlike in community MySQL binlog, the `binlog_checksum` doesn't act as a dynamic parameter when the enhanced binlog is turned on. For the change to this parameter to take effect, you must manually reboot the DB cluster even when the `ApplyMethod` is `immediate`.
- The value you set on the `binlog_order_commits` parameter has no effect on the order of the commits when enhanced binlog is turned on. The commits are always ordered without any further performance implications.

## Differences between enhanced binlog and community MySQL binlog

Enhanced binlog interacts differently with clones, backups, and Aurora global database when compared to community MySQL binlog. We recommend that you understand the following differences before using enhanced binlog.

- Enhanced binlog files from the source DB cluster aren't available on a cloned DB cluster.
- Enhanced binlog files aren't included in Aurora backups. Therefore, enhanced binlog files from the source DB cluster aren't available after restoring a DB cluster despite any retention period set on it.
- When used with an Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the DB cluster in the secondary regions.

## Examples

The following examples illustrate the differences between enhanced binlog and community MySQL binlog.

### On a restored or cloned DB cluster

When enhanced binlog is turned on, the historical binlog files aren't available in the restored or cloned DB cluster. After a restore or clone operation, if binlog is turned on, the new DB cluster starts writing its own sequence of binlog files, starting from 1 (`mysql-bin-changelog.000001`).

To turn on enhanced binlog after a restore or clone operation, set the required DB cluster parameters on the restored or cloned DB cluster. For more information, see [Configuring enhanced binlog parameters](#).

### Example Example: Clone or restore operation performed when enhanced binlog is turned on

Source DB Cluster:

```
mysql> show binary logs;
```

```
+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        |
| mysql-bin-changelog.000002 |      156 | No        |
| mysql-bin-changelog.000003 |      156 | No        |
| mysql-bin-changelog.000004 |      156 | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000005 |      156 | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000006 |      156 | No        | --> Enhanced Binlog turned on
+-----+-----+-----+
6 rows in set (0.00 sec)
```

On a restored or cloned DB cluster, binlog files aren't backed up when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog are also not available.

```
mysql>show binary logs;
```

```
+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        | --> New sequence of Binlog files
+-----+-----+-----+
1 row in set (0.00 sec)
```

### Example Example: Clone or restore operation performed when enhanced binlog is turned off

Source DB cluster:

```
mysql>show binary logs;
```

```
+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        |
| mysql-bin-changelog.000002 |      156 | No        | --> Enhanced Binlog enabled
```

```

| mysql-bin-changelog.000003 |      156 | No      | --> Enhanced Binlog enabled
| mysql-bin-changelog.000004 |      156 | No      |
| mysql-bin-changelog.000005 |      156 | No      |
| mysql-bin-changelog.000006 |      156 | No      |
+-----+-----+-----+
6 rows in set (0.00 sec)

```

Enhanced binlog is disabled after `mysql-bin-changelog.000003`. On a restored or cloned DB cluster, binlog files written after turning off the enhanced binlog are available.

```

mysql>show binary logs;

+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000004 |      156 | No      |
| mysql-bin-changelog.000005 |      156 | No      |
| mysql-bin-changelog.000006 |      156 | No      |
+-----+-----+-----+
1 row in set (0.00 sec)

```

### On an Amazon Aurora global database

On an Amazon Aurora global database, the binlog data of the primary DB cluster isn't replicated to the secondary DB clusters. After a cross-Region failover process, the binlog data isn't available in the newly promoted primary DB cluster. If binlog is turned on, the newly promoted DB cluster starts its own sequence of binlog files, starting from 1 (`mysql-bin-changelog.000001`).

To turn on enhanced binlog after failover, you must set the required DB cluster parameters on the secondary DB cluster. For more information, see [Configuring enhanced binlog parameters](#).

### Example Example: Global database failover operation is performed when enhanced binlog is turned on

Old primary DB Cluster (before failover):

```
mysql>show binary logs;
```

```

+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        |
| mysql-bin-changelog.000002 |      156 | No        |
| mysql-bin-changelog.000003 |      156 | No        |
| mysql-bin-changelog.000004 |      156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000005 |      156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000006 |      156 | No        | --> Enhanced Binlog enabled
+-----+-----+-----+
6 rows in set (0.00 sec)

```

New primary DB cluster (after failover):

Binlog files aren't replicated to secondary regions when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog aren't available.

```

mysql>show binary logs;

+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        | --> Fresh sequence of Binlog
files
+-----+-----+-----+
1 row in set (0.00 sec)

```

**Example Example: Global database failover operation is performed when enhanced binlog is turned off**

Source DB Cluster:

```

mysql>show binary logs;

+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000001 |      156 | No        |

```

```

| mysql-bin-changelog.000002 |      156 | No      | --> Enhanced Binlog enabled
| mysql-bin-changelog.000003 |      156 | No      | --> Enhanced Binlog enabled
| mysql-bin-changelog.000004 |      156 | No      |
| mysql-bin-changelog.000005 |      156 | No      |
| mysql-bin-changelog.000006 |      156 | No      |
+-----+-----+-----+
6 rows in set (0.00 sec)

```

### Restored or cloned DB cluster:

Enhanced binlog is disabled after `mysql-bin-changelog.000003`. Binlog files that are written after turning off the enhanced binlog are replicated and are available in the newly promoted DB cluster.

```

mysql>show binary logs;

+-----+-----+-----+
| Log_name          | File_size | Encrypted |
+-----+-----+-----+
| mysql-bin-changelog.000004 |      156 | No      |
| mysql-bin-changelog.000005 |      156 | No      |
| mysql-bin-changelog.000006 |      156 | No      |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

### Amazon CloudWatch metrics for enhanced binlog

The following Amazon CloudWatch metrics are published only when enhanced binlog is turned on.

CloudWatch metric	Description	Units
ChangeLogBytesUsed	The amount of storage used by the enhanced binlog.	Bytes
ChangeLogReadIOPs	The number of read I/O operations performed in the enhanced binlog within a 5-minute interval.	Count per 5 minutes

CloudWatch metric	Description	Units
ChangeLogWriteIOPs	The number of write disk I/O operations performed in the enhanced binlog within a 5-minute interval.	Count per 5 minutes

## Enhanced binlog limitations

The following limitations apply to Amazon Aurora DB clusters when enhanced binlog is turned on.

- Enhanced binlog is only supported on Aurora MySQL version 3.03.1 and higher.
- The enhanced binlog files written on the primary DB cluster aren't copied to the cloned or restored DB clusters.
- When used with Amazon Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the secondary DB clusters. Therefore, after the failover process, the historical binlog data isn't available in the new primary DB cluster.
- The following binlog configuration parameters are ignored:
  - `binlog_group_commit_sync_delay`
  - `binlog_group_commit_sync_no_delay_count`
  - `binlog_max_flush_queue_time`
- You can't drop or rename a corrupted table in a database. To drop these tables, you can contact Amazon Web Services Support.
- The binlog I/O cache is disabled when enhanced binlog is turned on. For more information, see [Optimizing binary log replication for Aurora MySQL](#).

### Note

Enhanced binlog provides similar read performance improvements as binlog I/O cache and better write performance improvements.

- The backtrack feature is not supported. Enhanced binlog can't be turned on in a DB cluster under the following conditions:
  - DB cluster with the backtrack feature currently enabled.
  - DB cluster where the backtrack feature was previously enabled, but is now disabled.

- DB cluster restored from a source DB cluster or a snapshot with the backtrack feature enabled.

## Using GTID-based replication

The following content explains how to use global transaction identifiers (GTIDs) with binary log (binlog) replication between an Aurora MySQL cluster and an external source.

### Note

For Aurora, you can use this feature only with Aurora MySQL clusters that use binlog replication to or from an external MySQL database. The other database might be an Amazon RDS MySQL instance, an on-premises MySQL database, or an Aurora DB cluster in a different Amazon Web Services Region. To learn how to configure that kind of replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see [Replication with global transaction identifiers](#) in the MySQL documentation.

GTID-based replication is supported for Aurora MySQL version 2 and 3.

### Topics

- [Overview of global transaction identifiers \(GTIDs\)](#)
- [Parameters for GTID-based replication](#)
- [Enabling GTID-based replication for an Aurora MySQL cluster](#)
- [Disabling GTID-based replication for an Aurora MySQL DB cluster](#)

## Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

### Note

When Aurora synchronizes data among the DB instances in a cluster, that replication mechanism doesn't involve the binary log (binlog). For Aurora MySQL, GTID-based

replication only applies when you also use binlog replication to replicate into or out of an Aurora MySQL DB cluster from an external MySQL-compatible database.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You typically use GTID-based replication with Aurora when replicating from an external MySQL-compatible database into an Aurora cluster. You can set up this replication configuration as part of a migration from an on-premises or Amazon RDS database into Aurora MySQL. If the external database already uses GTIDs, enabling GTID-based replication for the Aurora cluster simplifies the replication process.

You configure GTID-based replication for an Aurora MySQL cluster by first setting the relevant configuration parameters in a DB cluster parameter group. You then associate that parameter group with the cluster.

## Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

Parameter	Valid values	Description
<code>gtid_mode</code>	<code>OFF</code> , <code>OFF_PERMISSIVE</code> , <code>ON_PERMISSIVE</code> , <code>ON</code>	<p><code>OFF</code> specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</p> <p><code>OFF_PERMISSIVE</code> specifies that new transactions are anonymous transactions, but all transactions can be replicated.</p>

Parameter	Valid values	Description
		<p><code>ON_PERMISSIVE</code> specifies that new transactions are GTID transactions, but all transactions can be replicated.</p> <p><code>ON</code> specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</p>
<code>enforce_gtid_consistency</code>	OFF, ON, WARN	<p>OFF allows transactions to violate GTID consistency.</p> <p>ON prevents transactions from violating GTID consistency.</p> <p>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</p>

 **Note**

In the Amazon Web Services Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the DB cluster parameter group for your Aurora MySQL DB cluster:

- `ON` and `ON_PERMISSIVE` apply only to outgoing replication from an Aurora MySQL cluster. Both of these values cause your Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. `ON` requires that the external database also use GTID-based replication. `ON_PERMISSIVE` makes GTID-based replication optional on the external database.
- `OFF_PERMISSIVE`, if set, means that your Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.

- OFF, if set, means that your Aurora DB cluster only accepts incoming replication from external databases that don't use GTID-based replication.

**Tip**

Incoming replication is the most common binlog replication scenario for Aurora MySQL clusters. For incoming replication, we recommend that you set the GTID mode to OFF\_PERMISSIVE. That setting allows incoming replication from external databases regardless of the GTID settings at the replication source.

For more information about parameter groups, see [Parameter groups for Amazon Aurora](#).

## Enabling GTID-based replication for an Aurora MySQL cluster

When GTID-based replication is enabled for an Aurora MySQL DB cluster, the GTID settings apply to both inbound and outbound binlog replication.

### To enable GTID-based replication for an Aurora MySQL cluster

1. Create or edit a DB cluster parameter group using the following parameter settings:
  - `gtid_mode` – ON or ON\_PERMISSIVE
  - `enforce_gtid_consistency` – ON
2. Associate the DB cluster parameter group with the Aurora MySQL cluster. To do so, follow the procedures in [Parameter groups for Amazon Aurora](#).
3. (Optional) Specify how to assign GTIDs to transactions that don't include them. To do so, call the stored procedure in [mysql.rds\\_assign\\_gtids\\_to\\_anonymous\\_transactions \(Aurora MySQL version 3\)](#).

## Disabling GTID-based replication for an Aurora MySQL DB cluster

You can disable GTID-based replication for an Aurora MySQL DB cluster. Doing so means that the Aurora cluster can't perform inbound or outbound binlog replication with external databases that use GTID-based replication.

**Note**

In the following procedure, *read replica* means the replication target in an Aurora configuration with binlog replication to or from an external database. It doesn't mean the read-only Aurora Replica DB instances. For example, when an Aurora cluster accepts incoming replication from an external source, the Aurora primary instance acts as the read replica for binlog replication.

For more details about the stored procedures mentioned in this section, see [Aurora MySQL stored procedure reference](#).

**To disable GTID-based replication for an Aurora MySQL DB cluster**

1. On the Aurora replicas, run the following procedure:

For version 3

```
CALL mysql.rds_set_source_auto_position(0);
```

For version 2

```
CALL mysql.rds_set_master_auto_position(0);
```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.
  - a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `ON_PERMISSIVE`.

For more information about setting configuration parameters using parameter groups, see [Parameter groups for Amazon Aurora](#).
  - b. Restart the Aurora MySQL DB cluster.
3. Reset the `gtid_mode` to `OFF_PERMISSIVE`.
  - a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `OFF_PERMISSIVE`.
  - b. Restart the Aurora MySQL DB cluster.

4. Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following steps:
  - a. On the Aurora primary instance, run the `SHOW MASTER STATUS` command.

Your output should be similar to the following output.

```
File                Position
-----
mysql-bin-changelog.000031    107
-----
```

Note the file and position in your output.

- b. On each read replica, use the file and position information from its source instance in the previous step to run the following query:

For version 3

```
SELECT SOURCE_POS_WAIT('file', position);
```

For version 2

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement:

For version 3

```
SELECT SOURCE_POS_WAIT('mysql-bin-changelog.000031', 107);
```

For version 2

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

5. Reset the GTID parameters to disable GTID-based replication.

- a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has the following parameter settings:
  - `gtid_mode` – OFF
  - `enforce_gtid_consistency` – OFF
- b. Restart the Aurora MySQL DB cluster.

# Using local write forwarding in an Amazon Aurora MySQL DB cluster

*Local (in-cluster) write forwarding* allows your applications to issue read/write transactions directly on an Aurora Replica. These transactions are then forwarded to the writer DB instance to be committed. You can use local write forwarding when your applications require *read-after-write consistency*, which is the ability to read the latest write in a transaction.

Read replicas receive updates asynchronously from the writer. Without write forwarding, you have to transact any reads that require read-after-write consistency on the writer DB instance. Or you have to develop complex custom application logic to take advantage of multiple read replicas for scalability. Your applications must fully split all read and write traffic, maintaining two sets of database connections to send the traffic to the correct endpoint. This development overhead complicates application design when the queries are part of a single logical session, or transaction, within the application. Moreover, because replication lag can differ among read replicas, it's difficult to achieve global read consistency across all instances in the database.

Write forwarding avoids the need to split those transactions or send them exclusively to the writer, which simplifies application development. This new capability makes it easy to achieve read scale for workloads that need to read the latest write in a transaction and aren't sensitive to write latency.

Local write forwarding is different from global write forwarding, which forwards writes from a secondary DB cluster to the primary DB cluster in an Aurora global database. You can use local write forwarding in a DB cluster that is part of an Aurora global database. For more information, see [Using write forwarding in an Amazon Aurora global database](#).

Local write forwarding requires Aurora MySQL version 3.04 or higher.

## Topics

- [Enabling local write forwarding](#)
- [Checking if a DB cluster has write forwarding enabled](#)
- [Application and SQL compatibility with write forwarding](#)
- [Isolation levels for write forwarding](#)
- [Read consistency for write forwarding](#)
- [Running multipart statements with write forwarding](#)
- [Transactions with write forwarding](#)

- [Configuration parameters for write forwarding](#)
- [Amazon CloudWatch metrics and Aurora MySQL status variables for write forwarding](#)
- [Identifying forwarded transactions and queries](#)

## Enabling local write forwarding

By default, local write forwarding isn't enabled for Aurora MySQL DB clusters. You enable local write forwarding at the cluster level, not at the instance level.

### Important

You can also enable local write forwarding for cross-Region read replicas that use binary logging, but write operations aren't forwarded to the source Amazon Web Services Region. They're forwarded to the writer DB instance of the binlog read replica cluster.

Use this method only if you have a use case for writing to the binlog read replica in the secondary Amazon Web Services Region. Otherwise, you might end up with a "split-brain" scenario where replicated datasets are inconsistent with each other.

We recommend that you use global write forwarding with global databases, rather than local write forwarding on cross-Region read replicas, unless absolutely necessary. For more information, see [Using write forwarding in an Amazon Aurora global database](#).

### Console

Using the Amazon Web Services Management Console, select the **Turn on local write forwarding** check box under **Read replica write forwarding** when you create or modify a DB cluster.

### Amazon CLI

To enable write forwarding with the Amazon CLI, use the `--enable-local-write-forwarding` option. This option works when you create a new DB cluster using the `create-db-cluster` command. It also works when you modify an existing DB cluster using the `modify-db-cluster` command. You can disable write forwarding by using the `--no-enable-local-write-forwarding` option with these same CLI commands.

The following example creates an Aurora MySQL DB cluster with write forwarding enabled.

```
aws rds create-db-cluster \  
  --db-cluster-identifier write-forwarding-test-cluster \  
  --enable-local-write-forwarding
```

```
--enable-local-write-forwarding \  
--engine aurora-mysql \  
--engine-version 8.0.mysql_aurora.3.04.0 \  
--master-username myuser \  
--master-user-password mypassword \  
--backup-retention 1
```

You then create writer and reader DB instances so that you can use write forwarding. For more information, see [Creating an Amazon Aurora DB cluster](#).

## RDS API

To enable write forwarding using the Amazon RDS API, set the `EnableLocalWriteForwarding` parameter to `true`. This parameter works when you create a new DB cluster using the `CreateDBCluster` operation. It also works when you modify an existing DB cluster using the `ModifyDBCluster` operation. You can disable write forwarding by setting the `EnableLocalWriteForwarding` parameter to `false`.

## Enabling write forwarding for database sessions

The `aurora_replica_read_consistency` parameter is a DB parameter and DB cluster parameter that enables write forwarding. You can specify `EVENTUAL`, `SESSION`, or `GLOBAL` for the read consistency level. To learn more about consistency levels, see [Read consistency for write forwarding](#).

The following rules apply to this parameter:

- The default value is "" (null).
- Write forwarding is available only if you set `aurora_replica_read_consistency` to `EVENTUAL`, `SESSION`, or `GLOBAL`. This parameter is relevant only in reader instances of DB clusters that have write forwarding enabled.
- You can't set this parameter (when empty) or unset it (when already set) inside a multistatement transaction. You can change it from one valid value to another valid value during such a transaction, but we don't recommend this action.

## Checking if a DB cluster has write forwarding enabled

To determine that you can use write forwarding in a DB cluster, confirm that the cluster has the attribute `LocalWriteForwardingStatus` set to `enabled`.

In the Amazon Web Services Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Local read replica write forwarding**.

To see the status of the write forwarding setting for all of your clusters, run the following Amazon CLI command.

### Example

```
aws rds describe-db-clusters \  
--query '*[.]'.  
{DBClusterIdentifier:DBClusterIdentifier,LocalWriteForwardingStatus:LocalWriteForwardingStatus}  
  
[  
  {  
    "LocalWriteForwardingStatus": "enabled",  
    "DBClusterIdentifier": "write-forwarding-test-cluster-1"  
  },  
  {  
    "LocalWriteForwardingStatus": "disabled",  
    "DBClusterIdentifier": "write-forwarding-test-cluster-2"  
  },  
  {  
    "LocalWriteForwardingStatus": "requested",  
    "DBClusterIdentifier": "test-global-cluster-2"  
  },  
  {  
    "LocalWriteForwardingStatus": "null",  
    "DBClusterIdentifier": "aurora-mysql-v2-cluster"  
  }  
]
```

A DB cluster can have the following values for `LocalWriteForwardingStatus`:

- `disabled` – Write forwarding is disabled.
- `disabling` – Write forwarding is in the process of being disabled.
- `enabled` – Write forwarding is enabled.
- `enabling` – Write forwarding is in the process of being enabled.
- `null` – Write forwarding isn't available for this DB cluster.
- `requested` – Write forwarding has been requested, but is not yet active.

## Application and SQL compatibility with write forwarding

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- SELECT ... LOCK IN SHARE MODE and SELECT FOR UPDATE statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a DB cluster with write forwarding. In addition, user defined functions and user defined procedures aren't supported. Thus, the `EnableLocalWriteForwarding` setting is disabled by default for DB clusters. Before enabling it, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding.

In some cases, you can use the statements on DB clusters with write forwarding enabled. This approach works if write forwarding isn't enabled within the session by the `aurora_replica_read_consistency` configuration parameter. If you try to use a statement when it's not allowed because of write forwarding, then you will see an error message similar to the following:

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation' with write forwarding'.
```

### Data definition language (DDL)

Connect to the writer DB instance to run DDL statements. You can't run them from reader DB instances.

### Updating a permanent table using data from a temporary table

You can use temporary tables on DB clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an INSERT ... SELECT statement that takes the data from a temporary table.

## XA transactions

You can't use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is empty. Before enabling write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

## LOAD statements for permanent tables

You can't use the following statements on a DB cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

## Plugin statements

You can't use the following statements on a DB cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

## SAVEPOINT statements

You can't use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before enabling write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```

## Isolation levels for write forwarding

In sessions that use write forwarding, you can only use the REPEATABLE READ isolation level. Although you can also use the READ COMMITTED isolation level with Aurora Replicas, that isolation level doesn't work with write forwarding. For information about the REPEATABLE READ and READ COMMITTED isolation levels, see [Aurora MySQL isolation levels](#).

## Read consistency for write forwarding

You can control the degree of read consistency on a DB cluster. The read consistency level determines how long the DB cluster waits before each read operation to ensure that some or all changes are replicated from the writer. You can adjust the read consistency level to make sure that all forwarded write operations from your session are visible in the DB cluster before any subsequent queries. You can also use this setting to make sure that queries on the DB cluster always see the most current updates from the writer. This setting also applies to queries submitted by other sessions or other clusters. To specify this type of behavior for your application, choose a value for the `aurora_replica_read_consistency` DB parameter or DB cluster parameter.

### Important

Always set the `aurora_replica_read_consistency` DB parameter or DB cluster parameter when you want to forward writes. If you don't, then Aurora doesn't forward writes. This parameter has an empty value by default, so choose a specific value when you use this parameter. The `aurora_replica_read_consistency` parameter only affects DB clusters or instances that have write forwarding enabled.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between DB instances. You can choose the balance between fast response time and making sure that changes made in other DB instances are fully available before your queries run.

You can specify the following values for the `aurora_replica_read_consistency` parameter:

- **EVENTUAL** – Results of write operations in the same session aren't visible until the write operation is performed on the writer DB instance. The query doesn't wait for the updated results to be available. Thus it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag. This is the same consistency as for Aurora MySQL DB clusters that don't use write forwarding.

- **SESSION** – All queries that use write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated.
- **GLOBAL** – A session sees all committed changes across all sessions and instances in the DB cluster. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the DB cluster is up-to-date with all committed data from the writer, as of the time that the query began.

For information about the configuration parameters involved in write forwarding, see [Configuration parameters for write forwarding](#).

### Note

You can also use `aurora_replica_read_consistency` as a session variable, for example:

```
mysql> set aurora_replica_read_consistency = 'session';
```

## Examples of using write forwarding

The following examples show the effects of the `aurora_replica_read_consistency` parameter on running `INSERT` statements followed by `SELECT` statements. The results can differ, depending on the value of `aurora_replica_read_consistency` and the timing of the statements.

To achieve higher consistency, you might wait briefly before issuing the `SELECT` statement. Or Aurora can automatically wait until the results finish replicating before proceeding with `SELECT`.

For information on setting DB parameters, see [Parameter groups for Amazon Aurora](#).

### Example with `aurora_replica_read_consistency` set to `EVENTUAL`

Running an `INSERT` statement, immediately followed by a `SELECT` statement, returns a value for `COUNT(*)` with the number of rows before the new row is inserted. Running the `SELECT` again a short time later returns the updated row count. The `SELECT` statements don't wait.

```
mysql> select count(*) from t1;  
+-----+
```

```

| count(*) |
+-----+
|      5 |
+-----+
1 row in set (0.00 sec)

mysql> insert into t1 values (6); select count(*) from t1;
+-----+
| count(*) |
+-----+
|      5 |
+-----+
1 row in set (0.00 sec)

mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      6 |
+-----+
1 row in set (0.00 sec)

```

### Example with `aurora_replica_read_consistency` set to `SESSION`

A `SELECT` statement immediately after an `INSERT` waits until the changes from the `INSERT` statement are visible. Subsequent `SELECT` statements don't wait.

```

mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      6 |
+-----+
1 row in set (0.01 sec)

mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+-----+
| count(*) |
+-----+
|      7 |
+-----+
1 row in set (0.37 sec)

```

```
+-----+
| count(*) |
+-----+
|         7 |
+-----+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `SESSION`, introducing a brief wait after performing an `INSERT` statement makes the updated row count available by the time the next `SELECT` statement runs.

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+-----+
| sleep(2) |
+-----+
|         0 |
+-----+
1 row in set (2.01 sec)
+-----+
| count(*) |
+-----+
|         8 |
+-----+
1 row in set (0.00 sec)
```

### Example with `aurora_replica_read_consistency` set to `GLOBAL`

Each `SELECT` statement waits for all data changes, as of the start time of the statement, to be visible before performing the query. The wait time for each `SELECT` statement varies, depending on the amount of replication lag.

```
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|         8 |
+-----+
1 row in set (0.75 sec)

mysql> select count(*) from t1;
+-----+
```

```
| count(*) |
+-----+
|      8 |
+-----+
1 row in set (0.37 sec)

mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      8 |
+-----+
1 row in set (0.66 sec)
```

## Running multipart statements with write forwarding

A DML statement might consist of multiple parts, such as an `INSERT . . . SELECT` statement or a `DELETE . . . WHERE` statement. In this case, the entire statement is forwarded to the writer DB instance and run there.

## Transactions with write forwarding

If the transaction access mode is set to read only, write forwarding isn't used. You can specify the access mode for the transaction by using the `SET TRANSACTION` statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the [transaction\\_read\\_only](#) session variable. You can change this session value only while you're connected to a DB cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can set the `aurora_fwd_writer_idle_timeout` parameter to increase it up to one day. A transaction that exceeds the idle timeout is canceled by the writer instance. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the DB cluster or if you disable write forwarding.

When a writer instance in a cluster using local write forwarding is restarted, any active, forwarded transactions and queries on reader instances using local write forwarding are automatically closed. After the writer instance is available again, you can retry these transactions.

## Configuration parameters for write forwarding

The Aurora DB parameter groups include settings for the write forwarding feature. Details about these parameters are summarized in the following table, with usage notes after the table.

Parameter	Scope	Type	Default value	Valid values
<code>aurora_fwd_writer_idle_timeout</code>	Cluster	Unsigned integer	60	1–86,400
<code>aurora_fwd_writer_max_connections_pct</code>	Cluster	Unsigned long integer	10	0–90
<code>aurora_replica_read_consistency</code>	Cluster or instance	Enum	" (null)	EVENTUAL, SESSION, GLOBAL

To control incoming write requests, use these settings:

- `aurora_fwd_writer_idle_timeout` – The number of seconds the writer DB instance waits for activity on a connection that's forwarded from a reader instance before closing it. If the session remains idle beyond this period, Aurora cancels the session.
- `aurora_fwd_writer_max_connections_pct` – The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from reader instances. It's expressed as a percentage of the `max_connections` setting for the writer. For example, if `max_connections` is 800 and `aurora_fwd_master_max_connections_pct` or `aurora_fwd_writer_max_connections_pct` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting.

This setting applies only on the writer when it has write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a DB cluster. The default value is 10, representing 10% of the `max_connections` value.

**Note**

Because `aurora_fwd_writer_idle_timeout` and `aurora_fwd_writer_max_connections_pct` are DB cluster parameters, all DB instances in each cluster have the same values for these parameters.

For more information about `aurora_replica_read_consistency`, see [Read consistency for write forwarding](#).

For more information on DB parameter groups, see [Parameter groups for Amazon Aurora](#).

## Amazon CloudWatch metrics and Aurora MySQL status variables for write forwarding

The following Amazon CloudWatch metrics and Aurora MySQL status variables apply when you use write forwarding for Aurora MySQL. For more information about metrics for Aurora MySQL writer and reader DB instances, see the following topics.

### Topics

- [Metrics for write forwarding for Aurora MySQL writer DB instances](#)
- [Metrics for write forwarding for Aurora MySQL reader DB instances](#)

### Metrics for write forwarding for Aurora MySQL writer DB instances

The following Amazon CloudWatch metrics apply when you use write forwarding on one or more DB clusters. These metrics are all measured on the writer DB instance.

CloudWatch metric	Unit	Description
ForwardingWriterDMLLatency	Milliseconds	<p>Average time to process each forwarded DML statement on the writer DB instance.</p> <p>It doesn't include the time for the DB cluster to forward the write request, or the time to</p>

CloudWatch metric	Unit	Description
		replicate changes back to the writer.
ForwardingWriterDMLThroughput	Count per second	Number of forwarded DML statements processed each second by this writer DB instance.
ForwardingWriterOpenSessions	Count	Number of forwarded sessions on the writer DB instance.

The following Aurora MySQL status variables apply when you use write forwarding on one or more DB clusters. These status variables are all measured on the writer DB instance.

Aurora MySQL status variable	Unit	Description
Aurora_fwd_writer_dml_stmt_count	Count	Total number of DML statements forwarded to this writer DB instance.
Aurora_fwd_writer_dml_stmt_duration	Microseconds	Total duration of DML statements forwarded to this writer DB instance.
Aurora_fwd_writer_open_sessions	Count	Number of forwarded sessions on the writer DB instance.
Aurora_fwd_writer_select_stmt_count	Count	Total number of SELECT statements forwarded to this writer DB instance.

Aurora MySQL status variable	Unit	Description
Aurora_fwd_writer_select_stmt_duration	Microseconds	Total duration of SELECT statements forwarded to this writer DB instance.

## Metrics for write forwarding for Aurora MySQL reader DB instances

The following CloudWatch metrics are measured on each reader DB instance in a DB cluster with write forwarding enabled.

CloudWatch metric	Unit	Description
ForwardingReplicaDMLLatency	Milliseconds	Average response time of forwarded DMLs on replica.
ForwardingReplicaDMLThroughput	Count per second	Number of forwarded DML statements processed each second.
ForwardingReplicaOpenSessions	Count	Number of sessions that are using write forwarding on a reader DB instance.
ForwardingReplicaReaderWaitLatency	Milliseconds	<p>Average wait time that a SELECT statement on a reader DB instance waits to catch up to the writer.</p> <p>The degree to which the reader DB instance waits before processing a query depends on the <code>aurora_replica_read_consistency</code> setting.</p>

CloudWatch metric	Unit	Description
ForwardingReplicaReadWaitThroughput	Count per second	Total number of SELECT statements processed each second in all sessions that are forwarding writes.
ForwardingReplicaSelectLatency	Milliseconds	Forwarded SELECT latency, averaged over all forwarded SELECT statements within the monitoring period.
ForwardingReplicaSelectThroughput	Count per second	Forwarded SELECT throughput per second average within the monitoring period.

The following Aurora MySQL status variables are measured on each reader DB instance in a DB cluster with write forwarding enabled.

Aurora MySQL status variable	Unit	Description
Aurora_fwd_replica_dml_stmt_count	Count	Total number of DML statements forwarded from this reader DB instance.
Aurora_fwd_replica_dml_stmt_duration	Microseconds	Total duration of all DML statements forwarded from this reader DB instance.
Aurora_fwd_replica_errors_session_limit	Count	Number of sessions rejected by the primary cluster due to one of the following error conditions: <ul style="list-style-type: none"> <li>writer full</li> </ul>

Aurora MySQL status variable	Unit	Description
		<ul style="list-style-type: none"> <li>Too many forwarded statements in progress.</li> </ul>
Aurora_fwd_replica_open_sessions	Count	Number of sessions that are using write forwarding on a reader DB instance.
Aurora_fwd_replica_read_wait_count	Count	Total number of read-after-write waits on this reader DB instance.
Aurora_fwd_replica_read_wait_duration	Microseconds	Total duration of waits due to the read consistency setting on this reader DB instance.
Aurora_fwd_replica_select_stmt_count	Count	Total number of SELECT statements forwarded from this reader DB instance.
Aurora_fwd_replica_select_stmt_duration	Microseconds	Total duration of SELECT statements forwarded from this reader DB instance.

## Identifying forwarded transactions and queries

You can use the `information_schema.aurora_forwarding_processlist` table to identify forwarded transactions and queries. For more information on this table, see [information\\_schema.aurora\\_forwarding\\_processlist](#).

The following example shows all forwarded connections on a writer DB instance.

```
mysql> select * from information_schema.AURORA_FORWARDING_PROCESSLIST where
IS_FORWARDED=1 order by REPLICA_SESSION_ID;
```

```

+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
| ID | USER      | HOST                | DB      | COMMAND | TIME | STATE      |
INFO                                | IS_FORWARDED | REPLICAS_ID |
REPLICAS_INSTANCE_IDENTIFIER      | REPLICAS_CLUSTER_NAME | REPLICAS_REGION |
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
| 648 | myuser    | IP_address:port1   | sysbench | Query   | 0    | async commit |
UPDATE sbtest58 SET k=k+1 WHERE id=4802579 |          1 |                637 | my-
db-cluster-instance-2          | my-db-cluster          | us-west-2      |
| 650 | myuser    | IP_address:port2   | sysbench | Query   | 0    | async commit |
UPDATE sbtest54 SET k=k+1 WHERE id=2503953 |          1 |                639 | my-
db-cluster-instance-2          | my-db-cluster          | us-west-2      |
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+

```

On the forwarding reader DB instance, you can see the threads associated with these writer DB connections by running `SHOW PROCESSLIST`. The `REPLICAS_SESSION_ID` values on the writer, 637 and 639, are the same as the `Id` values on the reader.

```

mysql> select @@aurora_server_id;

+-----+-----+
| @@aurora_server_id |
+-----+-----+
| my-db-cluster-instance-2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> show processlist;

+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
| Id | User      | Host                | db      | Command | Time | State      | Info
|
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
| 637 | myuser    | IP_address:port1   | sysbench | Query   | 0    | async commit |
UPDATE sbtest12 SET k=k+1 WHERE id=4802579 |

```

```
| 639 | myuser | IP_address:port2 | sysbench | Query | 0 | async commit |  
UPDATE sbtest61 SET k=k+1 WHERE id=2503953 |  
+-----+-----+-----+-----+-----+-----+-----+-----+  
+-----+  
12 rows in set (0.00 sec)
```

# Integrating Amazon Aurora MySQL with other Amazon services

Amazon Aurora MySQL integrates with other Amazon services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the Amazon Cloud. Your Aurora MySQL DB cluster can use Amazon services to do the following:

- Synchronously or asynchronously invoke an Amazon Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](#).
- Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).
- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Amazon Aurora Auto Scaling with Aurora Replicas](#).
- Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker AI. For more information, see [Using Amazon Aurora machine learning](#).

Aurora secures the ability to access other Amazon services by using Amazon Identity and Access Management (IAM). You grant permission to access other Amazon services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other Amazon services on your behalf, see [Authorizing Amazon Aurora MySQL to access other Amazon services on your behalf](#).

## Authorizing Amazon Aurora MySQL to access other Amazon services on your behalf

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an Amazon Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other Amazon services. For more information, see [Setting up IAM roles to access Amazon services](#).

You must also configure your Aurora DB cluster to allow outbound connections to the target Amazon service. For more information, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

If you do so, your database users can perform these actions using other Amazon services:

- Synchronously or asynchronously invoke an Amazon Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an Amazon Lambda function using the `mysql.lambda_async` procedure. For more information, see [Invoking a Lambda function with an Aurora MySQL native function](#).
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).
- Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).
- Export log data to Amazon CloudWatch Logs MySQL. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](#).
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Amazon Aurora Auto Scaling with Aurora Replicas](#).

## Setting up IAM roles to access Amazon services

To permit your Aurora DB cluster to access another Amazon service, do the following:

1. Create an IAM policy that grants permission to the Amazon service. For more information, see the following topics.
  - [Creating an IAM policy to access Amazon S3 resources](#)
  - [Creating an IAM policy to access Amazon Lambda resources](#)
  - [Creating an IAM policy to access CloudWatch Logs resources](#)
  - [Creating an IAM policy to access Amazon KMS resources](#)
2. Create an IAM role and attach the policy that you created. For more information, see [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).
3. Associate that IAM role with your Aurora DB cluster. For more information, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

## Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

Feature	Bucket permissions	Object permissions
LOAD DATA FROM S3	ListBucket	GetObject GetObjectVersion
LOAD XML FROM S3	ListBucket	GetObject GetObjectVersion
SELECT INTO OUTFILE S3	ListBucket	AbortMultipartUpload DeleteObject GetObject ListMultipartUploadParts PutObject

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToExampleBucket",
```

```

    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:AbortMultipartUpload",
        "s3:ListBucket",
        "s3:DeleteObject",
        "s3:GetObjectVersion",
        "s3:ListMultipartUploadParts"
    ],
    "Resource": [
        "arn:aws-cn:s3:::amzn-s3-demo-bucket/*",
        "arn:aws-cn:s3:::amzn-s3-demo-bucket"
    ]
}
]
}

```

### Note

Make sure to include both entries for the Resource value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket. Based on your use case, you might not need to add all of the permissions in the sample policy. Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add `kms:Decrypt` permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the `AmazonS3ReadOnlyAccess` or `AmazonS3FullAccess` predefined IAM policy instead of creating your own.

### To create an IAM policy to grant access to your Amazon S3 resources

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.

5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions needed for the IAM policy.

Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see [Permissions for object operations](#).

6. Choose **Resources**, and choose **Add ARN** for **bucket**.
7. In the **Add ARN(s)** dialog box, provide the details about your resource, and choose **Add**.

Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named *amzn-s3-demo-bucket*, then set the Amazon Resource Name (ARN) value to `arn:aws-cn:s3:::amzn-s3-demo-bucket`.

8. If the **object** resource is listed, choose **Add ARN** for **object**.
9. In the **Add ARN(s)** dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose **Any** to grant permissions to any object in the bucket.

 **Note**

You can set **Amazon Resource Name (ARN)** to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see [Managing access permissions to your Amazon S3 resources](#).

10. (Optional) Choose **Add ARN** for **bucket** to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

 **Note**

You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

11. Choose **Review policy**.

- For **Name**, enter a name for your IAM policy, for example `AllowAuroraToExampleBucket`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
- Choose **Create policy**.
- Complete the steps in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).

### Creating an IAM policy to access Amazon Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an Amazon Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an Amazon Lambda function on your behalf.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws-cn:lambda:us-
east-1:123456789012:function:example_function"
    }
  ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an Amazon Lambda function on your behalf. To allow Aurora to invoke all of your Amazon Lambda functions, you can skip these steps and use the predefined `AWSLambdaRole` policy instead of creating your own.

### To create an IAM policy to grant invoke to your Amazon Lambda functions

- Open the [IAM console](#).

2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Lambda**.
5. For **Actions**, choose **Expand all**, and then choose the Amazon Lambda permissions needed for the IAM policy.

Ensure that `InvokeFunction` is selected. It is the minimum required permission to enable Amazon Aurora to invoke an Amazon Lambda function.

6. Choose **Resources** and choose **Add ARN for function**.
7. In the **Add ARN(s)** dialog box, provide the details about your resource.

Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named `example_function`, then set the ARN value to `arn:aws-cn:lambda:::function:example_function`.

For more information on how to define an access policy for Amazon Lambda, see [Authentication and access control for Amazon Lambda](#).

8. Optionally, choose **Add additional permissions** to add another Amazon Lambda function to the policy, and repeat the previous steps for the function.

 **Note**

You can repeat this to add corresponding function permission statements to your policy for each Amazon Lambda function that you want Aurora to access.

9. Choose **Review policy**.
10. Set **Name** to a name for your IAM policy, for example `AllowAuroraToExampleFunction`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
11. Choose **Create policy**.
12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).

## Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",
      "Effect": "Allow",
      "Action": [
        "logs:GetLogEvents",
        "logs:PutLogEvents"
      ],
      "Resource": "arn:aws-cn:logs:*:*:log-group:/aws/rds/*:log-stream:*"
    },
    {
      "Sid":
"EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutRetentionPolicy",
        "logs:CreateLogGroup"
      ],
      "Resource": "arn:aws-cn:logs:*:*:log-group:/aws/rds/*"
    }
  ]
}
```

You can modify the ARNs in the policy to restrict access to a specific Amazon Region and account.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the `CloudWatchLogsFullAccess` predefined IAM policy instead of creating your own. For more information, see [Using identity-based policies \(IAM policies\) for CloudWatch Logs](#) in the *Amazon CloudWatch User Guide*.

### To create an IAM policy to grant access to your CloudWatch Logs resources

1. Open the [IAM console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **CloudWatch Logs**.
5. For **Actions**, choose **Expand all** (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

Ensure that the following permissions are selected:

- `CreateLogGroup`
  - `CreateLogStream`
  - `DescribeLogStreams`
  - `GetLogEvents`
  - `PutLogEvents`
  - `PutRetentionPolicy`
6. Choose **Resources** and choose **Add ARN** for **log-group**.
  7. In the **Add ARN(s)** dialog box, enter the following values:
    - **Region** – An Amazon Region or \*
    - **Account** – An account number or \*
    - **Log Group Name** – `/aws/rds/*`
  8. In the **Add ARN(s)** dialog box, choose **Add**.
  9. Choose **Add ARN** for **log-stream**.
  10. In the **Add ARN(s)** dialog box, enter the following values:
    - **Region** – An Amazon Region or \*
    - **Account** – An account number or \*

- **Log Group Name** – `/aws/rds/*`
  - **Log Stream Name** – `*`
11. In the **Add ARN(s)** dialog box, choose **Add**.
  12. Choose **Review policy**.
  13. Set **Name** to a name for your IAM policy, for example `AmazonRDSCloudWatchLogs`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
  14. Choose **Create policy**.
  15. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).

### Creating an IAM policy to access Amazon KMS resources

Aurora can access the Amazon KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToAccessKey",
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": "arn:aws-cn:kms:us-east-1:123456789012:key/key-ID"
    }
  ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

## To create an IAM policy to grant access to your KMS keys

1. Open the [IAM console](#).
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **KMS**.
5. For **Actions**, choose **Write**, and then choose **Decrypt**.
6. Choose **Resources**, and choose **Add ARN**.
7. In the **Add ARN(s)** dialog box, enter the following values:
  - **Region** – Type the Amazon Region, such as us-west-2.
  - **Account** – Type the user account number.
  - **Log Stream Name** – Type the KMS key identifier.
8. In the **Add ARN(s)** dialog box, choose **Add**.
9. Choose **Review policy**.
10. Set **Name** to a name for your IAM policy, for example AmazonRDSKMSKey. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
11. Choose **Create policy**.
12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).

## Creating an IAM role to allow Amazon Aurora to access Amazon services

After creating an IAM policy to allow Aurora to access Amazon resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other Amazon services on your behalf, take the following steps.

## To create an IAM role to allow Amazon RDS to access Amazon services

1. Open the [IAM console](#).
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Under **Amazon service**, choose **RDS**.

5. Under **Select your use case**, choose **RDS – Add Role to Database**.
6. Choose **Next**.
7. On the **Permissions policies** page, enter the name of your policy in the **Search** field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
  - [Creating an IAM policy to access Amazon S3 resources](#)
  - [Creating an IAM policy to access Amazon Lambda resources](#)
  - [Creating an IAM policy to access CloudWatch Logs resources](#)
  - [Creating an IAM policy to access Amazon KMS resources](#)
9. Choose **Next**.
10. In **Role name**, enter a name for your IAM role, for example RDSLoadFromS3. You can also add an optional **Description** value.
11. Choose **Create Role**.
12. Complete the steps in [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

## Associating an IAM role with an Amazon Aurora MySQL DB cluster

To permit database users in an Amazon Aurora DB cluster to access other Amazon services, you associate the IAM role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with that DB cluster. You can also have Amazon create a new IAM role by associating the service directly.

### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster. For more information, see [Using Amazon Aurora Serverless v1](#).

You can associate an IAM role with an Aurora Serverless v2 DB cluster.

To associate an IAM role with a DB cluster you do two things:

1. Add the role to the list of associated roles for a DB cluster by using the RDS console, the [add-role-to-db-cluster](#) Amazon CLI command, or the [AddRoleToDBCluster](#) RDS API operation.

You can add a maximum of five IAM roles for each Aurora DB cluster.

2. Set the cluster-level parameter for the related Amazon service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other Amazon services.

Cluster-level parameter	Description
<code>aws_default_lambda_role</code>	Used when invoking a Lambda function from your DB cluster.
<code>aws_default_logs_role</code>	This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about service-linked roles, see <a href="#">Using service-linked roles for Amazon Aurora</a> .
<code>aws_default_s3_role</code>	<p>Used when invoking the <code>LOAD DATA FROM S3</code>, <code>LOAD XML FROM S3</code>, or <code>SELECT INTO OUTFILE S3</code> statement from your DB cluster.</p> <p>In Aurora MySQL version 2, the IAM role specified in this parameter is used if an IAM role isn't specified for <code>aurora_load_from_s3_role</code> or <code>aurora_select_into_s3_role</code> for the appropriate statement.</p> <p>In Aurora MySQL version 3, the IAM role specified for this parameter is always used.</p>

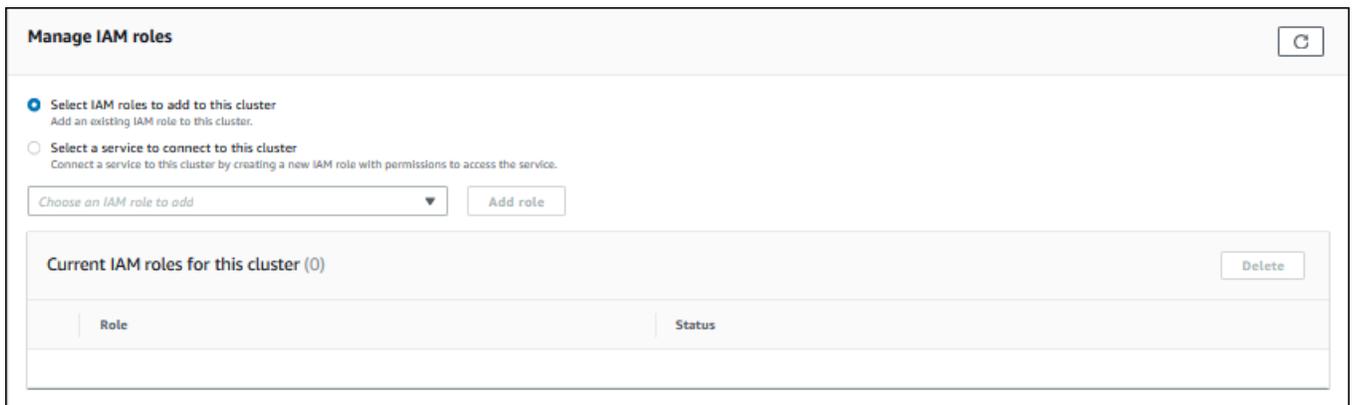

Cluster-level parameter	Description
aurora_load_from_s3_role	<p>Used when invoking the <code>LOAD DATA FROM S3</code> or <code>LOAD XML FROM S3</code> statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used.</p> <p>In Aurora MySQL version 3, this parameter isn't available.</p>
aurora_select_into_s3_role	<p>Used when invoking the <code>SELECT INTO OUTFILE S3</code> statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used.</p> <p>In Aurora MySQL version 3, this parameter isn't available.</p>

To associate an IAM role to permit your Amazon RDS cluster to communicate with other Amazon services on your behalf, take the following steps.

## Console

### To associate an IAM role with an Aurora DB cluster using the console

1. Open the RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the **Connectivity & security** tab, in the **Manage IAM roles** section, do one of the following:
  - **Select IAM roles to add to this cluster** (default)
  - **Select a service to connect to this cluster**

5. To use an existing IAM role, choose it from the menu, then choose **Add role**.

If adding the role is successful, its status shows as Pending, then Available.

6. To connect a service directly:
  - a. Choose **Select a service to connect to this cluster**.
  - b. Choose the service from the menu, then choose **Connect service**.
  - c. For **Connect cluster to *Service Name***, enter the Amazon Resource Name (ARN) to use to connect to the service, then choose **Connect service**.

Amazon creates a new IAM role for connecting to the service. Its status shows as Pending, then Available.

7. (Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and then choose **Delete**.

### To set the cluster-level parameter for the associated IAM role

1. In the RDS console, choose **Parameter groups** in the navigation pane.
2. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:
  - a. Choose **Create parameter group**.

- b. For **Parameter group family**, choose `aurora-mysql8.0` for an Aurora MySQL 8.0-compatible DB cluster, or `aurora-mysql5.7` for an Aurora MySQL 5.7-compatible DB cluster.
- c. For **Type**, choose **DB Cluster Parameter Group**.
- d. For **Group name**, type the name of your new DB cluster parameter group.
- e. For **Description**, type a description for your new DB cluster parameter group.

- f. Choose **Create**.
3. On the **Parameter groups** page, select your DB cluster parameter group and choose **Edit** for **Parameter group actions**.
  4. Set the appropriate cluster-level [parameters](#) to the related IAM role ARN values.

For example, you can set just the `aws_default_s3_role` parameter to `arn:aws-cn:iam::123456789012:role/AllowS3Access`.

5. Choose **Save changes**.
6. To change the DB cluster parameter group for your DB cluster, complete the following steps:
  - a. Choose **Databases**, and then choose your Aurora DB cluster.
  - b. Choose **Modify**.
  - c. Scroll to **Database options** and set **DB cluster parameter group** to the DB cluster parameter group.
  - d. Choose **Continue**.
  - e. Verify your changes and then choose **Apply immediately**.

- f. Choose **Modify cluster**.
- g. Choose **Databases**, and then choose the primary instance for your DB cluster.
- h. For **Actions**, choose **Reboot**.

When the instance has rebooted, your IAM role is associated with your DB cluster.

For more information about cluster parameter groups, see [Aurora MySQL configuration parameters](#).

## CLI

### To associate an IAM role with a DB cluster by using the Amazon CLI

1. Call the `add-role-to-db-cluster` command from the Amazon CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

```
PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws-cn:iam::123456789012:role/AllowAuroraS3Role
PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws-cn:iam::123456789012:role/AllowAuroraLambdaRole
```

2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the Amazon CLI, as shown following.

```
PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess \
--db-parameter-group-family aurora5.7 --description "Allow access to Amazon S3 and Amazon Lambda"
```

For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

```
PROMPT> aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name
AllowAWSAccess \
    --parameters "ParameterName=aws_default_s3_role,ParameterValue=arn:aws-
cn:iam::123456789012:role/AllowAuroraS3Role,method=pending-reboot" \
    --parameters "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws-
cn:iam::123456789012:role/AllowAuroraLambdaRole,method=pending-reboot"
```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

```
PROMPT> aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-
parameter-group-name AllowAWSAccess
PROMPT> aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

For more information about cluster parameter groups, see [Aurora MySQL configuration parameters](#).

## Enabling network communication from Amazon Aurora to other Amazon services

To use certain other Amazon services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- Invoking Amazon Lambda functions. To learn about this feature, see [Invoking a Lambda function with an Aurora MySQL native function](#).
- Accessing files from Amazon S3. To learn about this feature, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#) and [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).
- Accessing Amazon KMS endpoints. Amazon KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see [Monitoring Amazon Aurora with Database Activity Streams](#).
- Accessing SageMaker AI endpoints. SageMaker AI access is required to use SageMaker AI machine learning with Aurora MySQL. To learn about this feature, see [Using Amazon Aurora machine learning with Aurora MySQL](#).

Aurora returns the following error messages if it can't connect to a service endpoint.

```
ERROR 1871 (HY000): S3 API returned error: Network Connection
```

```
ERROR 1873 (HY000): Lambda API returned error: Network Connection. Unable to connect to endpoint
```

```
ERROR 1815 (HY000): Internal error: Unable to initialize S3Stream
```

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the Amazon KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding Amazon services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the Amazon Web Services Management Console, **Publicly Accessible** is **Yes** if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see [Working with a DB cluster in a VPC](#). For more information about public Amazon VPC subnets, see [Your VPC and subnets](#).

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker AI, and Amazon Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table, see [Working with a DB cluster in a VPC](#). For more information about configuring NAT in your VPC, see [NAT gateways](#). For more information about configuring VPC endpoints, see [VPC endpoints](#). You can also create an S3 gateway endpoint to access your S3 bucket. For more information, see [Gateway endpoints for Amazon S3](#).

You might also have to open the ephemeral ports for your network access control lists (ACLs) in the outbound rules for your VPC security group. For more information on ephemeral ports for network ACLs, see [Ephemeral ports](#) in the *Amazon Virtual Private Cloud User Guide*.

## Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement to load data from files stored in an Amazon S3 bucket. In Aurora MySQL, the files are first stored on the local disk, and then imported to the database. After the imports to the database are done, the local files are deleted.

### Note

Loading data into a table from text files isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

## Contents

    - [Verifying loaded files using the `aurora\_s3\_load\_history` table](#)
  - [Examples](#)
- [LOAD XML FROM S3](#)
  - [Syntax](#)
  - [Parameters](#)

## Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

### To give Aurora MySQL access to Amazon S3

1. Create an Amazon Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see [Creating an IAM policy to access Amazon S3 resources](#).

#### Note

In Aurora MySQL version 3.05 and higher, you can load objects that are encrypted using customer-managed Amazon KMS keys. To do so, include the `kms:Decrypt` permission in your IAM policy. For more information, see [Creating an IAM policy to access Amazon KMS resources](#).

You don't need this permission to load objects that are encrypted using Amazon managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon S3 resources](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).
3. Make sure the DB cluster is using a custom DB cluster parameter group.

For more information about creating a custom DB cluster parameter group, see [Creating a DB cluster parameter group in Amazon Aurora](#).

4. For Aurora MySQL version 2, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

For Aurora MySQL version 3, use `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters](#).

- To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).
- Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

If your DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You can create an S3 gateway endpoint to access your S3 bucket. For more information, see [Gateway endpoints for Amazon S3](#).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Granting privileges to load data in Amazon Aurora MySQL

The database user that issues the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the `AWS_LOAD_S3_ACCESS` role. In Aurora MySQL version 2, you grant the `LOAD FROM S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

### Tip

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model](#). For more details, see [Using roles](#) in the *MySQL Reference Manual*.

This only applies to the current active session. When you reconnect, you must run the SET ROLE statement again to grant privileges. For more information, see [SET ROLE statement](#) in the *MySQL Reference Manual*.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the SET ROLE statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the *MySQL Reference Manual*.

However, you must call SET ROLE ALL explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.

Use the following statement for Aurora MySQL version 2:

```
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_LOAD_S3_ACCESS` role and `LOAD FROM S3` privilege are specific to Amazon Aurora and are not available for external MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication source and a MySQL database as the replication client, then the GRANT statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL instance, use the [mysql\\_rds\\_skip\\_repl\\_error](#) procedure. To skip the error on an external MySQL database, use the [slave\\_skip\\_errors](#) system variable (Aurora MySQL version 2) or [replica\\_skip\\_errors](#) system variable (Aurora MySQL version 3).

### Note

The database user must have INSERT privileges for the database into which it's loading data.

## Specifying the path (URI) to an Amazon S3 bucket

The syntax for specifying the path (URI) to files stored on an Amazon S3 bucket is as follows.

```
s3-region://amzn-s3-demo-bucket/file-name-or-prefix
```

The path includes the following values:

- `region` (optional) – The Amazon Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a `region` value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.
- `bucket-name` – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.
- `file-name-or-prefix` – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see [Using a manifest to specify data files to load](#).

### To copy the URI for files in an S3 bucket

1. Sign in to the Amazon Web Services Management Console and open the Amazon S3 console at <https://console.amazonaws.cn/s3/>.
2. In the navigation pane, choose **Buckets**, and then choose the bucket whose URI you want to copy.
3. Select the prefix or file that you want to load from S3.
4. Choose **Copy S3 URI**.

## LOAD DATA FROM S3

You can use the `LOAD DATA FROM S3` statement to load data from any text file format that is supported by the MySQL [LOAD DATA INFILE](#) statement, such as text data that is comma-delimited. Compressed files are not supported.

### Note

Make sure that your Aurora MySQL DB cluster allows outbound connections to S3. For more information, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

## Syntax

```
LOAD DATA [FROM] S3 [FILE | PREFIX | MANIFEST] 'S3-URI'  
[REPLACE | IGNORE]
```

```

INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]

```

### Note

In Aurora MySQL version 3.05 and higher, the keyword FROM is optional.

## Parameters

The LOAD DATA FROM S3 statement uses the following required and optional parameters. You can find more details about some of these parameters in [LOAD DATA Statement](#) in the MySQL documentation.

### FILE | PREFIX | MANIFEST

Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. FILE is the default.

### S3-URI

Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in [Specifying the path \(URI\) to an Amazon S3 bucket](#).

### REPLACE | IGNORE

Determines what action to take if an input row has the same unique key values as an existing row in the database table.

- Specify REPLACE if you want the input row to replace the existing row in the table.

- Specify IGNORE if you want to discard the input row.

## INTO TABLE

Identifies the name of the database table to load the input rows into.

## PARTITION

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

## CHARACTER SET

Identifies the character set of the data in the input file.

## FIELDS | COLUMNS

Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.

## LINES

Identifies how the lines in the input file are delimited. Lines are delimited by a newline character ('`\n`') by default.

## IGNORE *number* LINES | ROWS

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names, or IGNORE 2 ROWS to skip over the first two rows of data in the input file. If you also use PREFIX, IGNORE skips a certain number of lines or rows at the start of the first input file.

## col\_name\_or\_user\_var, ...

Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of table1, and sets the value of the table\_column2 column in table1 to the input value of the second column divided by 100.

```
LOAD DATA FROM S3 's3://amzn-s3-demo-bucket/data.txt'
```

```
INTO TABLE table1
(column1, @var1)
SET table_column2 = @var1/100;
```

## SET

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```
LOAD DATA FROM S3 's3://amzn-s3-demo-bucket/data.txt'
INTO TABLE table1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You can't use the LOCAL keyword of the LOAD DATA FROM S3 statement if you're loading data from an Amazon S3 bucket.

### Using a manifest to specify data files to load

You can use the LOAD DATA FROM S3 statement with the MANIFEST keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster.

The following JSON schema describes the format and content of a manifest file.

```
{
  "$schema": "http://json-schema.org/draft-04/schema#",
  "additionalProperties": false,
  "definitions": {},
  "id": "Aurora_LoadFromS3_Manifest",
  "properties": {
    "entries": {
      "additionalItems": false,
```

```

    "id": "/properties/entries",
    "items": {
      "additionalProperties": false,
      "id": "/properties/entries/items",
      "properties": {
        "mandatory": {
          "default": "false",
          "id": "/properties/entries/items/properties/mandatory",
          "type": "boolean"
        },
        "url": {
          "id": "/properties/entries/items/properties/url",
          "maxLength": 1024,
          "minLength": 1,
          "type": "string"
        }
      },
      "required": [
        "url"
      ],
      "type": "object"
    },
    "type": "array",
    "uniqueItems": true
  }
},
"required": [
  "entries"
],
"type": "object"
}

```

Each `url` in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```

{
  "entries": [
    {
      "url": "s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory": true
    }
  ]
}

```

```
  },
  {
    "url": "s3-us-west-2://aurora-bucket-usw2/2013-10-05-customerdata",
    "mandatory": true
  },
  {
    "url": "s3://aurora-bucket/2013-10-04-customerdata",
    "mandatory": false
  },
  {
    "url": "s3://aurora-bucket/2013-10-05-customerdata"
  }
]
}
```

The optional `mandatory` flag specifies whether `LOAD DATA FROM S3` should return an error if the file is not found. The `mandatory` flag defaults to `false`. Regardless of how `mandatory` is set, `LOAD DATA FROM S3` terminates if no files are found.

Manifest files can have any extension. The following example runs the `LOAD DATA FROM S3` statement with the manifest in the previous example, which is named **customer.manifest**.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
  INTO TABLE CUSTOMER
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (ID, FIRSTNAME, LASTNAME, EMAIL);
```

After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

### Verifying loaded files using the `aurora_s3_load_history` table

Every successful `LOAD DATA FROM S3` statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the `LOAD DATA FROM S3` statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the statement, use the `WHERE` clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the `timestamp` field.

```
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

Field	Description
<code>load_prefix</code>	<p>The URI that was specified in the load statement. This URI can map to any of the following:</p> <ul style="list-style-type: none"> <li>• A single data file for a <code>LOAD DATA FROM S3 FILE</code> statement</li> <li>• An Amazon S3 prefix that maps to multiple data files for a <code>LOAD DATA FROM S3 PREFIX</code> statement</li> <li>• A single manifest file that contains the names of files to be loaded for a <code>LOAD DATA FROM S3 MANIFEST</code> statement</li> </ul>
<code>file_name</code>	The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the <code>load_prefix</code> field.
<code>version_number</code>	The version number of the file identified by the <code>file_name</code> field that was loaded, if the Amazon S3 bucket has a version number.
<code>bytes_loaded</code>	The size of the file loaded, in bytes.
<code>load_timestamp</code>	The timestamp when the <code>LOAD DATA FROM S3</code> statement completed.

## Examples

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `amzn-s3-demo-bucket` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`.

```
LOAD DATA FROM S3 's3://amzn-s3-demo-bucket/customerdata.csv'
  INTO TABLE store-schema.customer-table
  FIELDS TERMINATED BY ','
```

```

LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);

```

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the `employee-data` object prefix in the *amzn-s3-demo-bucket* Amazon S3 bucket in the `us-west-2` region, and then loads the data into the `employees` table.

```

LOAD DATA FROM S3 PREFIX 's3-us-west-2://amzn-s3-demo-bucket/employee_data'
  INTO TABLE employees
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);

```

The following statement loads data from the files specified in a JSON manifest file named `q1_sales.json` into the `sales` table.

```

LOAD DATA FROM S3 MANIFEST 's3-us-west-2://amzn-s3-demo-bucket1/q1_sales.json'
  INTO TABLE sales
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (MONTH, STORE, GROSS, NET);

```

## LOAD XML FROM S3

You can use the `LOAD XML FROM S3` statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a `<row>` element. The attribute value identifies the contents of the table field.

```
<row column1="value1" column2="value2" .../>
```

- Column names as child elements of a `<row>` element. The value of the child element identifies the contents of the table field.

```

<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>

```

- Column names in the name attribute of `<field>` elements in a `<row>` element. The value of the `<field>` element identifies the contents of the table field.

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

## Syntax

```
LOAD XML FROM S3 'S3-URI'
  [REPLACE | IGNORE]
  INTO TABLE tbl_name
  [PARTITION (partition_name,...)]
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<element-name>']
  [IGNORE number {LINES | ROWS}]
  [(field_name_or_user_var,...)]
  [SET col_name = expr,...]
```

## Parameters

The `LOAD XML FROM S3` statement uses the following required and optional parameters. You can find more details about some of these parameters in [LOAD XML Statement](#) in the MySQL documentation.

### FILE | PREFIX

Identifies whether to load the data from a single file, or from all files that match a given prefix. `FILE` is the default.

### REPLACE | IGNORE

Determines what action to take if an input row has the same unique key values as an existing row in the database table.

- Specify `REPLACE` if you want the input row to replace the existing row in the table.
- Specify `IGNORE` if you want to discard the input row. `IGNORE` is the default.

### INTO TABLE

Identifies the name of the database table to load the input rows into.

## PARTITION

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

## CHARACTER SET

Identifies the character set of the data in the input file.

## ROWS IDENTIFIED BY

Identifies the element name that identifies a row in the input file. The default is <row>.

## IGNORE *number* LINES | ROWS

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use `IGNORE 1 LINES` to skip over the first line in the text file, or `IGNORE 2 ROWS` to skip over the first two rows of data in the input XML.

## field\_name\_or\_user\_var, ...

Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose must match the name of an element from the XML file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.

```
LOAD XML FROM S3 's3://amzn-s3-demo-bucket/data.xml'  
  INTO TABLE table1  
  (column1, @var1)  
  SET table_column2 = @var1/100;
```

## SET

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```
LOAD XML FROM S3 's3://amzn-s3-demo-bucket/data.xml'  
  INTO TABLE table1  
  (column1, column2)  
  SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you can't use a subquery to select from the table that's being loaded.

## Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket

You can use the `SELECT INTO OUTFILE S3` statement to query data from an Amazon Aurora MySQL DB cluster and save it into text files stored in an Amazon S3 bucket. In Aurora MySQL, the files are first stored on the local disk, and then exported to S3. After the exports are done, the local files are deleted.

You can encrypt the Amazon S3 bucket using an Amazon S3 managed key (SSE-S3) or Amazon KMS key (SSE-KMS: Amazon managed key or customer managed key).

The `LOAD DATA FROM S3` statement can use files created by the `SELECT INTO OUTFILE S3` statement to load data into an Aurora DB cluster. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).

### Note

This feature isn't supported for Aurora Serverless v1 DB clusters. It is supported for Aurora Serverless v2 DB clusters.

You can also save DB cluster data and DB cluster snapshot data to Amazon S3 using the Amazon Web Services Management Console, Amazon CLI, or Amazon RDS API. For more information, see [Exporting DB cluster data to Amazon S3](#) and [Exporting DB cluster snapshot data to Amazon S3](#).

## Contents

- [Giving Aurora MySQL access to Amazon S3](#)
- [Granting privileges to save data in Aurora MySQL](#)

- [Specifying a path to an Amazon S3 bucket](#)
- [Creating a manifest to list data files](#)
- [SELECT INTO OUTFILE S3](#)
  - [Syntax](#)
  - [Parameters](#)
  - [Considerations](#)
  - [Examples](#)

## Giving Aurora MySQL access to Amazon S3

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

### To give Aurora MySQL access to Amazon S3

1. Create an Amazon Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see [Creating an IAM policy to access Amazon S3 resources](#).

#### Note

In Aurora MySQL version 3.05 and higher, you can encrypt objects using Amazon KMS customer managed keys. To do so, include the `kms:GenerateDataKey` permission in your IAM policy. For more information, see [Creating an IAM policy to access Amazon KMS resources](#).

You don't need this permission to encrypt objects using Amazon managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon S3 resources](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).
3. For Aurora MySQL version 2, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

For Aurora MySQL version 3, use `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters](#).

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with the DB cluster.

For an Aurora global database, associate the role with each Aurora cluster in the global database.

For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Granting privileges to save data in Aurora MySQL

The database user that issues the `SELECT INTO OUTFILE S3` statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the `AWS_SELECT_S3_ACCESS` role. In Aurora MySQL version 2, you grant the `SELECT INTO S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model](#). For more details, see [Using roles](#) in the *MySQL Reference Manual*.

This only applies to the current active session. When you reconnect, you must run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the *MySQL Reference Manual*.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the *MySQL Reference Manual*.

However, you must call `SET ROLE ALL` explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.

Use the following statement for Aurora MySQL version 2:

```
GRANT SELECT INTO S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_SELECT_S3_ACCESS` role and `SELECT INTO S3` privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication source and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the [mysql\\_rds\\_skip\\_repl\\_error](#) procedure. To skip the error on an external MySQL database, use the [slave\\_skip\\_errors](#) system variable (Aurora MySQL version 2) or [replica\\_skip\\_errors](#) system variable (Aurora MySQL version 3).

## Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the `LOAD DATA FROM S3 PREFIX` statement, as shown following.

```
s3-region://bucket-name/file-prefix
```

The path includes the following values:

- `region` (optional) – The Amazon Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a `region` value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- `bucket-name` – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- `file-prefix` – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the `SELECT INTO OUTFILE S3` statement use the following path, in which `00000` represents a 5-digit, zero-based integer number.

```
s3-region://bucket-name/file-prefix.part_00000
```

For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.

- `s3-us-west-2://bucket/prefix.part_00000`
- `s3-us-west-2://bucket/prefix.part_00001`
- `s3-us-west-2://bucket/prefix.part_00002`

## Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see [Using a manifest to specify data files to load](#).

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```
{
```

```

"entries": [
  {
    "url": "s3-us-west-2://bucket/prefix.part_00000"
  },
  {
    "url": "s3-us-west-2://bucket/prefix.part_00001"
  },
  {
    "url": "s3-us-west-2://bucket/prefix.part_00002"
  }
]
}

```

## SELECT INTO OUTFILE S3

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket.

Compressed files aren't supported. Encrypted files are supported starting in Aurora MySQL version 2.09.0.

### Syntax

```

SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
  [PARTITION partition_list]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT [{offset,} row_count | row_count OFFSET offset]}]
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[export_options]
[MANIFEST {ON | OFF}]

```

```

[OVERWRITE {ON | OFF}]
[ENCRYPTION {ON | OFF | SSE_S3 | SSE_KMS ['cmk_id']}]

export_options:
[FORMAT {CSV|TEXT} [HEADER]]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
]

```

## Parameters

The SELECT INTO OUTFILE S3 statement uses the following required and optional parameters that are specific to Aurora.

### s3-uri

Specifies the URI for an Amazon S3 prefix to use. Use the syntax described in [Specifying a path to an Amazon S3 bucket](#).

### FORMAT {CSV|TEXT} [HEADER]

Optionally saves the data in CSV format.

The TEXT option is the default and produces the existing MySQL export format.

The CSV option produces comma-separated data values. The CSV format follows the specification in [RFC-4180](#). If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with Amazon ML services. For more information about using exported Aurora data with Amazon ML services, see [Exporting data to Amazon S3 for SageMaker AI model training \(Advanced\)](#).

### MANIFEST {ON | OFF}

Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the

LOAD DATA FROM S3 MANIFEST statement. For more information about LOAD DATA FROM S3 MANIFEST, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).

If MANIFEST ON is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

```
s3-region://bucket-name/file-prefix.manifest
```

For more information about the format of the manifest file's contents, see [Creating a manifest to list data files](#).

### OVERWRITE {ON | OFF}

Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If OVERWRITE ON is specified, existing files that match the file prefix in the URI specified in s3-uri are overwritten. Otherwise, an error occurs.

### ENCRYPTION {ON | OFF | SSE\_S3 | SSE\_KMS ['cmk\_id']}

Indicates whether to use server-side encryption with Amazon S3 managed keys (SSE-S3) or Amazon KMS keys (SSE-KMS, including Amazon managed keys and customer managed keys). The SSE\_S3 and SSE\_KMS settings are available in Aurora MySQL version 3.05 and higher.

You can also use the aurora\_select\_into\_s3\_encryption\_default session variable instead of the ENCRYPTION clause, as shown in the following example. Use either the SQL clause or the session variable, but not both.

```
set session set session aurora_select_into_s3_encryption_default={ON | OFF | SSE_S3 | SSE_KMS};
```

The SSE\_S3 and SSE\_KMS settings are available in Aurora MySQL version 3.05 and higher.

When you set aurora\_select\_into\_s3\_encryption\_default to the following value:

- OFF – The default encryption policy of the S3 bucket is followed. The default value of aurora\_select\_into\_s3\_encryption\_default is OFF.
- ON or SSE\_S3 – The S3 object is encrypted using Amazon S3 managed keys (SSE-S3).
- SSE\_KMS – The S3 object is encrypted using an Amazon KMS key.

In this case, you also include the session variable `aurora_s3_default_cmk_id`, for example:

```
set session aurora_select_into_s3_encryption_default={SSE_KMS};
set session aurora_s3_default_cmk_id={NULL | 'cmk_id'};
```

- When `aurora_s3_default_cmk_id` is `NULL`, the S3 object is encrypted using an Amazon managed key.
- When `aurora_s3_default_cmk_id` is a nonempty string `cmk_id`, the S3 object is encrypted using a customer managed key.

The value of `cmk_id` can't be an empty string.

When you use the `SELECT INTO OUTFILE S3` command, Aurora determines the encryption as follows:

- If the `ENCRYPTION` clause is present in the SQL command, Aurora relies only on the value of `ENCRYPTION`, and doesn't use a session variable.
- If the `ENCRYPTION` clause isn't present, Aurora relies on the value of the session variable.

For more information, see [Using server-side encryption with Amazon S3 managed keys \(SSE-S3\)](#) and [Using server-side encryption with Amazon KMS keys \(SSE-KMS\)](#) in the *Amazon Simple Storage Service User Guide*.

You can find more details about other parameters in [SELECT statement](#) and [LOAD DATA statement](#), in the MySQL documentation.

## Considerations

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the `SELECT INTO OUTFILE S3` statement and the file size threshold for Aurora MySQL. The default file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the file size threshold results in a row being split across two

data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.

- Because each `SELECT` statement in Aurora MySQL runs as an atomic transaction, a `SELECT INTO OUTFILE S3` statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.
- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple `SELECT INTO OUTFILE S3` statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different `file_prefix` in the `s3-uri` parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.
- If multiple `SELECT INTO OUTFILE S3` statements that use the same `file_prefix` in the `s3-uri` parameter run in parallel to select data into Amazon S3, the behavior is undefined.
- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.
- In some cases, you might re-run a `SELECT INTO OUTFILE S3` query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in `s3-uri`, or include `OVERWRITE ON` in the `SELECT INTO OUTFILE S3` query.

The `SELECT INTO OUTFILE S3` statement returns a typical MySQL error number and response on success or failure. If you don't have access to the MySQL error number and response, the easiest way to determine when it's done is by specifying `MANIFEST ON` in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there's no way to directly monitor the progress of the `SELECT INTO OUTFILE S3` statement while it runs. However, suppose that you're writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the

statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

## Examples

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (`\n`) character. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/
sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n';
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (`\n`) character, and also a manifest file. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/
sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    MANIFEST ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (`\n`) character. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/
sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
OVERWRITE ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/
sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    MANIFEST ON
OVERWRITE ON;
```

## Invoking a Lambda function from an Amazon Aurora MySQL DB cluster

You can invoke an Amazon Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see [Giving Aurora access to Lambda](#). For information about the `lambda_sync` and `lambda_async` stored functions, see [Invoking a Lambda function with an Aurora MySQL native function](#).

You can also call an Amazon Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 2, for MySQL 5.7-compatible clusters.
- Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure isn't available in Aurora MySQL version 3.

For information about giving Aurora access to Lambda and invoking a Lambda function, see the following topics.

## Topics

- [Giving Aurora access to Lambda](#)
- [Invoking a Lambda function with an Aurora MySQL native function](#)
- [Invoking a Lambda function with an Aurora MySQL stored procedure \(deprecated\)](#)

## Giving Aurora access to Lambda

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.

### To give Aurora MySQL access to Lambda

1. Create an Amazon Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see [Creating an IAM policy to access Amazon Lambda resources](#).
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon Lambda resources](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access Amazon services](#).
3. Set the `aws_default_lambda_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters](#).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with the DB cluster. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

## Invoking a Lambda function with an Aurora MySQL native function

### Note

You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL version 2, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL](#).

You can invoke an Amazon Lambda function from an Aurora MySQL DB cluster by calling the native functions `lambda_sync` and `lambda_async`. This approach can be useful when you want to integrate your database running on Aurora MySQL with other Amazon services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

### Contents

- [Working with native functions to invoke a Lambda function](#)
  - [Granting the role in Aurora MySQL version 3](#)
  - [Granting the privilege in Aurora MySQL version 2](#)
  - [Syntax for the `lambda\_sync` function](#)
  - [Parameters for the `lambda\_sync` function](#)
  - [Example for the `lambda\_sync` function](#)
  - [Syntax for the `lambda\_async` function](#)
  - [Parameters for the `lambda\_async` function](#)
  - [Example for the `lambda\_async` function](#)
  - [Invoking a Lambda function within a trigger](#)

## Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don't need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

### Granting the role in Aurora MySQL version 3

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT AWS_LAMBDA_ACCESS TO user@domain-or-ip-address
```

You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```

#### Tip

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model](#). For more details, see [Using roles](#) in the *MySQL Reference Manual*.

This only applies to the current active session. When you reconnect, you must run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the *MySQL Reference Manual*.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate\\_all\\_roles\\_on\\_login](#) in the *MySQL Reference Manual*.

However, you must call `SET ROLE ALL` explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.

If you get an error such as the following when you try to invoke a Lambda function, then run a SET ROLE statement.

```
SQL Error [1227] [42000]: Access denied; you need (at least one of) the Invoke Lambda privilege(s) for this operation
```

Make sure that you're granting the role to the correct user, as shown in the `mysql.users` table entries. There might be multiple users with the same name, but on different hosts. Depending on which application or host is invoking the `lambda_sync` function, MySQL selects the user with the best match according to the host column entries.

## Granting the privilege in Aurora MySQL version 2

In Aurora MySQL version 2, the user invoking a native function must be granted the INVOKE LAMBDA privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT INVOKE LAMBDA ON *.* TO user@domain-or-ip-address
```

You can revoke this privilege by running the following statement.

```
REVOKE INVOKE LAMBDA ON *.* FROM user@domain-or-ip-address
```

## Syntax for the `lambda_sync` function

You invoke the `lambda_sync` function synchronously with the `RequestResponse` invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_sync (  
  lambda_function_ARN,  
  JSON_payload  
)
```

## Parameters for the `lambda_sync` function

The `lambda_sync` function has the following parameters.

### *lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

## *JSON\_payload*

The payload for the invoked Lambda function, in JSON format.

### Note

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

## Example for the `lambda_sync` function

The following query based on `lambda_sync` invokes the Lambda function `BasicTestLambda` synchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```
SELECT lambda_sync(  
    'arn:aws-cn:lambda:us-east-1:123456789012:function:BasicTestLambda',  
    '{"operation": "ping"}');
```

## Syntax for the `lambda_async` function

You invoke the `lambda_async` function asynchronously with the Event invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_async (  
    lambda_function_ARN,  
    JSON_payload  
)
```

## Parameters for the `lambda_async` function

The `lambda_async` function has the following parameters.

### *lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

### *JSON\_payload*

The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

**Example for the lambda\_async function**

The following query based on `lambda_async` invokes the Lambda function `BasicTestLambda` asynchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```
SELECT lambda_async(  
    'arn:aws-cn:lambda:us-east-1:123456789012:function:BasicTestLambda',  
    '{"operation": "ping"}');
```

**Invoking a Lambda function within a trigger**

You can use triggers to call Lambda on data-modifying statements. The following example uses the `lambda_async` native function and stores the result in a variable.

```
mysql>SET @result=0;  
mysql>DELIMITER //  
mysql>CREATE TRIGGER myFirstTrigger  
    AFTER INSERT  
    ON Test_trigger FOR EACH ROW  
    BEGIN  
    SELECT lambda_async(  
        'arn:aws-cn:lambda:us-east-1:123456789012:function:BasicTestLambda',  
        '{"operation": "ping"}')  
    INTO @result;  
    END; //  
mysql>DELIMITER ;
```

**Note**

Triggers aren't run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes.

Be careful when invoking an Amazon Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your Amazon Lambda function.

## Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an Amazon Lambda function from an Aurora MySQL DB cluster by calling the `mysql.lambda_async` procedure. This approach can be useful when you want to integrate your database running on Aurora MySQL with other Amazon services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

### Contents

- [Aurora MySQL version considerations](#)
- [Working with the `mysql.lambda\_async` procedure to invoke a Lambda function \(deprecated\)](#)
  - [Syntax](#)
  - [Parameters](#)
  - [Examples](#)

### Aurora MySQL version considerations

Starting in Aurora MySQL version 2, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see [Working with native functions to invoke a Lambda function](#).

In Aurora MySQL version 2, the stored procedure `mysql.lambda_async` is no longer supported. We strongly recommend that you work with native Lambda functions instead.

In Aurora MySQL version 3, the stored procedure isn't available.

### Working with the `mysql.lambda_async` procedure to invoke a Lambda function (deprecated)

The `mysql.lambda_async` procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have EXECUTE privilege on the `mysql.lambda_async` stored procedure.

## Syntax

The `mysql.lambda_async` procedure has the following syntax.

```
CALL mysql.lambda_async (  
    lambda_function_ARN,  
    lambda_function_input  
)
```

## Parameters

The `mysql.lambda_async` procedure has the following parameters.

*lambda\_function\_ARN*

The Amazon Resource Name (ARN) of the Lambda function to invoke.

*lambda\_function\_input*

The input string, in JSON format, for the invoked Lambda function.

## Examples

As a best practice, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.

### Note

Be careful when invoking an Amazon Lambda function from triggers on tables that experience high write traffic. `INSERT`, `UPDATE`, and `DELETE` triggers are activated per row. A write-heavy workload on a table with `INSERT`, `UPDATE`, or `DELETE` triggers results in a large number of calls to your Amazon Lambda function.

Although calls to the `mysql.lambda_async` procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn't wait for the call to the Amazon Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

## Example Example: Invoke an Amazon Lambda function to send email

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

### Amazon Lambda Function

```
import boto3

ses = boto3.client('ses')

def SES_send_email(event, context):

    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [
                event['email_to'],
            ]
        },

        Message={
            'Subject': {
                'Data': event['email_subject']
            },
            'Body': {
                'Text': {
                    'Data': event['email_body']
                }
            }
        }
    )
```

### Stored Procedure

```
DROP PROCEDURE IF EXISTS SES_send_email;
DELIMITER ;;
CREATE PROCEDURE SES_send_email(IN email_from VARCHAR(255),
                                IN email_to VARCHAR(255),
                                IN subject VARCHAR(255),
                                IN body TEXT) LANGUAGE SQL
BEGIN
    CALL mysql.lambda_async(
```

```

        'arn:aws-cn:lambda:us-west-2:123456789012:function:SES_send_email',
        CONCAT('{ "email_to" : "', email_to,
              '", "email_from" : "', email_from,
              '", "email_subject" : "', subject,
              '", "email_body" : "', body, '"}')
    );
END
;;
DELIMITER ;

```

## Call the Stored Procedure to Invoke the Amazon Lambda Function

```
mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email
subject', 'Email content');
```

### Example Example: Invoke an Amazon Lambda function to publish an event from a trigger

The following example creates a stored procedure that publishes an event by using Amazon SNS. The code calls the procedure from a trigger when a row is added to a table.

#### Amazon Lambda Function

```
import boto3

sns = boto3.client('sns')

def SNS_publish_message(event, context):

    return sns.publish(
        TopicArn='arn:aws-cn:sns:us-west-2:123456789012:Sample_Topic',
        Message=event['message'],
        Subject=event['subject'],
        MessageStructure='string'
    )

```

#### Stored Procedure

```

DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
                                     IN message TEXT) LANGUAGE SQL
BEGIN

```

```
CALL mysql.lambda_async('arn:aws-cn:lambda:us-
west-2:123456789012:function:SNS_publish_message',
    CONCAT('{ "subject" : "', subject,
            '", "message" : "', message, '" }')
    );
END
;;
DELIMITER ;
```

## Table

```
CREATE TABLE 'Customer_Feedback' (
  'id' int(11) NOT NULL AUTO_INCREMENT,
  'customer_name' varchar(255) NOT NULL,
  'customer_feedback' varchar(1024) NOT NULL,
  PRIMARY KEY ('id')
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

## Trigger

```
DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
  AFTER INSERT ON Customer_Feedback
  FOR EACH ROW
  BEGIN
    SELECT CONCAT('New customer feedback from ', NEW.customer_name),
    NEW.customer_feedback INTO @subject, @feedback;
    CALL SNS_Publish_Message(@subject, @feedback);
  END
;;
DELIMITER ;
```

## Insert a Row into the Table to Trigger the Notification

```
mysql> insert into Customer_Feedback (customer_name, customer_feedback) VALUES ('Sample
Customer', 'Good job guys!');
```

## Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-

time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see [Selecting general query and slow query log output destinations](#) in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see [Enabling Advanced Auditing](#).

### Note

- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs, depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the Amazon CLI, or the CloudWatch Logs API.
- An alternative way to publish audit logs to CloudWatch Logs is by enabling Advanced Auditing, then creating a custom DB cluster parameter group and setting the `server_audit_logs_upload` parameter to 1. The default for the `server_audit_logs_upload` DB cluster parameter is 0. For information on enabling Advanced Auditing, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the `aws_default_logs_role` cluster-level parameter to the ARN for this role. For information about creating the role, see [Setting up IAM roles to access Amazon services](#). However, if you have the `AWSServiceRoleForRDS` service-linked role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information about service-linked roles for Amazon RDS, see [Using service-linked roles for Amazon Aurora](#).

- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the Amazon Web Services Management Console, the Amazon CLI, the RDS API, and the `server_audit_logs_upload` parameter.
- The procedure is slightly different for Aurora Serverless v1 DB clusters than for DB clusters with provisioned or Aurora Serverless v2 DB instances. Aurora Serverless v1

clusters automatically upload all of the logs that you enable through configuration parameters.

Therefore, you turn on or turn off log upload for Aurora Serverless v1 DB clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself through the Amazon Web Services Management Console, Amazon CLI, or RDS API. For information about turning on and off MySQL logs for Aurora Serverless v1 clusters, see [Parameter groups for Aurora Serverless v1](#).

## Console

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

### To publish Aurora MySQL logs from the console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.
4. Choose **Modify**.
5. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
6. Choose **Continue**, and then choose **Modify DB Cluster** on the summary page.

## Amazon CLI

You can publish Aurora MySQL logs for provisioned clusters with the Amazon CLI. To do so, you run the [modify-db-cluster](#) Amazon CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following Amazon CLI commands:

- [create-db-cluster](#)
- [restore-db-cluster-from-s3](#)

- [restore-db-cluster-from-snapshot](#)
- [restore-db-cluster-to-point-in-time](#)

Run one of these Amazon CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the Amazon CLI command that you run.

### Example

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":  
["error","general","slowquery","audit","instance"]}'
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":  
["error","general","slowquery","audit","instance"]}'
```

### Example

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --engine aurora \  
  --enable-cloudwatch-logs-exports  
'["error","general","slowquery","audit","instance"]'
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --engine aurora ^  
  --enable-cloudwatch-logs-exports  
'["error","general","slowquery","audit","instance"]'
```

## RDS API

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the [ModifyDBCluster](#) operation with the following options:

- `DBClusterIdentifier`—The DB cluster identifier.
- `CloudwatchLogsExportConfiguration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- [CreateDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

Run the RDS API operation with the following parameters:

- `DBClusterIdentifier`—The DB cluster identifier.
- `Engine`—The database engine.

- `EnableCloudwatchLogsExports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the Amazon CLI command that you run.

## Monitoring log events in Amazon CloudWatch

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which *cluster-name* represents the DB cluster name, and *log\_type* represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, if you configure the export function to include the slow query log for a DB cluster named `mydbcluster`, slow query data is stored in the `/aws/rds/cluster/mydbcluster/slowquery` log group.

The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

- A log group with the specified name exists.

Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as Amazon CloudFormation.

- A log group with the specified name doesn't exist.

When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of **Never Expire**.

To change the log retention period, use the CloudWatch Logs console, the Amazon CLI, or the CloudWatch Logs API. For more information about changing log retention periods in CloudWatch Logs, see [Change log data retention in CloudWatch Logs](#).

To search for information within the log events for a DB cluster, use the CloudWatch Logs console, the Amazon CLI, or the CloudWatch Logs API. For more information about searching and filtering log data, see [Searching and filtering log data](#).

# Amazon Aurora MySQL lab mode

## Important

Lab mode was introduced in Aurora MySQL version 2 to enable the [Fast DDL](#) optimization, which improved the efficiency of certain DDL operations. In Aurora MySQL version 3, lab mode has been removed, and Fast DDL has been replaced by the MySQL 8.0 feature called [Instant DDL](#).

Aurora lab mode is used to enable Aurora features that are available in the current Aurora database version, but are not enabled by default. While Aurora lab mode features are not recommended for use in production DB clusters, you can use Aurora lab mode to enable these features for DB clusters in your development and test environments. For more information about Aurora features available when Aurora lab mode is enabled, see [Aurora lab mode features](#).

The `aurora_lab_mode` parameter is an instance-level parameter that is in the default parameter group. The parameter is set to 0 (disabled) in the default parameter group. To enable Aurora lab mode, create a custom parameter group, set the `aurora_lab_mode` parameter to 1 (enabled) in the custom parameter group, and modify one or more DB instances in your Aurora cluster to use the custom parameter group. Then connect to the appropriate instance endpoint to try the lab mode features. For information on modifying a DB parameter group, see [Modifying parameters in a DB parameter group in Amazon Aurora](#). For information on parameter groups and Amazon Aurora, see [Aurora MySQL configuration parameters](#).

## Aurora lab mode features

The following Aurora feature is currently available when Aurora lab mode is enabled. You must enable Aurora lab mode before any of these features can be used.

### Fast DDL

This feature allows you to run an `ALTER TABLE tbl_name ADD COLUMN col_name column_definition` operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Because it doesn't consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.

Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. For more information about using this feature, see [Altering tables in Amazon Aurora using Fast DDL](#).

# Best practices with Amazon Aurora MySQL

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora MySQL DB cluster. The information in this topic summarizes and reiterates some of the guidelines and procedures that you can find in [Managing an Amazon Aurora DB cluster](#).

## Determining which DB instance you are connected to

To determine which DB instance in an Aurora MySQL DB cluster a connection is connected to, check the `innodb_read_only` global variable, as shown in the following example.

```
SHOW GLOBAL VARIABLES LIKE 'innodb_read_only';
```

The `innodb_read_only` variable is set to ON if you are connected to a reader DB instance. This setting is OFF if you are connected to a writer DB instance, such as primary instance in a provisioned cluster.

This approach can be helpful if you want to add logic to your application code to balance the workload or to ensure that a write operation is using the correct connection.

## Best practices for Aurora MySQL performance and scaling

You can apply the following best practices to improve the performance and scalability of your Aurora MySQL clusters.

### Topics

- [Using T instance classes for development and testing](#)
- [Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch](#)
- [Optimizing large Aurora MySQL join queries with hash joins](#)
- [Using Amazon Aurora to scale reads for your MySQL database](#)
- [Optimizing timestamp operations](#)
- [Virtual index ID overflow errors](#)

## Using T instance classes for development and testing

Amazon Aurora MySQL instances that use the `db.t2`, `db.t3`, or `db.t4g` DB instance classes are best suited for applications that do not support a high workload for an extended amount of time. The T instances are designed to provide moderate baseline performance and the capability to burst to significantly higher performance as required by your workload. They are intended for workloads

that don't use the full CPU often or consistently, but occasionally need to burst. We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Burstable performance instances](#).

If your Aurora cluster is larger than 40 TB, don't use the T instance classes. When your database has a large volume of data, the memory overhead for managing schema objects can exceed the capacity of a T instance.

Don't enable the MySQL Performance Schema on Amazon Aurora MySQL T instances. If the Performance Schema is enabled, the instance might run out of memory.

 **Tip**

If your database is sometimes idle but at other times has a substantial workload, you can use Aurora Serverless v2 as an alternative to T instances. With Aurora Serverless v2, you define a capacity range and Aurora automatically scales your database up or down depending on the current workload. For usage details, see [Using Aurora Serverless v2](#). For the database engine versions that you can use with Aurora Serverless v2, see [Requirements and limitations for Aurora Serverless v2](#).

When you use a T instance as a DB instance in an Aurora MySQL DB cluster, we recommend the following:

- Use the same DB instance class for all instances in your DB cluster. For example, if you use `db.t2.medium` for your writer instance, then we recommend that you use `db.t2.medium` for your reader instances also.
- Don't adjust any memory-related configuration settings, such as `innodb_buffer_pool_size`. Aurora uses a highly tuned set of default values for memory buffers on T instances. These special defaults are needed for Aurora to run on memory-constrained instances. If you change any memory-related settings on a T instance, you are much more likely to encounter out-of-memory conditions, even if your change is intended to increase buffer sizes.
- Monitor your CPU Credit Balance (`CPUCreditBalance`) to ensure that it is at a sustainable level. That is, CPU credits are being accumulated at the same rate as they are being used.

When you have exhausted the CPU credits for an instance, you see an immediate drop in the available CPU and an increase in the read and write latency for the instance. This situation results in a severe decrease in the overall performance of the instance.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

For more information on monitoring metrics, see [Viewing metrics in the Amazon RDS console](#).

- Monitor the replica lag (AuroraReplicaLag) between the writer instance and the reader instances.

If a reader instance runs out of CPU credits before the writer instance does, the resulting lag can cause the reader instance to restart frequently. This result is common when an application has a heavy load of read operations distributed among reader instances, at the same time that the writer instance has a minimal load of write operations.

If you see a sustained increase in replica lag, make sure that your CPU credit balance for the reader instances in your DB cluster is not being exhausted.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

- Keep the number of inserts per transaction below 1 million for DB clusters that have binary logging enabled.

If the DB cluster parameter group for your DB cluster has the `binlog_format` parameter set to a value other than `OFF`, then your DB cluster might experience out-of-memory conditions if the DB cluster receives transactions that contain over 1 million rows to insert. You can monitor the freeable memory (`FreeableMemory`) metric to determine if your DB cluster is running out of available memory. You then check the write operations (`VolumeWriteIOPS`) metric to see if a writer instance is receiving a heavy load of write operations. If this is the case, then we recommend that you update your application to limit the number of inserts in a transaction to less than 1 million. Alternatively, you can modify your instance to use one of the supported R DB instance classes (scale compute).

## Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch

Aurora MySQL can use the asynchronous key prefetch (AKP) feature to improve the performance of queries that join tables across indexes. This feature improves performance by anticipating the rows needed to run queries in which a JOIN query requires use of the Batched Key Access (BKA) Join algorithm and Multi-Range Read (MRR) optimization features. For more information about BKA

and MRR, see [Block nested-loop and batched key access joins](#) and [Multi-range read optimization](#) in the MySQL documentation.

To take advantage of the AKP feature, a query must use both BKA and MRR. Typically, such a query occurs when the JOIN clause of a query uses a secondary index, but also needs some columns from the primary index. For example, you can use AKP when a JOIN clause represents an equijoin on index values between a small outer and large inner table, and the index is highly selective on the larger table. AKP works in concert with BKA and MRR to perform a secondary to primary index lookup during the evaluation of the JOIN clause. AKP identifies the rows required to run the query during the evaluation of the JOIN clause. It then uses a background thread to asynchronously load the pages containing those rows into memory before running the query.

AKP is available for Aurora MySQL version 2.10 and higher, and version 3. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL](#).

### Enabling asynchronous key prefetch

You can enable the AKP feature by setting `aurora_use_key_prefetch`, a MySQL server variable, to `on`. By default, this value is set to `on`. However, AKP can't be enabled until you also enable the BKA Join algorithm and disable cost-based MRR functionality. To do so, you must set the following values for `optimizer_switch`, a MySQL server variable:

- Set `batched_key_access` to `on`. This value controls the use of the BKA Join algorithm. By default, this value is set to `off`.
- Set `mrr_cost_based` to `off`. This value controls the use of cost-based MRR functionality. By default, this value is set to `on`.

Currently, you can set these values only at the session level. The following example illustrates how to set these values to enable AKP for the current session by executing SET statements.

```
mysql> set @@session.aurora_use_key_prefetch=on;
mysql> set @@session.optimizer_switch='batched_key_access=on,mrr_cost_based=off';
```

Similarly, you can use SET statements to disable AKP and the BKA Join algorithm and re-enable cost-based MRR functionality for the current session, as shown in the following example.

```
mysql> set @@session.aurora_use_key_prefetch=off;
```

```
mysql> set @@session.optimizer_switch='batched_key_access=off,mrr_cost_based=on';
```

For more information about the **batched\_key\_access** and **mrr\_cost\_based** optimizer switches, see [Switchable optimizations](#) in the MySQL documentation.

## Optimizing queries for asynchronous key prefetch

You can confirm whether a query can take advantage of the AKP feature. To do so, use the EXPLAIN statement to profile the query before running it. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the `Extra` column describes additional information included with the execution plan. If the AKP feature applies to a table used in the query, this column includes one of the following values:

- Using Key Prefetching
- Using join buffer (Batched Key Access with Key Prefetching)

The following example shows the use of EXPLAIN to view the execution plan for a query that can take advantage of AKP.

```
mysql> explain select sql_no_cache
->   ps_partkey,
->   sum(ps_supplycost * ps_availqty) as value
-> from
->   partsupp,
->   supplier,
->   nation
-> where
->   ps_suppkey = s_suppkey
->   and s_nationkey = n_nationkey
->   and n_name = 'ETHIOPIA'
-> group by
->   ps_partkey having
->     sum(ps_supplycost * ps_availqty) > (
->       select
->         sum(ps_supplycost * ps_availqty) * 0.0000003333
->       from
->         partsupp,
->         supplier,
```

```

->          nation
->      where
->          ps_suppkey = s_suppkey
->          and s_nationkey = n_nationkey
->          and n_name = 'ETHIOPIA'
->      )
-> order by
->     value desc;
+----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+

For more information about the EXPLAIN output format, see [Extended EXPLAIN output format](#) in the MySQL documentation.

## Optimizing large Aurora MySQL join queries with hash joins

When you need to join a large amount of data by using an equijoin, a hash join can improve query performance. You can enable hash joins for Aurora MySQL.

A hash join column can be any complex expression. In a hash join column, you can compare across data types in the following ways:

- You can compare anything across the category of precise numeric data types, such as `int`, `bigint`, `numeric`, and `bit`.
- You can compare anything across the category of approximate numeric data types, such as `float` and `double`.
- You can compare items across string types if the string types have the same character set and collation.
- You can compare items with date and timestamp data types if the types are the same.

### Note

You can't compare data types in different categories.

The following restrictions apply to hash joins for Aurora MySQL:

- Left-right outer joins aren't supported for Aurora MySQL version 2, but are supported for version 3.
- Semijoins such as subqueries aren't supported, unless the subqueries are materialized first.
- Multiple-table updates or deletes aren't supported.

### Note

Single-table updates or deletes are supported.

- BLOB and spatial data type columns can't be join columns in a hash join.

## Enabling hash joins

To enable hash joins:

- Aurora MySQL version 2 – Set the DB parameter or DB cluster parameter `aurora_disable_hash_join` to 0. Turning off `aurora_disable_hash_join` sets the value of `optimizer_switch` to `hash_join=on`.
- Aurora MySQL version 3 – Set the MySQL server parameter `optimizer_switch` to `block_nested_loop=on`.

Hash joins are turned on by default in Aurora MySQL version 3 and turned off by default in Aurora MySQL version 2. The following example illustrates how to enable hash joins for Aurora MySQL version 3. You can issue the statement `select @@optimizer_switch` first to see what other settings are present in the SET parameter string. Updating one setting in the `optimizer_switch` parameter doesn't erase or modify the other settings.

```
mysql> SET optimizer_switch='block_nested_loop=on';
```

#### Note

For Aurora MySQL version 3, hash join support is available in all minor versions and is turned on by default.

For Aurora MySQL version 2, hash join support is available in all minor versions. In Aurora MySQL version 2, the hash join feature is always controlled by the `aurora_disable_hash_join` value.

With this setting, the optimizer chooses to use a hash join based on cost, query characteristics, and resource availability. If the cost estimation is incorrect, you can force the optimizer to choose a hash join. You do so by setting `hash_join_cost_based`, a MySQL server variable, to `off`. The following example illustrates how to force the optimizer to choose a hash join.

```
mysql> SET optimizer_switch='hash_join_cost_based=off';
```

#### Note

This setting overrides the decisions of the cost-based optimizer. While the setting can be useful for testing and development, we recommend that you not use it in production.

## Optimizing queries for hash joins

To find out whether a query can take advantage of a hash join, use the EXPLAIN statement to profile the query first. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the Extra column describes additional information included with the execution plan. If a hash join applies to the tables used in the query, this column includes values similar to the following:

- Using where; Using join buffer (Hash Join Outer table *table1\_name*)
- Using where; Using join buffer (Hash Join Inner table *table2\_name*)

The following example shows the use of EXPLAIN to view the execution plan for a hash join query.

```
mysql> explain SELECT sql_no_cache * FROM hj_small, hj_big, hj_big2
->      WHERE hj_small.col1 = hj_big.col1 and hj_big.col1=hj_big2.col1 ORDER BY 1;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table  | type | possible_keys | key  | key_len | ref  | rows |
Extra
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE      | hj_small | ALL  | NULL          | NULL | NULL    | NULL | 6 |
Using temporary; Using filesort
| 1 | SIMPLE      | hj_big   | ALL  | NULL          | NULL | NULL    | NULL | 10 |
Using where; Using join buffer (Hash Join Outer table hj_big)
| 1 | SIMPLE      | hj_big2  | ALL  | NULL          | NULL | NULL    | NULL | 15 |
Using where; Using join buffer (Hash Join Inner table hj_big2)
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.04 sec)
```

In the output, the Hash Join Inner table is the table used to build hash table, and the Hash Join Outer table is the table that is used to probe the hash table.

For more information about the extended EXPLAIN output format, see [Extended EXPLAIN Output Format](#) in the MySQL product documentation.

In Aurora MySQL 2.08 and higher, you can use SQL hints to influence whether a query uses hash join or not, and which tables to use for the build and probe sides of the join. For details, see [Aurora MySQL hints](#).

## Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. Then connect to the Aurora MySQL cluster to process the read queries. The source database can be an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS. For more information, see [Scaling reads for your MySQL database with Amazon Aurora](#).

## Optimizing timestamp operations

When the value of the system variable `time_zone` is set to `SYSTEM`, each MySQL function call that requires a time zone calculation makes a system library call. When you run SQL statements that return or change such `TIMESTAMP` values at high concurrency, you might experience increased latency, lock contention, and CPU usage. For more information, see [time\\_zone](#) in the MySQL documentation.

To avoid this behavior, we recommend that you change the value of the `time_zone` DB cluster parameter to `UTC`. For more information, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

While the `time_zone` parameter is dynamic (doesn't require a database server restart), the new value is used only for new connections. To make sure that all connections are updated to use the new `time_zone` value, we recommend that you recycle your application connections after updating the DB cluster parameter.

## Virtual index ID overflow errors

Aurora MySQL limits values for virtual index IDs to 8 bits prevent an issue caused by the undo format in MySQL. If an index exceeds the virtual index ID limit, your cluster might not be available. When an index approaches the virtual index ID limit or when you attempt to create an index above the virtual index ID limit, RDS might throw error code 63955 or warning code 63955. To address a virtual index ID limit error, we recommend you recreate your database with a logical dump and restore.

For more information about logical dump and restore for Amazon Aurora MySQL, see [Migrate very large databases to Amazon Aurora MySQL using MyDumper and MyLoader](#). For more information about accessing error logs in Amazon Aurora, see [Monitoring Amazon Aurora log files](#).

## Best practices for Aurora MySQL high availability

You can apply the following best practices to improve the availability of your Aurora MySQL clusters.

### Topics

- [Using Amazon Aurora for Disaster Recovery with your MySQL databases](#)
- [Migrating from MySQL to Amazon Aurora MySQL with reduced downtime](#)
- [Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances](#)

## Using Amazon Aurora for Disaster Recovery with your MySQL databases

You can use Amazon Aurora with your MySQL DB instance to create an offsite backup for disaster recovery. To use Aurora for disaster recovery of your MySQL DB instance, create an Amazon Aurora DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

### Important

When you set up replication between a MySQL DB instance and an Amazon Aurora MySQL DB cluster, you should monitor the replication to ensure that it remains healthy and repair it if necessary.

For instructions on how to create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance, follow the procedure in [Using Amazon Aurora to scale reads for your MySQL database](#).

For more information on disaster recovery models, see [How to choose the best disaster recovery option for your Amazon Aurora MySQL cluster](#).

## Migrating from MySQL to Amazon Aurora MySQL with reduced downtime

When importing data from a MySQL database that supports a live application to an Amazon Aurora MySQL DB cluster, you might want to reduce the time that service is interrupted while you

migrate. To do so, you can use the procedure documented in [Importing data to an Amazon RDS for MySQL DB instance with reduced downtime](#) in the *Amazon Relational Database Service User Guide*. This procedure can especially help if you are working with a very large database. You can use the procedure to reduce the cost of the import by minimizing the amount of data that is passed across the network to Amazon.

The procedure lists steps to transfer a copy of your database data to an Amazon EC2 instance and import the data into a new RDS for MySQL DB instance. Because Amazon Aurora is compatible with MySQL, you can instead use an Amazon Aurora DB cluster for the target Amazon RDS MySQL DB instance.

## Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances

If you're running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you're running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch, Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see [Monitoring metrics in an Amazon Aurora cluster](#).

If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see [Amazon Aurora DB instance classes](#).

## Recommendations for MySQL features in Aurora MySQL

The following features are available in Aurora MySQL for MySQL compatibility. However, they have performance, scalability, stability, or compatibility issues in the Aurora environment. Thus, we recommend that you follow certain guidelines in your use of these features. For example, we recommend that you don't use certain features for production Aurora deployments.

### Topics

- [Using multithreaded replication in Aurora MySQL](#)
- [Invoking Amazon Lambda functions using native MySQL functions](#)

- [Avoiding XA transactions with Amazon Aurora MySQL](#)
- [Keeping foreign keys turned on during DML statements](#)
- [Configuring how frequently the log buffer is flushed](#)
- [Minimizing and troubleshooting Aurora MySQL deadlocks](#)

## Using multithreaded replication in Aurora MySQL

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by a coordinator thread. The binary log events are applied in parallel when possible.

Multithreaded replication is supported in Aurora MySQL version 3, and in Aurora MySQL version 2.12.1 and higher.

For Aurora MySQL versions lower than 3.04, Aurora uses single-threaded replication by default when an Aurora MySQL DB cluster is used as a read replica for binary log replication.

Earlier versions of Aurora MySQL version 2 inherited several issues regarding multithreaded replication from MySQL Community Edition. For those versions, we recommend that you not use multithreaded replication in production.

If you do use multithreaded replication, we recommend that you test it thoroughly.

For more information about using replication in Amazon Aurora, see [Replication with Amazon Aurora](#). For more information about multithreaded replication in Aurora MySQL, see [Multithreaded binary log replication](#).

## Invoking Amazon Lambda functions using native MySQL functions

We recommend using the native MySQL functions `lambda_sync` and `lambda_async` to invoke Lambda functions.

If you are using the deprecated `mysql.lambda_async` procedure, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure. You can call this stored procedure from different sources, such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier for your database programmers to invoke Lambda functions.

For more information on invoking Lambda functions from Amazon Aurora, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](#).

## Avoiding XA transactions with Amazon Aurora MySQL

We recommend that you don't use eXtended Architecture (XA) transactions with Aurora MySQL, because they can cause long recovery times if the XA was in the PREPARED state. If you must use XA transactions with Aurora MySQL, follow these best practices:

- Don't leave an XA transaction open in the PREPARED state.
- Keep XA transactions as small as possible.

For more information about using XA transactions with MySQL, see [XA transactions](#) in the MySQL documentation.

## Keeping foreign keys turned on during DML statements

We strongly recommend that you don't run any data definition language (DDL) statements when the `foreign_key_checks` variable is set to 0 (off).

If you need to insert or update rows that require a transient violation of foreign keys, follow these steps:

1. Set `foreign_key_checks` to 0.
2. Make your data manipulation language (DML) changes.
3. Make sure that your completed changes don't violate any foreign key constraints.
4. Set `foreign_key_checks` to 1 (on).

In addition, follow these other best practices for foreign key constraints:

- Make sure that your client applications don't set the `foreign_key_checks` variable to 0 as a part of the `init_connect` variable.
- If a restore from a logical backup such as `mysqldump` fails or is incomplete, make sure that `foreign_key_checks` is set to 1 before starting any other operations in the same session. A logical backup sets `foreign_key_checks` to 0 when it starts.

## Configuring how frequently the log buffer is flushed

In MySQL Community Edition, to make transactions durable, the InnoDB log buffer must be flushed to durable storage. You use the `innodb_flush_log_at_trx_commit` parameter to configure how frequently the log buffer is flushed to disk.

When you set the `innodb_flush_log_at_trx_commit` parameter to the default value of 1, the log buffer is flushed at each transaction commit. This setting helps to keep the database [ACID](#) compliant. We recommend that you keep the default setting of 1.

Changing `innodb_flush_log_at_trx_commit` to a nondefault value can help reduce data manipulation language (DML) latency, but sacrifices the durability of the log records. This lack of durability makes the database ACID noncompliant. We recommend that your databases be ACID compliant to avoid the risk of data loss in the event of a server restart. For more information on this parameter, see [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) in the MySQL documentation.

In Aurora MySQL, redo log processing is offloaded to the storage layer, so no flushing to log files occurs on the DB instance. When a write is issued, redo logs are sent from the writer DB instance directly to the Aurora cluster volume. The only writes that cross the network are redo log records. No pages are ever written from the database tier.

By default, each thread committing a transaction waits for confirmation from the Aurora cluster volume. This confirmation indicates that this record and all previous redo log records are written and have achieved [quorum](#). Persisting the log records and achieving quorum make the transaction durable, whether through autocommit or explicit commit. For more information on the Aurora storage architecture, see [Amazon Aurora storage demystified](#).

Aurora MySQL doesn't flush logs to data files as MySQL Community Edition does. However, you can use the `innodb_flush_log_at_trx_commit` parameter to relax durability constraints when writing redo log records to the Aurora cluster volume.

For Aurora MySQL version 2:

- `innodb_flush_log_at_trx_commit = 0` or `2` – The database doesn't wait for confirmation that the redo log records are written to the Aurora cluster volume.
- `innodb_flush_log_at_trx_commit = 1` – The database waits for confirmation that the redo log records are written to the Aurora cluster volume.

For Aurora MySQL version 3:

- `innodb_flush_log_at_trx_commit = 0` – The database doesn't wait for confirmation that the redo log records are written to the Aurora cluster volume.
- `innodb_flush_log_at_trx_commit = 1` or `2` – The database waits for confirmation that the redo log records are written to the Aurora cluster volume.

Therefore, to obtain the same nondefault behavior in Aurora MySQL version 3 that you would with the value set to 0 or 2 in Aurora MySQL version 2, set the parameter to 0.

While these settings can lower DML latency to the client, they can also result in data loss in the event of a failover or restart. Therefore, we recommend that you keep the `innodb_flush_log_at_trx_commit` parameter set to the default value of 1.

While data loss can occur in both MySQL Community Edition and Aurora MySQL, behavior differs in each database because of their different architectures. These architectural differences can lead to varying degrees of data loss. To make sure that your database is ACID compliant, always set `innodb_flush_log_at_trx_commit` to 1.

#### Note

In Aurora MySQL version 3, before you can change `innodb_flush_log_at_trx_commit` to a value other than 1, you must first change the value of `innodb_trx_commit_allow_data_loss` to 1. By doing so, you acknowledge the risk of data loss.

## Minimizing and troubleshooting Aurora MySQL deadlocks

Users running workloads that regularly experience constraint violations on unique secondary indexes or foreign keys, when modifying records on the same data page concurrently, might experience increased deadlocks and lock wait timeouts. These deadlocks and timeouts are because of a MySQL Community Edition [bug fix](#).

This fix is included in MySQL Community Edition versions 5.7.26 and higher, and was backported into Aurora MySQL versions 2.10.3 and higher. The fix is necessary for enforcing *serializability*, by implementing additional locking for these types of data manipulation language (DML) operations, on changes made to records in an InnoDB table. This issue was uncovered as part of an investigation into deadlock issues introduced by a previous MySQL Community Edition [bug fix](#).

The fix changed the internal handling for the *partial rollback* of a tuple (row) update in the InnoDB storage engine. Operations that generate constraint violations on foreign keys or unique secondary indexes cause partial rollback. This includes, but isn't limited to, concurrent `INSERT . . . ON DUPLICATE KEY UPDATE`, `REPLACE INTO`, and `INSERT IGNORE` statements (*upserts*).

In this context, partial rollback doesn't refer to the rollback of application-level transactions, but rather an internal InnoDB rollback of changes to a clustered index, when a constraint violation is encountered. For example, a duplicate key value is found during an upsert operation.

In a normal insert operation, InnoDB atomically creates [clustered](#) and secondary index entries for each index. If InnoDB detects a duplicate value on a unique secondary index during an upsert operation, the inserted entry in the clustered index has to be reverted (partial rollback), and the update then has to be applied to the existing duplicate row. During this internal partial rollback step, InnoDB must lock each record seen as part of the operation. The fix ensures transaction serializability by introducing additional locking after the partial rollback.

## Minimizing InnoDB deadlocks

You can take the following approaches to reduce the frequency of deadlocks in your database instance. More examples can be found in the [MySQL documentation](#).

1. To reduce the chances of deadlocks, commit transactions immediately after making a related set of changes. You can do this by breaking up large transactions (multiple row updates between commits) into smaller ones. If you're batch inserting rows, then try to reduce batch insert sizes, especially when using the upsert operations mentioned previously.

To reduce the number of possible partial rollbacks, you can try some of the following approaches:

- a. Replace batch insert operations with inserting one row at a time. This can reduce the amount of time where locks are held by transactions that might have conflicts.
- b. Instead of using `REPLACE INTO`, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;  
DELETE conflicting rows;  
INSERT new rows;  
COMMIT;
```

- c. Instead of using `INSERT . . . ON DUPLICATE KEY UPDATE`, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;  
SELECT rows that conflict on secondary indexes;  
UPDATE conflicting rows;  
INSERT new rows;  
COMMIT;
```

2. Avoid long-running transactions, active or idle, that might hold onto locks. This includes interactive MySQL client sessions that might be open for an extended period with an uncommitted transaction. When optimizing transaction sizes or batch sizes, the impact can vary depending on a number of factors such as concurrency, number of duplicates, and table structure. Any changes should be implemented and tested based on your workload.
3. In some situations, deadlocks can occur when two transactions attempt to access the same datasets, either in one or multiple tables, in different orders. To prevent this, you can modify the transactions to access the data in the same order, thereby serializing the access. For example, create a queue of transactions to be completed. This approach can help to avoid deadlocks when multiple transactions occur concurrently.
4. Adding carefully chosen indexes to your tables can improve selectivity and reduce the need to access rows, which leads to less locking.
5. If you encounter [gap locking](#), you can modify the transaction isolation level to READ COMMITTED for the session or transaction to prevent it. For more information on InnoDB isolation levels and their behaviors, see [Transaction isolation levels](#) in the MySQL documentation.

### Note

While you can take precautions to reduce the possibility of deadlocks occurring, deadlocks are an expected database behavior and can still occur. Applications should have the necessary logic to handle deadlocks when they are encountered. For example, implement retry and backing-off logic in the application. It's best to address the root cause of the issue but if a deadlock does occur, the application has the option to wait and retry.

## Monitoring InnoDB deadlocks

[Deadlocks](#) can occur in MySQL when application transactions try to take table-level and row-level locks in a way that results in circular waiting. An occasional InnoDB deadlock isn't necessarily

an issue, because the InnoDB storage engine detects the condition immediately and rolls back one of the transactions automatically. If you encounter deadlocks frequently, we recommend reviewing and modifying your application to alleviate performance issues and avoid deadlocks. When [deadlock detection](#) is turned on (the default), InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

- `SHOW ENGINE` statement – The `SHOW ENGINE INNODB STATUS \G` statement contains [details](#) of the most recent deadlock encountered on the database since the last restart.
- MySQL error log – If you encounter frequent deadlocks where the output of the `SHOW ENGINE` statement is inadequate, you can turn on the [innodb\\_print\\_all\\_deadlocks](#) DB cluster parameter.

When this parameter is turned on, information about all deadlocks in InnoDB user transactions is recorded in the Aurora MySQL [error log](#).

- Amazon CloudWatch metrics – We also recommend that you proactively monitor deadlocks using the CloudWatch metric `Deadlocks`. For more information, see [Instance-level metrics for Amazon Aurora](#).
- Amazon CloudWatch Logs – With CloudWatch Logs, you can view metrics, analyze log data, and create real-time alarms. For more information, see [Monitor errors in Amazon Aurora MySQL and Amazon RDS for MySQL using Amazon CloudWatch and send notifications using Amazon SNS](#).

Using CloudWatch Logs with `innodb_print_all_deadlocks` turned on, you can configure alarms to notify you when the number of deadlocks exceeds a given threshold. To define a threshold, we recommend that you observe your trends and use a value based on your normal workload.

- Performance Insights – When you use Performance Insights, you can monitor the `innodb_deadlocks` and `innodb_lock_wait_timeout` metrics. For more information on these metrics, see [Non-native counters for Aurora MySQL](#).

## Evaluating DB instance usage for Aurora MySQL with Amazon CloudWatch metrics

You can use CloudWatch metrics to monitor your DB instance throughput and determine whether your DB instance class provides sufficient resources for your applications. For information about

your DB instance class limits, see [Hardware specifications for DB instance classes for Aurora](#). Find the specifications for your DB instance class to find the network performance.

If your DB instance usage is near the instance class limit, then performance may begin to slow. The CloudWatch metrics can confirm this situation so you can plan to manually scale-up to a larger instance class.

Combine the following CloudWatch metrics values to find out if you are nearing the instance class limit:

- **NetworkThroughput** – The amount of network throughput received and transmitted by the clients for each instance in the Aurora DB cluster. This throughput value doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **StorageNetworkThroughput** – The amount of network throughput received and sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.

Add the **NetworkThroughput** to the **StorageNetworkThroughput** to find the network throughput received from and sent to the Aurora storage subsystem by each instance in your Aurora DB cluster. The instance class limit for your instance should be greater than the sum of these two combined metrics.

You can use the following metrics to review additional details of the network traffic from your client applications when sending and receiving:

- **NetworkReceiveThroughput** – The amount of network throughput received from clients by each DB instance in the Aurora MySQL DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **NetworkTransmitThroughput** – The amount of network throughput sent to clients by each instance in the Aurora DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **StorageNetworkReceiveThroughput** – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.
- **StorageNetworkTransmitThroughput** – The amount of network throughput sent to the Aurora storage subsystem by each instance in the DB cluster.

Add all of these metrics together to evaluate how your network usage compares to the DB instance class limit. The instance class limit should be greater than the sum of these combined metrics.

The network limits and CPU usage for storage are directly related. When the network throughput increases, then the CPU usage also increases. Monitoring the CPU and network usage provides information about how and why the resources are being exhausted.

To help minimize network usage, you can consider the following:

- Using a larger DB instance class.
- Dividing the write requests in batches to reduce overall transactions.
- Directing the read-only workload to a read-only instance.
- Deleting any unused indexes.

# Troubleshooting Amazon Aurora MySQL database performance

This topic focuses on some common Aurora MySQL DB performance issues, and how to troubleshoot or collect information to remediate these issues quickly. We divide database performance into two categories:

- Server performance – The entire database server runs slower.
- Query performance – One or more queries take longer to run.

## Amazon monitoring options

We recommend that you use the following Amazon monitoring options to help with troubleshooting:

- Amazon CloudWatch – Amazon CloudWatch monitors your Amazon resources and the applications you run on Amazon in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications. For more information, see [What is Amazon CloudWatch?](#).

You can view all of the system metrics and process information for your DB instances on the Amazon Web Services Management Console. You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. This allows you to view trends, maintain logs if a host is impacted, and create a baseline for "normal" performance to easily identify anomalies or changes. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](#).

- Enhanced Monitoring – To enable additional Amazon CloudWatch metrics for an Aurora MySQL database, turn on Enhanced Monitoring. When you create or modify an Aurora DB cluster, select **Enable Enhanced Monitoring**. This allows Aurora to publish performance metrics to CloudWatch. Some of the key metrics available include CPU usage, database connections, storage usage, and query latency. These can help identify performance bottlenecks.

The amount of information transferred for a DB instance is directly proportional to the defined granularity for Enhanced Monitoring. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your Amazon Web Services accounts. The default granularity at creation of an instance is 60 seconds. For more information, see [Cost of Enhanced Monitoring](#).

- Performance Insights – You can view all of the database call metrics. This includes DB locks, waits, and the number of rows processed, all of which you can use for troubleshooting. When you create or modify an Aurora DB cluster, select **Turn on Performance Insights**. By default, Performance Insights has a 7-day data retention period, but can be customized to analyze longer-term performance trends. For longer than 7-day retention, you need to upgrade to the paid tier. For more information, see [Performance Insights pricing](#). You can set the data retention period for each Aurora DB instance separately. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

## Most common reasons for Aurora MySQL database performance issues

You can use the following steps to troubleshoot performance issues in your Aurora MySQL database. We list these steps in the logical order of investigation, but they're not intended to be linear. One discovery could jump across steps, which allow for a series of investigative paths.

1. [Workload](#) – Understand your database workload.
2. [Logging](#) – Review all of the database logs.
3. [Database connections](#) – Make sure that the connections between your applications and your database are reliable.
4. [Query performance](#) – Examine your query execution plans to see if they've changed. Code changes can cause plans to change.

## Troubleshooting workload issues for Aurora MySQL databases

Database workload can be viewed as reads and writes. With an understanding of "normal" database workload, you can tune queries and the database server to meet demand as it changes. There are a number of different reasons why performance can change, so the first step is to understand what has changed.

- Has there been a major or minor version upgrade?

A major version upgrade includes changes to the engine code, particularly in the optimizer, that can change the query execution plan. When upgrading database versions, especially major versions, it's very important that you analyze the database workload and tune accordingly. Tuning can involve optimizing and rewriting queries, or adding and updating parameter settings, depending on the results of testing. Understanding what is causing the impact will allow you to start focusing on that specific area.

For more information, see [What is new in MySQL 8.0](#) and [Server and status variables and options added, deprecated, or removed in MySQL 8.0](#) in the MySQL documentation, and [Comparing Aurora MySQL version 2 and Aurora MySQL version 3](#).

- Has there been an increase in data being processed (row counts)?
- Are there more queries running concurrently?
- Are there schema or database changes?
- Have there been code defects or fixes?

## Instance host metrics

Monitor instance host metrics such as CPU, memory, and network activity to help understand whether there has been a workload change. There are two main concepts for understanding workload changes:

- Utilization – The usage of a device, such as CPU or disk. It can be time-based or capacity-based.
  - Time-based – The amount of time that a resource is busy over a particular observation period.
  - Capacity-based – The amount of throughput that a system or component can deliver, as a percentage of its capacity.
- Saturation – The degree to which more work is required of a resource than it can process. When capacity-based usage reaches 100%, the extra work can't be processed and must be queued.

## CPU usage

You can use the following tools to identify CPU usage and saturation:

- CloudWatch provides the `CPUUtilization` metric. If this reaches 100%, then the instance is saturated. However, CloudWatch metrics are averaged over 1 minute, and lack granularity.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

- Enhanced Monitoring provides metrics returned by the operating system `top` command. It shows load averages and the following CPU states, with 1-second granularity:
  - `Idle (%)` = Idle time
  - `IRQ (%)` = Software interrupts
  - `Nice (%)` = Nice time for processes with a [niced](#) priority.
  - `Steal (%)` = Time spent serving other tenants (virtualization related)
  - `System (%)` = System time
  - `User (%)` = User time
  - `Wait (%)` = I/O wait

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

## Memory usage

If the system is under memory pressure, and resource consumption is reaching saturation, you should be observing a high degree of page scanning, paging, swapping, and out-of-memory errors.

You can use the following tools to identify memory usage and saturation:

CloudWatch provides the `FreeableMemory` metric, that shows how much memory can be reclaimed by flushing some of the OS caches and the current free memory.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

Enhanced Monitoring provides the following metrics that can help you identify memory usage issues:

- `Buffers (KB)` – The amount of memory used for buffering I/O requests before writing to the storage device, in kilobytes.
- `Cached (KB)` – The amount of memory used for caching file system–based I/O.
- `Free (KB)` – The amount of unassigned memory, in kilobytes.
- `Swap – Cached, Free, and Total`.

For example, if you see that your DB instance uses Swap memory, then the total amount of memory for your workload is larger than your instance currently has available. We recommend increasing the size of your DB instance or tuning your workload to use less memory.

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

For more detailed information on using the Performance Schema and `sys` schema to determine which connections and components are using memory, see [Troubleshooting memory usage issues for Aurora MySQL databases](#).

## Network throughput

CloudWatch provides the following metrics for total network throughput, all averaged over 1 minute:

- `NetworkReceiveThroughput` – The amount of network throughput received from clients by each instance in the Aurora DB cluster.
- `NetworkTransmitThroughput` – The amount of network throughput sent to clients by each instance in the Aurora DB cluster.

- `NetworkThroughput` – The amount of network throughput both received from and transmitted to clients by each instance in the Aurora DB cluster.
- `StorageNetworkReceiveThroughput` – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.
- `StorageNetworkTransmitThroughput` – The amount of network throughput sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.
- `StorageNetworkThroughput` – The amount of network throughput received from and sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

Enhanced Monitoring provides the network received (**RX**) and transmitted (**TX**) graphs, with up to 1-second granularity.

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

## Database metrics

Examine the following CloudWatch metrics for workload changes:

- `BlockedTransactions` – The average number of transactions in the database that are blocked per second.
- `BufferCacheHitRatio` – The percentage of requests that are served by the buffer cache.
- `CommitThroughput` – The average number of commit operations per second.
- `DatabaseConnections` – The number of client network connections to the database instance.
- `Deadlocks` – The average number of deadlocks in the database per second.
- `DMLThroughput` – The average number of inserts, updates, and deletes per second.
- `ResultSetCacheHitRatio` – The percentage of requests that are served by the query cache.
- `RollbackSegmentHistoryListLength` – The undo logs that record committed transactions with delete-marked records.
- `RowLockTime` – The total time spent acquiring row locks for InnoDB tables.
- `SelectThroughput` – The average number of select queries per second.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

Consider the following questions when examining the workload:

1. Were there recent changes in DB instance class, for example reducing the instance size from 8xlarge to 4xlarge, or changing from db.r5 to db.r6?
2. Can you create a clone and reproduce the issue, or is it happening only on that one instance?
3. Is there server resource exhaustion, high CPU or memory exhaustion? If yes, this could mean that additional hardware is required.
4. Are one or more queries taking longer?
5. Are the changes caused by an upgrade, especially a major version upgrade? If yes, then compare the pre- and post-upgrade metrics.
6. Are there changes in the number of reader DB instances?
7. Have you enabled general, audit, or binary logging? For more information, see [Logging for Aurora MySQL databases](#).
8. Did you enable, disable, or change your use of binary log (binlog) replication?
9. Are there any long-running transactions holding large numbers of row locks? Examine the InnoDB history list length (HLL) for indications of long-running transactions.

For more information, see [The InnoDB history list length increased significantly](#) and the blog post [Why is my SELECT query running slowly on my Amazon Aurora MySQL DB cluster?](#).

- a. If a large HLL is caused by a write transaction, it means that UNDO logs are accumulating (not being cleaned regularly). In a large write transaction, this accumulation can grow quickly. In MySQL, UNDO is stored in the [SYSTEM tablespace](#). The SYSTEM tablespace is not shrinkable. The UNDO log might cause the SYSTEM tablespace to grow to several GB, or even TB. After the purge, release the allocated space by taking a logical backup (dump) of the data, then import the dump to a new DB instance.
  - b. If a large HLL is caused by a read transaction (long-running query), it can mean that the query is using a large amount of temporary space. Release the temporary space by rebooting. Examine Performance Insights DB metrics for any changes in the Temp section, such as `created_tmp_tables`. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).
10. Can you split long-running transactions into smaller ones that modify fewer rows?
  11. Are there any changes in blocked transactions or increases in deadlocks? Examine Performance Insights DB metrics for any changes in status variables in the Locks section, such as `innodb_row_lock_time`, `innodb_row_lock_waits`, and `innodb_dead_locks`. Use 1-minute or 5-minute intervals.

12 Are there increased wait events? Examine Performance Insights wait events and wait types using 1-minute or 5-minute intervals. Analyze the top wait events and see whether they are correlated to workload changes or database contention. For example, `buf_pool mutex` indicates buffer pool contention. For more information, see [Tuning Aurora MySQL with wait events](#).

## Troubleshooting memory usage issues for Aurora MySQL databases

While CloudWatch, Enhanced Monitoring, and Performance Insights provide a good overview of memory usage at the operating system level, such as how much memory the database process is using, they don't allow you to break down what connections or components within the engine might be causing this memory usage.

To troubleshoot this, you can use the Performance Schema and `sys` schema. In Aurora MySQL version 3, memory instrumentation is enabled by default when the Performance Schema is enabled. In Aurora MySQL version 2, only memory instrumentation for Performance Schema memory usage is enabled by default. For information on tables available in the Performance Schema to track memory usage and enabling Performance Schema memory instrumentation, see [Memory summary tables](#) in the MySQL documentation. For more information on using the Performance Schema with Performance Insights, see [Overview of the Performance Schema for Performance Insights on Aurora MySQL](#).

While detailed information is available in the Performance Schema to track current memory usage, the MySQL [sys schema](#) has views on top of Performance Schema tables that you can use to quickly pinpoint where memory is being used.

In the `sys` schema, the following views are available to track memory usage by connection, component, and query.

View	Description
<a href="#">memory_by_host_by_current_bytes</a>	Provides information on engine memory usage by host. This can be useful for identifying which application servers or client hosts are consuming memory.
<a href="#">memory_by_thread_by_current_bytes</a>	Provides information on engine memory usage by thread ID. The thread ID in MySQL can be a client connection or a background

View	Description
	thread. You can map thread IDs to MySQL connection IDs by using the <a href="#">sys.processlist</a> view or <a href="#">performance_schema.threads</a> table.
<a href="#">memory_by_user_by_current_bytes</a>	Provides information on engine memory usage by user. This can be useful for identifying which user accounts or clients are consuming memory.
<a href="#">memory_global_by_current_bytes</a>	Provides information on engine memory usage by engine component. This can be useful for identifying memory usage globally by engine buffers or components. For example, you might see the <code>memory/in_nodb/buf_buf_pool</code> event for the InnoDB buffer pool, or the <code>memory/sql/Prepared_statement::main_mem_root</code> event for prepared statements.
<a href="#">memory_global_total</a>	Provides an overview of total tracked memory usage in the database engine.

In Aurora MySQL version 3.05 and higher, you can also track maximum memory usage by statement digest in the [Performance Schema statement summary tables](#). The statement summary tables contain normalized statement digests and aggregated statistics on their execution. The `MAX_TOTAL_MEMORY` column can help you identify maximum memory used by query digest since the statistics were last reset, or since the database instance was restarted. This can be useful in identifying specific queries that might be consuming a lot of memory.

### Note

The Performance Schema and sys schema show you the current memory usage on the server, and the high-water marks for memory consumed per connection and engine component. Because the Performance Schema is maintained in memory, information is

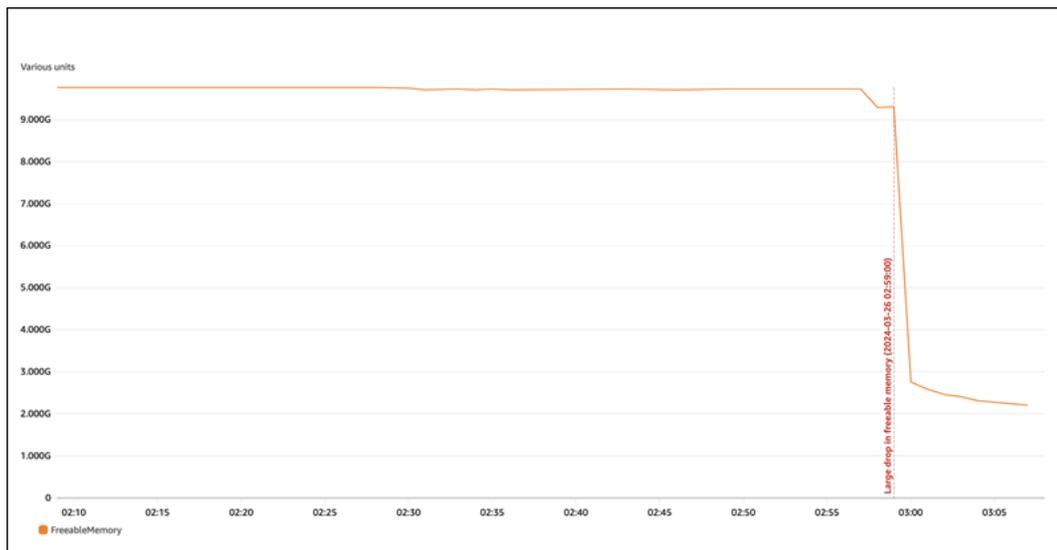

reset when the DB instance restarts. To maintain a history over time, we recommend that you configure retrieval and storage of this data outside of the Performance Schema.

## Topics

- [Example 1: Continuous high memory usage](#)
- [Example 2: Transient memory spikes](#)
- [Example 3: Freeable memory drops continuously and isn't reclaimed](#)

### Example 1: Continuous high memory usage

Looking globally at `FreeableMemory` in CloudWatch, we can see that memory usage greatly increased at 2024-03-26 02:59 UTC.

This doesn't tell us the whole picture. To determine which component is using the most memory, you can log into the database and look at `sys.memory_global_by_current_bytes`. This table contains a list of memory events that MySQL tracks, along with information on memory allocation per event. Each memory tracking event starts with `memory/%`, followed by other information on which engine component/feature the event is associated with.

For example, `memory/performance_schema/%` is for memory events related to the Performance Schema, `memory/innodb/%` is for InnoDB, and so on. For more information on event naming conventions, see [Performance Schema instrument naming conventions](#) in the MySQL documentation.

From the following query, we can find the likely culprit based on `current_alloc`, but we can also see many `memory/performance_schema/%` events.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes LIMIT 10;
```

event_name	current_count	current_alloc	current_avg_alloc	high_count	high_alloc	high_avg_alloc
memory/sql/Prepared_statement::main_mem_root	512817	4.91 GiB	10.04 KiB	512823	4.91 GiB	10.04 KiB
memory/performance_schema/prepared_statements_instances	252	488.25 MiB	1.94 MiB	252	488.25 MiB	1.94 MiB
memory/innodb/hash0hash	4	79.07 MiB	19.77 MiB	4	79.07 MiB	19.77 MiB
memory/performance_schema/events_errors_summary_by_thread_by_error	1028	52.27 MiB	52.06 KiB	1028	52.27 MiB	52.06 KiB
memory/performance_schema/events_statements_summary_by_thread_by_event_name	4	47.25 MiB	11.81 MiB	4	47.25 MiB	11.81 MiB
memory/performance_schema/events_statements_summary_by_digest	1	40.28 MiB	40.28 MiB	1	40.28 MiB	40.28 MiB
memory/performance_schema/memory_summary_by_thread_by_event_name	4	31.64 MiB	7.91 MiB	4	31.64 MiB	7.91 MiB
memory/innodb/memory	15227	27.44 MiB	1.85 KiB	20619	33.33 MiB	1.66 KiB
memory/sql/String::value	74411	21.85 MiB	307 bytes	76867	25.54 MiB	348 bytes
memory/sql/TABLE	8381	21.03 MiB	2.57 KiB	8381	21.03 MiB	2.57 KiB

```
10 rows in set (0.02 sec)
```

We mentioned previously that the Performance Schema is stored in memory, which means that it's also tracked in the `performance_schema` memory instrumentation.

**Note**

If you find that the Performance Schema is using a lot of memory, and want to limit its memory usage, you can tune database parameters based on your requirements. For more information, see [The Performance Schema memory-allocation model](#) in the MySQL documentation.

For readability, you can rerun the same query but exclude Performance Schema events. The output shows the following:

- The main memory consumer is `memory/sql/Prepared_statement::main_mem_root`.
- The `current_alloc` column tells us that MySQL has 4.91 GiB currently allocated to this event.
- The `high_alloc` column tells us that 4.91 GiB is the high-water mark of `current_alloc` since the stats were last reset or since the server restarted. This means that `memory/sql/Prepared_statement::main_mem_root` is at its highest value.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name NOT LIKE
'memory/performance_schema/%' LIMIT 10;
```

```

10 rows in set (0.06 sec)

```

From the name of the event, we can tell that this memory is being used for prepared statements. If you want to see which connections are using this memory, you can check [memory\\_by\\_thread\\_by\\_current\\_bytes](#).

In the following example, each connection has approximately 7 MiB allocated, with a high-water mark of approximately 6.29 MiB (`current_max_alloc`). This makes sense, because the example is using sysbench with 80 tables and 800 connections with prepared statements. If you want to reduce memory usage in this scenario, you can optimize your application's usage of prepared statements to reduce memory consumption.

```

mysql> SELECT * FROM sys.memory_by_thread_by_current_bytes;

+-----+-----+-----+-----+

```

As mentioned earlier, the thread ID (`thd_id`) value here can refer to server background threads or database connections. If you want to map thread ID values to database connection IDs, you can use the `performance_schema.threads` table or the `sys.processlist` view, where `conn_id` is the connection ID.

```

mysql> SELECT thd_id,conn_id,user,db,command,state,time,last_wait FROM sys.processlist
WHERE user='reinvent@10.0.4.4';

+-----+-----+-----+-----+-----+-----+-----+

```

Now we stop the sysbench workload, which closes the connections and released the memory. Checking the events again, we can confirm that memory is released, but `high_alloc` still tells us what the high-water mark is. The `high_alloc` column can be very useful in identifying short spikes in memory usage, where you might not be able to immediately identify usage from `current_alloc`, which shows only currently allocated memory.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name='memory/sql/
Prepared_statement::main_mem_root' LIMIT 10;
```

event_name	current_count	current_alloc	current_avg_alloc	high_count	high_alloc	high_avg_alloc
memory/sql/Prepared_statement::main_mem_root	17	253.80 KiB	14.93 KiB	512823	4.91 GiB	10.04 KiB

```
1 row in set (0.00 sec)
```

If you want to reset `high_alloc`, you can truncate the `performance_schema` memory summary tables, but this resets all memory instrumentation. For more information, see [Performance Schema general table characteristics](#) in the MySQL documentation.

In the following example, we can see that `high_alloc` is reset after truncation.

```
mysql> TRUNCATE `performance_schema`.`memory_summary_global_by_event_name`;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name='memory/sql/
Prepared_statement::main_mem_root' LIMIT 10;
```

event_name	current_count	current_alloc	current_avg_alloc	high_count	high_alloc	high_avg_alloc
memory/sql/Prepared_statement::main_mem_root	17	253.80 KiB	14.93 KiB	17	253.80 KiB	14.93 KiB

```
1 row in set (0.00 sec)
```

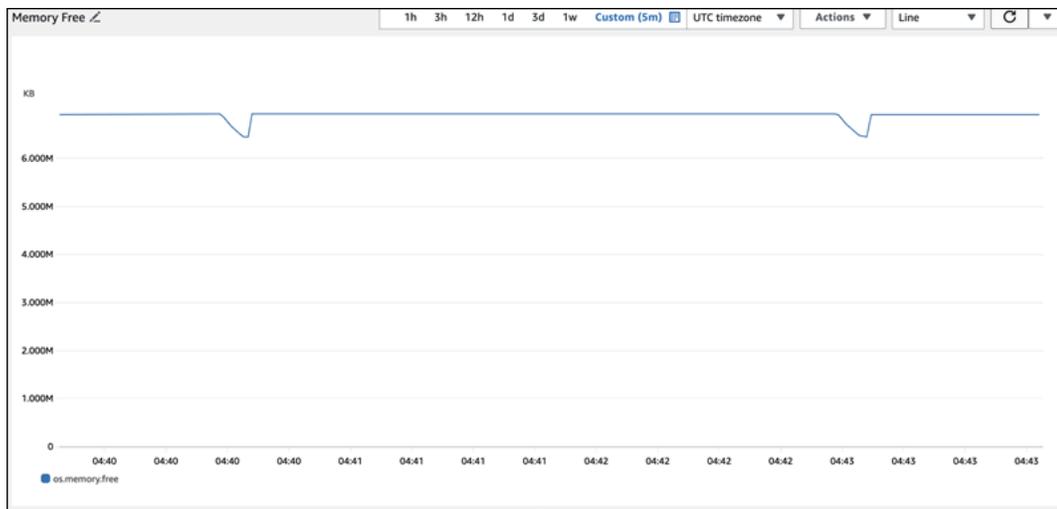

## Example 2: Transient memory spikes

Another common occurrence is short spikes in memory usage on a database server. These can be periodic drops in freeable memory that are difficult to troubleshoot using `current_alloc` in `sys.memory_global_by_current_bytes`, because the memory has already been freed.

### Note

If Performance Schema statistics have been reset, or the database instance has been restarted, this information won't be available in `sys` or `performance_schema`. To retain this information, we recommend that you configure external metrics collection.

The following graph of the `os.memory.free` metric in Enhanced Monitoring shows brief 7-second spikes in memory usage. Enhanced Monitoring allows you to monitor at intervals as short as 1 second, which is perfect for catching transient spikes like these.

To help diagnose the cause of the memory usage here, we can use a combination of `high_alloc` in the `sys` memory summary views and [Performance Schema statement summary tables](#) to try to identify offending sessions and connections.

As expected, because memory usage isn't currently high, we can't see any major offenders in the `sys` schema view under `current_alloc`.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes LIMIT 10;
```

```

```

Expanding the view to order by `high_alloc`, we can now see that the `memory/temptable/physical_ram` component is a very good candidate here. At its highest, it consumed 515.00 MiB.

As its name suggests, `memory/temptable/physical_ram` instruments memory usage for the TEMP storage engine in MySQL, which was introduced in MySQL 8.0. For more information on how MySQL uses temporary tables, see [Internal temporary table use in MySQL](#) in the MySQL documentation.

**Note**

We're using the `sys.x$memory_global_by_current_bytes` view in this example.

```
mysql> SELECT event_name, format_bytes(current_alloc) AS "currently allocated",
  sys.format_bytes(high_alloc) AS "high-water mark"
FROM sys.x$memory_global_by_current_bytes ORDER BY high_alloc DESC LIMIT 10;
```

event_name	currently allocated	high-water mark
memory/temptable/physical_ram	4.00 MiB	515.00 MiB
memory/innodb/hash0hash	79.07 MiB	79.07 MiB
memory/innodb/os0event	63.95 MiB	63.95 MiB
memory/performance_schema/events_statements_summary_by_digest	40.28 MiB	40.28 MiB
memory/mysys/KEY_CACHE	16.00 MiB	16.00 MiB
memory/performance_schema/events_statements_history_long	14.34 MiB	14.34 MiB
memory/performance_schema/events_errors_summary_by_thread_by_error	13.07 MiB	13.07 MiB
memory/performance_schema/events_statements_summary_by_thread_by_event_name	11.81 MiB	11.81 MiB
memory/performance_schema/events_statements_summary_by_digest.digest_text	9.77 MiB	9.77 MiB
memory/performance_schema/events_statements_history_long.sql_text	9.77 MiB	9.77 MiB

10 rows in set (0.00 sec)

In [Example 1: Continuous high memory usage](#), we checked the current memory usage for each connection to determine which connection is responsible for using the memory in question. In this

example, the memory is already freed, so checking the memory usage for current connections isn't useful.

To dig deeper and find the offending statements, users, and hosts, we use the Performance Schema. The Performance Schema contains multiple statement summary tables that are sliced by different dimensions such as event name, statement digest, host, thread, and user. Each view will allow you dig deeper into where certain statements are being run and what they are doing. This section is focused on `MAX_TOTAL_MEMORY`, but you can find more information on all of the columns available in the [Performance Schema statement summary tables](#) documentation.

```
mysql> SHOW TABLES IN performance_schema LIKE 'events_statements_summary_%';

+-----+
| Tables_in_performance_schema (events_statements_summary_%) |
+-----+
| events_statements_summary_by_account_by_event_name          |
| events_statements_summary_by_digest                        |
| events_statements_summary_by_host_by_event_name            |
| events_statements_summary_by_program                      |
| events_statements_summary_by_thread_by_event_name          |
| events_statements_summary_by_user_by_event_name            |
| events_statements_summary_global_by_event_name             |
+-----+
7 rows in set (0.00 sec)
```

First we check `events_statements_summary_by_digest` to see `MAX_TOTAL_MEMORY`.

From this we can see the following:

- The query with digest `20676ce4a690592ff05debcffcbbc26faeb76f22005e7628364d7a498769d0c4a` seems to be a good candidate for this memory usage. The `MAX_TOTAL_MEMORY` is `537450710`, which matches the high-water mark we saw for the `memory/temptable/physical_ram` event in `sys.x$memory_global_by_current_bytes`.
- It has been run four times (`COUNT_STAR`), first at `2024-03-26 04:08:34.943256`, and last at `2024-03-26 04:43:06.998310`.

```
mysql> SELECT SCHEMA_NAME,DIGEST,COUNT_STAR,MAX_TOTAL_MEMORY,FIRST_SEEN,LAST_SEEN
FROM performance_schema.events_statements_summary_by_digest ORDER BY MAX_TOTAL_MEMORY
DESC LIMIT 5;
```

```

+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+

5 rows in set (0.00 sec)

```

Now that we know the offending digest, we can get more details such as the query text, the user who ran it, and where it was run. Based on the digest text returned, we can see that this is a common table expression (CTE) that creates four temporary tables and performs four table scans, which is very inefficient.

```

mysql> SELECT
  SCHEMA_NAME,DIGEST_TEXT,QUERY_SAMPLE_TEXT,MAX_TOTAL_MEMORY,SUM_ROWS_SENT,SUM_ROWS_EXAMINED,SUM
FROM performance_schema.events_statements_summary_by_digest
WHERE DIGEST='20676ce4a690592ff05debcffcbc26faeb76f22005e7628364d7a498769d0c4a'\G;

1 row in set (10.53 sec)

```

But who ran it? We can see in the Performance Schema that the `destructive_operator` user had `MAX_TOTAL_MEMORY` of 537450710, which again matches the previous results.

### Note

The Performance Schema is stored in memory, so should not be relied upon as the sole source for auditing. If you need to maintain a history of statements run, and from which users, we recommend that you enable [Aurora Advanced Auditing](#). If you also need to maintain information on memory usage, we recommend that you configure monitoring to export and store these values.

```

mysql> SELECT USER,EVENT_NAME,COUNT_STAR,MAX_TOTAL_MEMORY FROM
  performance_schema.events_statements_summary_by_user_by_event_name
ORDER BY MAX_CONTROLLED_MEMORY DESC LIMIT 5;

```

```

### Example 3: Freeable memory drops continuously and isn't reclaimed

The InnoDB database engine employs a range of specialized memory tracking events for different components. These specific events allow for granular tracking of memory usage in key InnoDB subsystems, for example:

- `memory/innodb/buf0buf` – Dedicated to monitoring memory allocations for the InnoDB buffer pool.
- `memory/innodb/ibuf0ibuf` – Specifically tracks memory changes related to the InnoDB change buffer.

To identify the top consumers of memory, we can query `sys.memory_global_by_current_bytes`:

```

mysql> SELECT event_name,current_alloc FROM sys.memory_global_by_current_bytes LIMIT
10;

```

```

+-----+-----+-----+-----+
| event_name          | current_alloc              |
+-----+-----+-----+-----+
| memory/innodb/memory | 5.28 GiB                  |
| memory/performance_schema/table_io_waits_summary_by_index_usage | 495.00 MiB                |
| memory/performance_schema/table_shares | 488.00 MiB                |

```

```

| memory/sql/TABLE_SHARE::mem_root          | 388.95 MiB |
| memory/innodb/std                          | 226.88 MiB |
| memory/innodb/fil0fil                      | 198.49 MiB |
| memory/sql/binlog_io_cache                 | 128.00 MiB |
| memory/innodb/mem0mem                     | 96.82 MiB  |
| memory/innodb/dict0dict                   | 96.76 MiB  |
| memory/performance_schema/rwlock_instances | 88.00 MiB  |
+-----+-----+-----+-----+-----+
10 rows in set (0.00 sec)

```

The results show that `memory/innodb/memory` is the top consumer, using 5.28 GiB of currently allocated memory. This event serves as a category for memory allocations across various InnoDB components not associated with more specific wait events, such as `memory/innodb/buf0buf` mentioned previously.

Having established that InnoDB components are the primary consumers of memory, we can dive deeper into the specifics using the following MySQL command:

```
SHOW ENGINE INNODB STATUS \G;
```

The [SHOW ENGINE INNODB STATUS](#) command provides a comprehensive status report for the InnoDB storage engine, including detailed memory usage statistics for different InnoDB components. It can help identify which specific InnoDB structures or operations are consuming the most memory. For more information, see [InnoDB in-memory structures](#) in the MySQL documentation.

Analyzing the `BUFFER POOL AND MEMORY` section of the InnoDB status report, we see that 5,051,647,748 bytes (4.7 GiB) is allocated to the [dictionary object cache](#), which accounts for 89% of the memory tracked by `memory/innodb/memory`.

```

-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 0
Dictionary memory allocated 5051647748
Buffer pool size 170512
Free buffers 142568
Database pages 27944
Old database pages 10354
Modified db pages 6
Pending reads 0

```

The dictionary object cache is a shared global cache that stores previously accessed data dictionary objects in memory to enable object reuse and improve performance. The high memory allocation to the dictionary object cache suggests a large number of database objects in the data dictionary cache.

Now that we know that the data dictionary cache is a primary consumer, we proceed to inspect the data dictionary cache for open tables. To find the number of tables in the table definition cache, query the global status variable [open\\_table\\_definitions](#).

```
mysql> show global status like 'open_table_definitions';

+-----+-----+
| Variable_name      | Value |
+-----+-----+
| Open_table_definitions | 20000 |
+-----+-----+
1 row in set (0.00 sec)
```

For more information, see [How MySQL opens and closes tables](#) in the MySQL documentation.

You can limit the number of table definitions in the data dictionary cache by limiting the `table_definition_cache` parameter in the DB cluster or DB instance parameter group. For Aurora MySQL, this value serves as a soft limit for the number of tables in the table definition cache. The default value is dependent on the instance class and is set to the following:

```
LEAST({DBInstanceClassMemory/393040}, 20000)
```

When the number of tables exceeds the `table_definition_cache` limit, a least recently used (LRU) mechanism evicts and remove tables from the cache. However, tables involved in foreign key relationships aren't placed in the LRU list, preventing their removal.

In our current scenario, we run [FLUSH TABLES](#) to clear the table definition cache. This action results in a significant drop in the [Open\\_table\\_definitions](#) global status variable, from 20,000 to 12, as shown here:

```
mysql> show global status like 'open_table_definitions';

+-----+-----+
| Variable_name      | Value |
+-----+-----+
```

```
| Open_table_definitions | 12 |
+-----+-----+
1 row in set (0.00 sec)
```

Despite this reduction, we observe that the memory allocation for `memory/innodb/memory` remains high at 5.18 GiB, and the dictionary memory allocated also remains unchanged. This is evident from the following query results:

```
mysql> SELECT event_name,current_alloc FROM sys.memory_global_by_current_bytes LIMIT
10;
```

```
+-----+-----+
| event_name | current_alloc |
+-----+-----+
| memory/innodb/memory | 5.18 GiB |
| memory/performance_schema/table_io_waits_summary_by_index_usage | 495.00 MiB |
| memory/performance_schema/table_shares | 488.00 MiB |
| memory/sql/TABLE_SHARE::mem_root | 388.95 MiB |
| memory/innodb/std | 226.88 MiB |
| memory/innodb/fil0fil | 198.49 MiB |
| memory/sql/binlog_io_cache | 128.00 MiB |
| memory/innodb/mem0mem | 96.82 MiB |
| memory/innodb/dict0dict | 96.76 MiB |
| memory/performance_schema/rwlock_instances | 88.00 MiB |
+-----+-----+
10 rows in set (0.00 sec)
```

```
-----
BUFFER POOL AND MEMORY
-----
```

```
Total large memory allocated 0
Dictionary memory allocated 5001599639
Buffer pool size 170512
Free buffers 142568
Database pages 27944
Old database pages 10354
Modified db pages 6
Pending reads 0
```

This persistently high memory usage can be attributed to tables involved in foreign key relationships. These tables aren't placed in the LRU list for removal, explaining why the memory allocation remains high even after flushing the table definition cache.

To address this issue:

1. Review and optimize your database schema, particularly foreign key relationships.
2. Consider moving to a larger DB instance class that has more memory to accommodate your dictionary objects.

By following these steps and understanding the memory allocation patterns, you can better manage memory usage in your Aurora MySQL DB instance and prevent potential performance issues due to memory pressure.

## Troubleshooting out-of-memory issues for Aurora MySQL databases

The Aurora MySQL `aurora_oom_response` instance-level parameter can enable the DB instance to monitor the system memory and estimate the memory consumed by various statements and connections. If the system runs low on memory, it can perform a list of actions to attempt to release that memory. It does so in an attempt to avoid a database restart due to out-of-memory (OOM) issues. The instance-level parameter takes a string of comma-separated actions that a DB instance performs when its memory is low. The `aurora_oom_response` parameter is supported for Aurora MySQL versions 2 and 3.

The following values, and combinations of them, can be used for the `aurora_oom_response` parameter. An empty string means that no action is taken, and effectively turns off the feature, leaving the database prone to OOM restarts.

- `decline` – Declines new queries when the DB instance is low on memory.
- `kill_connect` – Closes database connections that are consuming a large amount of memory, and ends current transactions and Data Definition Language (DDL) statements. This response isn't supported for Aurora MySQL version 2.

For more information, see [KILL statement](#) in the MySQL documentation.

- `kill_query` – Ends queries in descending order of memory consumption until the instance memory surfaces above the low threshold. DDL statements aren't ended.

For more information, see [KILL statement](#) in the MySQL documentation.

- `print` – Only prints the queries that are consuming a large amount of memory.
- `tune` – Tunes the internal table caches to release some memory back to the system. Aurora MySQL decreases the memory used for caches such as `table_open_cache` and

`table_definition_cache` in low-memory conditions. Eventually, Aurora MySQL sets their memory usage back to normal when the system is no longer low on memory.

For more information, see [table\\_open\\_cache](#) and [table\\_definition\\_cache](#) in the MySQL documentation.

- `tune_buffer_pool` – Decreases the size of the buffer pool to release some memory and make it available for the database server to process connections. This response is supported for Aurora MySQL version 3.06 and higher.

You must pair `tune_buffer_pool` with either `kill_query` or `kill_connect` in the `aurora_oom_response` parameter value. If not, buffer pool resizing won't happen, even when you include `tune_buffer_pool` in the parameter value.

In Aurora MySQL versions lower than 3.06, for DB instance classes with memory less than or equal to 4 GiB, when the instance is under memory pressure, the default actions include `print`, `tune`, `decline`, and `kill_query`. For DB instance classes with memory greater than 4 GiB, the parameter value is empty by default (disabled).

In Aurora MySQL version 3.06 and higher, for DB instance classes with memory less than or equal to 4 GiB, Aurora MySQL also closes the top memory-consuming connections (`kill_connect`). For DB instance classes with memory greater than 4 GiB, the default parameter value is `print`.

In Aurora MySQL version 3.09 and higher, for DB instance classes with memory greater than 4 GiB, the default parameter value is `print, decline, kill_connect`.

If you frequently run into out-of-memory issues, memory usage can be monitored using [memory summary tables](#) when `performance_schema` is enabled.

For Amazon CloudWatch metrics related to OOM, see [Instance-level metrics for Amazon Aurora](#). For global status variables related to OOM, see [Aurora MySQL global status variables](#).

## Logging for Aurora MySQL databases

Aurora MySQL logs provide essential information about database activity and errors. By enabling these logs, you can identify and troubleshoot issues, understand database performance, and audit database activity. We recommend that you enable these logs for all of your Aurora MySQL DB instances to ensure optimal performance and availability of the databases. The following types of logging can be enabled. Each log contains specific information that can lead to uncovering impacts to database processing.

- **Error** – Aurora MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry. Error logging is enabled by default. For more information, see [Aurora MySQL error logs](#).
- **General** – The general log provides detailed information about database activity, including all SQL statements executed by the database engine. For more information on enabling general logging and setting logging parameters, see [Aurora MySQL slow query and general logs](#), and [The general query log](#) in the MySQL documentation.

### Note

General logs can grow to be very large and consume your storage. For more information, see [Log rotation and retention for Aurora MySQL](#).

- **Slow query** – The slow query log consists of SQL statements that take more than [long\\_query\\_time](#) seconds to run and require at least [min\\_examined\\_row\\_limit](#) rows to be examined. You can use the slow query log to find queries that take a long time to run and are therefore candidates for optimization.

The default value for `long_query_time` is 10 seconds. We recommend that you start with a high value to identify the slowest queries, then work your way down for fine tuning.

You can also use related parameters, such as `log_slow_admin_statements` and `log_queries_not_using_indexes`. Compare `rows_examined` with `rows_returned`. If `rows_examined` is much greater than `rows_returned`, then those queries can potentially be blocking.

In Aurora MySQL version 3, you can enable `log_slow_extra` to obtain more details. For more information, see [Slow query log contents](#) in the MySQL documentation. You can also modify `long_query_time` at the session level for debugging query execution interactively, which is especially useful if `log_slow_extra` is enabled globally.

For more information on enabling slow query logging and setting logging parameters, see [Aurora MySQL slow query and general logs](#), and [The slow query log](#) in the MySQL documentation.

- **Audit** – The audit log monitors and logs database activity. Audit logging for Aurora MySQL is called Advanced Auditing. To enable Advanced Auditing, you set certain DB cluster parameters. For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).
- **Binary** – The binary log (binlog) contains events that describe database changes, such as table creation operations and changes to table data. It also contains events for statements that potentially could have made changes (for example, a [DELETE](#) that matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrease.

 **Note**

Aurora MySQL doesn't require binary logging for restore operations.

For more information on enabling binary logging and setting the binlog format, see [Configuring Aurora MySQL binary logging for Single-AZ databases](#), and [The binary log](#) in the MySQL documentation.

You can publish the error, general, slow, query, and audit logs to Amazon CloudWatch Logs. For more information, see [Publishing database logs to Amazon CloudWatch Logs](#).

Another useful tool for summarizing slow, general, and binary log files is [pt-query-digest](#).

# Troubleshooting connection issues for Aurora MySQL databases

Ensuring reliable connectivity between your applications and your RDS DB instance is crucial for the smooth operation of your workloads. However, connectivity issues can arise because of various factors, such as network configurations, authentication problems, or resource constraints. This guide aims to provide a comprehensive approach to troubleshooting connectivity issues with Aurora MySQL.

## Contents

- [Identifying database connectivity issues for Aurora MySQL](#)
- [Gathering data on connectivity issues for Aurora MySQL](#)
- [Monitoring database connections for Aurora MySQL](#)
  - [Additional monitoring for Aurora MySQL](#)
- [Connectivity error codes for Aurora MySQL](#)
- [Parameter tuning recommendations for Aurora MySQL](#)
- [Examples of troubleshooting database connection issues for Aurora MySQL](#)
  - [Example 1: Troubleshooting failed connection attempts](#)
  - [Example 2: Troubleshooting abnormal client disconnects](#)
  - [Example 3: Troubleshooting IAM failed connection attempts](#)

## Identifying database connectivity issues for Aurora MySQL

Identifying the specific category of the connectivity issue can help narrow down the potential causes and guide the troubleshooting process. Each category might require different approaches and techniques for diagnosis and resolution. Database connectivity issues can broadly be classified into the following categories.

### Connection errors and exceptions

Connection errors and exceptions can occur for various reasons, such as incorrect connection strings, authentication failures, network disruptions, or database server issues. Causes can include misconfigured connection parameters, invalid credentials, network outages, or database server crashes or restarts. Misconfigured security groups, virtual private cloud (VPC) settings, network Access Control Lists (ACLs), and route tables associated with subnets can also lead to connection issues.

## Connection limit reached

This issue arises when the number of concurrent connections to the database server exceeds the maximum allowed limit. Database servers typically have a configurable maximum connection limit defined by the parameter `max_connections` in the clusters and instance parameter groups. By imposing a connection limit, the database server ensures that it has sufficient resources (for example, memory, CPU, and file handles) to handle the existing connections efficiently and provide acceptable performance. Causes can include connection leaks in the application, inefficient connection pooling, or an unexpected surge in connection requests.

## Connection timeouts

Connection timeouts occur when the client application is unable to establish a connection with the database server within a specified timeout period. Common causes include network issues, server overload, firewall rules, and misconfigured connection settings.

## Idle connection timeouts

Idle connections that remain inactive for a prolonged period might be closed automatically by the database server to conserve resources. This timeout is typically configurable using the `wait_timeout` and `interactive_timeout` parameters, and should be adjusted based on the application's connection usage patterns. Causes can include application logic that leaves connections idle for extended periods, or improper connection management.

## Intermittent disconnect of existing connections

This class of errors refers to a scenario where established connections between a client application and the database are unexpectedly terminated or disconnected at irregular intervals, despite being active and in use. These disconnections occur intermittently, meaning they happen at irregular intervals and not consistently. The causes can include the following:

- Database server issues such as restarts or failovers
- Improper application connection handling
- Load balancing and proxy issues
- Network instability
- Problems with third-party components or middleware involved in the connection path
- Query execution timeouts
- Resource constraints on the server or client side

Identifying the root cause through comprehensive monitoring, logging, and analysis is crucial, while implementing proper error handling, connection pooling, and retry mechanisms can help

mitigate the impact of these intermittent disconnections on the application's functionality and user experience.

## Gathering data on connectivity issues for Aurora MySQL

Gathering comprehensive data related to the application, database, network, and infrastructure components is crucial for effectively troubleshooting connectivity issues between an application and an Aurora MySQL database. By collecting relevant logs, configurations, and diagnostic information, you gain valuable insights that can help identify the root cause of the connectivity problems and guide you towards an appropriate resolution.

Network logs and configurations, such as security group rules, VPC settings, and route tables, are essential for identifying potential network-related bottlenecks or misconfigurations that could be preventing the application from establishing a successful connection with the database. By analyzing these network components, you can make sure that the necessary ports are open, IP addresses are allowed, and routing configurations are set up correctly.

### Timestamps

Record the exact timestamps when the connectivity issues occur. This can help identify patterns or correlate the issues with other events or activities.

### DB engine logs

In addition to the general database logs, review the database engine logs (for example, the MySQL error log and slow query log) for any relevant information or errors that might be related to the intermittent connectivity issues. For more information, see [Logging for Aurora MySQL databases](#).

### Client application logs

Collect detailed logs from the client applications that connect to the database. Application logs provide visibility into the connection attempts, errors, and any relevant information from the application's perspective, which can reveal issues related to connection strings, authentication credentials, or application-level connection handling.

Database logs, on the other hand, offer insights into database-side errors, slow queries, or events that might be contributing to the connectivity issues. For more information, see [Logging for Aurora MySQL databases](#).

## Client environment variables

Check whether any environment variables or configuration settings on the client side might be affecting the database connection, such as proxy settings, SSL/TLS settings, or any other relevant variables.

## Client library versions

Make sure that the client is using the latest versions of any database drivers, libraries, or frameworks used for database connectivity. Outdated versions can have known issues or compatibility problems.

## Client network capture

Perform a network capture on the client side using a tool such as Wireshark or tcpdump during the times when connectivity issues occur. This can help identify any network-related issues or anomalies on the client side.

## Client network topology

Understand the client's network topology, including any firewalls, load balancers, or other components such as RDS Proxy or Proxy SQL that are making connections to the database instead of the client directly making connections.

## Client operating system settings

Check the client's operating system settings that might affect network connectivity, such as firewall rules, network adapter settings, and any other relevant settings.

## Connection pooling configuration

If you're using a connection pooling mechanism in your application, review the configuration settings and monitor the pool metrics (for example, active connections, idle connections, and connection timeouts) to ensure that the pool is functioning correctly. Also review the pool settings, such as the maximum pool size, minimum pool size, and connection validation settings, to ensure that they are configured correctly.

## Connection string

The connection string typically includes parameters such as the hostname or endpoint, port number, database name, and authentication credentials. Analyzing the connection string can help identify potential misconfigurations or incorrect settings that may be causing connectivity problems. For example, an incorrect hostname or port number can prevent the client from reaching the database instance, while invalid authentication credentials can lead to authentication failures and connection rejections. Additionally, the connection string can reveal

issues related to connection pooling, timeouts, or other connection-specific settings that could contribute to connectivity issues. Providing the complete connection string used by the client application can help pinpoint any misconfigurations on the client.

### Database metrics

Monitor database metrics such as CPU usage, memory usage, and disk I/O during the times when connectivity issues occur. These can help identify whether the DB instance is experiencing resource contention or performance issues.

### DB engine version

Note the Aurora MySQL DB engine version. Amazon regularly releases updates addressing known issues, security vulnerabilities, and introducing performance enhancements. Therefore, we highly recommend that you upgrade to the latest available versions, as these updates often include bug fixes and improvements specifically related to connectivity, performance, and stability. Providing the database version information, along with the other collected details, can assist Amazon Web Services Support in effectively diagnosing and resolving connectivity issues.

### Network metrics

Collect network metrics such as latency, packet loss, and throughput during the times when connectivity issues occur. Tools such as `ping`, `traceroute`, and network monitoring tools can help gather this data.

### Source and client details

Determine the IP addresses of the application servers, load balancers, or any other components that are initiating the database connections. This could be a single IP address or a range of IP addresses (CIDR notation). If the source is an Amazon EC2 instance, it also helps to review the instance type, Availability Zone, subnet ID, and security groups associated with the instance, and network interface details such as private IP address and public IP address.

By thoroughly analyzing the gathered data, you can identify misconfigurations, resource constraints, network disruptions, or other underlying issues that are causing the intermittent or persistent connectivity problems. This information allows you to take targeted actions, such as adjusting configurations, resolving network issues, or addressing application-level connection handling.

## Monitoring database connections for Aurora MySQL

To monitor and troubleshoot connectivity issues, you can use the following metrics and features.

## CloudWatch metrics

- **CPUUtilization** – High CPU usage on the DB instance can lead to slow query execution, which can result in connection timeouts or rejections.
- **DatabaseConnections** – Monitor the number of active connections to the DB instance. A high number of connections close to the configured maximum can indicate potential connectivity issues or connection pool exhaustion.
- **FreeableMemory** – Low available memory can cause performance issues and connectivity problems because of resource constraints.
- **NetworkReceiveThroughput** and **NetworkTransmitThroughput** – Unusual spikes or drops in network throughput can indicate connectivity issues or network bottlenecks.

## Performance Insights metrics

To troubleshoot connectivity issues in Aurora MySQL using Performance Insights, analyze Database metrics such as the following:

- **Aborted\_clients**
- **Aborted\_connects**
- **Connections**
- **max\_connections**
- **Threads\_connected**
- **Threads\_created**
- **Threads\_running**

These metrics can help you to identify connection bottlenecks, detect network or authentication problems, optimize connection pooling, and ensure efficient thread management. For more information, see [Performance Insights counters for Aurora MySQL](#).

## Performance Insights features

- **Database Load** – Visualize the database load over time and correlate it with connectivity issues or performance degradation.
- **SQL Statistics** – Analyze SQL statistics to identify inefficient queries or database operations that might contribute to connectivity problems.
- **Top Queries** – Identify and analyze the most resource-intensive queries, which can help identify potential performance bottlenecks or long-running queries that may be causing connectivity issues.

By monitoring these metrics and leveraging Performance Insights, you can gain visibility into the database instance's performance, resource usage, and potential bottlenecks that might be causing connectivity issues. For example:

- High `DatabaseConnections` close to the maximum limit can indicate connection pool exhaustion or improper connection handling, leading to connectivity problems.
- High `CPUUtilization` or low `FreeableMemory` can indicate resource constraints, which may cause slow query execution and connection timeouts or rejections.
- Analyzing the **Top Queries** and **SQL Statistics** can help identify inefficient or resource-intensive queries that may be contributing to connectivity issues.

Additionally, monitoring CloudWatch Logs and setting up alarms can help you proactively identify and respond to connectivity problems before they escalate.

It's important to note that while these metrics and tools can provide valuable insights, they should be used in conjunction with other troubleshooting steps. By also reviewing network configurations, security group rules, and application-level connection handling, you can comprehensively diagnose and resolve connectivity issues with Aurora MySQL DB instances.

## Additional monitoring for Aurora MySQL

### CloudWatch metrics

- `AbortedClients` – Tracks the number of client connections that have not been closed properly.
- `AuroraSlowConnectionHandleCount` – Tracks the number of slow connection handle operations, indicating potential connectivity issues or performance bottlenecks.
- `AuroraSlowHandshakeCount` – Measures the number of slow handshake operations, which can also be an indicator of connectivity problems.
- `ConnectionAttempts` – Measures the number of connection attempts made to the Aurora MySQL DB instance.

### Global status variables

`Aurora_external_connection_count` – Shows the number of database connections to the DB instance, excluding RDS service connections used for database health checks.

By monitoring these metrics and global status variables you can gain visibility into the connection patterns, errors, and potential bottlenecks that may be causing connectivity issues with your Amazon Aurora MySQL instance.

For example, a high number of `AbortedClients` or `AuroraSlowConnectionHandleCount` can indicate connectivity problems.

Additionally, setting up CloudWatch alarms and notifications can help you proactively identify and respond to connectivity issues before they escalate and impact your application's performance.

## Connectivity error codes for Aurora MySQL

The following are some common connectivity errors for Aurora MySQL databases, along with their error codes and explanations.

### Error Code 1040: Too many connections

This error occurs when the client tries to establish more connections than the maximum allowed by the database server. Possible causes include the following:

- Connection pooling misconfiguration – If using a connection pooling mechanism, ensure that the maximum pool size is not set too high, and that connections are being properly released back to the pool.
- Database instance configuration – Verify the maximum allowed connections setting for the database instance and adjust it if necessary by setting the `max_connections` parameter.
- High concurrency – If multiple clients or applications are connecting to the database simultaneously, the maximum allowed connections limit may be reached.

### Error Code 1045: Access denied for user '...'@'...' (using password: YES/NO)

This error indicates an authentication failure when attempting to connect to the database. Possible causes include the following:

- Authentication plugin compatibility – Check whether the authentication plugin used by the client is compatible with the database server's authentication mechanism.
- Incorrect username or password – Verify that the correct username and password are being used in the connection string or authentication mechanism.
- User permissions – Make sure that the user has the necessary permissions to connect to the database instance from the specified host or network.

### **Error Code 1049: Unknown database '...'**

This error indicates that the client is attempting to connect to a database that does not exist on the server. Possible causes include the following:

- Database not created – Make sure that the specified database has been created on the database server.
- Incorrect database name – Double-check the database name used in the connection string or query for accuracy.
- User permissions – Verify that the user has the necessary permissions to access the specified database.

### **Error Code 1153: Got a packet bigger than 'max\_allowed\_packet' bytes**

This error occurs when the client attempts to send or receive data that exceeds the maximum packet size allowed by the database server. Possible causes include the following:

- Large queries or result sets – If executing queries that involve large amounts of data, the packet size limit may be exceeded.
- Misconfigured packet size settings – Check the `max_allowed_packet` setting on the database server and adjust it if necessary.
- Network configuration issues – Make sure that the network configuration (for example, MTU size) allows for the required packet sizes.

### **Error Code 1226: User '...' has exceeded the 'max\_user\_connections' resource (current value: ...)**

This error indicates that the user has exceeded the maximum number of concurrent connections allowed by the database server. Possible causes include the following:

- Connection pooling misconfiguration – If using a connection pooling mechanism, ensure that the maximum pool size is not set too high for the user's connection limit.
- Database instance configuration – Verify the `max_user_connections` setting for the database instance and adjust it if necessary.
- High concurrency – If multiple clients or applications are connecting to the database simultaneously using the same user, the user-specific connection limit may be reached.

### **Error Code 2003: Can't connect to MySQL server on '...' (10061)**

This error typically occurs when the client is unable to establish a TCP/IP connection with the database server. It can be caused by various issues, such as the following:

- Database instance status – Make sure that the database instance is in the available state, and not undergoing any maintenance or backup operations.

- Firewall rules – Check whether any firewalls (operating system, network, or security group) are blocking the connection on the specified port (usually 3306 for MySQL).
- Incorrect hostname or endpoint – Make sure that the hostname or endpoint used in the connection string is correct and matches the database instance.
- Network connectivity issues – Verify that the client machine can reach the database instance over the network. Check for any network outages, routing issues, or VPC or subnet misconfigurations.

### **Error Code 2005: Unknown MySQL server host '...' (11001)**

This error occurs when the client is unable to resolve the hostname or endpoint of the database server to an IP address. Possible causes include the following:

- DNS resolution issues – Verify that the client machine can resolve the hostname correctly using DNS. Check the DNS settings, DNS cache, and try using the IP address instead of the hostname.
- Incorrect hostname or endpoint – Double-check the hostname or endpoint used in the connection string for accuracy.
- Network configuration issues – Make sure that the client's network configuration (for example, VPC, subnet, and route tables) allows DNS resolution and connectivity to the database instance.

### **Error Code 2026: SSL connection error**

This error occurs when there is an issue with the SSL/TLS configuration or certificate validation during the connection attempt. Possible causes include the following:

- Certificate expiration – Check whether the SSL/TLS certificate used by the server has expired and needs to be renewed.
- Certificate validation issues – Verify that the client is able to validate the server's SSL/TLS certificate correctly, and that the certificate is trusted.
- Network configuration issues – Make sure that the network configuration allows for SSL/TLS connections and doesn't block or interfere with the SSL/TLS handshake process.
- SSL/TLS configuration mismatch – Make sure that the SSL/TLS settings (for example, cipher suites and protocol versions) on the client and server are compatible.

By understanding the detailed explanations and potential causes for each error code, you can better troubleshoot and resolve connectivity issues when working with Aurora MySQL databases.

## Parameter tuning recommendations for Aurora MySQL

### Maximum connections

Adjusting these parameters can help prevent connection issues caused by reaching the maximum allowed connections limit. Make sure that these values are set appropriately based on your application's concurrency requirements and resource constraints.

- `max_connections` – This parameter specifies the maximum number of concurrent connections allowed to the DB instance.
- `max_user_connections` – This parameter can be specified during user creation and modification, and sets the maximum number of concurrent connections allowed for a specific user account.

### Network buffer size

Increasing these values can improve network performance, especially for workloads involving large data transfers or result sets. However, be cautious as larger buffer sizes can consume more memory.

- `net_buffer_length` – This parameter sets the initial size for client connection and result buffers, balancing memory usage with query performance.
- `max_allowed_packet` – This parameter specifies the maximum size of a single network packet that can be sent or received by the DB instance.

### Network compression (client side)

Enabling network compression can reduce network bandwidth usage, but it can increase CPU overhead on both the client and server sides.

- `compress` – This parameter enables or disables network compression for client/server communication.
- `compress_protocol` – This parameter specifies the compression protocol to use for network communication.

### Network performance tuning

Adjusting these timeouts can help manage idle connections and prevent resource exhaustion, but be cautious as low values can cause premature connection terminations.

- `interactive_timeout` – This parameter specifies the number of seconds the server waits for activity on an interactive connection before closing it.

- `wait_timeout` – This parameter determines the number of seconds the server waits for activity on a noninteractive connection before closing it.

## Network timeout settings

Adjusting these timeouts can help address issues related to slow or unresponsive connections. But be careful not to set them too low, as it can cause premature connection failures.

- `net_read_timeout` – This parameter specifies the number of seconds to wait for more data from a connection before ending the read operation.
- `net_write_timeout` – This parameter determines the number of seconds to wait for a block to be written to a connection before ending the write operation.

## Examples of troubleshooting database connection issues for Aurora MySQL

The following examples show how to identify and troubleshoot database connection issues for Aurora MySQL.

### Example 1: Troubleshooting failed connection attempts

Connection attempts can fail for several reasons, including authentication failures, SSL/TLS handshake failures, `max_connections` limit reached, and resource constraints on the DB instance.

You can track the number of failed connections either from Performance Insights or by using the following command.

```
mysql> show global status like 'aborted_connects';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_connects | 7 |
+-----+-----+
1 row in set (0.00 sec)
```

If the number of `Aborted_connects` increases over time, then the application could be having intermittent connectivity issues.

You can use [Aurora Advanced Auditing](#) to log the connects and disconnects from the client connections. You can do this by setting the following parameters in the DB cluster parameter group:

- `server_audit_logging = 1`

- `server_audit_events = CONNECT`

The following is an extract from the audit logs for a failed login.

```
1728498527380921, aurora-mysql-node1, user_1, 172.31.49.222, 147189, 0, FAILED_CONNECT, , , 1045
1728498527380940, aurora-mysql-node1, user_1, 172.31.49.222, 147189, 0, DISCONNECT, , , 0
```

Where:

- 1728498527380921 – The epoch timestamp of when the failed login occurred
- `aurora-mysql-node1` – The instance identifier of the node of the Aurora MySQL cluster on which the connection failed
- `user_1` – The name of the database user for which the login failed
- 172.31.49.222 – The private IP address of the client from which the connection was established
- 147189 – The connection ID of the failed login
- `FAILED_CONNECT` – Indicates that the connection failed.
- 1045 – The return code. A nonzero value indicates an error. In this case, 1045 corresponds to access denied.

For more information, see [Server error codes](#) and [Client error codes](#) in the MySQL documentation.

You can also examine the Aurora MySQL error logs for any related error messages, for example:

```
2024-10-09T19:26:59.310443Z 220 [Note] [MY-010926] [Server] Access denied for user
'user_1'@'172.31.49.222' (using password: YES) (sql_authentication.cc:1502)
```

## Example 2: Troubleshooting abnormal client disconnects

You can track the number of abnormal client disconnects either from Performance Insights or by using the following command.

```
mysql> show global status like 'aborted_clients';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 9     |
```

```
+-----+-----+
1 row in set (0.01 sec)
```

If the number of `Aborted_clients` increases over time, then the application isn't closing the connections to the database correctly. If connections aren't closed properly, it can lead to resource leaks and potential performance issues. Leaving connections open unnecessarily can consume system resources, such as memory and file descriptors, which can eventually cause the application or server to become unresponsive or restart.

You can use the following query to identify accounts that aren't closing connections properly. It retrieves the user account name, the host from which the user is connecting, the number of connections not closed, and the percentage of connections not closed.

```
SELECT
  ess.user,
  ess.host,
  (a.total_connections - a.current_connections) - ess.count_star AS not_closed,
  (((a.total_connections - a.current_connections) - ess.count_star) * 100) /
  (a.total_connections - a.current_connections) AS pct_not_closed
FROM
  performance_schema.events_statements_summary_by_account_by_event_name AS ess
  JOIN performance_schema.accounts AS a ON (ess.user = a.user AND ess.host = a.host)
WHERE
  ess.event_name = 'statement/com/quit'
  AND (a.total_connections - a.current_connections) > ess.count_star;
```

```
+-----+-----+-----+-----+
| user   | host           | not_closed | pct_not_closed |
+-----+-----+-----+-----+
| user1  | 172.31.49.222 | 1         | 33.3333       |
| user1  | 172.31.93.250 | 1024      | 12.1021       |
| user2  | 172.31.93.250 | 10        | 12.8551       |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

After you identify the user accounts and hosts from which the connections aren't closed, you can proceed to check the code that isn't closing the connections gracefully.

For example, with the MySQL connector in Python, use the `close()` method of the connection object to close connections. Here's an example function that establishes a connection to a database, performs a query, and closes the connection:

```
import mysql.connector

def execute_query(query):
    # Establish a connection to the database
    connection = mysql.connector.connect(
        host="your_host",
        user="your_username",
        password="your_password",
        database="your_database"
    )

    try:
        # Create a cursor object
        cursor = connection.cursor()

        # Execute the query
        cursor.execute(query)

        # Fetch and process the results
        results = cursor.fetchall()
        for row in results:
            print(row)

    finally:
        # Close the cursor and connection
        cursor.close()
        connection.close()
```

In this example, the `connection.close()` method is called in the `finally` block to make sure that the connection is closed, whether or not an exception occurs.

### Example 3: Troubleshooting IAM failed connection attempts

Connectivity with Amazon Identity and Access Management (IAM) users can fail for several reasons, such as:

- Incorrect IAM policy configuration
- Expired security credentials
- Network connectivity issues
- Database permission mismatches

To troubleshoot these authentication errors, enable the `iam-db-auth-error` log export feature in your Amazon Relational Database Service (RDS) or Aurora database. This will allow you to view detailed authentication error messages in CloudWatch Log group for your Amazon RDS or Amazon Aurora cluster.

Once enabled, you can review these logs to identify and resolve the specific cause of your IAM authentication failures.

For example:

```
2025-09-22T12:02:30,806 [ERROR] Failed to authorize the connection request for user 'user_1' due to an internal IAM DB Auth error. (Status Code: 500, Error Code: InternalError)
```

and

```
2025-09-22T12:02:51,954 [ERROR] Failed to authenticate the connection request for user 'user_2' because the provided token is malformed or otherwise invalid. (Status Code: 400, Error Code: InvalidToken)
```

For troubleshooting guidance, refer to the [Aurora](#) troubleshooting guide for IAM DB authentication.

## Troubleshooting query performance for Aurora MySQL databases

MySQL provides [query optimizer control](#) through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model. These data points can be helpful not only while comparing different MySQL environments, but also to compare previous query execution plans with current execution plans, and to understand the overall execution of a MySQL query at any point.

Query performance depends on many factors, including the execution plan, table schema and size, statistics, resources, indexes, and parameter configuration. Query tuning requires identifying bottlenecks and optimizing the execution path.

- Find the execution plan for the query and check whether the query is using appropriate indexes. You can optimize your query by using EXPLAIN and reviewing the details of each plan.
- Aurora MySQL version 3 (compatible with MySQL 8.0 Community Edition) uses an EXPLAIN ANALYZE statement. The EXPLAIN ANALYZE statement is a profiling tool that shows where MySQL spends time on your query and why. With EXPLAIN ANALYZE, Aurora MySQL plans, prepares, and runs the query while counting rows and measuring the time spent at various points of the execution plan. When the query completes, EXPLAIN ANALYZE prints the plan and its measurements instead of the query result.
- Keep your schema statistics updated by using the ANALYZE statement. The query optimizer can sometimes choose poor execution plans because of outdated statistics. This can lead to poor performance of a query because of inaccurate cardinality estimates of both tables and indexes. The `last_update` column of the [innodb\\_table\\_stats](#) table shows the last time your schema statistics were updated, which is a good indicator of "staleness."
- Other issues can occur, such as distribution skew of data, that aren't taken into account for table cardinality. For more information, see [Estimating ANALYZE TABLE complexity for InnoDB tables](#) and [Histogram statistics in MySQL](#) in the MySQL documentation.

### Understanding the time spent by queries

The following are ways to determine the time spent by queries:

- [Profiling](#)
- [Performance Schema](#)
- [Query optimizer](#)

## Profiling

By default, profiling is disabled. Enable profiling, then run the slow query and review its profile.

```
SET profiling = 1;  
Run your query.  
SHOW PROFILE;
```

1. Identify the stage where the most time is spent. According to [General thread states](#) in the MySQL documentation, reading and processing rows for a SELECT statement is often the longest-running state over the lifetime of a given query. You can use the EXPLAIN statement to understand how MySQL runs this query.
2. Review the slow query log to evaluate `rows_examined` and `rows_sent` to make sure that the workload is similar in each environment. For more information, see [Logging for Aurora MySQL databases](#).
3. Run the following command for tables that are part of the identified query:

```
SHOW TABLE STATUS\G;
```

4. Capture the following outputs before and after running the query on each environment:

```
SHOW GLOBAL STATUS;
```

5. Run the following commands on each environment to see if there are any other query/session influencing the performance of this sample query.

```
SHOW FULL PROCESSLIST;  
  
SHOW ENGINE INNODB STATUS\G;
```

Sometimes, when resources on the server are busy, it impacts every other operation on the server, including queries. You can also capture information periodically when queries are run or set up a cron job to capture information at useful intervals.

## Performance Schema

The Performance Schema provides useful information about server runtime performance, while having minimal impact on that performance. This is different from the `information_schema`, which provides schema information about the DB instance. For more information, see [Overview of the Performance Schema for Performance Insights on Aurora MySQL](#).

## Query optimizer trace

To understand why a particular [query plan was chosen for execution](#), you can set up `optimizer_trace` to access the MySQL query optimizer.

Run an optimizer trace to show extensive information on all the paths available to the optimizer and its choice.

```
SET SESSION OPTIMIZER_TRACE="enabled=on";
SET optimizer_trace_offset=-5, optimizer_trace_limit=5;

-- Run your query.
SELECT * FROM table WHERE x = 1 AND y = 'A';

-- After the query completes:
SELECT * FROM information_schema.OPTIMIZER_TRACE;
SET SESSION OPTIMIZER_TRACE="enabled=off";
```

## Reviewing query optimizer settings

Aurora MySQL version 3 (compatible with MySQL 8.0 Community Edition) has many optimizer-related changes compared with Aurora MySQL version 2 (compatible with MySQL 5.7 Community Edition). If you have some custom values for the `optimizer_switch`, we recommend that you review the differences in the defaults and set `optimizer_switch` values that work best for your workload. We also recommend that you test the options available for Aurora MySQL version 3 to examine how your queries perform.

### Note

Aurora MySQL version 3 uses the community default value of 20 for the [innodb\\_stats\\_persistent\\_sample\\_pages](#) parameter.

You can use the following command to show the `optimizer_switch` values:

```
SELECT @@optimizer_switch\G;
```

The following table shows the default `optimizer_switch` values for Aurora MySQL versions 2 and 3.

Setting	Aurora MySQL version 2	Aurora MySQL version 3
batched_key_access	off	off
block_nested_loop	on	on
condition_fanout_filter	on	on
derived_condition_pushdown	–	on
derived_merge	on	on
duplicateweedout	on	on
engine_condition_pushdown	on	on
firstmatch	on	on
hash_join	off	on
hash_join_cost_based	on	–
hypergraph_optimizer	–	off
index_condition_pushdown	on	on
index_merge	on	on
index_merge_intersection	on	on
index_merge_sort_union	on	on
index_merge_union	on	on
loosescan	on	on
materialization	on	on
mrr	on	on
mrr_cost_based	on	on

Setting	Aurora MySQL version 2	Aurora MySQL version 3
prefer_ordering_index	on	on
semijoin	on	on
skip_scan	–	on
subquery_materialization_cost_based	on	on
subquery_to_derived	–	off
use_index_extensions	on	on
use_invisible_indexes	–	off

For more information, see [Switchable optimizations \(MySQL 5.7\)](#) and [Switchable optimizations \(MySQL 8.0\)](#) in the MySQL documentation.

# Amazon Aurora MySQL reference

This reference includes information about Aurora MySQL parameters, status variables, and general SQL extensions or differences from the community MySQL database engine.

## Topics

- [Aurora MySQL configuration parameters](#)
- [Aurora MySQL global status variables](#)
- [Aurora MySQL wait events](#)
- [Aurora MySQL thread states](#)
- [Aurora MySQL isolation levels](#)
- [Aurora MySQL hints](#)
- [Aurora MySQL stored procedure reference](#)
- [Aurora MySQL-specific information\\_schema tables](#)

## Aurora MySQL configuration parameters

You manage your Amazon Aurora MySQL DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Aurora MySQL DB cluster apply to the entire cluster. Other parameters apply only to a particular DB instance in the DB cluster.

To manage cluster-level parameters, use DB cluster parameter groups. To manage instance-level parameters, use DB parameter groups. Each DB instance in an Aurora MySQL DB cluster is compatible with the MySQL database engine. However, you apply some of the MySQL database engine parameters at the cluster level, and you manage these parameters using DB cluster parameter groups. You can't find cluster-level parameters in the DB parameter group for an instance in an Aurora DB cluster. A list of cluster-level parameters appears later in this topic.

You can manage both cluster-level and instance-level parameters using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API. You use separate commands for managing cluster-level parameters and instance-level parameters. For example, you can use the [modify-db-cluster-parameter-group](#) CLI command to manage cluster-level parameters in a DB cluster parameter group. You can use the [modify-db-parameter-group](#) CLI command to manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

You can view both cluster-level and instance-level parameters in the console, or by using the CLI or RDS API. For example, you can use the [describe-db-cluster-parameters](#) Amazon CLI command to view cluster-level parameters in a DB cluster parameter group. You can use the [describe-db-parameters](#) CLI command to view instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

### Note

Each [default parameter group](#) contains the default values for all parameters in the parameter group. If the parameter has "engine default" for this value, see the version-specific MySQL or PostgreSQL documentation for the actual default value. Unless otherwise noted, parameters listed in the following tables are valid for Aurora MySQL versions 2 and 3.

For more information about DB parameter groups, see [Parameter groups for Amazon Aurora](#). For rules and restrictions for Aurora Serverless v1 clusters, see [Parameter groups for Aurora Serverless v1](#).

## Topics

- [Cluster-level parameters](#)
- [Instance-level parameters](#)
- [MySQL parameters that don't apply to Aurora MySQL](#)

## Cluster-level parameters

The following table shows all of the parameters that apply to the entire Aurora MySQL DB cluster.

Parameter name	Modifiable	Notes
aurora_binlog_read_buffer_size	Yes	Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> .

Parameter name	Modifiable	Notes
		Removed from Aurora MySQL version 3.
aurora_binlog_replication_max_yield_seconds	Yes	Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replicating between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> .
aurora_binlog_replication_sec_index_parallel_workers	Yes	<p>Sets the total number of parallel threads available to apply secondary index changes when replicating transactions for large tables with more than one secondary index. The parameter is set to 0 (disabled) by default.</p> <p>This parameter is available in Aurora MySQL version 306 and higher. For more information, see <a href="#">Optimizing binary log replication for Aurora MySQL</a>.</p>
aurora_binlog_use_large_read_buffer	Yes	<p>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see <a href="#">Replicating between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a>.</p> <p>Removed from Aurora MySQL version 3.</p>

Parameter name	Modifiable	Notes
<code>aurora_disable_hash_join</code>	Yes	Set this parameter to ON to turn off hash join optimization in Aurora MySQL version 2.09 or higher. It isn't supported for version 3. For more information, see <a href="#">Parallel query for Amazon Aurora MySQL</a> .
<code>aurora_enable_replica_log_compression</code>	Yes	For more information, see <a href="#">Performance considerations for Amazon Aurora MySQL replication</a> . Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.
<code>aurora_enable_repl_bin_log_filtering</code>	Yes	For more information, see <a href="#">Performance considerations for Amazon Aurora MySQL replication</a> . Doesn't apply to clusters that are part of an Aurora global database. Removed from Aurora MySQL version 3.
<code>aurora_enable_staggered_replica_restart</code>	Yes	This setting is available in Aurora MySQL version 3, but it isn't used.
<code>aurora_enable_zdr</code>	Yes	This setting is turned on by default in Aurora MySQL 2.10 and higher.
<code>aurora_in_memory_relaylog</code>	Yes	Sets the in memory relay log mode. You can use this feature on binlog replicas to improve binary log replication performance. To turn this feature off, set the parameter to OFF. To turn this feature on, set the parameter to ON.

Parameter name	Modifiable	Notes
<code>aurora_enhanced_binlog</code>	Yes	Set the value of this parameter to 1 to turn on the enhanced binlog in Aurora MySQL version 3.03.1 and higher. For more information, see <a href="#">Setting up enhanced binlog for Aurora MySQL</a> .
<code>aurora_full_double_precision_in_json</code>	Yes	Set the value of this parameter to enable the parsing of floating point numbers in JSON documents with full precision.
<code>aurora_jemalloc_background_thread</code>	Yes	Use this parameter to enable a background thread to perform memory maintenance operations. The allowed values are 0 (disabled) and 1 (enabled). The default value is 0.  This parameter applies to Aurora MySQL version 3.05 and higher.
<code>aurora_jemalloc_dirty_decay_ms</code>	Yes	Use this parameter to retain freed memory for a certain amount of time (in milliseconds). Retaining memory allows for faster reuse. The allowed values are 0–18446744073709551615. The default value is 10000 (10 seconds).  You can use a shorter delay to help avoid out-of-memory issues, at the expense of slower performance.  This parameter applies to Aurora MySQL version 3.05 and higher.

Parameter name	Modifiable	Notes
<code>aurora_jemalloc_tcache_enabled</code>	Yes	<p>Use this parameter to serve small memory requests (up to 32 KiB) in a thread local cache, bypassing the memory arenas. The allowed values are 0 (disabled) and 1 (enabled). The default value is 1.</p> <p>This parameter applies to Aurora MySQL version 3.05 and higher.</p>
<code>aurora_load_from_s3_role</code>	Yes	<p>For more information, see <a href="#">Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket</a>. Currently not available in Aurora MySQL version 3. Use <code>aws_default_s3_role</code>.</p>
<code>aurora_mask_password_hashes_type</code>	Yes	<p>This setting is turned on by default in Aurora MySQL 2.11 and higher.</p> <p>Use this setting to mask Aurora MySQL password hashes in the slow query and audit logs. The allowed values are 0 and 1 (default). When set to 1, passwords are logged as &lt;secret&gt;. When set to 0, passwords are logged as hash (#) values.</p>
<code>aurora_select_into_s3_role</code>	Yes	<p>For more information, see <a href="#">Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket</a>. Currently not available in Aurora MySQL version 3. Use <code>aws_default_s3_role</code>.</p>

Parameter name	Modifiable	Notes
authentication_kerberos_case_insensitive_cmp	Yes	Controls case-insensitive username comparison for the authentication_kerberos plugin. Set it to true for case-insensitive comparison. By default, case-sensitive comparison is used (false). For more information, see <a href="#">Using Kerberos authentication for Aurora MySQL</a> .  This parameter is available in Aurora MySQL version 3.03 and higher.
auto_increment_increment	Yes	None
auto_increment_offset	Yes	None
aws_default_lambda_role	Yes	For more information, see <a href="#">Invoking a Lambda function from an Amazon Aurora MySQL DB cluster</a> .

Parameter name	Modifiable	Notes
aws_default_s3_role	Yes	<p>Used when invoking the LOAD DATA FROM S3, LOAD XML FROM S3, or SELECT INTO OUTFILE S3 statement from your DB cluster.</p> <p>In Aurora MySQL version 2, the IAM role specified in this parameter is used if an IAM role isn't specified for <code>aurora_load_from_s3_role</code> or <code>aurora_select_into_s3_role</code> for the appropriate statement.</p> <p>In Aurora MySQL version 3, the IAM role specified for this parameter is always used.</p> <p>For more information, see <a href="#">Associating an IAM role with an Amazon Aurora MySQL DB cluster</a>.</p>
binlog_backup	Yes	<p>Set the value of this parameter to 0 to turn on the enhanced binlog in Aurora MySQL version 3.03.1 and higher. You can turn off this parameter only when you use enhanced binlog. For more information, see <a href="#">Setting up enhanced binlog for Aurora MySQL</a>.</p>
binlog_checksum	Yes	<p>The Amazon CLI and RDS API report a value of None if this parameter isn't set. In that case, Aurora MySQL uses the engine default value, which is CRC32. This is different from the explicit setting of NONE, which turns off the checksum.</p>

Parameter name	Modifiable	Notes
binlog-do-db	Yes	This parameter applies to Aurora MySQL version 3.
binlog_format	Yes	For more information, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> .
binlog_group_commit_sync_delay	Yes	This parameter applies to Aurora MySQL version 3.
binlog_group_commit_sync_no_delay_count	Yes	This parameter applies to Aurora MySQL version 3.
binlog-ignore-db	Yes	This parameter applies to Aurora MySQL version 3.
binlog_replication_globaldb	Yes	Set the value of this parameter to 0 to turn on the enhanced binlog in Aurora MySQL version 3.03.1 and higher. You can turn off this parameter only when you use enhanced binlog. For more information, see <a href="#">Setting up enhanced binlog for Aurora MySQL</a> .
binlog_row_image	No	None
binlog_row_metadata	Yes	This parameter applies to Aurora MySQL version 3.
binlog_row_value_options	Yes	This parameter applies to Aurora MySQL version 3.
binlog_rows_query_log_events	Yes	None

Parameter name	Modifiable	Notes
<code>binlog_transaction_compression</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>binlog_transaction_compression_level_zstd</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>binlog_transaction_dependency_history_size</code>	Yes	This parameter sets an upper limit on the number of row hashes that are kept in memory and used for looking up the transaction that last modified a given row. After this number of hashes has been reached, the history is purged.  This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.
<code>binlog_transaction_dependency_tracking</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>character-set-client-handshake</code>	Yes	None
<code>character_set_client</code>	Yes	None
<code>character_set_connection</code>	Yes	None
<code>character_set_database</code>	Yes	The character set used by the default database. The default value is <code>utf8mb4</code> .
<code>character_set_filesystem</code>	Yes	None
<code>character_set_results</code>	Yes	None
<code>character_set_server</code>	Yes	None
<code>collation_connection</code>	Yes	None

Parameter name	Modifiable	Notes
<code>collation_server</code>	Yes	None
<code>completion_type</code>	Yes	None
<code>default_storage_engine</code>	No	Aurora MySQL clusters use the InnoDB storage engine for all of your data.
<code>enforce_gtid_consistency</code>	Sometimes	Modifiable in Aurora MySQL version 2 and higher.
<code>event_scheduler</code>	Yes	Indicates the status of the Event Scheduler.  Modifiable only at the cluster level in Aurora MySQL version 3.
<code>gtid-mode</code>	Sometimes	Modifiable in Aurora MySQL version 2 and higher.
<code>information_schema_stats_expiry</code>	Yes	The number of seconds after which the MySQL database server fetches data from the storage engine and replaces the data in the cache. The allowed values are 0–31536000.  This parameter applies to Aurora MySQL version 3.

Parameter name	Modifiable	Notes
<code>init_connect</code>	Yes	<p>The command to be run by the server for each client that connects. Use double quotes (") for settings to avoid connection failures, for example:</p> <pre>SET optimizer_switch="hash_join=off"</pre> <p>In Aurora MySQL version 3, this parameter doesn't apply for users who have the <code>CONNECTION_ADMIN</code> privilege. This includes the Aurora master user. For more information, see <a href="#">Role-based privilege model</a>.</p>
<code>innodb_adaptive_hash_index</code>	Yes	<p>You can modify this parameter at the DB cluster level in Aurora MySQL versions 2 and 3.</p> <p>The Adaptive Hash Index isn't supported on reader DB instances.</p>

Parameter name	Modifiable	Notes
<code>innodb_aurora_instant_alter_column_allowed</code>	Yes	<p>Controls whether the INSTANT algorithm can be used for ALTER COLUMN operations at the global level. The allowed values are the following:</p> <ul style="list-style-type: none"> <li>• 0 – The INSTANT algorithm isn't allowed for ALTER COLUMN operations (OFF). Reverts to other algorithms.</li> <li>• 1 – The INSTANT algorithm is allowed for ALTER COLUMN operations (ON). This is the default value.</li> </ul> <p>For more information, see <a href="#">Column Operations</a> in the MySQL documentation.</p> <p>This parameter applies to Aurora MySQL version 3.05 and higher.</p>
<code>innodb_autoinc_lock_mode</code>	Yes	None
<code>innodb_checksums</code>	No	Removed from Aurora MySQL version 3.
<code>innodb_cmp_per_index_enabled</code>	Yes	None
<code>innodb_commit_concurrency</code>	Yes	None
<code>innodb_data_home_dir</code>	No	Aurora MySQL uses managed instances where you don't access the file system directly.

Parameter name	Modifiable	Notes
<code>innodb_deadlock_detect</code>	Yes	<p>This option is used to disable deadlock detection in Aurora MySQL version 2.11 and higher and version 3.</p> <p>On high-concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. Consult the MySQL documentation for more information on this parameter.</p>
<code>innodb_default_row_format</code>	Yes	<p>This parameter defines the default row format for InnoDB tables (including user-created InnoDB temporary tables). It applies to Aurora MySQL versions 2 and 3.</p> <p>Its value can be DYNAMIC, COMPACT, or REDUNDANT.</p>
<code>innodb_file_per_table</code>	Yes	<p>This parameter affects how table storage is organized. For more information, see <a href="#">Storage scaling</a>.</p>
<code>innodb_flush_log_at_trx_commit</code>	Yes	<p>We highly recommend that you use the default value of 1.</p> <p>In Aurora MySQL version 3, before you can set this parameter to a value other than 1, you must set the value of <code>innodb_trx_commit_allow_data_loss</code> to 1.</p> <p>For more information, see <a href="#">Configuring how frequently the log buffer is flushed</a>.</p>

Parameter name	Modifiable	Notes
<code>innodb_ft_max_token_size</code>	Yes	None
<code>innodb_ft_min_token_size</code>	Yes	None
<code>innodb_ft_num_word_optimize</code>	Yes	None
<code>innodb_ft_sort_pll_degree</code>	Yes	None
<code>innodb_online_alter_log_max_size</code>	Yes	None
<code>innodb_optimize_fulltext_only</code>	Yes	None
<code>innodb_page_size</code>	No	None
<code>innodb_print_all_deadlocks</code>	Yes	When turned on, records information about all InnoDB deadlocks in the Aurora MySQL error log. For more information, see <a href="#">Minimizing and troubleshooting Aurora MySQL deadlocks</a> .
<code>innodb_purge_batch_size</code>	Yes	None
<code>innodb_purge_threads</code>	Yes	None
<code>innodb_rollback_on_timeout</code>	Yes	None
<code>innodb_rollback_segments</code>	Yes	None
<code>innodb_spin_wait_delay</code>	Yes	None
<code>innodb_strict_mode</code>	Yes	None
<code>innodb_support_xa</code>	Yes	Removed from Aurora MySQL version 3.

Parameter name	Modifiable	Notes
<code>innodb_sync_array_size</code>	Yes	None
<code>innodb_sync_spin_loops</code>	Yes	None
<code>innodb_stats_include_delete_marked</code>	Yes	<p>When this parameter is enabled, InnoDB includes delete-marked records when calculating persistent optimizer statistics.</p> <p>This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.</p>
<code>innodb_table_locks</code>	Yes	None
<code>innodb_trx_commit_allow_data_loss</code>	Yes	<p>In Aurora MySQL version 3, set the value of this parameter to 1 so that you can change the value of <code>innodb_flush_log_at_trx_commit</code>.</p> <p>The default value of <code>innodb_trx_commit_allow_data_loss</code> is 0.</p> <p>For more information, see <a href="#">Configuring how frequently the log buffer is flushed</a>.</p>
<code>innodb_undo_directory</code>	No	Aurora MySQL uses managed instances where you don't access the file system directly.

Parameter name	Modifiable	Notes
<code>internal_tmp_disk_storage_engine</code>	Yes	<p>Controls which in-memory storage engine is used for internal temporary tables. Allowed values are INNODB and MYISAM.</p> <p>This parameter applies to Aurora MySQL version 2.</p>
<code>internal_tmp_mem_storage_engine</code>	Yes	<p>Controls which in-memory storage engine is used for internal temporary tables. Allowed values are MEMORY and TempTable .</p> <p>This parameter applies to Aurora MySQL version 3.</p>
<code>key_buffer_size</code>	Yes	<p>Key cache for MyISAM tables. For more information, see <a href="#">keycache-&gt;cache_lock mutex</a>.</p>
<code>lc_time_names</code>	Yes	None
<code>log_error_suppression_list</code>	Yes	<p>Specifies a list of error codes that aren't logged in the MySQL error log. This allows you to ignore certain noncritical error conditions to help keep your error logs clean. For more information, see <a href="#">log_error_suppression_list</a> in the MySQL documentation.</p> <p>This parameter applies to Aurora MySQL version 3.03 and higher.</p>

Parameter name	Modifiable	Notes
low_priority_updates	Yes	<p>INSERT, UPDATE, DELETE, and LOCK TABLE WRITE operations wait until there's no pending SELECT operation . This parameter affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE).</p> <p>This parameter applies to Aurora MySQL version 3.</p>

Parameter name	Modifiable	Notes
<code>lower_case_table_names</code>	<p>Yes (Aurora MySQL version 2)</p> <p>Only at cluster creation time (Aurora MySQL version 3)</p>	<p>In Aurora MySQL version 2.10 and higher 2.x versions, make sure to reboot all reader instances after changing this setting and rebooting the writer instance. For details, see <a href="#">Rebooting an Aurora cluster with read availability</a>.</p> <p>In Aurora MySQL version 3, the value of this parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading, and specify the parameter group during the snapshot restore operation that creates the version 3 cluster.</p> <p>With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the <code>lower_case_table_names</code> parameter is turned on. For more information on the methods that you can use, see <a href="#">Major version upgrades</a>.</p>
<code>master-info-repository</code>	Yes	Removed from Aurora MySQL version 3.
<code>master_verify_checksum</code>	Yes	Aurora MySQL version 2. Use <code>source_verify_checksum</code> in Aurora MySQL version 3.

Parameter name	Modifiable	Notes
max_delayed_threads	Yes	<p>Sets the maximum number of threads to handle INSERT DELAYED statements.</p> <p>This parameter applies to Aurora MySQL version 3.</p>
max_error_count	Yes	<p>The maximum number of error, warning, and note messages to be stored for display.</p> <p>This parameter applies to Aurora MySQL version 3.</p>
max_execution_time	Yes	<p>The timeout for running SELECT statements, in milliseconds. The value can be from 0–18446744073709551615. When set to 0, there is no timeout.</p> <p>For more information, see <a href="#">max_execution_time</a> in the MySQL documentation.</p>
min_examined_row_limit	Yes	<p>Use this parameter to prevent queries that examine fewer than the specified number of rows from being logged.</p>
partial_revokes	No	<p>This parameter applies to Aurora MySQL version 3.</p>
preload_buffer_size	Yes	<p>The size of the buffer that's allocated when preloading indexes.</p> <p>This parameter applies to Aurora MySQL version 3.</p>

Parameter name	Modifiable	Notes
query_cache_type	Yes	Removed from Aurora MySQL version 3.

Parameter name	Modifiable	Notes
read_only	Yes	<p>When this parameter is turned on, the server permits no updates except from those performed by replica threads.</p> <p>For Aurora MySQL version 2, valid values are the following:</p> <ul style="list-style-type: none"> <li>• 0 – OFF</li> <li>• 1 – ON</li> <li>• {TrueIfReplica} – ON for read replicas. This is the default value.</li> <li>• {TrueIfClusterReplica} – ON for replica clusters such as cross-Region read replicas, secondary clusters in an Aurora global database, and blue/green deployments.</li> </ul> <p>For Aurora MySQL version 3, valid values are the following:</p> <ul style="list-style-type: none"> <li>• 0 – OFF. This is the default value.</li> <li>• 1 – ON</li> <li>• {TrueIfClusterReplica} – ON for replica clusters such as cross-Region read replicas, secondary clusters in an Aurora global database, and blue/green deployments.</li> </ul> <p>In Aurora MySQL version 3, this parameter doesn't apply for users who have the CONNECTION_ADMIN privilege. This includes the Aurora</p>

Parameter name	Modifiable	Notes
		master user. For more information, see <a href="#">Role-based privilege model</a> .
<code>relay-log-space-limit</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replica_parallel_type</code>	Yes	<p>This parameter enables parallel execution on the replica of all uncommitted threads already in the prepare phase, without violating consistency. It applies to Aurora MySQL version 3.</p> <p>In Aurora MySQL version 3.03.* and lower, the default value is DATABASE. In Aurora MySQL version 3.04 and higher, the default value is LOGICAL_C LOCK.</p>
<code>replica_preserve_commit_order</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replica_transaction_retries</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replica_type_conversions</code>	Yes	<p>This parameter determines the type conversions used on replicas. The allowed values are: ALL_LOSSY , ALL_NON_LOSSY , ALL_SIGNED , and ALL_UNSIGNED . For more information, see <a href="#">Replication with differing table definitions on source and replica</a> in the MySQL documentation.</p> <p>This parameter applies to Aurora MySQL version 3.</p>

Parameter name	Modifiable	Notes
<code>replicate-do-db</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replicate-do-table</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replicate-ignore-db</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replicate-ignore-table</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replicate-wild-do-table</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>replicate-wild-ignore-table</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>require_secure_transport</code>	Yes	This parameter applies to Aurora MySQL version 2 and 3. For more information, see <a href="#">TLS connections to Aurora MySQL DB clusters</a> .
<code>rpl_read_size</code>	Yes	This parameter applies to Aurora MySQL version 3.
<code>server_audit_cw_upload</code>	No	This parameter has been deprecated in Aurora MySQL. Use <code>server_audit_logs_upload</code> .  For more information, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs</a> .
<code>server_audit_events</code>	Yes	For more information, see <a href="#">Using Advanced Auditing with an Amazon Aurora MySQL DB cluster</a> .

Parameter name	Modifiable	Notes
server_audit_excl_users	Yes	For more information, see <a href="#">Using Advanced Auditing with an Amazon Aurora MySQL DB cluster</a> .
server_audit_incl_users	Yes	For more information, see <a href="#">Using Advanced Auditing with an Amazon Aurora MySQL DB cluster</a> .
server_audit_logging	Yes	For instructions on uploading the logs to Amazon CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs</a> .
server_audit_logs_upload	Yes	<p>You can publish audit logs to CloudWatch Logs by enabling Advanced Auditing and setting this parameter to 1. The default for the <code>server_audit_logs_upload</code> parameter is 0.</p> <p>For more information, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs</a>.</p>
server_id	No	None
skip-character-set-client-handshake	Yes	None
skip_name_resolve	No	None
slave-skip-errors	Yes	Only applies to Aurora MySQL version 2 clusters, with MySQL 5.7 compatibility.
source_verify_checksum	Yes	This parameter applies to Aurora MySQL version 3.

Parameter name	Modifiable	Notes
sync_frm	Yes	Removed from Aurora MySQL version 3.
thread_cache_size	Yes	The number of threads to be cached. This parameter applies to Aurora MySQL versions 2 and 3.
time_zone	Yes	By default, the time zone for an Aurora DB cluster is Universal Time Coordinated (UTC). You can set the time zone for instances in your DB cluster to the local time zone for your application instead. For more information, see <a href="#">Local time zone for Amazon Aurora DB clusters</a> .
tls_version	Yes	For more information, see <a href="#">TLS versions for Aurora MySQL</a> .

## Instance-level parameters

The following table shows all of the parameters that apply to a specific DB instance in an Aurora MySQL DB cluster.

Parameter name	Modifiable	Notes
activate_all_roles_on_login	Yes	This parameter applies to Aurora MySQL version 3.
allow-suspicious-udfs	No	None
aurora_disable_hash_join	Yes	Set this parameter to ON to turn off hash join optimization in Aurora MySQL version 2.09 or higher. It isn't supported for version 3. For more

Parameter name	Modifiable	Notes
		information, see <a href="#">Parallel query for Amazon Aurora MySQL</a> .
aurora_lab_mode	Yes	For more information, see <a href="#">Amazon Aurora MySQL lab mode</a> . Removed from Aurora MySQL version 3.
aurora_oom_response	Yes	This parameter is supported for Aurora MySQL versions 2 and 3. For more information, see <a href="#">Troubleshooting out-of-memory issues for Aurora MySQL databases</a> .
aurora_parallel_query	Yes	Set to ON to turn on parallel query in Aurora MySQL version 2.09 or higher. The old <code>aurora_pq</code> parameter isn't used in these versions. For more information, see <a href="#">Parallel query for Amazon Aurora MySQL</a> .
aurora_pq	Yes	Set to OFF to turn off parallel query for specific DB instances in Aurora MySQL versions before 2.09. In version 2.09 or higher, turn parallel query on and off with <code>aurora_parallel_query</code> instead. For more information, see <a href="#">Parallel query for Amazon Aurora MySQL</a> .

Parameter name	Modifiable	Notes
<code>aurora_read_replica_read_committed</code>	Yes	Enables READ COMMITTED isolation level for Aurora Replicas and changes the isolation behavior to reduce purge lag during long-running queries. Enable this setting only if you understand the behavior changes and how they affect your query results. For example, this setting uses less-strict isolation than the MySQL default. When it's enabled, long-running queries might see more than one copy of the same row because Aurora reorganizes the table data while the query is running. For more information, see <a href="#">Aurora MySQL isolation levels</a> .
<code>aurora_tmptable_enable_per_table_limit</code>	Yes	Determines whether the <code>tmp_table_size</code> parameter controls the maximum size of in-memory temporary tables created by the TempTable storage engine in Aurora MySQL version 3.04 and higher.  For more information, see <a href="#">Limiting the size of internal, in-memory temporary tables</a> .
<code>aurora_use_vector_instructions</code>	Yes	When this parameter is enabled, Aurora MySQL uses optimized vector processing instructions provided by modern CPUs to improve performance on I/O-intensive workloads.  This setting is enabled by default in Aurora MySQL version 3.05 and higher.

Parameter name	Modifiable	Notes
autocommit	Yes	None
automatic_sp_privileges	Yes	None
back_log	Yes	None
basedir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
binlog_cache_size	Yes	None
binlog_max_flush_queue_time	Yes	None
binlog_order_commits	Yes	None
binlog_stmt_cache_size	Yes	None
binlog_transaction_compression	Yes	This parameter applies to Aurora MySQL version 3.
binlog_transaction_compression_level_zstd	Yes	This parameter applies to Aurora MySQL version 3.
bulk_insert_buffer_size	Yes	None
concurrent_insert	Yes	None
connect_timeout	Yes	None
core-file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
datadir	No	Aurora MySQL uses managed instances where you don't access the file system directly.

Parameter name	Modifiable	Notes
default_authentication_plugin	No	This parameter applies to Aurora MySQL version 3.
default_time_zone	No	None
default_tmp_storage_engine	Yes	The default storage engine for temporary tables.
default_week_format	Yes	None
delay_key_write	Yes	None
delayed_insert_limit	Yes	None
delayed_insert_timeout	Yes	None
delayed_queue_size	Yes	None
div_precision_increment	Yes	None
end_markers_in_json	Yes	None
eq_range_index_dive_limit	Yes	None
event_scheduler	Sometimes	Indicates the status of the Event Scheduler.  Modifiable only at the cluster level in Aurora MySQL version 3.
explicit_defaults_for_timestamp	Yes	None
flush	No	None
flush_time	Yes	None
ft_boolean_syntax	No	None

Parameter name	Modifiable	Notes
ft_max_word_len	Yes	None
ft_min_word_len	Yes	None
ft_query_expansion_limit	Yes	None
ft_stopword_file	Yes	None
general_log	Yes	For instructions on uploading the logs to CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs</a> .
general_log_file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
group_concat_max_len	Yes	None
host_cache_size	Yes	None
init_connect	Yes	<p>The command to be run by the server for each client that connects. Use double quotes (") for settings to avoid connection failures, for example:</p> <pre>SET optimizer_switch="hash_join=off"</pre> <p>In Aurora MySQL version 3, this parameter doesn't apply for users who have the CONNECTION_ADMIN privilege, including the Aurora master user. For more information, see <a href="#">Role-based privilege model</a>.</p>

Parameter name	Modifiable	Notes
<code>innodb_adaptive_hash_index</code>	Yes	<p>You can modify this parameter at the DB instance level in Aurora MySQL version 2. It's modifiable only at the DB cluster level in Aurora MySQL version 3.</p> <p>The Adaptive Hash Index isn't supported on reader DB instances.</p>
<code>innodb_adaptive_max_sleep_delay</code>	Yes	<p>Modifying this parameter has no effect because <code>innodb_thread_concurrency</code> is always 0 for Aurora.</p>
<code>innodb_aurora_max_partitions_for_range</code>	Yes	<p>In some cases where persisted statistics aren't available, you can use this parameter to improve the performance of row count estimations on partitioned tables.</p> <p>You can set it to a value from 0–8192, where the value determines the number of partitions to check during row count estimation. The default value is 0, which estimates using all of the partitions, consistent with default MySQL behavior.</p> <p>This parameter is available for Aurora MySQL version 3.03.1 and higher.</p>
<code>innodb_autoextend_increment</code>	Yes	None
<code>innodb_buffer_pool_dump_at_shutdown</code>	No	None
<code>innodb_buffer_pool_dump_now</code>	No	None

Parameter name	Modifiable	Notes
<code>innodb_buffer_pool_filename</code>	No	None
<code>innodb_buffer_pool_load_abort</code>	No	None
<code>innodb_buffer_pool_load_at_startup</code>	No	None
<code>innodb_buffer_pool_load_now</code>	No	None
<code>innodb_buffer_pool_size</code>	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables</a> .
<code>innodb_change_buffer_max_size</code>	No	Aurora MySQL doesn't use the InnoDB change buffer at all.
<code>innodb_compression_failure_threshold_pct</code>	Yes	None
<code>innodb_compression_level</code>	Yes	None
<code>innodb_compression_pad_pct_max</code>	Yes	None
<code>innodb_concurrency_tickets</code>	Yes	Modifying this parameter has no effect, because <code>innodb_thread_concurrency</code> is always 0 for Aurora.

Parameter name	Modifiable	Notes
<code>innodb_deadlock_detect</code>	Yes	This option is used to disable deadlock detection in Aurora MySQL version 2.11 and higher and version 3.  On high-concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. Consult the MySQL documentation for more information on this parameter.
<code>innodb_file_format</code>	Yes	Removed from Aurora MySQL version 3.
<code>innodb_flushing_avg_loops</code>	No	None
<code>innodb_force_load_corrupted</code>	No	None
<code>innodb_ft_aux_table</code>	Yes	None
<code>innodb_ft_cache_size</code>	Yes	None
<code>innodb_ft_enable_stopword</code>	Yes	None
<code>innodb_ft_server_stopword_table</code>	Yes	None
<code>innodb_ft_user_stopword_table</code>	Yes	None
<code>innodb_large_prefix</code>	Yes	Removed from Aurora MySQL version 3.
<code>innodb_lock_wait_timeout</code>	Yes	None
<code>innodb_log_compressed_pages</code>	No	None

Parameter name	Modifiable	Notes
<code>innodb_lru_scan_depth</code>	Yes	None
<code>innodb_max_purge_lag</code>	Yes	None
<code>innodb_max_purge_lag_delay</code>	Yes	None
<code>innodb_monitor_disable</code>	Yes	None
<code>innodb_monitor_enable</code>	Yes	None
<code>innodb_monitor_reset</code>	Yes	None
<code>innodb_monitor_reset_all</code>	Yes	None
<code>innodb_old_blocks_pct</code>	Yes	None
<code>innodb_old_blocks_time</code>	Yes	None
<code>innodb_open_files</code>	Yes	None
<code>innodb_print_all_deadlocks</code>	Yes	When turned on, records information about all InnoDB deadlocks in the Aurora MySQL error log. For more information, see <a href="#">Minimizing and troubleshooting Aurora MySQL deadlocks</a> .
<code>innodb_random_read_ahead</code>	Yes	None
<code>innodb_read_ahead_threshold</code>	Yes	None
<code>innodb_read_io_threads</code>	No	None

Parameter name	Modifiable	Notes
<code>innodb_read_only</code>	No	Aurora MySQL manages the read-only and read/write state of DB instances based on the type of cluster. For example, a provisioned cluster has one read/write DB instance (the <i>primary instance</i> ) and any other instances in the cluster are read-only (the Aurora Replicas).
<code>innodb_replication_delay</code>	Yes	None
<code>innodb_sort_buffer_size</code>	Yes	None
<code>innodb_stats_auto_recalc</code>	Yes	None
<code>innodb_stats_method</code>	Yes	None
<code>innodb_stats_on_metadata</code>	Yes	None
<code>innodb_stats_persistent</code>	Yes	None
<code>innodb_stats_persistent_sample_pages</code>	Yes	None
<code>innodb_stats_transient_sample_pages</code>	Yes	None
<code>innodb_thread_concurrency</code>	No	None
<code>innodb_thread_sleep_delay</code>	Yes	Modifying this parameter has no effect because <code>innodb_thread_concurrency</code> is always 0 for Aurora.

Parameter name	Modifiable	Notes
<code>interactive_timeout</code>	Yes	Aurora evaluates the minimum value of <code>interactive_timeout</code> and <code>wait_timeout</code> . It then uses that minimum as the timeout to end all idle sessions, both interactive and noninteractive.
<code>internal_tmp_disk_storage_engine</code>	Yes	Controls which in-memory storage engine is used for internal temporary tables. Allowed values are INNODB and MYISAM.  This parameter applies to Aurora MySQL version 2.
<code>internal_tmp_mem_storage_engine</code>	Sometimes	Controls which in-memory storage engine is used for internal temporary tables. Allowed values for writer DB instances are MEMORY and TempTable .  For reader DB instances, this parameter is set to TempTable and can't be modified.  This parameter applies to Aurora MySQL version 3.
<code>join_buffer_size</code>	Yes	None
<code>keep_files_on_create</code>	Yes	None
<code>key_buffer_size</code>	Yes	Key cache for MyISAM tables. For more information, see <a href="#">keycache-&gt;cache_lock mutex</a> .
<code>key_cache_age_threshold</code>	Yes	None

Parameter name	Modifiable	Notes
key_cache_block_size	Yes	None
key_cache_division_limit	Yes	None
local_infile	Yes	None
lock_wait_timeout	Yes	None
log-bin	No	Setting <code>binlog_format</code> to <code>STATEMENT</code> , <code>MIXED</code> , or <code>ROW</code> automatically sets <code>log-bin</code> to <code>ON</code> . Setting <code>binlog_format</code> to <code>OFF</code> automatically sets <code>log-bin</code> to <code>OFF</code> . For more information, see <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)</a> .
log_bin_trust_function_creators	Yes	None
log_bin_use_v1_row_events	Yes	Removed from Aurora MySQL version 3.
log_error	No	None
log_error_suppression_list	Yes	Specifies a list of error codes that aren't logged in the MySQL error log. This allows you to ignore certain noncritical error conditions to help keep your error logs clean. For more information, see <a href="#">log_error_suppression_list</a> in the MySQL documentation.  This parameter applies to Aurora MySQL version 3.03 and higher.

Parameter name	Modifiable	Notes
log_output	Yes	None
log_queries_not_using_indexes	Yes	None
log_slave_updates	No	Aurora MySQL version 2. Use log_replica_updates in Aurora MySQL version 3.
log_replica_updates	No	Aurora MySQL version 3
log_throttle_queries_not_using_indexes	Yes	None
log_warnings	Yes	Removed from Aurora MySQL version 3.
long_query_time	Yes	None
low_priority_updates	Yes	INSERT, UPDATE, DELETE, and LOCK TABLE WRITE operations wait until there's no pending SELECT operation . This parameter affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE).  This parameter applies to Aurora MySQL version 3.
max_allowed_packet	Yes	None
max_binlog_cache_size	Yes	None
max_binlog_size	No	None
max_binlog_stmt_cache_size	Yes	None
max_connect_errors	Yes	None

Parameter name	Modifiable	Notes
max_connections	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables</a> . For the default values depending on the instance class, see <a href="#">Maximum connections to an Aurora MySQL DB instance</a> .
max_delayed_threads	Yes	Sets the maximum number of threads to handle <code>INSERT DELAYED</code> statements.  This parameter applies to Aurora MySQL version 3.
max_error_count	Yes	The maximum number of error, warning, and note messages to be stored for display.  This parameter applies to Aurora MySQL version 3.
max_execution_time	Yes	The timeout for running <code>SELECT</code> statements, in milliseconds. The value can be from <code>0-18446744073709551615</code> . When set to <code>0</code> , there is no timeout.  For more information, see <a href="#">max_execution_time</a> in the MySQL documentation.
max_heap_table_size	Yes	None
max_insert_delayed_threads	Yes	None

Parameter name	Modifiable	Notes
max_join_size	Yes	None
max_length_for_sort_data	Yes	Removed from Aurora MySQL version 3.
max_prepared_stmt_count	Yes	None
max_seeks_for_key	Yes	None
max_sort_length	Yes	None
max_sp_recursion_depth	Yes	None
max_tmp_tables	Yes	Removed from Aurora MySQL version 3.
max_user_connections	Yes	None
max_write_lock_count	Yes	None
metadata_locks_cache_size	Yes	Removed from Aurora MySQL version 3.
min_examined_row_limit	Yes	Use this parameter to prevent queries that examine fewer than the specified number of rows from being logged.  This parameter applies to Aurora MySQL version 3.
myisam_data_pointer_size	Yes	None
myisam_max_sort_file_size	Yes	None
myisam_mmap_size	Yes	None
myisam_sort_buffer_size	Yes	None
myisam_stats_method	Yes	None

Parameter name	Modifiable	Notes
myisam_use_mmap	Yes	None
net_buffer_length	Yes	None
net_read_timeout	Yes	None
net_retry_count	Yes	None
net_write_timeout	Yes	None
old-style-user-limits	Yes	None
old_passwords	Yes	Removed from Aurora MySQL version 3.
optimizer_prune_level	Yes	None
optimizer_search_depth	Yes	None
optimizer_switch	Yes	For information about Aurora MySQL features that use this switch, see <a href="#">Best practices with Amazon Aurora MySQL</a> .
optimizer_trace	Yes	None
optimizer_trace_features	Yes	None
optimizer_trace_limit	Yes	None
optimizer_trace_max_mem_size	Yes	None
optimizer_trace_offset	Yes	None

Parameter name	Modifiable	Notes
performance-schema-consumer-events-waits-current	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to Modified, performance schema is using the parameter <code>performance-schema-consumer-events-waits-current</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance-schema-instrument	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to Modified, performance schema is using the parameter <code>performance-schema-instrument</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema	Yes	If the <b>Source</b> column is set to Modified, Performance Insights is managing the Performance Schema. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_accounts_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_accounts_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_global_instrumentation	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_global_instrumentation. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_thread_instrumentation	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_thread_instrumentation. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_consumer_events_stages_current	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_stages_current. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_events_stages_history	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_stages_history. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_events_stages_history_long	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_stages_history_long. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_consumer_events_statements_current	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_statements_current . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_events_statements_history	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_statements_history . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_events_statements_history_long	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_statements_history_long . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_consumer_events_waits_history	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_waits_history. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_events_waits_history_long	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_events_waits_history_long. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_consumer_statements_digest	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_consumer_statements_digest. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_digests_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_digests_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_stages_history_long_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_events_stages_history_long_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_stages_history_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_events_stages_history_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_events_statements_history_long_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_events_statements_history_long_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_statements_history_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_events_statements_history_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_transactions_history_long_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_events_transactions_history_long_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_events_transactions_history_size	Yes	If the <b>Source</b> column for the parameter performance_schema_events_transactions_history_size is set to Modified, performance schema is using the parameter performance_schema_events_transactions_history_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_waits_history_long_size	Yes	If the <b>Source</b> column for the parameter performance_schema_events_waits_history_long_size is set to Modified, performance schema is using the parameter performance_schema_events_waits_history_long_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_events_waits_history_size	Yes	If the <b>Source</b> column for the parameter performance_schema_events_waits_history_size is set to Modified, performance schema is using the parameter performance_schema_events_waits_history_size. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_hosts_size	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to <code>Modified</code> , performance schema is using the parameter <code>performance_schema_hosts_size</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_cond_classes	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to <code>Modified</code> , performance schema is using the parameter <code>performance_schema_max_cond_classes</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_cond_instances	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to <code>Modified</code> , performance schema is using the parameter <code>performance_schema_max_cond_instances</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_digest_length	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_digest_length. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_file_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_file_classes. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_file_handles	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_file_handles. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_file_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_file_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_index_stat	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_index_stat . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_memory_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_memory_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_metadata_locks	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_metadata_locks . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_mutex_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_mutex_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_mutex_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_mutex_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_prepared_statements_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_prepared_statements_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_program_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_program_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_rwlock_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_rwlock_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_rwlock_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_rwlock_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_socket_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_socket_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_socket_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_socket_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_sql_text_length	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_sql_text_length . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_stages_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_stages_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_statement_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_statement_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_statement_stack	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_statement_stack. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_table_handles	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_table_handles. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_table_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_table_instances. For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_max_table_lock_stat	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_table_lock_stat . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_thread_classes	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_thread_classes . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_max_thread_instances	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_max_thread_instances . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_session_connect_attrs_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_session_connect_attrs_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_setup_actors_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_setup_actors_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
performance_schema_setup_objects_size	Yes	If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_setup_objects_size . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .

Parameter name	Modifiable	Notes
performance_schema_show_processlist	Yes	<p>This parameter determines which SHOW PROCESSLIST implementation to use:</p> <ul style="list-style-type: none"> <li>• The default implementation iterates across active threads from within the thread manager while holding a global mutex. This can cause slow performance, especially on busy systems.</li> <li>• The alternative SHOW PROCESSLIST implementation is based on the Performance Schema processlist table. This implementation queries active thread data from the Performance Schema rather than the thread manager and doesn't require a mutex.</li> </ul> <p>This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.</p> <p>If the <b>Source</b> column for the parameter performance_schema is set to Modified, performance schema is using the parameter performance_schema_show_processlist . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a>.</p>

Parameter name	Modifiable	Notes
performance_schema_users_size	Yes	If the <b>Source</b> column for the parameter <code>performance_schema</code> is set to <code>Modified</code> , performance schema is using the parameter <code>performance_schema_users_size</code> . For more information about enabling the Performance Schema, see <a href="#">Determining whether Performance Insights is managing the Performance Schema</a> .
pid_file	No	None
plugin_dir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
port	No	Aurora MySQL manages the connection properties and enforces consistent settings for all DB instances in a cluster.
preload_buffer_size	Yes	The size of the buffer that's allocated when preloading indexes.  This parameter applies to Aurora MySQL version 3.
profiling_history_size	Yes	None
query_alloc_block_size	Yes	None
query_cache_limit	Yes	Removed from Aurora MySQL version 3.
query_cache_min_res_unit	Yes	Removed from Aurora MySQL version 3.

Parameter name	Modifiable	Notes
query_cache_size	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables</a> .  Removed from Aurora MySQL version 3.
query_cache_type	Yes	Removed from Aurora MySQL version 3.
query_cache_wlock_invalidate	Yes	Removed from Aurora MySQL version 3.
query_prealloc_size	Yes	None
range_alloc_block_size	Yes	None
read_buffer_size	Yes	None

Parameter name	Modifiable	Notes
<code>read_only</code>	Yes	<p>When this parameter is turned on, the server permits no updates except from those performed by replica threads.</p> <p>For Aurora MySQL version 2, valid values are the following:</p> <ul style="list-style-type: none"><li>• 0 – OFF</li><li>• 1 – ON</li><li>• {TrueIfReplica} – ON for read replicas. This is the default value.</li><li>• {TrueIfClusterReplica} – ON for instances in replica clusters such as cross-Region read replicas, secondary clusters in an Aurora global database, and blue/green deployments.</li></ul> <p>We recommend that you use the DB cluster parameter group in Aurora MySQL version 2 to make sure that the <code>read_only</code> parameter is applied to new writer instances on failover.</p> <div data-bbox="933 1369 1507 1774"><p> <b>Note</b></p><p>Reader instances are always read only, because Aurora MySQL sets <code>innodb_read_only</code> to 1 on all readers. Therefore, <code>read_only</code> is redundant on reader instances.</p></div>

Parameter name	Modifiable	Notes
		Removed at the instance level from Aurora MySQL version 3.
read_rnd_buffer_size	Yes	None
relay-log	No	None
relay_log_info_repository	Yes	Removed from Aurora MySQL version 3.
relay_log_recovery	No	None
replica_checkpoint_group	Yes	Aurora MySQL version 3
replica_checkpoint_period	Yes	Aurora MySQL version 3
replica_parallel_workers	Yes	Aurora MySQL version 3
replica_pending_jobs_size_max	Yes	Aurora MySQL version 3
replica_skip_errors	Yes	Aurora MySQL version 3
replica_sql_verify_checksum	Yes	Aurora MySQL version 3
safe-user-create	Yes	None
secure_auth	Yes	This parameter is always turned on in Aurora MySQL version 2. Trying to turn it off generates an error.  Removed from Aurora MySQL version 3.
secure_file_priv	No	Aurora MySQL uses managed instances where you don't access the file system directly.

Parameter name	Modifiable	Notes
show_create_table_verbosity	Yes	Enabling this variable causes <a href="#">SHOW_CREATE_TABLE</a> to display the ROW_FORMAT regardless of whether it's the default format.  This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.
skip-slave-start	No	None
skip_external_locking	No	None
skip_show_database	Yes	None
slave_checkpoint_group	Yes	Aurora MySQL version 2. Use replica_checkpoint_group in Aurora MySQL version 3.
slave_checkpoint_period	Yes	Aurora MySQL version 2. Use replica_checkpoint_period in Aurora MySQL version 3.
slave_parallel_workers	Yes	Aurora MySQL version 2. Use replica_parallel_workers in Aurora MySQL version 3.
slave_pending_jobs_size_max	Yes	Aurora MySQL version 2. Use replica_pending_jobs_size_max in Aurora MySQL version 3.
slave_sql_verify_checksum	Yes	Aurora MySQL version 2. Use replica_sql_verify_checksum in Aurora MySQL version 3.
slow_launch_time	Yes	None

Parameter name	Modifiable	Notes
slow_query_log	Yes	For instructions on uploading the logs to CloudWatch Logs, see <a href="#">Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs</a> .
slow_query_log_file	No	Aurora MySQL uses managed instances where you don't access the file system directly.
socket	No	None
sort_buffer_size	Yes	None
sql_mode	Yes	None
sql_select_limit	Yes	None
stored_program_cache	Yes	None
sync_binlog	No	None
sync_master_info	Yes	None
sync_source_info	Yes	This parameter applies to Aurora MySQL version 3.
sync_relay_log	Yes	Removed from Aurora MySQL version 3.
sync_relay_log_info	Yes	None
sysdate-is-now	Yes	None
table_cache_element_entry_time	No	None

Parameter name	Modifiable	Notes
table_definition_cache	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables</a> .
table_open_cache	Yes	The default value is represented by a formula. For details about how the <code>DBInstanceClassMemory</code> value in the formula is calculated, see <a href="#">DB parameter formula variables</a> .
table_open_cache_instances	Yes	None
temp-pool	Yes	Removed from Aurora MySQL version 3.
temptable_max_mmap	Yes	This parameter applies to Aurora MySQL version 3. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3</a> .
temptable_max_ram	Yes	This parameter applies to Aurora MySQL version 3. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3</a> .
temptable_use_mmap	Yes	This parameter applies to Aurora MySQL version 3. For details, see <a href="#">New temporary table behavior in Aurora MySQL version 3</a> .
thread_cache_size	Yes	The number of threads to be cached. This parameter applies to Aurora MySQL versions 2 and 3.

Parameter name	Modifiable	Notes
thread_handling	No	None
thread_stack	Yes	None
timed_mutexes	Yes	None
tmp_table_size	Yes	<p>Defines the maximum size of internal in-memory temporary tables created by the MEMORY storage engine in Aurora MySQL version 3.</p> <p>In Aurora MySQL version 3.04 and higher, defines the maximum size of internal in-memory temporary tables created by the TempTable storage engine when <code>aurora_tmptable_enable_per_table_limit</code> is ON.</p> <p>For more information, see <a href="#">Limiting the size of internal, in-memory temporary tables</a>.</p>
tmpdir	No	Aurora MySQL uses managed instances where you don't access the file system directly.
transaction_alloc_block_size	Yes	None
transaction_isolation	Yes	This parameter applies to Aurora MySQL version 3. It replaces <code>tx_isolation</code> .
transaction_prealloc_size	Yes	None

Parameter name	Modifiable	Notes
<code>tx_isolation</code>	Yes	Removed from Aurora MySQL version 3. It is replaced by <code>transaction_isolation</code> .
<code>updatable_views_with_limit</code>	Yes	None
<code>validate-password</code>	No	None
<code>validate_password_dictionary_file</code>	No	None
<code>validate_password_length</code>	No	None
<code>validate_password_mixed_case_count</code>	No	None
<code>validate_password_number_count</code>	No	None
<code>validate_password_policy</code>	No	None
<code>validate_password_special_char_count</code>	No	None
<code>wait_timeout</code>	Yes	Aurora evaluates the minimum value of <code>interactive_timeout</code> and <code>wait_timeout</code> . It then uses that minimum as the timeout to end all idle sessions, both interactive and noninteractive.

## MySQL parameters that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL parameters don't apply to Aurora MySQL.

The following MySQL parameters don't apply to Aurora MySQL. This list isn't exhaustive.

- `activate_all_roles_on_login` – This parameter doesn't apply to Aurora MySQL version 2. It is available in Aurora MySQL version 3.
- `big_tables`
- `bind_address`
- `character_sets_dir`
- `innodb_adaptive_flushing`
- `innodb_adaptive_flushing_lwm`
- `innodb_buffer_pool_chunk_size`
- `innodb_buffer_pool_instances`
- `innodb_change_buffering`
- `innodb_checksum_algorithm`
- `innodb_data_file_path`
- `innodb_dedicated_server`
- `innodb_doublewrite`
- `innodb_flush_log_at_timeout` – This parameter doesn't apply to Aurora MySQL. For more information, see [Configuring how frequently the log buffer is flushed](#).
- `innodb_flush_method`
- `innodb_flush_neighbors`
- `innodb_io_capacity`
- `innodb_io_capacity_max`
- `innodb_log_buffer_size`
- `innodb_log_file_size`
- `innodb_log_files_in_group`
- `innodb_log_spin_cpu_abs_lwm`
- `innodb_log_spin_cpu_pct_hwm`
- `innodb_log_writer_threads`
- `innodb_max_dirty_pages_pct`
- `innodb_numa_interleave`
- `innodb_page_size`
- `innodb_redo_log_capacity`
- `innodb_redo_log_encrypt`

- `innodb_undo_log_encrypt`
- `innodb_undo_log_truncate`
- `innodb_undo_logs`
- `innodb_undo_tablespaces`
- `innodb_use_native_aio`
- `innodb_write_io_threads`

## Aurora MySQL global status variables

Aurora MySQL includes status variables from community MySQL and variables that are unique to Aurora. You can examine these variables to learn about what's happening inside the database engine. For more information about the status variables in community MySQL, see [Server Status Variables](#) in the community MySQL 8.0 documentation.

You can find the current values for Aurora MySQL global status variables by using a statement such as the following:

```
show global status like '%aurora%';
```

### Note

Global status variables are cleared when the DB engine reboots.

The following table describes the global status variables that Aurora MySQL uses.

Name	Description
<code>AuroraDb_commits</code>	The total number of commits since the last restart.
<code>AuroraDb_commit_latency</code>	The aggregate commit latency since the last restart.
<code>AuroraDb_ddl_stmt_duration</code>	The aggregate DDL latency since the last restart.

Name	Description
AuroraDb_select_stmt_duration	The aggregate SELECT statement latency since the last restart.
AuroraDb_insert_stmt_duration	The aggregate INSERT statement latency since the last restart.
AuroraDb_update_stmt_duration	The aggregate UPDATE statement latency since the last restart.
AuroraDb_delete_stmt_duration	The aggregate DELETE statement latency since the last restart.
Aurora_binlog_io_cache_allocated	The number of bytes allocated to the binlog I/O cache.
Aurora_binlog_io_cache_read_requests	The number of read requests made to the binlog I/O cache.
Aurora_binlog_io_cache_reads	The number of read requests that were served from the binlog I/O cache.
Aurora_enhanced_binlog	Indicates whether enhanced binlog is enabled or disabled for this DB instance. For more information, see <a href="#">Setting up enhanced binlog for Aurora MySQL</a> .
Aurora_external_connection_count	The number of database connections to the DB instance, excluding RDS service connections used for database health checks.
Aurora_fast_insert_cache_hits	A counter that's incremented when the cached cursor is successfully retrieved and verified. For more information on the fast insert cache, see <a href="#">Amazon Aurora MySQL performance enhancements</a> .

Name	Description
Aurora_fast_insert_cache_misses	A counter that's incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal. For more information on the fast insert cache, see <a href="#">Amazon Aurora MySQL performance enhancements</a> .
Aurora_fts_cache_memory_used	The amount of memory in bytes that the InnoDB full-text search system is using. This variable applies to Aurora MySQL version 3.07 and higher.
Aurora_fwd_master_dml_stmt_count	The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.
Aurora_fwd_master_dml_stmt_duration	The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.
Aurora_fwd_master_errors_rpc_timeout	The number of times a forwarded connection failed to be established on the writer.
Aurora_fwd_master_errors_session_limit	The number of forwarded queries that get rejected due to <code>session full</code> on the writer.
Aurora_fwd_master_errors_session_timeout	The number of times a forwarding session is ended due to a timeout on the writer.
Aurora_fwd_master_open_sessions	The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 2.
Aurora_fwd_master_select_stmt_count	The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.

Name	Description
Aurora_fwd_master_select_stmt_duration	The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.
Aurora_fwd_writer_dml_stmt_count	The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.
Aurora_fwd_writer_dml_stmt_duration	The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.
Aurora_fwd_writer_errors_rpc_timeout	The number of times a forwarded connection failed to be established on the writer.
Aurora_fwd_writer_errors_session_limit	The number of forwarded queries that get rejected due to session full on the writer.
Aurora_fwd_writer_errors_session_timeout	The number of times a forwarding session is ended due to a timeout on the writer.
Aurora_fwd_writer_open_sessions	The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 3.
Aurora_fwd_writer_select_stmt_count	The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.
Aurora_fwd_writer_select_stmt_duration	The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.
Aurora_lockmgr_buffer_pool_memory_used	The amount of buffer pool memory in bytes that the Aurora MySQL lock manager is using.

Name	Description
Aurora_lockmgr_memory_used	The amount of memory in bytes that the Aurora MySQL lock manager is using.
Aurora_ml_actual_request_cnt	The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
Aurora_ml_actual_response_cnt	The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
Aurora_ml_cache_hit_cnt	The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
Aurora_ml_logical_request_cnt	The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than <code>Aurora_ml_actual_request_cnt</code> . For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .

Name	Description
Aurora_ml_logical_response_cnt	The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
Aurora_ml_retry_request_cnt	The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
Aurora_ml_single_request_cnt	The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a> .
aurora_oom_avoidance_recoverystate	Indicates whether Aurora out-of-memory (OOM) avoidance recovery is in the ACTIVE or INACTIVE state for this DB instance.  This variable applies to Aurora MySQL version 3.06.0 and higher.

Name	Description
aurora_oom_reserved_mem_enter_kb	<p>Represents the threshold for entering the RESERVED state in Aurora's OOM handling mechanism.</p> <p>When the available memory on the server falls below this threshold, <code>aurora_oom_status</code> changes to RESERVED, indicating that the server is approaching a critical level of memory usage.</p> <p>This variable applies to Aurora MySQL version 3.06.0 and higher.</p>
aurora_oom_reserved_mem_exit_kb	<p>Represents the threshold for exiting the RESERVED state in Aurora's OOM handling mechanism.</p> <p>When the available memory on the server rises above this threshold, <code>aurora_oom_status</code> reverts to NORMAL, indicating that the server has returned to a more stable state with sufficient memory resources.</p> <p>This variable applies to Aurora MySQL version 3.06.0 and higher.</p>

Name	Description
aurora_oom_status	<p>Represents the current OOM status of this DB instance. When the value is NORMAL, it indicates that there are sufficient memory resources.</p> <p>If the value changes to RESERVED, it indicates that the server has low available memory. Actions are taken based on the <code>aurora_oom_response</code> parameter configuration.</p> <p>For more information, see <a href="#">Troubleshooting out-of-memory issues for Aurora MySQL databases</a>.</p> <p>This variable applies to Aurora MySQL version 3.06.0 and higher.</p>
Aurora_pq_bytes_returned	<p>The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against <code>Aurora_pq_pages_pushed_down</code>.</p>
Aurora_pq_max_concurrent_requests	<p>The maximum number of parallel query sessions that can run concurrently on this Aurora DB instance. This is a fixed number that depends on the Amazon DB instance class.</p>
Aurora_pq_pages_pushed_down	<p>The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.</p>
Aurora_pq_request_attempted	<p>The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.</p>

Name	Description
Aurora_pq_request_executed	The number of parallel query sessions run successfully.
Aurora_pq_request_failed	The number of parallel query sessions that returned an error to the client. In some cases, a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism . If the retried query also fails, an error is returned to the client and this counter is incremented.
Aurora_pq_request_in_progress	The number of parallel query sessions currently in progress. This number applies to the particular Aurora DB instance that you are connected to, not the entire Aurora DB cluster. To see if a DB instance is close to its concurrency limit, compare this value to <code>Aurora_pq_max_concurrent_requests</code> .
Aurora_pq_request_not_chosen	The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_below_min_rows	The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.

Name	Description
Aurora_pq_request_not_chosen_column_bit	The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.
Aurora_pq_request_not_chosen_column_geometry	The number of parallel query requests that use the nonparallel query processing path because the table has columns with the GEOMETRY data type. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a> .
Aurora_pq_request_not_chosen_column_lob	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a> .
Aurora_pq_request_not_chosen_column_virtual	The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.
Aurora_pq_request_not_chosen_custom_charset	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.
Aurora_pq_request_not_chosen_fast_ddl	The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER statement.

Name	Description
Aurora_pq_request_not_chosen_few_pages_outside_buffer_pool	The number of times parallel query wasn't chosen, even though less than 95 percent of the table data was in the buffer pool, because there wasn't enough unbuffered table data to make parallel query worthwhile.
Aurora_pq_request_not_chosen_full_text_index	The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.
Aurora_pq_request_not_chosen_high_buffer_pool_pct	The number of times parallel query wasn't chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_index_hint	The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.
Aurora_pq_request_not_chosen_innodb_table_format	The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.

Name	Description
Aurora_pq_request_not_chosen_long_trx	The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_no_where_clause	The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.
Aurora_pq_request_not_chosen_range_scan	The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.
Aurora_pq_request_not_chosen_row_length_too_long	The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.
Aurora_pq_request_not_chosen_small_table	The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
Aurora_pq_request_not_chosen_temporary_table	The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.

Name	Description
Aurora_pq_request_not_chosen_tx_isolation	The number of parallel query requests that use the nonparallel query processing path because query uses an unsupported transaction isolation level. On reader DB instances, parallel query only applies to the REPEATABLE READ and READ COMMITTED isolation levels.
Aurora_pq_request_not_chosen_update_delete_stmts	The number of parallel query requests that use the nonparallel query processing path because the query is part of an UPDATE or DELETE statement.
Aurora_pq_request_not_chosen_unsupported_access	The number of parallel query requests that use the nonparallel query processing path because the WHERE clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a DELETE or UPDATE statement.
Aurora_pq_request_not_chosen_unsupported_storage_type	The number of parallel query requests that use the nonparallel query processing path because the Aurora MySQL DB cluster isn't using a supported Aurora cluster storage configuration. For more information, see <a href="#">Limitations</a> .  This parameter applies to Aurora MySQL version 3.04 and higher.
Aurora_pq_request_throttled	The number of times parallel query wasn't chosen due to the maximum number of concurrent parallel queries already running on a particular Aurora DB instance.

Name	Description
Aurora_repl_bytes_received	Number of bytes replicated to an Aurora MySQL reader database instance since the last restart. For more information, see <a href="#">Replication with Amazon Aurora MySQL</a> .
Aurora_reserved_mem_exceeded_incidents	The number of times since the last restart that the engine has exceeded reserved memory limits. If <code>aurora_oom_response</code> is configured, this threshold defines when out-of-memory (OOM) avoidance activities are triggered. For more information on the Aurora MySQL OOM response, see <a href="#">Troubleshooting out-of-memory issues for Aurora MySQL databases</a> .
aurora_temptable_max_ram_allocation	The maximum amount of memory, in bytes, used at any point by internal temporary tables since the last restart.
aurora_temptable_ram_allocation	The current amount of memory, in bytes, used by internal temporary tables.
Aurora_in_memory_relaylog_status	The current status of in memory relay log feature, the value can be ENABLED or DISABLED.
Aurora_in_memory_relaylog_disabled_reason	Shows the reason of current in memory relay log feature status, if the feature is disabled, display a message of explanation on why the feature is disabled.

Name	Description
Aurora_in_memory_relaylog_fallback_count	Show the total number of fallbacks of in memory relay log feature to persistent relay log mode (legacy). Fallback can be caused by either single event larger than cache size (currently 128MB) or transaction retry exceed the replica transaction retry limit replica_transaction_retries.
Aurora_in_memory_relaylog_recovery_count	Shows the total number of in memory relay log recovery performed automatically. This count includes the total number of fallbacks and the number of automatic mode switch back to in memory relay log mode after the temporary fallbacks.
Aurora_thread_pool_thread_count	The current number of threads in the Aurora thread pool. For more information on the thread pool in Aurora MySQL, see <a href="#">Thread pool</a> .
Aurora_tmz_version	<p>Denotes the current version of the time zone information used by the DB cluster. The values follow the Internet Assigned Numbers Authority (IANA) format: <code>YYYYsuffix</code> , for example <code>2022a</code> and <code>2023c</code>.</p> <p>This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.04 and higher.</p>
Aurora_zdr_oom_threshold	Represents the memory threshold, in kilobytes (KB), for an Aurora DB instance to initiate a zero downtime restart (ZDR) to recover from potential memory-related issues.

Name	Description
server_aurora_das_running	Indicates whether Database Activity Streams (DAS) are enabled or disabled on this DB instance. For more information, see <a href="#">Monitoring Amazon Aurora with Database Activity Streams</a> .

## MySQL status variables that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL status variables don't apply to Aurora MySQL.

The following MySQL status variables don't apply to Aurora MySQL. This list isn't exhaustive.

- `innodb_buffer_pool_bytes_dirty`
- `innodb_buffer_pool_pages_dirty`
- `innodb_buffer_pool_pages_flushed`

Aurora MySQL version 3 removes the following status variables that were in Aurora MySQL version 2:

- `AuroraDb_lockmgr_bitmaps0_in_use`
- `AuroraDb_lockmgr_bitmaps1_in_use`
- `AuroraDb_lockmgr_bitmaps_mem_used`
- `AuroraDb_thread_deadlocks`
- `available_alter_table_log_entries`
- `Aurora_lockmgr_memory_used`
- `Aurora_missing_history_on_replica_incidents`
- `Aurora_new_lock_manager_lock_release_cnt`
- `Aurora_new_lock_manager_lock_release_total_duration_micro`
- `Aurora_new_lock_manager_lock_timeout_cnt`
- `Aurora_total_op_memory`

- Aurora\_total\_op\_temp\_space
- Aurora\_used\_alter\_table\_log\_entries
- Aurora\_using\_new\_lock\_manager
- Aurora\_volume\_bytes\_allocated
- Aurora\_volume\_bytes\_left\_extent
- Aurora\_volume\_bytes\_left\_total
- Com\_alter\_db\_upgrade
- Compression
- External\_threads\_connected
- Innodb\_available\_undo\_logs
- Last\_query\_cost
- Last\_query\_partial\_plans
- Slave\_heartbeat\_period
- Slave\_last\_heartbeat
- Slave\_received\_heartbeats
- Slave\_retried\_transactions
- Slave\_running
- Time\_since\_zero\_connections

These MySQL status variables are available in Aurora MySQL version 2, but they aren't available in Aurora MySQL version 3:

- Innodb\_redo\_log\_enabled
- Innodb\_undo\_tablespaces\_total
- Innodb\_undo\_tablespaces\_implicit
- Innodb\_undo\_tablespaces\_explicit
- Innodb\_undo\_tablespaces\_active

## Aurora MySQL wait events

The following are some common wait events for Aurora MySQL.

**Note**

For information on tuning Aurora MySQL performance using wait events, see [Tuning Aurora MySQL with wait events](#).

For information about the naming conventions used in MySQL wait events, see [Performance Schema instrument naming conventions](#) in the MySQL documentation.

**cpu**

The number of active connections that are ready to run is consistently higher than the number of vCPUs. For more information, see [cpu](#).

**io/aurora\_redo\_log\_flush**

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see [io/aurora\\_redo\\_log\\_flush](#).

**io/aurora\_respond\_to\_client**

Query processing has completed and results are being returned to the application client for the following Aurora MySQL versions: 2.10.2 and higher 2.10 versions, 2.09.3 and higher 2.09 versions, and 2.07.7 and higher 2.07 versions. Compare the network bandwidth of the DB instance class with the size of the result set being returned. Also, check client-side response times. If the client is unresponsive and can't process the TCP packets, packet drops and TCP retransmissions can occur. This situation negatively affects network bandwidth. In versions lower than 2.10.2, 2.09.3, and 2.07.7, the wait event erroneously includes idle time. To learn how to tune your database when this wait is prominent, see [io/aurora\\_respond\\_to\\_client](#).

**io/file/csv/data**

Threads are writing to tables in comma-separated value (CSV) format. Check your CSV table usage. A typical cause of this event is setting `log_output` on a table.

**io/file/sql/binlog**

A thread is waiting on a binary log (binlog) file that is being written to disk.

**io/redo\_log\_flush**

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see [io/redo\\_log\\_flush](#).

## **io/socket/sql/client\_connection**

The `mysqld` program is busy creating threads to handle incoming new client connections. For more information, see [io/socket/sql/client\\_connection](#).

## **io/table/sql/handler**

The engine is waiting for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. For more information, see [io/table/sql/handler](#).

## **lock/table/sql/handler**

This wait event is a table lock wait event handler. For more information about atom and molecule events in the Performance Schema, see [Performance Schema atom and molecule events](#) in the MySQL documentation.

## **synch/cond/innodb/row\_lock\_wait**

Multiple data manipulation language (DML) statements are accessing the same database rows at the same time. For more information, see [synch/cond/innodb/row\\_lock\\_wait](#).

## **synch/cond/innodb/row\_lock\_wait\_cond**

Multiple DML statements are accessing the same database rows at the same time. For more information, see [synch/cond/innodb/row\\_lock\\_wait\\_cond](#).

## **synch/cond/sql/MDL\_context::COND\_wait\_status**

Threads are waiting on a table metadata lock. The engine uses this type of lock to manage concurrent access to a database schema and to ensure data consistency. For more information, see [Optimizing locking operations](#) in the MySQL documentation. To learn how to tune your database when this event is prominent, see [synch/cond/sql/MDL\\_context::COND\\_wait\\_status](#).

## **synch/cond/sql/MYSQL\_BIN\_LOG::COND\_done**

You have turned on binary logging. There might be a high commit throughput, large number transactions committing, or replicas reading binlogs. Consider using `multirow` statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication, or use the `aurora_binlog_*` parameters.

## **synch/mutex/innodb/aurora\_lock\_thread\_slot\_futex**

Multiple DML statements are accessing the same database rows at the same time. For more information, see [synch/mutex/innodb/aurora\\_lock\\_thread\\_slot\\_futex](#).

### **`synch/mutex/innodb/buf_pool_mutex`**

The buffer pool isn't large enough to hold the working data set. Or the workload accesses pages from a specific table, which leads to contention in the buffer pool. For more information, see [synch/mutex/innodb/buf\\_pool\\_mutex](#).

### **`synch/mutex/innodb/fil_system_mutex`**

The process is waiting for access to the tablespace memory cache. For more information, see [synch/mutex/innodb/fil\\_system\\_mutex](#).

### **`synch/mutex/innodb/trx_sys_mutex`**

Operations are checking, updating, deleting, or adding transaction IDs in InnoDB in a consistent or controlled manner. These operations require a `trx_sys` mutex call, which is tracked by Performance Schema instrumentation. Operations include management of the transaction system when the database starts or shuts down, rollbacks, undo cleanups, row read access, and buffer pool loads. High database load with a large number of transactions results in the frequent appearance of this wait event. For more information, see [synch/mutex/innodb/trx\\_sys\\_mutex](#).

### **`synch/mutex/mysys/KEY_CACHE::cache_lock`**

The `keycache->cache_lock` mutex controls access to the key cache for MyISAM tables. While Aurora MySQL doesn't allow usage of MyISAM tables to store persistent data, they are used to store internal temporary tables. Consider checking the `created_tmp_tables` or `created_tmp_disk_tables` status counters, because in certain situations, temporary tables are written to disk when they no longer fit in memory.

### **`synch/mutex/sql/FILE_AS_TABLE::LOCK_offsets`**

The engine acquires this mutex when opening or creating a table metadata file. When this wait event occurs with excessive frequency, the number of tables being created or opened has spiked.

### **`synch/mutex/sql/FILE_AS_TABLE::LOCK_shim_lists`**

The engine acquires this mutex while performing operations such as `reset_size`, `detach_contents`, or `add_contents` on the internal structure that keeps track of opened tables. The mutex synchronizes access to the list contents. When this wait event occurs with high frequency, it indicates a sudden change in the set of tables that were previously accessed. The engine needs to access new tables or let go of the context related to previously accessed tables.

## **synch/mutex/sql/LOCK\_open**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](#).

## **synch/mutex/sql/LOCK\_table\_cache**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see [How MySQL opens and closes tables](#).

## **synch/mutex/sql/LOG**

In this wait event, there are threads waiting on a log lock. For example, a thread might wait for a lock to write to the slow query log file.

## **synch/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_commit**

In this wait event, there is a thread that is waiting to acquire a lock with the intention of committing to the binary log. Binary logging contention can occur on databases with a very high change rate. Depending on your version of MySQL, there are certain locks being used to protect the consistency and durability of the binary log. In RDS for MySQL, binary logs are used for replication and the automated backup process. In Aurora MySQL, binary logs are not needed for native replication or backups. They are disabled by default but can be enabled and used for external replication or change data capture. For more information, see [The binary log](#) in the MySQL documentation.

## **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_dump\_thread\_metrics\_collection**

If binary logging is turned on, the engine acquires this mutex when it prints active dump threads metrics to the engine error log and to the internal operations map.

## **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_inactive\_binlogs\_map**

If binary logging is turned on, the engine acquires this mutex when it adds to, deletes from, or searches through the list of binlog files behind the latest one.

## **sync/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_io\_cache**

If binary logging is turned on, the engine acquires this mutex during Aurora binlog IO cache operations: allocate, resize, free, write, read, purge, and access cache info. If this event occurs frequently, the engine is accessing the cache where binlog events are stored. To reduce wait times, reduce commits. Try grouping multiple statements into a single transaction.

### **synch/mutex/sql/MYSQL\_BIN\_LOG::LOCK\_log**

You have turned on binary logging. There might be high commit throughput, many transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication or use the `aurora_binlog_*` parameters.

### **synch/mutex/sql/SERVER\_THREAD::LOCK\_sync**

The mutex `SERVER_THREAD::LOCK_sync` is acquired during the scheduling, processing, or launching of threads for file writes. The excessive occurrence of this wait event indicates increased write activity in the database.

### **synch/mutex/sql/TABLESPACES:lock**

The engine acquires the `TABLESPACES:lock` mutex during the following tablespace operations: create, delete, truncate, and extend. The excessive occurrence of this wait event indicates a high frequency of tablespace operations. An example is loading a large amount of data into the database.

### **synch/rwlock/innodb/dict**

In this wait event, there are threads waiting on an rwlock held on the InnoDB data dictionary.

### **synch/rwlock/innodb/dict\_operation\_lock**

In this wait event, there are threads holding locks on InnoDB data dictionary operations.

### **synch/rwlock/innodb/dict sys RW lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

### **synch/rwlock/innodb/index\_tree\_rw\_lock**

A large number of similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

### **synch/sxlock/innodb/dict\_operation\_lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

### **synch/sxlock/innodb/dict\_sys\_lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

### **synch/sxlock/innodb/hash\_table\_locks**

The session couldn't find pages in the buffer pool. The engine either needs to read a file or modify the least-recently used (LRU) list for the buffer pool. Consider increasing the buffer cache size and improving access paths for the relevant queries.

### **synch/sxlock/innodb/index\_tree\_rw\_lock**

Many similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

### **synch/mutex/innodb/temp\_pool\_manager\_mutex**

This wait event occurs when a session is waiting to acquire a mutex for managing the pool of session temporary tablespaces.

For more information on troubleshooting synch wait events, see [Why is my MySQL DB instance showing a high number of active sessions waiting on SYNCH wait events in Performance Insights?](#)

## **Aurora MySQL thread states**

The following are some common thread states for Aurora MySQL.

### **checking permissions**

The thread is checking whether the server has the required privileges to run the statement.

### **checking query cache for query**

The server is checking whether the current query is present in the query cache.

### **cleaned up**

This is the final state of a connection whose work is complete but which hasn't been closed by the client. The best solution is to explicitly close the connection in code. Or you can set a lower value for `wait_timeout` in your parameter group.

## **closing tables**

The thread is flushing the changed table data to disk and closing the used tables. If this isn't a fast operation, verify the network bandwidth consumption metrics against the instance class network bandwidth. Also, check that the parameter values for `table_open_cache` and `table_definition_cache` parameter allow for enough tables to be simultaneously open so that the engine doesn't need to open and close tables frequently. These parameters influence the memory consumption on the instance.

## **converting HEAP to MyISAM**

The query is converting a temporary table from in-memory to on-disk. This conversion is necessary because the temporary tables created by MySQL in the intermediate steps of query processing grew too big for memory. Check the values of `tmp_table_size` and `max_heap_table_size`. In later versions, this thread state name is `converting HEAP to ondisk`.

## **converting HEAP to ondisk**

The thread is converting an internal temporary table from an in-memory table to an on-disk table.

## **copy to tmp table**

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it. For a thread in this state, you can use the Performance Schema to obtain information about the progress of the copy operation.

## **creating sort index**

Aurora MySQL is performing a sort because it can't use an existing index to satisfy the `ORDER BY` or `GROUP BY` clause of a query. For more information, see [creating sort index](#).

## **creating table**

The thread is creating a permanent or temporary table.

## **delayed commit ok done**

An asynchronous commit in Aurora MySQL has received an acknowledgement and is complete.

## **delayed commit ok initiated**

The Aurora MySQL thread has started the async commit process but is waiting for acknowledgement. This is usually the genuine commit time of a transaction.

## **delayed send ok done**

An Aurora MySQL worker thread that is tied to a connection can be freed while a response is sent to the client. The thread can begin other work. The state `delayed send ok` means that the asynchronous acknowledgement to the client completed.

## **delayed send ok initiated**

An Aurora MySQL worker thread has sent a response asynchronously to a client and is now free to do work for other connections. The transaction has started an async commit process that hasn't yet been acknowledged.

## **executing**

The thread has begun running a statement.

## **freeing items**

The thread has run a command. Some freeing of items done during this state involves the query cache. This state is usually followed by cleaning up.

## **init**

This state occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions in this state include flushing the binary log or InnoDB log, and some cleanup of the query cache.

## **Source has sent all binlog to replica; waiting for more updates**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

## **opening tables**

The thread is trying to open a table. This operation is fast unless an `ALTER TABLE` or a `LOCK TABLE` statement needs to finish, or it exceeds the value of `table_open_cache`.

## **optimizing**

The server is performing initial optimizations for a query.

## **preparing**

This state occurs during query optimization.

## **query end**

This state occurs after processing a query but before the freeing items state.

## removing duplicates

Aurora MySQL couldn't optimize a DISTINCT operation in the early stage of a query. Aurora MySQL must remove all duplicated rows before sending the result to the client.

## searching rows for update

The thread is finding all matching rows before updating them. This stage is necessary if the UPDATE is changing the index that the engine uses to find the rows.

## sending binlog event to slave

The thread read an event from the binary log and is sending it to the replica.

## sending cached result to client

The server is taking the result of a query from the query cache and sending it to the client.

## sending data

The thread is reading and processing rows for a SELECT statement but hasn't yet started sending data to the client. The process is identifying which pages contain the results necessary to satisfy the query. For more information, see [sending data](#).

## sending to client

The server is writing a packet to the client. In earlier MySQL versions, this wait event was labeled `writing to net`.

## starting

This is the first stage at the beginning of statement execution.

## statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound while performing other work.

## storing result in query cache

The server is storing the result of a query in the query cache.

## system lock

The thread has called `mysql_lock_tables`, but the thread state hasn't been updated since the call. This general state occurs for many reasons.

## update

The thread is preparing to start updating the table.

## **updating**

The thread is searching for rows and is updating them.

## **user lock**

The thread issued a GET\_LOCK call. The thread either requested an advisory lock and is waiting for it, or is planning to request it.

## **waiting for more updates**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

## **waiting for schema metadata lock**

This is a wait for a metadata lock.

## **waiting for stored function metadata lock**

This is a wait for a metadata lock.

## **waiting for stored procedure metadata lock**

This is a wait for a metadata lock.

## **waiting for table flush**

The thread is executing FLUSH TABLES and is waiting for all threads to close their tables. Or the thread received notification that the underlying structure for a table changed, so it must reopen the table to get the new structure. To reopen the table, the thread must wait until all other threads have closed the table. This notification takes place if another thread has used one of the following statements on the table: FLUSH TABLES, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE.

## **waiting for table level lock**

One session is holding a lock on a table while another session tries to acquire the same lock on the same table.

## **waiting for table metadata lock**

Aurora MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. In this wait event, one session is holding a metadata lock on a table while another session tries to acquire the same lock on the same table. When the Performance Schema is enabled, this thread state is reported as the wait event `synch/cond/sql/MDL_context::COND_wait_status`.

## writing to net

The server is writing a packet to the network. In later MySQL versions, this wait event is labeled `Sending to client`.

## Aurora MySQL isolation levels

Learn how DB instances in an Aurora MySQL cluster implement the database property of isolation. This topic explains how the Aurora MySQL default behavior balances between strict consistency and high performance. You can use this information to help you decide when to change the default settings based on the traits of your workload.

### Available isolation levels for writer instances

You can use the isolation levels `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE` on the primary instance of an Aurora MySQL DB cluster. These isolation levels work the same in Aurora MySQL as in RDS for MySQL.

### REPEATABLE READ isolation level for reader instances

By default, Aurora MySQL DB instances that are configured as read-only Aurora Replicas always use the `REPEATABLE READ` isolation level. These DB instances ignore any `SET TRANSACTION ISOLATION LEVEL` statements and continue using the `REPEATABLE READ` isolation level.

### READ COMMITTED isolation level for reader instances

If your application includes a write-intensive workload on the primary instance and long-running queries on the Aurora Replicas, you might experience substantial purge lag. *Purge lag* happens when internal garbage collection is blocked by long-running queries. The symptom that you see is a high value for `history list length` in the output from the `SHOW ENGINE INNODB STATUS` command. You can monitor this value using the `RollbackSegmentHistoryListLength` metric in CloudWatch. Substantial purge lag can reduce the effectiveness of secondary indexes, decrease overall query performance, and lead to wasted storage space.

If you experience such issues, you can set an Aurora MySQL session-level configuration setting, `aurora_read_replica_read_committed`, to use the `READ COMMITTED` isolation level on Aurora Replicas. When you apply this setting, you can help reduce slowdowns and wasted space that can result from performing long-running queries at the same time as transactions that modify your tables.

We recommend making sure that you understand the specific Aurora MySQL behavior of the `READ COMMITTED` isolation before using this setting. The Aurora Replica `READ COMMITTED` behavior complies with the ANSI SQL standard. However, the isolation is less strict than typical MySQL `READ COMMITTED` behavior that you might be familiar with. Therefore, you might see different query results under `READ COMMITTED` on an Aurora MySQL read replica than you might see for the same query under `READ COMMITTED` on the Aurora MySQL primary instance or on RDS for MySQL. You might consider using the `aurora_read_replica_read_committed` setting for such cases as a comprehensive report that scans a very large database. In contrast, you might avoid it for short queries with small result sets, where precision and repeatability are important.

The `READ COMMITTED` isolation level isn't available for sessions within a secondary cluster in an Aurora global database that use the write forwarding feature. For information about write forwarding, see [Using write forwarding in an Amazon Aurora global database](#).

### Using `READ COMMITTED` for readers

To use the `READ COMMITTED` isolation level for Aurora Replicas, set the `aurora_read_replica_read_committed` configuration setting to `ON`. Use this setting at the session level while connected to a specific Aurora Replica. To do so, run the following SQL commands.

```
set session aurora_read_replica_read_committed = ON;
set session transaction isolation level read committed;
```

You might use this configuration setting temporarily to perform interactive, one-time queries. You might also want to run a reporting or data analysis application that benefits from the `READ COMMITTED` isolation level, while leaving the default setting unchanged for other applications.

When the `aurora_read_replica_read_committed` setting is turned on, use the `SET TRANSACTION ISOLATION LEVEL` command to specify the isolation level for the appropriate transactions.

```
set transaction isolation level read committed;
```

### Differences in `READ COMMITTED` behavior on Aurora replicas

The `aurora_read_replica_read_committed` setting makes the `READ COMMITTED` isolation level available for an Aurora Replica, with consistency behavior that is optimized for long-running transactions. The `READ COMMITTED` isolation level on Aurora Replicas has less strict isolation than

on Aurora primary instances. For that reason, enable this setting only on Aurora Replicas where you know that your queries can accept the possibility of certain types of inconsistent results.

Your queries can experience certain kinds of read anomalies when the `aurora_read_replica_read_committed` setting is turned on. Two kinds of anomalies are especially important to understand and handle in your application code. A *non-repeatable read* occurs when another transaction commits while your query is running. A long-running query can see different data at the start of the query than it sees at the end. A *phantom read* occurs when other transactions cause existing rows to be reorganized while your query is running, and one or more rows are read twice by your query.

Your queries might experience inconsistent row counts as a result of phantom reads. Your queries might also return incomplete or inconsistent results due to non-repeatable reads. For example, suppose that a join operation refers to tables that are concurrently modified by SQL statements such as `INSERT` or `DELETE`. In this case, the join query might read a row from one table but not the corresponding row from another table.

The ANSI SQL standard allows both of these behaviors for the `READ COMMITTED` isolation level. However, those behaviors are different than the typical MySQL implementation of `READ COMMITTED`. Thus, before enabling the `aurora_read_replica_read_committed` setting, check any existing SQL code to verify if it operates as expected under the looser consistency model.

Row counts and other results might not be strongly consistent under the `READ COMMITTED` isolation level while this setting is enabled. Thus, you typically enable the setting only while running analytic queries that aggregate large amounts of data and don't require absolute precision. If you don't have these kinds of long-running queries alongside a write-intensive workload, you probably don't need the `aurora_read_replica_read_committed` setting. Without the combination of long-running queries and a write-intensive workload, you're unlikely to encounter issues with the length of the history list.

### **Example Queries showing isolation behavior for `READ COMMITTED` on Aurora Replicas**

The following example shows how `READ COMMITTED` queries on an Aurora Replica might return non-repeatable results if transactions modify the associated tables at the same time. The table `BIG_TABLE` contains 1 million rows before any queries start. Other data manipulation language (DML) statements add, remove, or change rows while they are running.

The queries on the Aurora primary instance under the `READ COMMITTED` isolation level produce predictable results. However, the overhead of keeping the consistent read view for the lifetime of every long-running query can lead to expensive garbage collection later.

The queries on the Aurora Replica under the READ COMMITTED isolation level are optimized to minimize this garbage collection overhead. The tradeoff is that the results might vary depending on whether the queries retrieve rows that are added, removed, or reorganized by transactions that are committed while the query is running. The queries are allowed to consider these rows, but aren't required to. For demonstration purposes, the queries check only the number of rows in the table by using the COUNT(\*) function.

Time	DML statement on Aurora primary instance	Query on Aurora primary instance with READ COMMITTED	Query on Aurora Replica with READ COMMITTED
T1	INSERT INTO big_table SELECT * FROM other_table LIMIT 1000000; COMMIT;		
T2		<b>Q1:</b> SELECT COUNT(*) FROM big_table;	<b>Q2:</b> SELECT COUNT(*) FROM big_table;
T3	INSERT INTO big_table (c1, c2) VALUES (1, 'one more row'); COMMIT;		
T4		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or 1,000,001.
T5	DELETE FROM big_table LIMIT 2; COMMIT;		
T6		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or

Time	DML statement on Aurora primary instance	Query on Aurora primary instance with READ COMMITTED	Query on Aurora Replica with READ COMMITTED
			1,000,001 or 999,999 or 999,998.
T7	<pre>UPDATE big_table SET c2 = CONCAT(c2 ,c2,c2); COMMIT;</pre>		
T8		If Q1 finishes now, result is 1,000,000.	If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999, or possibly some higher number.
T9		<b>Q3:</b> SELECT COUNT(*) FROM big_table;	<b>Q4:</b> SELECT COUNT(*) FROM big_table;
T10		If Q3 finishes now, result is 999,999.	If Q4 finishes now, result is 999,999.
T11		<b>Q5:</b> SELECT COUNT(*) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000;	<b>Q6:</b> SELECT COUNT(*) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000;

Time	DML statement on Aurora primary instance	Query on Aurora primary instance with READ COMMITTED	Query on Aurora Replica with READ COMMITTED
T12	<pre>INSERT INTO parent_table (id, s) VALUES (1000, 'hello'); INSERT INTO child_table (id, s) VALUES (1000, 'world'); COMMIT;</pre>		
T13		If Q5 finishes now, result is 0.	If Q6 finishes now, result is 0 or 1.

If the queries finish quickly, before any other transactions perform DML statements and commit, the results are predictable and the same between the primary instance and the Aurora Replica. Let's examine the differences in behavior in detail, starting with the first query.

The results for Q1 are highly predictable because READ COMMITTED on the primary instance uses a strong consistency model similar to the REPEATABLE READ isolation level.

The results for Q2 might vary depending on what transactions are committed while that query is running. For example, suppose that other transactions perform DML statements and commit while the queries are running. In this case, the query on the Aurora Replica with the READ COMMITTED isolation level might or might not take the changes into account. The row counts aren't predictable in the same way as under the REPEATABLE READ isolation level. They also aren't as predictable as queries running under the READ COMMITTED isolation level on the primary instance, or on an RDS for MySQL instance.

The UPDATE statement at T7 doesn't actually change the number of rows in the table. However, by changing the length of a variable-length column, this statement can cause rows to be reorganized internally. A long-running READ COMMITTED transaction might see the old version of a row, and

later within the same query see the new version of the same row. The query can also skip both the old and new versions of the row, so the row count might be different than expected.

The results of Q5 and Q6 might be identical or slightly different. Query Q6 on the Aurora Replica under `READ COMMITTED` is able to see, but is not required to see, the new rows that are committed while the query is running. It might also see the row from one table, but not from the other table. If the join query doesn't find a matching row in both tables, it returns a count of zero. If the query does find both the new rows in `PARENT_TABLE` and `CHILD_TABLE`, the query returns a count of one. In a long-running query, the lookups from the joined tables might happen at widely separated times.

### Note

These differences in behavior depend on the timing of when transactions are committed and when the queries process the underlying table rows. Thus, you're most likely to see such differences in report queries that take minutes or hours and that run on Aurora clusters processing OLTP transactions at the same time. These are the kinds of mixed workloads that benefit the most from the `READ COMMITTED` isolation level on Aurora Replicas.

## Aurora MySQL hints

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.

### Tip

To verify the effect that a hint has on a query, examine the query plan produced by the `EXPLAIN` statement. Compare the query plans with and without the hint.

In Aurora MySQL version 3, you can use all the hints that are available in MySQL Community Edition 8.0. For more information about these hints, see [Optimizer Hints](#) in the *MySQL Reference Manual*.

The following hints are available in Aurora MySQL version 2. These hints apply to queries that use the hash join feature in Aurora MySQL version 2, especially queries that use parallel query optimization.

## PQ, NO\_PQ

Specifies whether to force the optimizer to use parallel query on a per-table or per-query basis.

PQ forces the optimizer to use parallel query for specified tables or the whole query (block). NO\_PQ prevents the optimizer from using parallel query for specified tables or the whole query (block).

This hint is available in Aurora MySQL version 2.11 and higher. The following examples show you how to use this hint.

### Note

Specifying a table name forces the optimizer to apply the PQ/NO\_PQ hint only on those select tables. Not specifying a table name forces the PQ/NO\_PQ hint on all tables affected by the query block.

```
EXPLAIN SELECT /*+ PQ() */ f1, f2
  FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ PQ(t1) */ f1, f2
  FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ PQ(t1,t2) */ f1, f2
  FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;

EXPLAIN SELECT /*+ NO_PQ() */ f1, f2
  FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ NO_PQ(t1) */ f1, f2
  FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ NO_PQ(t1,t2) */ f1, f2
  FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;
```

## HASH\_JOIN, NO\_HASH\_JOIN

Turns on or off the ability of the parallel query optimizer to choose whether to use the hash join optimization method for a query. `HASH_JOIN` lets the optimizer use hash join if that mechanism is more efficient. `NO_HASH_JOIN` prevents the optimizer from using hash join for the query. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show you how to use this hint.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ NO_HASH_JOIN(t2) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;
```

## HASH\_JOIN\_PROBING, NO\_HASH\_JOIN\_PROBING

In a hash join query, specifies whether to use the specified table for the probe side of the join. The query tests if column values from the build table exist in the probe table, instead of reading the entire contents of the probe table. You can use `HASH_JOIN_PROBING` and `HASH_JOIN_BUILDING` to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the `HASH_JOIN_PROBING` hint for the table T2 has the same effect as specifying `NO_HASH_JOIN_PROBING` for the table T1.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_PROBING(t2) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_PROBING(t1) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;
```

## HASH\_JOIN\_BUILDING, NO\_HASH\_JOIN\_BUILDING

In a hash join query, specifies whether to use the specified table for the build side of the join. The query processes all the rows from this table to build the list of column values to cross-reference with the other table. You can use `HASH_JOIN_PROBING` and `HASH_JOIN_BUILDING` to specify how hash join queries are processed without reordering the tables within the query

text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following example shows you how to use this hint. Specifying the `HASH_JOIN_BUILDING` hint for the table T2 has the same effect as specifying `NO_HASH_JOIN_BUILDING` for the table T1.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_BUILDING(t2) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_BUILDING(t1) */ f1, f2
  FROM t1, t2 WHERE t1.f1 = t2.f1;
```

## JOIN\_FIXED\_ORDER

Specifies that tables in the query are joined based on the order they are listed in the query. It is useful with queries involving three or more tables. It is intended as a replacement for the MySQL `STRAIGHT_JOIN` hint and is equivalent to the MySQL [JOIN\\_FIXED\\_ORDER](#) hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_FIXED_ORDER() */ f1, f2
  FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_ORDER

Specifies the join order for the tables in the query. It is useful with queries involving three or more tables. It is equivalent to the MySQL [JOIN\\_ORDER](#) hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2, t1, t3) */ f1, f2
  FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_PREFIX

Specifies the tables to put first in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL [JOIN\\_PREFIX](#) hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_PREFIX (t4, t2) */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

## JOIN\_SUFFIX

Specifies the tables to put last in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL [JOIN\\_SUFFIX](#) hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_SUFFIX (t1) */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

For information about using hash join queries, see [Optimizing large Aurora MySQL join queries with hash joins](#).

## Aurora MySQL stored procedure reference

You can manage your Aurora MySQL DB cluster by calling built-in stored procedures.

### Topics

## Collecting and maintaining the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see [Managing the Global Status History](#).

The following stored procedures manage how the Global Status History is collected and maintained.

### Topics

- [mysql.rds\\_collect\\_global\\_status\\_history](#)
- [mysql.rds\\_disable\\_gsh\\_collector](#)
- [mysql.rds\\_disable\\_gsh\\_rotation](#)
- [mysql.rds\\_enable\\_gsh\\_collector](#)
- [mysql.rds\\_enable\\_gsh\\_rotation](#)
- [mysql.rds\\_rotate\\_global\\_status\\_history](#)
- [mysql.rds\\_set\\_gsh\\_collector](#)
- [mysql.rds\\_set\\_gsh\\_rotation](#)

### **mysql.rds\_collect\_global\_status\_history**

Takes a snapshot on demand for the Global Status History.

#### Syntax

```
CALL mysql.rds_collect_global_status_history;
```

### **mysql.rds\_disable\_gsh\_collector**

Turns off snapshots taken by the Global Status History.

#### Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

## **mysql.rds\_disable\_gsh\_rotation**

Turns off rotation of the `mysql.global_status_history` table.

### **Syntax**

```
CALL mysql.rds_disable_gsh_rotation;
```

## **mysql.rds\_enable\_gsh\_collector**

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

### **Syntax**

```
CALL mysql.rds_enable_gsh_collector;
```

## **mysql.rds\_enable\_gsh\_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

### **Syntax**

```
CALL mysql.rds_enable_gsh_rotation;
```

## **mysql.rds\_rotate\_global\_status\_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

### **Syntax**

```
CALL mysql.rds_rotate_global_status_history;
```

## **mysql.rds\_set\_gsh\_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

## Syntax

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

## Parameters

### *intervalPeriod*

The interval, in minutes, between snapshots. Default value is 5.

## **mysql.rds\_set\_gsh\_rotation**

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

## Syntax

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

## Parameters

### *intervalPeriod*

The interval, in days, between table rotations. Default value is 7.

## Configuring, starting, and stopping binary log (binlog) replication

You can call the following stored procedures while connected to the primary instance in an Aurora MySQL cluster. These procedures control how transactions are replicated from an external database into Aurora MySQL, or from Aurora MySQL to an external database.

### Topics

- [mysql.rds\\_disable\\_session\\_binlog \(Aurora MySQL version 2\)](#)

- [mysql.rds\\_stop\\_replication](#)

### **mysql.rds\_disable\_session\_binlog (Aurora MySQL version 2)**

Turns off binary logging for the current session by setting the `sql_log_bin` variable to OFF.

## Syntax

```
CALL mysql.rds_disable_session_binlog;
```

## Parameters

None

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7-compatible versions.

### Note

In Aurora MySQL version 3, you can use the following command to disable binary logging for the current session if you have the `SESSION_VARIABLES_ADMIN` privilege:

```
SET SESSION sql_log_bin = OFF;
```

## **mysql.rds\_enable\_session\_binlog (Aurora MySQL version 2)**

Turns on binary logging for the current session by setting the `sql_log_bin` variable to ON.

## Syntax

```
CALL mysql.rds_enable_session_binlog;
```

## Parameters

None

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7-compatible versions.

### Note

In Aurora MySQL version 3, you can use the following command to enable binary logging for the current session if you have the `SESSION_VARIABLES_ADMIN` privilege:

```
SET SESSION sql_log_bin = ON;
```

## mysql.rds\_import\_binlog\_ssl\_material

Imports the certificate authority certificate, client certificate, and client key into an Aurora MySQL DB cluster. The information is required for SSL communication and encrypted replication.

### Note

Currently, this procedure is supported for Aurora MySQL version 2: 2.09.2, 2.10.0, 2.10.1, and 2.11.0; and version 3: 3.01.1 and higher.

## Syntax

```
CALL mysql.rds_import_binlog_ssl_material (  
    ssl_material  
);
```

## Parameters

### *ssl\_material*

JSON payload that contains the contents of the following .pem format files for a MySQL client:

- "ssl\_ca": "*Certificate authority certificate*"
- "ssl\_cert": "*Client certificate*"
- "ssl\_key": "*Client key*"

## Usage notes

Prepare for encrypted replication before you run this procedure:

- If you don't have SSL enabled on the external MySQL source database instance and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
- If SSL is enabled on the external source database instance, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key you used to configure SSL on the external MySQL source database instance.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

### Important

After you prepare for encrypted replication, use an SSL connection to run this procedure. The client key must not be transferred across an insecure connection.

This procedure imports SSL information from an external MySQL database into an Aurora MySQL DB cluster. The SSL information is in .pem format files that contain the SSL information for the Aurora MySQL DB cluster. During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

You can copy the information from these files into the `ssl_material` parameter in the correct JSON payload. To support encrypted replication, import this SSL information into the Aurora MySQL DB cluster.

The JSON payload must be in the following format.

```
'{"ssl_ca": "-----BEGIN CERTIFICATE-----  
ssl_ca_pem_body_code  
-----END CERTIFICATE-----\n", "ssl_cert": "-----BEGIN CERTIFICATE-----  
ssl_cert_pem_body_code
```

```
-----END CERTIFICATE-----\n", "ssl_key": "-----BEGIN RSA PRIVATE KEY-----
ssl_key_pem_body_code
-----END RSA PRIVATE KEY-----\n"}'
```

## Examples

The following example imports SSL information into an Aurora MySQL. In .pem format files, the body code typically is longer than the body code shown in the example.

```
call mysql.rds_import_binlog_ssl_material(
 '{"ssl_ca": "-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAQCLKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706V

```

## mysql.rds\_next\_master\_log (Aurora MySQL version 2)

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

### Syntax

```
CALL mysql.rds_next_master_log(
 curr_master_log
```

);

## Parameters

### *curr\_master\_log*

The index of the current master log file. For example, if the current file is named `mysql-bin-change.log.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

## Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

### Warning

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

## Examples

Assume replication fails on an Aurora MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
***** 1. row *****
      Replica_IO_State:
        Source_Host: myhost.XXXXXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
        Source_User: MasterUser
        Source_Port: 3306
        Connect_Retry: 10
        Source_Log_File: mysql-bin-change.log.012345
      Read_Source_Log_Pos: 1219393
        Relay_Log_File: relaylog.012340
        Relay_Log_Pos: 30223388
```

```
Relay_Source_Log_File: mysql-bin-changelog.012345
  Replica_IO_Running: No
  Replica_SQL_Running: Yes
    Replicate_Do_DB:
  Replicate_Ignore_DB:
  Replicate_Do_Table:
  Replicate_Ignore_Table:
  Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
    Last_Errno: 0
    Last_Error:
    Skip_Counter: 0
  Exec_Source_Log_Pos: 30223232
  Relay_Log_Space: 5248928866
  Until_Condition: None
  Until_Log_File:
  Until_Log_Pos: 0
  Source_SSL_Allowed: No
  Source_SSL_CA_File:
  Source_SSL_CA_Path:
  Source_SSL_Cert:
  Source_SSL_Cipher:
  Source_SSL_Key:
  Seconds_Behind_Master: NULL
Source_SSL_Verify_Server_Cert: No
  Last_IO_Errno: 1236
  Last_IO_Error: Got fatal error 1236 from master when reading data from
binary log: 'Client requested master to start replication from impossible position;
the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
'/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

## mysql.rds\_next\_source\_log (Aurora MySQL version 3)

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

### Syntax

```
CALL mysql.rds_next_source_log(  
curr_source_log  
);
```

### Parameters

#### *curr\_source\_log*

The index of the current source log file. For example, if the current file is named `mysql-bin-change.log.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS` command and view the `Source_Log_File` field.

### Usage notes

The administrative user must run the `mysql.rds_next_source_log` procedure.

#### **Warning**

Call `mysql.rds_next_source_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_source_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred. You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, even though this might reduce performance.

## Examples

Assume replication fails on an Aurora MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
***** 1. row *****
      Replica_IO_State:
            Source_Host: myhost.XXXXXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
            Source_User: MasterUser
            Source_Port: 3306
            Connect_Retry: 10
            Source_Log_File: mysql-bin-changelog.012345
Read_Source_Log_Pos: 1219393
            Relay_Log_File: relaylog.012340
            Relay_Log_Pos: 30223388
Relay_Source_Log_File: mysql-bin-changelog.012345
      Replica_IO_Running: No
      Replica_SQL_Running: Yes
            Replicate_Do_DB:
      Replicate_Ignore_DB:
            Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
            Last_Errno: 0
            Last_Error:
            Skip_Counter: 0
      Exec_Source_Log_Pos: 30223232
            Relay_Log_Space: 5248928866
            Until_Condition: None
            Until_Log_File:
            Until_Log_Pos: 0
      Source_SSL_Allowed: No
      Source_SSL_CA_File:
      Source_SSL_CA_Path:
            Source_SSL_Cert:
            Source_SSL_Cipher:
            Source_SSL_Key:
      Seconds_Behind_Source: NULL
Source_SSL_Verify_Server_Cert: No
            Last_IO_Errno: 1236
            Last_IO_Error: Got fatal error 1236 from source when reading data from
binary log: 'mysql-bin-changelog.013406' at 1219393, the last event read from
```

```
'/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/  
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'  
    Last_SQL_Errno: 0  
    Last_SQL_Error:  
Replicate_Ignore_Server_Ids:  
    Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log` with the following parameter:

```
CALL mysql.rds_next_source_log(12345);
```

### **mysql.rds\_remove\_binlog\_ssl\_material**

Removes the certificate authority certificate, client certificate, and client key for SSL communication and encrypted replication. This information is imported by using [mysql.rds\\_import\\_binlog\\_ssl\\_material](#).

#### **Syntax**

```
CALL mysql.rds_remove_binlog_ssl_material;
```

### **mysql.rds\_reset\_external\_master (Aurora MySQL version 2)**

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

#### **Important**

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

#### **Syntax**

```
CALL mysql.rds_reset_external_master;
```

## Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

### Note

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

For more information about using replication to import data from an instance of MySQL running external to Aurora MySQL, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

### `mysql.rds_reset_external_source` (Aurora MySQL version 3)

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

## Syntax

```
CALL mysql.rds_reset_external_source;
```

## Usage notes

The administrative user must run the `mysql.rds_reset_external_source` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

**mysql.rds\_set\_binlog\_source\_ssl (Aurora MySQL version 3)**

Enables SOURCE\_SSL encryption for binlog replication. For more information, see [CHANGE REPLICATION SOURCE TO statement](#) in the MySQL documentation.

**Syntax**

```
CALL mysql.rds_set_binlog_source_ssl(mode);
```

**Parameters***mode*

A value that indicates whether SOURCE\_SSL encryption is enabled:

- 0 – SOURCE\_SSL encryption is disabled. The default is 0.
- 1 – SOURCE\_SSL encryption is enabled. You can configure encryption using SSL or TLS.

**Usage notes**

This procedure is supported for Aurora MySQL version 3.06 and higher.

**mysql.rds\_set\_external\_master (Aurora MySQL version 2)**

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

The `mysql.rds_set_external_master` procedure is deprecated and will be removed in a future release. Use [mysql.rds\\_set\\_external\\_source](#) instead.

**⚠ Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

**Syntax**

```
CALL mysql.rds_set_external_master (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , mysql_binary_log_file_name  
    , mysql_binary_log_file_location  
    , ssl_encryption  
);
```

**Parameters***host\_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

*host\_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

*replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

*replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source database instance that contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

#### Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

## Usage notes

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

## To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

### MySQL 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

## MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

### Note

Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl\_user' user for your domain.

## MySQL 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

## MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the [mysql.rds\\_import\\_binlog\\_ssl\\_material](#) procedure.

### Note

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds\\_start\\_replication](#) on the read replica to start the replication process. You can call [mysql.rds\\_reset\\_external\\_master \(Aurora MySQL version 2\)](#) to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

## Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master(  
  'Externaldb.some.com',  
  3306,  
  'repl_user',  
  'password',  
  'mysql-bin-changelog.0777',  
  120,  
  1);
```

## mysql.rds\_set\_external\_source (Aurora MySQL version 3)

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

## Syntax

```
CALL mysql.rds_set_external_source (  
  host_name
```

```
, host_port
, replication_user_name
, replication_user_password
, mysql_binary_log_file_name
, mysql_binary_log_file_location
, ssl_encryption
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

### *host\_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in replication\_user\_name.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source database instance that contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the mysql\_binary\_log\_file\_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

## *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

### Note

You must have imported a custom SSL certificate using [mysql.rds\\_import\\_binlog\\_ssl\\_material](#) to enable this option. If you haven't imported a custom SSL certificate, then set this parameter to 0 and use [mysql.rds\\_set\\_binlog\\_source\\_ssl \(Aurora MySQL version 3\)](#) to enable SSL for binary log replication.

The SOURCE\_SSL\_VERIFY\_SERVER\_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

## Usage notes

The administrative user must run the `mysql.rds_set_external_source` procedure. This procedure must be run on the Aurora MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_source`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

## To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

### Note

Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl\_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the [mysql.rds\\_import\\_binlog\\_ssl\\_material](#) procedure.

### Note

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

After calling `mysql.rds_set_external_source` to configure an Aurora MySQL DB instance as a read replica, you can call [mysql.rds\\_start\\_replication](#) on the read replica to start the replication process. You can call [mysql.rds\\_reset\\_external\\_source \(Aurora MySQL version 3\)](#) to remove the read replica configuration.

When `mysql.rds_set_external_source` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

## Examples

When run on an Aurora MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_source(  
  'Externaldb.some.com',  
  3306,  
  'repl_user',  
  'password',  
  'mysql-bin-changelog.0777',  
  120,
```

```
1);
```

## mysql.rds\_set\_external\_master\_with\_auto\_position (Aurora MySQL version 2)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

### Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , ssl_encryption  
);
```

### Parameters

#### *host\_name*

The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

#### *host\_port*

The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

#### *replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

#### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

## *ssl\_encryption*

This option isn't currently implemented. The default is 0.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. The master user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 2. For Aurora MySQL version 3, use the procedure [mysql.rds\\_set\\_external\\_source\\_with\\_auto\\_position \(Aurora MySQL version 3\)](#) instead.

Before you run `mysql.rds_set_external_master_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external MySQL instance.

### To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external MySQL instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl\_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassW0rd'
```

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(Aurora MySQL version 2 and 3\)](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).

## Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```
call mysql.rds_set_external_master_with_auto_position(
  'Externaldb.some.com',
  3306,
  'repl_user'@'mydomain.com',
  'SomePassW0rd');
```

## mysql.rds\_set\_external\_source\_with\_auto\_position (Aurora MySQL version 3)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

## Syntax

```
CALL mysql.rds_set_external_source_with_auto_position (
  host_name
  , host_port
  , replication_user_name
  , replication_user_password
  , ssl_encryption
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

### *host\_port*

The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *ssl\_encryption*

This option isn't currently implemented. The default is 0.

#### **Note**

Use [mysql.rds\\_set\\_binlog\\_source\\_ssl \(Aurora MySQL version 3\)](#) to enable SSL for binary log replication.

## **Usage notes**

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. The administrative user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 3. This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

Before you run `mysql.rds_set_external_source_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values

must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external MySQL instance.

### To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external MySQL instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(Aurora MySQL version 2 and 3\)](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).

### Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```
call mysql.rds_set_external_source_with_auto_position(  
  'Externaldb.some.com',  
  3306,  
  'repl_user'@'mydomain.com',  
  'SomePassW0rd');
```

### `mysql.rds_set_master_auto_position` (Aurora MySQL version 2)

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

## Syntax

```
CALL mysql.rds_set_master_auto_position (  
auto_position_mode  
);
```

## Parameters

### *auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

## Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for Aurora MySQL version 2.

### **mysql.rds\_set\_read\_only (Aurora MySQL version 3)**

Turns `read_only` mode on or off globally for the DB instance.

## Syntax

```
CALL mysql.rds_set_read_only(mode);
```

## Parameters

### *mode*

A value that indicates whether `read_only` mode is on or off globally for the DB instance:

- 0 – OFF. The default is 0.
- 1 – ON

## Usage notes

The `mysql.rds_set_read_only` stored procedure modifies only the `read_only` parameter. The `innodb_read_only` parameter can't be changed on reader DB instances.

The `read_only` parameter change doesn't persist on rebooting. To make permanent changes to `read_only`, you must use the `read_only` DB cluster parameter.

This procedure is supported for Aurora MySQL version 3.06 and higher.

### **mysql.rds\_set\_session\_binlog\_format (Aurora MySQL version 2)**

Sets the binary log format for the current session.

#### **Syntax**

```
CALL mysql.rds_set_session_binlog_format(format);
```

#### **Parameters**

##### *format*

A value that indicates the binary log format for the current session:

- **STATEMENT** – The replication source writes events to the binary log based on SQL statements.
- **ROW** – The replication source writes events to the binary log that indicate changes to individual table rows.
- **MIXED** – Logging is generally based on SQL statements, but switches to rows under certain conditions. For more information, see [Mixed Binary Logging Format](#) in the MySQL documentation.

#### **Usage notes**

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

To use this stored procedure, you must have binary logging configured for the current session.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7–compatible versions.

### **mysql.rds\_set\_source\_auto\_position (Aurora MySQL version 3)**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

## Syntax

```
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

## Parameters

### *auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

## Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_source_auto_position` procedure.

## **mysql.rds\_skip\_repl\_error**

Skips and deletes a replication error on a MySQL DB read replica.

## Syntax

```
CALL mysql.rds_skip_repl_error;
```

## Usage notes

The master user must run the `mysql.rds_skip_repl_error` procedure on a read replica. For more information about this procedure, see [Skipping the current replication error](#).

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see [SHOW REPLICA STATUS statement](#) in the MySQL documentation.

For more information about addressing replication errors with Aurora MySQL, see [Diagnosing and resolving a MySQL read replication failure](#).

## Replication stopped error

When you call the `mysql.rds_skip_repl_error` procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error because of binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the [mysql.rds\\_set\\_configuration](#) procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

## mysql.rds\_start\_replication

Initiates replication from an Aurora MySQL DB cluster.

### Note

You can use the [mysql.rds\\_start\\_replication\\_until \(Aurora MySQL version 3\)](#) or [mysql.rds\\_start\\_replication\\_until\\_gtid \(Aurora MySQL version 3\)](#) stored procedure to

initiate replication from an Aurora MySQL DB instance and stop replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication;
```

## Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call [mysql.rds\\_set\\_external\\_master \(Aurora MySQL version 2\)](#) or [mysql.rds\\_set\\_external\\_source \(Aurora MySQL version 3\)](#) to build the replication configuration. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see [Replication stopped error](#).

### **mysql.rds\_start\_replication\_until (Aurora MySQL version 3)**

Initiates replication from an Aurora MySQL DB cluster and stops replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication_until (  
  replication_log_file  
  , replication_stop_point
```

```
);
```

## Parameters

### *replication\_log\_file*

The name of the binary log on the source database instance that contains the replication information.

### *replication\_stop\_point*

The location in the `replication_log_file` binary log at which replication will stop.

## Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

The `mysql.rds_start_replication_until` stored procedure isn't supported for managed replication, which includes the following:

- [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#)
- [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#)

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

## Examples

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until(  
  'mysql-bin-changelog.000777',  
  120);
```

## mysql.rds\_stop\_replication

Stops replication from a MySQL DB instance.

### Syntax

```
CALL mysql.rds_stop_replication;
```

### Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#).

The `mysql.rds_stop_replication` stored procedure isn't supported for managed replication, which includes the following:

- [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#)
- [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#)

## Ending a session or query

The following stored procedures end a session or query.

### Topics

- [mysql.rds\\_kill](#)
- [mysql.rds\\_kill\\_query](#)

### mysql.rds\_kill

Ends a connection to the MySQL server.

### Syntax

```
CALL mysql.rds_kill(processID);
```

### Parameters

*processID*

The identity of the connection thread to be ended.

### Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL [SHOW PROCESSLIST](#) command.

### Examples

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

### mysql.rds\_kill\_query

Ends a query running against the MySQL server.

## Syntax

```
CALL mysql.rds_kill_query(processID);
```

## Parameters

*processID*

The identity of the process or thread that is running the query to be ended.

## Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL [INFORMATION\\_SCHEMA.PROCESSLIST table](#) or use the MySQL [SHOW PROCESSLIST](#) command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the *processID*.

## Examples

The following example stops a query with a query thread ID of 230040:

```
CALL mysql.rds_kill_query(230040);
```

## Replicating transactions using GTIDs

The following stored procedures control how transactions are replicated using global transaction identifiers (GTIDs) with Aurora MySQL. To learn how to use replication based on GTIDs with Aurora MySQL, see [Using GTID-based replication](#).

### Topics

- [mysql.rds\\_assign\\_gtids\\_to\\_anonymous\\_transactions \(Aurora MySQL version 3\)](#)
- [mysql.rds\\_gtid\\_purged \(Aurora MySQL version 3\)](#)
- [mysql.rds\\_skip\\_transaction\\_with\\_gtid \(Aurora MySQL version 2 and 3\)](#)
- [mysql.rds\\_start\\_replication\\_until\\_gtid \(Aurora MySQL version 3\)](#)

### mysql.rds\_assign\_gtids\_to\_anonymous\_transactions (Aurora MySQL version 3)

Configures the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement. It makes the replication channel assign a GTID to replicated transactions that don't have one. That way, you can perform binary log replication from a source that doesn't use GTID-based replication to a replica that does. For more information, see [CHANGE REPLICATION SOURCE TO Statement](#) and [Replication From a Source Without GTIDs to a Replica With GTIDs](#) in the *MySQL Reference Manual*.

### Syntax

```
CALL mysql.rds_assign_gtids_to_anonymous_transactions(gtid_option);
```

### Parameters

*gtid\_option*

String value. The allowed values are OFF, LOCAL, or a specified UUID.

### Usage notes

This procedure has the same effect as issuing the statement `CHANGE REPLICATION SOURCE TO ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = gtid_option` in community MySQL.

GTID must be turned to ON for *gtid\_option* to be set to LOCAL or a specific UUID.

The default is OFF, meaning that the feature isn't used.

LOCAL assigns a GTID including the replica's own UUID (the `server_uuid` setting).

Passing a parameter that is a UUID assigns a GTID that includes the specified UUID, such as the `server_uuid` setting for the replication source server.

## Examples

To turn off this feature:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('OFF');
+-----+
| Message |
+-----+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: OFF |
+-----+
1 row in set (0.07 sec)
```

To use the replica's own UUID:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('LOCAL');
+-----+
| Message |
+-----+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: LOCAL |
+-----+
1 row in set (0.07 sec)
```

To use a specified UUID:

```
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('317a4760-
f3dd-3b74-8e45-0615ed29de0e');
+-----+
+
| Message |
+-----+
+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: 317a4760-
f3dd-3b74-8e45-0615ed29de0e |
+-----+
+
```

```
1 row in set (0.07 sec)
```

## mysql.rds\_gtid\_purged (Aurora MySQL version 3)

Sets the global value of the system variable `gtid_purged` to a given global transaction identifier (GTID) set. The `gtid_purged` system variable is a GTID set that consists of the GTIDs of all transactions that have been committed on the server, but don't exist in any binary log file on the server.

To allow compatibility with MySQL 8.0, there are two ways to set the value of `gtid_purged`:

- Replace the value of `gtid_purged` with your specified GTID set.
- Append your specified GTID set to the GTID set that `gtid_purged` already contains.

### Syntax

To replace the value of `gtid_purged` with your specified GTID set:

```
CALL mysql.rds_gtid_purged (gtid_set);
```

To append the value of `gtid_purged` to your specified GTID set:

```
CALL mysql.rds_gtid_purged (+gtid_set);
```

### Parameters

#### *gtid\_set*

The value of *gtid\_set* must be a superset of the current value of `gtid_purged`, and can't intersect with `gtid_subtract(gtid_executed, gtid_purged)`. That is, the new GTID set must include any GTIDs that were already in `gtid_purged`, and can't include any GTIDs in `gtid_executed` that haven't yet been purged. The *gtid\_set* parameter also can't include any GTIDs that are in the global `gtid_owned` set, the GTIDs for transactions that are currently being processed on the server.

### Usage notes

The master user must run the `mysql.rds_gtid_purged` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

## Examples

The following example assigns the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23 to the `gtid_purged` global variable.

```
CALL mysql.rds_gtid_purged('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

## mysql.rds\_skip\_transaction\_with\_gtid (Aurora MySQL version 2 and 3)

Skips replication of a transaction with the specified global transaction identifier (GTID) on an Aurora primary instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

## Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (  
gtid_to_skip  
);
```

## Parameters

*gtid\_to\_skip*

The GTID of the replication transaction to skip.

## Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for Aurora MySQL version 2 and 3.

## Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

## mysql.rds\_start\_replication\_until\_gtid (Aurora MySQL version 3)

Initiates replication from an Aurora MySQL DB cluster and stops replication immediately after the specified global transaction identifier (GTID).

### Syntax

```
CALL mysql.rds_start_replication_until_gtid(gtid);
```

### Parameters

*gtid*

The GTID after which replication is to stop.

### Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

The `mysql.rds_start_replication_until_gtid` stored procedure isn't supported for managed replication, which includes the following:

- [Replicating Amazon Aurora MySQL DB clusters across Amazon Web Services Regions](#)
- [Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica](#)

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

### Examples

The following example initiates replication and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

## Rotating the query logs

The following stored procedures rotate MySQL logs to backup tables. For more information, see [Aurora MySQL database log files](#).

### Topics

- [mysql.rds\\_rotate\\_general\\_log](#)
- [mysql.rds\\_rotate\\_slow\\_log](#)

### mysql.rds\_rotate\_general\_log

Rotates the `mysql.general_log` table to a backup table.

### Syntax

```
CALL mysql.rds_rotate_general_log;
```

### Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

### mysql.rds\_rotate\_slow\_log

Rotates the `mysql.slow_log` table to a backup table.

### Syntax

```
CALL mysql.rds_rotate_slow_log;
```

## Usage notes

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

## Setting and showing binary log configuration

The following stored procedures set and show configuration parameters, such as for binary log file retention.

### Topics

- [mysql.rds\\_set\\_configuration](#)
- [mysql.rds\\_show\\_configuration](#)

### mysql.rds\_set\_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

### Syntax

```
CALL mysql.rds_set_configuration(name, value);
```

### Parameters

#### *name*

The name of the configuration parameter to set.

#### *value*

The value of the configuration parameter.

### Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- [binlog retention hours](#)

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

## binlog retention hours

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon Aurora normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to Aurora.

The default value of `binlog retention hours` is NULL. For Aurora MySQL, NULL means binary logs are cleaned up lazily. Aurora MySQL binary logs might remain in the system for a certain period, which is usually not longer than a day.

To specify the number of hours to retain binary logs on a DB cluster, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

### Note

You can't use the value 0 for `binlog retention hours`.

For Aurora MySQL version 2.11.0 and higher and version 3 DB clusters, the maximum `binlog retention hours` value is 2160 (90 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

## mysql.rds\_show\_configuration

The number of hours that binary logs are retained.

### Syntax

```
CALL mysql.rds_show_configuration;
```

### Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

## Examples

The following example displays the retention period:

```
call mysql.rds_show_configuration;
      name                value    description
      binlog retention hours    24      binlog retention hours specifies
the duration in hours before binary logs are automatically deleted.
```

## Aurora MySQL-specific information\_schema tables

Aurora MySQL has certain information\_schema tables that are specific to Aurora.

### information\_schema.aurora\_global\_db\_instance\_status

The information\_schema.aurora\_global\_db\_instance\_status table contains information about the status of all DB instances in a global database's primary and secondary DB clusters. The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

#### Note

This information schema table is only available with Aurora MySQL version 3.04.0 and higher global databases.

Column	Data type	Description
SERVER_ID	varchar(100)	The identifier of the DB instance.
SESSION_ID	varchar(100)	A unique identifier for the current session. A value of MASTER_SESSION_ID identifies the Writer (primary) DB instance.
AWS_REGION	varchar(100)	The Amazon Web Services Region in which this global

Column	Data type	Description
		database instance runs. For a list of Regions, see <a href="#">Region availability</a> .
DURABLE_LSN	bigint unsigned	The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
HIGHEST_LSN_RCVD	bigint unsigned	The highest LSN received by the DB instance from the writer DB instance.
OLDEST_READ_VIEW_TRX_ID	bigint unsigned	The ID of the oldest transaction that the writer DB instance can purge to.
OLDEST_READ_VIEW_LSN	bigint unsigned	The oldest LSN used by the DB instance to read from storage.
VISIBILITY_LAG_IN_MSEC	float(10,0) unsigned	For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.

## information\_schema.aurora\_global\_db\_status

The `information_schema.aurora_global_db_status` table contains information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO). The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

### Note

This information schema table is only available with Aurora MySQL version 3.04.0 and higher global databases.

Column	Data type	Description
AWS_REGION	varchar(100)	The Amazon Web Services Region in which this global database instance runs. For a list of Regions, see <a href="#">Region availability</a> .
HIGHEST_LSN_WRITTEN	bigint unsigned	The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
DURABILITY_LAG_IN_MILLISECONDS	float(10,0) unsigned	The difference in the timestamp values between the HIGHEST_LSN_WRITTEN on a secondary DB cluster and the HIGHEST_LSN_WRITTEN on the

Column	Data type	Description
		primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.
RPO_LAG_IN_MILLISECONDS	float(10,0) unsigned	<p>The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database.</p> <p>In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.</p>

Column	Data type	Description
LAST_LAG_CALCULATION_TIMESTAMP	datetime	The timestamp that specifies when values were last calculated for DURABILITY_LAG_IN_MILLISECONDS and RPO_LAG_IN_MILLISECONDS . A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.
OLDEST_READ_VIEW_TRX_ID	bigint unsigned	The ID of the oldest transaction that the writer DB instance can purge to.

## information\_schema.replica\_host\_status

The `information_schema.replica_host_status` table contains replication information. The columns that you can use are shown in the following table. The remaining columns are for Aurora internal use only.

Column	Data type	Description
CPU	double	The CPU percentage usage of the replica host.
IS_CURRENT	tinyint	Whether the replica is current.
LAST_UPDATE_TIMESTAMP	datetime(6)	The time the last update occurred. Used to determine whether a record is stale.
REPLICA_LAG_IN_MILLISECONDS	double	The replica lag in milliseconds.
SERVER_ID	varchar(100)	The ID of the database server.

Column	Data type	Description
SESSION_ID	varchar(100)	The ID of the database session. Used to determine whether a DB instance is a writer or reader instance.

### Note

When a replica instance falls behind, the information queried from its `information_schema.replica_host_status` table might be outdated. In this situation, we recommend that you query from the writer instance instead. While the `mysql.ro_replica_status` table has similar information, we don't recommend that you use it.

## information\_schema.aurora\_forwarding\_processlist

The `information_schema.aurora_forwarding_processlist` table contains information about processes involved in write forwarding.

The contents of this table are visible only on the writer DB instance for a DB cluster with global or in-cluster write forwarding turned on. An empty result set is returned on reader DB instances.

Field	Data type	Description
ID	bigint	The identifier of the connection on the writer DB instance. This identifier is the same value displayed in the <code>Id</code> column of the <code>SHOW PROCESSLIST</code> statement and returned by the <code>CONNECTION_ID()</code> function within the thread.
USER	varchar(32)	The MySQL user that issued the statement.
HOST	varchar(255)	The MySQL client that issued the statement. For forwarded statements, this field shows the application client host

Field	Data type	Description
		address that established the connection on the forwarding reader DB instance.
DB	varchar(64)	The default database for the thread.
COMMAND	varchar(16)	The type of command the thread is executing on behalf of the client, or S1eep if the session is idle. For descriptions of thread commands, see the MySQL documentation on <a href="#">Thread Command Values</a> in the MySQL documentation.
TIME	int	The time in seconds that the thread has been in its current state.
STATE	varchar(64)	An action, event, or state that indicates what the thread is doing. For descriptions of state values, see <a href="#">General Thread States</a> in the MySQL documentation.
INFO	longtext	The statement that the thread is executing, or NULL if it isn't executing a statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements.
IS_FORWARDED	bigint	Indicates whether the thread is forwarded from a reader DB instance.
REPLICA_SESSION_ID	bigint	The connection identifier on the Aurora Replica. This identifier is the same value displayed in the Id column of the SHOW PROCESSLIST statement on the forwarding Aurora reader DB instance.
REPLICA_INSTANCE_IDENTIFIER	varchar(64)	The DB instance identifier of the forwarding thread.

Field	Data type	Description
REPLICA_CLUSTER_NAME	varchar(64)	The DB cluster identifier of the forwarding thread. For in-cluster write forwarding, this identifier is the same DB cluster as the writer DB instance.
REPLICA_REGION	varchar(64)	The Amazon Web Services Region from which the forwarding thread originates. For in-cluster write forwarding, this Region is the same Amazon Web Services Region as the writer DB instance.

# Database engine updates for Amazon Aurora MySQL

Amazon Aurora releases updates regularly. Updates are applied to Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, as well as the type of update.

Amazon Aurora releases are made available to all Amazon Regions over the course of multiple days. Some Regions might temporarily show an engine version that isn't available in a different Region yet.

Updates are applied to all instances in a DB cluster at the same time. An update requires a database restart on all instances in a DB cluster, so you experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the [Amazon Web Services Management Console](#).

For details about the Aurora MySQL versions that are supported by Amazon Aurora, see the [Release Notes for Aurora MySQL](#).

Following, you can learn how to choose the right Aurora MySQL version for your cluster, how to specify the version when you create or upgrade a cluster, and the procedures to upgrade a cluster from one version to another with minimal interruption.

## Topics

- [Checking Aurora MySQL version numbers](#)
- [Long-term support \(LTS\) and beta releases for Amazon Aurora MySQL](#)
- [Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support](#)
- [Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life](#)
- [Upgrading Amazon Aurora MySQL DB clusters](#)
- [Database engine updates and fixes for Amazon Aurora MySQL](#)

## Checking Aurora MySQL version numbers

Although Aurora MySQL-Compatible Edition is compatible with the MySQL database engines, Aurora MySQL includes features and bug fixes that are specific to particular Aurora MySQL versions. Application developers can check the Aurora MySQL version in their applications by using SQL. Database administrators can check and specify Aurora MySQL versions when creating or upgrading Aurora MySQL DB clusters and DB instances.

## Topics

- [Checking or specifying Aurora MySQL engine versions through Amazon](#)
- [Checking Aurora MySQL versions using SQL](#)

## Checking or specifying Aurora MySQL engine versions through Amazon

When you perform administrative tasks using the Amazon Web Services Management Console, Amazon CLI, or RDS API, you specify the Aurora MySQL version in a descriptive alphanumeric format.

Starting with Aurora MySQL version 2, Aurora engine versions have the following syntax.

```
mysql-major-version.mysql_aurora.aurora-mysql-version
```

The *mysql-major-version* portion is 5.7 or 8.0. This value represents the version of the client protocol and general level of MySQL feature support for the corresponding Aurora MySQL version.

The *aurora-mysql-version* is a dotted value with three parts: the Aurora MySQL major version, the Aurora MySQL minor version, and the patch level. The major version is 2 or 3. Those values represent Aurora MySQL compatible with MySQL 5.7 or 8.0, respectively. The minor version represents the feature release within the 2.x or 3.x series. The patch level begins at 0 for each minor version, and represents the set of subsequent bug fixes that apply to the minor version. Occasionally, a new feature is incorporated into a minor version but not made visible immediately. In these cases, the feature undergoes fine-tuning and is made public in a later patch level.

All 2.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.7.12 or higher. All 3.x Aurora MySQL engine versions are wire-compatible with MySQL 8.0.23 or higher. You can refer to release notes of the specific 3.x version to find the corresponding MySQL compatible version.

For example, the engine versions for Aurora MySQL 3.04.0 and 2.11.2 are the following.

```
8.0.mysql_aurora.3.04.0  
5.7.mysql_aurora.2.11.2
```

### Note

There isn't a one-to-one correspondence between community MySQL versions and the Aurora MySQL 2.x versions. For Aurora MySQL version 3, there is a more direct mapping.

To check which bug fixes and new features are in a particular Aurora MySQL release, see [Database engine updates for Amazon Aurora MySQL version 3](#) and [Database engine updates for Amazon Aurora MySQL version 2](#) in the *Release Notes for Aurora MySQL*. For a chronological list of new features and releases, see [Document history](#). To check the minimum version required for a security-related fix, see [Security vulnerabilities fixed in Aurora MySQL](#) in the *Release Notes for Aurora MySQL*.

You specify the Aurora MySQL engine version in some Amazon CLI commands and RDS API operations. For example, you specify the `--engine-version` option when you run the Amazon CLI commands [create-db-cluster](#) and [modify-db-cluster](#). You specify the `EngineVersion` parameter when you run the RDS API operations [CreateDBCluster](#) and [ModifyDBCluster](#).

In Aurora MySQL version 2 and higher, the engine version in the Amazon Web Services Management Console also includes the Aurora version. Upgrading the cluster changes the displayed value. This change helps you to specify and check the precise Aurora MySQL versions, without the need to connect to the cluster or run any SQL commands.

### Tip

For Aurora clusters managed through Amazon CloudFormation, this change in the `EngineVersion` setting can trigger actions by Amazon CloudFormation. For information about how Amazon CloudFormation treats changes to the `EngineVersion` setting, see [the Amazon CloudFormation documentation](#).

## Checking Aurora MySQL versions using SQL

The Aurora version numbers that you can retrieve in your application using SQL queries use the format `<major version>.<minor version>.<patch version>`. You can get this version number for any DB instance in your Aurora MySQL cluster by querying the `AURORA_VERSION` system variable. To get this version number, use one of the following queries.

```
select aurora_version();
select @@aurora_version;
```

Those queries produce output similar to the following.

```
mysql> select aurora_version(), @@aurora_version;
+-----+-----+
| aurora_version() | @@aurora_version |
+-----+-----+
| 3.05.2           | 3.05.2           |
+-----+-----+
```

The version numbers that the console, CLI, and RDS API return by using the techniques described in [Checking or specifying Aurora MySQL engine versions through Amazon](#) are typically more descriptive.

## Long-term support (LTS) and beta releases for Amazon Aurora MySQL

Aurora MySQL provides long-term support (LTS) and beta releases for some Aurora MySQL engine versions.

### Topics

- [Aurora MySQL long-term support \(LTS\) releases](#)
- [Aurora MySQL beta releases](#)

### Aurora MySQL long-term support (LTS) releases

Each new Aurora MySQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora MySQL version is no longer supported.

Aurora designates certain Aurora MySQL versions as long-term support (LTS) releases. DB clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. Database clusters that use LTS releases can stay on the same minor version for at least three years, or until end of standard support for the major version, whichever comes first. When a DB cluster that's on an LTS release is required to upgrade, Aurora upgrades it to the next LTS release. That way, the cluster doesn't need to be upgraded again for a long time.

During the lifetime of an Aurora MySQL LTS release, new patch levels introduce fixes to important issues. The patch levels don't include any new features. You can choose whether to apply such patches to DB clusters running the LTS release. We recommend customers running LTS releases to

upgrade to the latest patch release of the LTS minor version at least once a year to take advantage of high severity security and operational fixes. For certain critical fixes, Amazon might perform a managed upgrade to a patch level within the same LTS release. Such managed upgrades are performed automatically within the cluster maintenance window. All Aurora MySQL releases (both LTS and non-LTS releases) undergo extensive stability and operational testing. Select minor versions are designated as LTS releases to enable customers to stay on those minor versions longer without upgrading to a newer minor version.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora MySQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. The LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora MySQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora MySQL database engine.
- The database version for your Aurora MySQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora MySQL are as follows:

- Aurora MySQL version 3.10.\*.
- Aurora MySQL version 3.04.\*.

For more details about the LTS version, see [Database engine updates for Amazon Aurora MySQL version 3](#) in the *Release Notes for Aurora MySQL*.

#### Note

We recommend that you disable automatic minor version upgrades for LTS versions. Set the `AutoMinorVersionUpgrade` parameter to `false`, or clear the **Enable auto minor version upgrade** check box on the Amazon Web Services Management Console. If you don't disable it, your DB cluster could be upgraded to a non-LTS version.

## Aurora MySQL beta releases

An Aurora MySQL beta release is an early, security fix–only release in a limited number of Amazon Web Services Regions. These fixes are later deployed more broadly across all Regions with the next patch release.

The numbering for a beta release is similar to an Aurora MySQL minor version, but with an extra fourth digit, for example 2.12.0.1 or 3.05.0.1.

For more information, see [Database engine updates for Amazon Aurora MySQL version 2](#) and [Database engine updates for Amazon Aurora MySQL version 3](#) in the *Release Notes for Aurora MySQL*.

## Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support

Amazon Aurora MySQL-Compatible Edition version 2 (with MySQL 5.7 compatibility) is planned to reach the end of standard support on October 31, 2024. We recommend that you upgrade all clusters running Aurora MySQL version 2 to the default Aurora MySQL version 3 (with MySQL 8.0 compatibility) or higher before Aurora MySQL version 2 reaches the end of its standard support period. On October 31, 2024, Amazon RDS will automatically enroll your databases into [Amazon RDS Extended Support](#). If you're running Amazon Aurora MySQL version 2 (with MySQL 5.7 compatibility) in an Aurora Serverless version 1 cluster, this doesn't apply to you. If you want to upgrade your Aurora Serverless version 1 clusters to Aurora MySQL version 3, see [Upgrade path for Aurora Serverless v1 DB clusters](#).

You can find upcoming end-of-support dates for Aurora MySQL major versions in [Release calendar for Aurora MySQL major versions](#).

If you have clusters running Aurora MySQL version 2, you will receive periodic notices with the latest information about how to conduct an upgrade as we get closer to the end of standard support date. We will update this page periodically with the latest information.

### End of standard support timeline

1. Now through October 31, 2024 – You can upgrade clusters from Aurora MySQL version 2 (with MySQL 5.7 compatibility) to Aurora MySQL version 3 (with MySQL 8.0 compatibility).
2. October 31, 2024 – On this date, Aurora MySQL version 2 will reach the end of standard support and Amazon RDS automatically enrolls your clusters into Amazon RDS Extended Support.

We will automatically enroll you in RDS Extended Support. For more information, see [Amazon RDS Extended Support with Amazon Aurora](#).

## Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

### Important

Be sure to perform these instructions in every Amazon Web Services Region and for each Amazon Web Services account where your resources are located.

## Console

### To find an Aurora MySQL version 2 cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the **Filter by databases** box, enter **5.7**.
4. Check for Aurora MySQL in the engine column.

## Amazon CLI

To find clusters affected by this end-of-life process using the Amazon CLI, call the [describe-db-clusters](#) command. You can use the sample script following.

### Example

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?(Engine==`aurora-mysql` && contains(EngineVersion, `5.7.mysql_aurora`))].{EngineVersion:EngineVersion, DBClusterIdentifier:DBClusterIdentifier, EngineMode:EngineMode}' --output table
--region us-east-1
```

```
+-----+-----+-----+-----+
|                               DescribeDBClusters                               |
+-----+-----+-----+-----+
|          DBCI          |          EM          |          EV          |
+-----+-----+-----+-----+
```

aurora-mysql2	provisioned	5.7.mysql_aurora.2.11.3
aurora-serverlessv1	serverless	5.7.mysql_aurora.2.11.3

## RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 2, use the RDS [DescribeDBClusters](#) API operation with the following required parameters:

- DescribeDBClusters
  - Filters.Filter.N
    - Name
      - engine
  - Values.Value.N
    - ['aurora']

## Amazon RDS Extended Support

You can use Amazon RDS Extended Support over community MySQL 5.7 at no charge until the end of support date, October 31, 2024. On October 31, 2024, Amazon RDS automatically enrolls your databases into RDS Extended Support for Aurora MySQL version 2. RDS Extended Support for Aurora is a paid service that provides up to 28 additional months of support for Aurora MySQL version 2 until the end of RDS Extended Support in February 2027. RDS Extended Support will only be offered for Aurora MySQL minor versions 2.11 and 2.12. To use Amazon Aurora MySQL version 2 past the end of standard support, plan to run your databases on one of these minor versions before October 31, 2024.

For more information about RDS Extended Support, such as charges and other considerations, see [Amazon RDS Extended Support with Amazon Aurora](#).

## Performing an upgrade

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. We want to look at the upgrade as a three-step process, with activities before the upgrade, for the upgrade, and after the upgrade.

### Before the upgrade:

Before the upgrade, we recommend that you check for application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster, thereby confirming that post-upgrade your applications will work as expected. Here are five recommendations that will help provide you a better upgrade experience.

- First, it's critical to understand [How the Aurora MySQL in-place major version upgrade works](#).
- Next, explore the upgrade techniques that are available when [Upgrading from Aurora MySQL version 2 to version 3](#).
- To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current environment with [Comparing Aurora MySQL version 2 and Aurora MySQL version 3](#).
- After you've decided on the option that's convenient and works best, try a mock in-place upgrade on a cloned cluster, using [Planning a major version upgrade for an Aurora MySQL cluster](#).
- Review the [Major version upgrade prechecks for Aurora MySQL](#). The upgrade prechecker can run and determine whether your database can be upgraded successfully, and if there are any application incompatibility issues post-upgrade as well as performance, maintenance procedures, and similar considerations.
- Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. For more information, see [Aurora MySQL major version upgrade paths](#).

If you have any questions or concerns, the Amazon Support Team is available on the [community forums](#) and [Premium Support](#).

### Doing the upgrade:

You can use one of the following upgrade techniques. The amount of downtime your system will experience depends on the technique chosen.

- **Blue/Green Deployments** – For situations where the top priority is to reduce application downtime, you can use [Amazon RDS Blue/Green Deployments](#) for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make certain changes to the Aurora DB cluster in the green (staging) environment without affecting production workloads. The switchover typically takes under a minute with no data loss. For more information, see [Overview of Amazon Aurora Blue/Green Deployments](#). This minimizes downtime, but requires you to run additional resources while performing the upgrade.

- **In-place upgrades** – You can perform an [in-place upgrade](#) where Aurora automatically performs a precheck process for you, takes the cluster offline, backs up your cluster, performs the upgrade, and puts your cluster back online. An in-place major version upgrade can be performed in a few clicks, and doesn't involve other coordination or failovers with other clusters, but does involve downtime. For more information, see [How to perform an in-place upgrade](#)
- **Snapshot restore** – You can upgrade your Aurora MySQL version 2 cluster by restoring from an Aurora MySQL version 2 snapshot into an Aurora MySQL version 3 cluster. To do this, you should follow the process for taking a snapshot and [restoring](#) from it. This process involves database interruption because you're restoring from a snapshot.

### After the upgrade:

After the upgrade, you need to closely monitor your system (application and database) and make fine-tuning changes if necessary. Following the pre-upgrade steps closely will minimize the required changes needed. For more information, see [Troubleshooting Amazon Aurora MySQL database performance](#).

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read [Upgrading the major version of an Amazon Aurora MySQL DB cluster](#), including [Troubleshooting for Aurora MySQL in-place upgrade](#). Also, note that some instance types aren't supported for Aurora MySQL version 3. For more information, see [Amazon Aurora DB instance classes](#).

## Upgrade path for Aurora Serverless v1 DB clusters

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. We want to look at the upgrade as a three-step process, with activities before the upgrade, for the upgrade, and after the upgrade.

Aurora MySQL version 2 (with MySQL 5.7 compatibility) will continue to receive standard support for Aurora Serverless v1 clusters.

If you want to upgrade to Amazon Aurora MySQL 3 (with MySQL 8.0 compatibility) and continue running Aurora Serverless, you can use Amazon Aurora Serverless v2. To understand the differences between Aurora Serverless v1 and Aurora Serverless v2, see [Comparison of Aurora Serverless v2 and Aurora Serverless v1](#).

**Upgrade to Aurora Serverless v2:** You can upgrade an Aurora Serverless v1 cluster to Aurora Serverless v2. For more information, see [Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2](#).

## Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life

Amazon Aurora MySQL-Compatible Edition version 1 (with MySQL 5.6 compatibility) is planned to reach end of life on February 28, 2023. Amazon advises that you upgrade all clusters (provisioned and Aurora Serverless) running Aurora MySQL version 1 to Aurora MySQL version 2 (with MySQL 5.7 compatibility) or Aurora MySQL version 3 (with MySQL 8.0 compatibility). Do this before Aurora MySQL version 1 reaches the end of its support period.

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 2 by several methods. You can find instructions for the in-place upgrade mechanism in [How to perform an in-place upgrade](#). Another way to complete the upgrade is to take a snapshot of an Aurora MySQL version 1 cluster and restore the snapshot to an Aurora MySQL version 2 cluster. Or you can follow a multistep process that runs the old and new clusters side by side. For more details about each method, see [Upgrading the major version of an Amazon Aurora MySQL DB cluster](#).

For Aurora Serverless v1 DB clusters, you can perform an in-place upgrade from Aurora MySQL version 1 to Aurora MySQL version 2. For more details about this method, see [Modifying an Aurora Serverless v1 DB cluster](#).

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 3 by using a two-stage upgrade process:

1. Upgrade from Aurora MySQL version 1 to Aurora MySQL version 2 using the methods described preceding.
2. Upgrade from Aurora MySQL version 2 to Aurora MySQL version 3 using the same methods as for upgrading from version 1 to version 2. For more details, see [Upgrading from Aurora MySQL version 2 to version 3](#). Note the [Feature differences between Aurora MySQL version 2 and 3](#).

You can find upcoming end-of-life dates for Aurora major versions in [Amazon Aurora versions](#). Amazon automatically upgrades any clusters that you don't upgrade yourself before the end-of-life date. After the end-of-life date, these automatic upgrades to the subsequent major version occur during a scheduled maintenance window for clusters.

The following are additional milestones for upgrading Aurora MySQL version 1 clusters (provisioned and Aurora Serverless) that are reaching end of life. For each, the start time is 00:00 Universal Coordinated Time (UTC).

1. Now through February 28, 2023 – You can at any time start upgrades of Aurora MySQL version 1 (with MySQL 5.6 compatibility) clusters to Aurora MySQL version 2 (with MySQL 5.7 compatibility). From Aurora MySQL version 2, you can do a further upgrade to Aurora MySQL version 3 (with MySQL 8.0 compatibility) for Aurora provisioned DB clusters.
2. January 16, 2023 – After this time, you can't create new Aurora MySQL version 1 clusters or instances from either the Amazon Web Services Management Console or the Amazon Command Line Interface (Amazon CLI). You also can't add new secondary Regions to an Aurora global database. This might affect your ability to recover from an unplanned outage as outlined in [Recovering an Amazon Aurora global database from an unplanned outage](#), because you can't complete steps 5 and 6 after this time. You will also be unable to create a new cross-Region read replica running Aurora MySQL version 1. You can still do the following for existing Aurora MySQL version 1 clusters until February 28, 2023:
  - Restore a snapshot taken of an Aurora MySQL version 1 cluster to the same version as the original snapshot cluster.
  - Add read replicas (not applicable for Aurora Serverless DB clusters).
  - Change instance configuration.
  - Perform point-in-time restore.
  - Create clones of existing version 1 clusters.
  - Create a new cross-Region read replica running Aurora MySQL version 2 or higher.
3. February 28, 2023 – After this time, we plan to automatically upgrade Aurora MySQL version 1 clusters to the default version of Aurora MySQL version 2 within a scheduled maintenance window that follows. Restoring Aurora MySQL version 1 DB snapshots results in an automatic upgrade of the restored cluster to the default version of Aurora MySQL version 2 at that time.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time.

For situations where the top priority is to reduce downtime, you can also use [blue/green deployments](#) for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make changes to the Aurora DB cluster in the green (staging) environment without

affecting production workloads. The switchover typically takes under a minute with no data loss and no need for application changes. For more information, see [Overview of Amazon Aurora Blue/Green Deployments](#).

After the upgrade is finished, you also might have follow-up work to do. For example, you might need to follow up due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read [Upgrading the major version of an Amazon Aurora MySQL DB cluster](#).

## Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

### Important

Be sure to perform these instructions in every Amazon Web Services Region and for each Amazon Web Services account where your resources are located.

## Console

### To find an Aurora MySQL version 1 cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the **Filter by databases** box, enter **5.6**.
4. Check for Aurora MySQL in the engine column.

## Amazon CLI

To find clusters affected by this end-of-life process using the Amazon CLI, call the [describe-db-clusters](#) command. You can use the sample script following.

## Example

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?Engine==`aurora`].
{EV:EngineVersion, DBCI:DBClusterIdentifier, EM:EngineMode}' --output table --region
us-east-1
```

```
+-----+
|           DescribeDBClusters           |
+-----+-----+-----+-----+
|   DBCI   |   EM   |   EV   |
+-----+-----+-----+-----+
| my-database-1 | serverless | 5.6.10a |
+-----+-----+-----+-----+
```

## RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 1, use the RDS [DescribeDBClusters](#) API operation with the following required parameters:

- DescribeDBClusters
  - Filters.Filter.N
    - Name
      - engine
  - Values.Value.N
    - ['aurora']

## Upgrading Amazon Aurora MySQL DB clusters

You can upgrade an Aurora MySQL DB cluster to get bug fixes, new Aurora MySQL features, or to change to an entirely new version of the underlying database engine. The following sections show how.

### Note

The type of upgrade that you do depends on how much downtime you can afford for your cluster, how much verification testing you plan to do, how important the specific bug fixes or new features are for your use case, and whether you plan to do frequent small upgrades or occasional upgrades that skip several intermediate versions. For each upgrade, you can

change the major version, the minor version, and the patch level for your cluster. If you aren't familiar with the distinction between Aurora MySQL major versions, minor versions, and patch levels, you can read the background information at [Checking Aurora MySQL version numbers](#).

**Tip**

You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see [Using Amazon Aurora Blue/Green Deployments for database updates](#).

## Topics

- [Upgrading the minor version or patch level of an Aurora MySQL DB cluster](#)
- [Upgrading the major version of an Amazon Aurora MySQL DB cluster](#)

## Upgrading the minor version or patch level of an Aurora MySQL DB cluster

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:

- [Upgrading Aurora MySQL by modifying the engine version](#) (for Aurora MySQL version 2 and 3)
- [Enabling automatic upgrades between minor Aurora MySQL versions](#)

For information about how zero-downtime patching can reduce interruptions during the upgrade process, see [Using zero-downtime patching](#).

For information about performing a minor version upgrade for your Aurora MySQL DB cluster, see the following topics.

## Topics

- [Before performing a minor version upgrade](#)
- [Minor version upgrade prechecks for Aurora MySQL](#)
- [Upgrading Aurora MySQL by modifying the engine version](#)
- [Enabling automatic upgrades between minor Aurora MySQL versions](#)

- [Using zero-downtime patching](#)
- [Alternative blue/green upgrade technique](#)

## Before performing a minor version upgrade

We recommend that you perform the following actions to reduce the downtime during a minor version upgrade:

- The Aurora DB cluster maintenance should be performed during a period of low traffic. Use Performance Insights to identify these time periods in order to configure the maintenance windows correctly. For more information on Performance Insights, see [Monitoring DB load with Performance Insights on Amazon RDS](#). For more information on DB cluster maintenance window, [Adjusting the preferred DB cluster maintenance window](#).
- Use Amazon SDKs that support exponential backoff and jitter as a best practice. For more information, see [Exponential Backoff And Jitter](#).

## Minor version upgrade prechecks for Aurora MySQL

When you start a minor version upgrade, Amazon Aurora runs prechecks automatically.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon Aurora prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade by reducing the incompatibilities. For detailed information about removing incompatibilities, see [Preparing your installation for upgrade](#) in the MySQL documentation.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Aurora automatically cancels the upgrade before the DB instance is stopped. Aurora also generates an event for the incompatibility. For more information about Amazon Aurora events, see [Working with Amazon RDS event notification](#).

Aurora records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL

documentation for correcting the incompatibility. For more information about viewing log files, see [Viewing and listing database log files](#).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

## Upgrading Aurora MySQL by modifying the engine version

Upgrading the minor version of an Aurora MySQL DB cluster applies additional fixes and new features to an existing cluster.

This kind of upgrade applies to Aurora MySQL clusters where the original version and the upgraded version both have the same Aurora MySQL major version, either 2 or 3. The process is fast and straightforward because it doesn't involve any conversion for the Aurora MySQL metadata or reorganization of your table data.

You perform this kind of upgrade by modifying the engine version of the DB cluster using the Amazon Web Services Management Console, Amazon CLI, or the RDS API. For example, if your cluster is running Aurora MySQL 3.x, choose a higher 3.x version.

If you're performing a minor upgrade on an Aurora Global Database, upgrade all of the secondary clusters before you upgrade the primary cluster.

### Note

To perform a minor version upgrade to Aurora MySQL version 3.04.\* or higher, or version 2.12.\*, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in [Removing a cluster from an Amazon Aurora global database](#).
2. Upgrade the engine version of the primary Region to version 3.04.\* or higher, or version 2.12.\*, as applicable. Follow the steps in [To modify the engine version of a DB cluster](#).
3. Add secondary Regions to the global cluster. Follow the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

## To modify the engine version of a DB cluster

- **By using the console** – Modify the properties of your cluster. In the **Modify DB cluster** window, change the Aurora MySQL engine version in the **DB engine version** box. If you aren't familiar

with the general procedure for modifying a cluster, follow the instructions at [Modifying the DB cluster by using the console, CLI, and API](#).

- **By using the Amazon CLI** – Call the [modify-db-cluster](#) Amazon CLI command, and specify the name of your DB cluster for the `--db-cluster-identifier` option and the engine version for the `--engine-version` option.

For example, to upgrade to Aurora MySQL version 3.04.1, set the `--engine-version` option to `8.0.mysql_aurora.3.04.1`. Specify the `--apply-immediately` option to immediately update the engine version for your DB cluster.

- **By using the RDS API** – Call the [ModifyDBCluster](#) API operation, and specify the name of your DB cluster for the `DBClusterIdentifier` parameter and the engine version for the `EngineVersion` parameter. Set the `ApplyImmediately` parameter to `true` to immediately update the engine version for your DB cluster.

## Enabling automatic upgrades between minor Aurora MySQL versions

For an Amazon Aurora MySQL DB cluster, you can specify that Aurora upgrades the DB cluster automatically to new minor versions. You do so by setting the `AutoMinorVersionUpgrade` property (**Auto minor version upgrade** in the Amazon Web Services Management Console) of the DB cluster.

Automatic upgrades occur during the maintenance window. If the individual DB instances in the DB cluster have different maintenance windows from the cluster maintenance window, then the cluster maintenance window takes precedence.

Automatic minor version upgrade doesn't apply to the following kinds of Aurora MySQL clusters:

- Clusters that are part of an Aurora global database
- Clusters that have cross-Region replicas

The outage duration varies depending on workload, cluster size, the amount of binary log data, and if Aurora can use the zero-downtime patching (ZDP) feature. Aurora restarts the database cluster, so you might experience a short period of unavailability before resuming use of your cluster. In particular, the amount of binary log data affects recovery time. The DB instance processes the binary log data during recovery. Thus, a high volume of binary log data increases recovery time.

**Note**

Aurora only performs automatic upgrades if all DB instances in your DB cluster have the `AutoMinorVersionUpgrade` setting enabled. For information on how to set it, and how it works when applied at the cluster and instance levels, see [Automatic minor version upgrades for Aurora DB clusters](#).

Then if an upgrade path exists for the DB cluster's instances to a minor DB engine version that has `AutoUpgrade` set to true, the upgrade will take place. The `AutoUpgrade` setting is dynamic, and is set by RDS.

Auto minor version upgrades are performed to the default minor version.

You can use a CLI command such as the following to check the status of the `AutoMinorVersionUpgrade` setting for all of the DB instances in your Aurora MySQL clusters.

```
aws rds describe-db-instances \  
  --query '*[  
{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVer
```

That command produces output similar to the following:

```
[  
  {  
    "DBInstanceIdentifier": "db-t2-medium-instance",  
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",  
    "AutoMinorVersionUpgrade": true  
  },  
  {  
    "DBInstanceIdentifier": "db-t2-small-original-size",  
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",  
    "AutoMinorVersionUpgrade": false  
  },  
  {  
    "DBInstanceIdentifier": "instance-2020-05-01-2332",  
    "DBClusterIdentifier": "cluster-57-2020-05-01-4615",  
    "AutoMinorVersionUpgrade": true  
  },  
  ... output omitted ...  
]
```

In this example, **Enable auto minor version upgrade** is turned off for the DB cluster `cluster-57-2020-06-03-6411`, because it's turned off for one of the DB instances in the cluster.

## Using zero-downtime patching

Performing upgrades for Aurora MySQL DB clusters involves the possibility of an outage when the database is shut down and while it's being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora MySQL upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

ZDP doesn't apply to the following:

- Operating system (OS) patches and upgrades
- Major version upgrades

ZDP is available for all supported Aurora MySQL versions and DB instance classes.

ZDP isn't supported for Aurora Serverless v1 or Aurora global databases.

### Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [Using T instance classes for development and testing](#).

You can see metrics of important attributes during ZDP in the MySQL error log. You can also see information about when Aurora MySQL uses ZDP or chooses not to use ZDP on the **Events** page in the Amazon Web Services Management Console.

In Aurora MySQL, Aurora can perform a zero-downtime patch whether or not binary log replication is enabled. If binary log replication is enabled, Aurora MySQL automatically drops the connection

to the binlog target during a ZDP operation. Aurora MySQL automatically reconnects to the binlog target and resumes replication after the restart finishes.

ZDP also works in combination with the reboot enhancements in Aurora MySQL. Patching the writer DB instance automatically patches readers at the same time. After performing the patch, Aurora restores the connections on both the writer and reader DB instances.

ZDP might not complete successfully under the following conditions:

- Long-running queries or transactions are in progress. If Aurora can perform ZDP in this case, any open transactions are canceled but their connections are retained.
- Temporary tables, user locks, or table locks are in use, for example while data definition language (DDL) statements run. Aurora drops these connections.
- Pending parameter changes exist.

If no suitable time window for performing ZDP becomes available because of one or more of these conditions, patching reverts to the standard behavior.

Although connections remain intact following a successful ZDP operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime patching:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset after a restart that uses the ZDR or ZDP mechanisms.
- LAST\_INSERT\_ID.
- In-memory auto\_increment state for tables. The in-memory auto-increment state is reinitialized. For more information about auto-increment values, see [MySQL Reference Manual](#).
- Diagnostic information from INFORMATION\_SCHEMA and PERFORMANCE\_SCHEMA tables. This diagnostic information also appears in the output of commands such as SHOW PROFILE and SHOW PROFILES.

The following activities related to zero-downtime restart are reported on the **Events** page:

- Attempting to upgrade the database with zero downtime.

- Attempting to upgrade the database with zero downtime finished. The event reports how long the process took. The event also reports how many connections were preserved during the restart and how many connections were dropped. You can consult the database error log to see more details about what happened during the restart.

## Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see [Using Amazon Aurora Blue/Green Deployments for database updates](#).

## Upgrading the major version of an Amazon Aurora MySQL DB cluster

In an Aurora MySQL version number such as 3.04.1, the 3 represents the major version. Aurora MySQL version 2 is compatible with MySQL 5.7. Aurora MySQL version 3 is compatible with MySQL 8.0.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have followup work to do. For example, this might occur because of differences in SQL compatibility or the way certain MySQL-related features work. Or it might occur because of differing parameter settings between the old and new versions.

## Upgrading from Aurora MySQL version 2 to version 3

If you have a MySQL 5.7-compatible cluster and want to upgrade it to a MySQL-8.0 compatible cluster, you can do so by running an upgrade process on the cluster itself. This kind of upgrade is an *in-place upgrade*, in contrast to upgrades that you do by creating a new cluster. This technique keeps the same endpoint and other characteristics of the cluster. The upgrade is relatively fast because it doesn't require copying all your data to a new cluster volume. This stability helps to minimize any configuration changes in your applications. It also helps to reduce the amount of

testing for the upgraded cluster. This is because the number of DB instances and their instance classes all stay the same.

The in-place upgrade mechanism involves shutting down your DB cluster while the operation takes place. Aurora performs a clean shutdown and completes outstanding operations such as transaction rollback and undo purge. For more information, see [How the Aurora MySQL in-place major version upgrade works](#).

The in-place upgrade method is convenient, because it is simple to perform and minimizes configuration changes to associated applications. For example, an in-place upgrade preserves the endpoints and set of DB instances for your cluster. However, the time needed for an in-place upgrade can vary depending on the properties of your schema and how busy the cluster is. Thus, depending on the needs for your cluster, you can choose among the upgrade techniques:

- [In-place upgrade](#)
- [Blue/Green Deployment](#)
- [Snapshot restore](#)

 **Note**

If you use the Amazon CLI or RDS API for the snapshot restore upgrade method, you must run a subsequent operation to create a writer DB instance in the restored DB cluster.

For general information about Aurora MySQL version 3 and its new features, see [Aurora MySQL version 3 compatible with MySQL 8.0](#).

For details about planning an upgrade, see [Planning a major version upgrade for an Aurora MySQL cluster](#) and [How to perform an in-place upgrade](#).

### Aurora MySQL major version upgrade paths

Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. You can learn the appropriate upgrade path for each Aurora MySQL cluster by consulting the following table.

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
Aurora MySQL provisioned cluster, version 2	Yes	<p>In-place upgrade is supported for MySQL 5.7-compatible Aurora MySQL clusters.</p> <p>For information about upgrading to Aurora MySQL version 3, see <a href="#">Planning a major version upgrade for an Aurora MySQL cluster</a> and <a href="#">How to perform an in-place upgrade</a>.</p>
Aurora MySQL provisioned cluster, version 3	Not applicable	Use a minor version upgrade procedure to upgrade between Aurora MySQL version 3 versions.
Aurora Serverless v1 cluster	Not applicable	Aurora Serverless v1 is supported for Aurora MySQL only on version 2.
Aurora Serverless v2 cluster	Not applicable	Aurora Serverless v2 is supported for Aurora MySQL only on version 3.
Cluster in an Aurora global database	Yes	<p>To upgrade Aurora MySQL from version 2 to version 3, follow the <a href="#">procedure for doing an in-place upgrade</a> for clusters in an Aurora global database. Perform the upgrade on the global cluster. Aurora upgrades the primary cluster and all the secondary clusters in the global database at the same time.</p> <p>If you use the Amazon CLI or RDS API, call the <code>modify-global-cluster</code> command or <code>ModifyGlobalCluster</code> operation instead of <code>modify-db-cluster</code> or <code>ModifyDBCluster</code> .</p>

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
		<p>You can perform an in-place upgrade from Aurora MySQL version 2 to version 3 only if the <code>lower_case_table_names</code> parameter is set to default and you reboot your global database. For more information, see <a href="#">Major version upgrades</a>.</p>
Parallel query cluster	Yes	You can perform an in-place upgrade.
Cluster that is the target of binary log replication	Maybe	<p>If the binary log replication is from an Aurora MySQL cluster, you can perform an in-place upgrade. You can't perform the upgrade if the binary log replication is from an RDS for MySQL or an on-premises MySQL DB instance. In that case, you can upgrade using the snapshot restore mechanism.</p>
Cluster with zero DB instances	No	<p>Using the Amazon CLI or the RDS API, you can create an Aurora MySQL cluster without any attached DB instances. In the same way, you can also remove all DB instances from an Aurora MySQL cluster while leaving the data in the cluster volume intact. While a cluster has zero DB instances, you can't perform an in-place upgrade.</p> <p>The upgrade mechanism requires a writer instance in the cluster to perform conversions on the system tables, data files, and so on. In this case, use the Amazon CLI or the RDS API to create a writer instance for the cluster. Then you can perform an in-place upgrade.</p>

Type of Aurora MySQL DB cluster	Can it use in-place upgrade?	Action
Cluster with backtrack enabled	Yes	You can perform an in-place upgrade for an Aurora MySQL cluster that uses the Backtrack feature. However, after the upgrade, you can't backtrack the cluster to a time before the upgrade.

## How the Aurora MySQL in-place major version upgrade works

Aurora MySQL performs a major version upgrade as a multistage process. You can check the current status of an upgrade. Some of the upgrade steps also provide progress information. As each stage begins, Aurora MySQL records an event. You can examine events as they occur on the **Events** page in the RDS console. For more information about working with events, see [Working with Amazon RDS event notification](#).

### Important

Once the process begins, it runs until the upgrade either succeeds or fails. You can't cancel the upgrade while it's underway. If the upgrade fails, Aurora rolls back all the changes and your cluster has the same engine version, metadata, and so on as before.

The upgrade process consists of these stages:

1. Aurora performs a series of [prechecks](#) before beginning the upgrade process. Your cluster keeps running while Aurora does these checks. For example, the cluster can't have any XA transactions in the prepared state or be processing any data definition language (DDL) statements. For example, you might need to shut down applications that are submitting certain kinds of SQL statements. Or you might simply wait until certain long-running statements are finished. Then try the upgrade again. Some checks test for conditions that don't prevent the upgrade but might make the upgrade take a long time.

If Aurora detects that any required conditions aren't met, modify the conditions identified in the event details. Follow the guidance in [Troubleshooting for Aurora MySQL in-place upgrade](#). If

- Aurora detects conditions that might cause a slow upgrade, plan to monitor the upgrade over an extended period.
2. Aurora takes your cluster offline. Then Aurora performs a similar set of tests as in the previous stage, to confirm that no new issues arose during the shutdown process. If Aurora detects any conditions at this point that would prevent the upgrade, Aurora cancels the upgrade and brings the cluster back online. In this case, confirm when the conditions no longer apply and start the upgrade again.
  3. Aurora creates a snapshot of your cluster volume. Suppose that you discover compatibility or other kinds of issues after the upgrade is finished. Or suppose that you want to perform testing using both the original and upgraded clusters. In such cases, you can restore from this snapshot to create a new cluster with the original engine version and the original data.

 **Tip**

This snapshot is a manual snapshot. However, Aurora can create it and continue with the upgrade process even if you have reached your quota for manual snapshots. This snapshot remains permanently (if needed) until you delete it. After you finish all post-upgrade testing, you can delete this snapshot to minimize storage charges.

4. Aurora clones your cluster volume. Cloning is a fast operation that doesn't involve copying the actual table data. If Aurora encounters an issue during the upgrade, it reverts to the original data from the cloned cluster volume and brings the cluster back online. The temporary cloned volume during the upgrade isn't subject to the usual limit on the number of clones for a single cluster volume.
5. Aurora performs a clean shutdown for the writer DB instance. During the clean shutdown, progress events are recorded every 15 minutes for the following operations. You can examine events as they occur on the **Events** page in the RDS console.
  - Aurora purges the undo records for old versions of rows.
  - Aurora rolls back any uncommitted transactions.
6. Aurora upgrades the engine version on the writer DB instance:
  - Aurora installs the binary for the new engine version on the writer DB instance.
  - Aurora uses the writer DB instance to upgrade your data to MySQL 5.7-compatible format. During this stage, Aurora modifies the system tables and performs other conversions that affect the data in your cluster volume. In particular, Aurora upgrades the partition metadata in

the system tables to be compatible with the MySQL 5.7 partition format. This stage can take a long time if the tables in your cluster have a large number of partitions.

If any errors occur during this stage, you can find the details in the MySQL error logs. After this stage starts, if the upgrade process fails for any reason, Aurora restores the original data from the cloned cluster volume.

7. Aurora upgrades the engine version on the reader DB instances.
8. The upgrade process is completed. Aurora records a final event to indicate that the upgrade process completed successfully. Now your DB cluster is running the new major version.

## Planning a major version upgrade for an Aurora MySQL cluster

To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current environment:

- If you're converting from RDS for MySQL 8.0 or MySQL 8.0 Community Edition, see [Comparing Aurora MySQL version 3 and MySQL 8.0 Community Edition](#).
- If you're upgrading from Aurora MySQL version 2, RDS for MySQL 5.7, or community MySQL 5.7, see [Comparing Aurora MySQL version 2 and Aurora MySQL version 3](#).
- Create new MySQL 8.0-compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups. Consult [Parameter changes for Aurora MySQL version 3](#) to learn about parameter changes.
- Review your Aurora MySQL version 2 database schema and object definitions for the usage of new reserved keywords introduced in MySQL 8.0 Community Edition. Do so before you upgrade. For more information, see [MySQL 8.0 New Keywords and Reserved Words](#) in the MySQL documentation.

You can also find more MySQL-specific upgrade considerations and tips in [Changes in MySQL 8.0](#) in the *MySQL Reference Manual*. For example, you can use the command `mysqlcheck --check-upgrade` to analyze your existing Aurora MySQL databases and identify potential upgrade issues.

### Note

We recommend using larger DB instance classes when upgrading to Aurora MySQL version 3 using the in-place upgrade or snapshot restore technique. Examples are `db.r5.24xlarge` and `db.r6g.16xlarge`. This helps the upgrade process to complete faster by using the

majority of available CPU capacity on the DB instance. You can change to the DB instance class that you want after the major version upgrade is complete.

After you finish the upgrade itself, you can follow the post-upgrade procedures in [Post-upgrade cleanup for Aurora MySQL version 3](#). Finally, test your application's functionality and performance.

If you're converting from RDS from MySQL or community MySQL, follow the migration procedure explained in [Migrating data to an Amazon Aurora MySQL DB cluster](#). In some cases, you might use binary log replication to synchronize your data with an Aurora MySQL version 3 cluster as part of the migration. If so, the source system must run a version that's compatible with your target DB cluster.

To make sure that your applications and administration procedures work smoothly after upgrading a cluster between major versions, do some advance planning and preparation. To see what sorts of management code to update for your Amazon CLI scripts or RDS API-based applications, see [How in-place upgrades affect the parameter groups for a cluster](#). Also see [Changes to cluster properties between Aurora MySQL versions](#).

To learn what issues that you might encounter during the upgrade, see [Troubleshooting for Aurora MySQL in-place upgrade](#). For issues that might cause the upgrade to take a long time, you can test those conditions in advance and correct them.

#### Note

An in-place upgrade involves shutting down your DB cluster while the operation takes place. Aurora MySQL performs a clean shutdown and completes outstanding operations such as undo purge. An upgrade might take a long time if there many undo records to purge. We recommend performing the upgrade only after the history list length (HLL) is low. A generally acceptable value for the HLL is 100,000 or less. For more information, see this [blog post](#).

## Simulating the upgrade by cloning your DB cluster

You can check application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster. To do so, you can perform a simulation of the upgrade before doing the real upgrade. This technique can be especially useful for production clusters.

Here, it's important to minimize downtime and have the upgraded cluster ready to go as soon as the upgrade has finished.

Use the following steps:

1. Create a clone of the original cluster. Follow the procedure in [Cloning a volume for an Amazon Aurora DB cluster](#).
2. Set up a similar set of writer and reader DB instances as in the original cluster.
3. Perform an in-place upgrade of the cloned cluster. Follow the procedure in [How to perform an in-place upgrade](#).

Start the upgrade immediately after creating the clone. That way, the cluster volume is still identical to the state of the original cluster. If the clone sits idle before you do the upgrade, Aurora performs database cleanup processes in the background. In that case, the upgrade of the clone isn't an accurate simulation of upgrading the original cluster.

4. Test application compatibility, performance, administration procedures, and so on, using the cloned cluster.
5. If you encounter any issues, adjust your upgrade plans to account for them. For example, adapt any application code to be compatible with the feature set of the higher version. Estimate how long the upgrade is likely to take based on the amount of data in your cluster. You might also choose to schedule the upgrade for a time when the cluster isn't busy.
6. After you're satisfied that your applications and workload work properly with the test cluster, you can perform the in-place upgrade for your production cluster.
7. Work to minimize the total downtime of your cluster during a major version upgrade. To do so, make sure that the workload on the cluster is low or zero at the time of the upgrade. In particular, make sure that there are no long running transactions in progress when you start the upgrade.

## Blue/Green Deployments

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see [Using Amazon Aurora Blue/Green Deployments for database updates](#).

## Major version upgrade prechecks for Aurora MySQL

Upgrading MySQL from one major version to another, such as going from MySQL 5.7 to MySQL 8.0, involves some significant architectural changes that require careful planning and preparation. Unlike minor version upgrades where the focus is mainly on updating the database engine software and in some cases system tables, major MySQL upgrades often introduce fundamental changes to how the database stores and manages its metadata.

To assist you in identifying such incompatibilities, when upgrading from Aurora MySQL version 2 to version 3, Aurora runs upgrade compatibility checks (prechecks) automatically to examine objects in your database cluster and identify known incompatibilities that can block the upgrade from proceeding. For details about the Aurora MySQL prechecks, see [Precheck descriptions reference for Aurora MySQL](#). The Aurora prechecks run in addition to those run by the Community MySQL [upgrade checker utility](#).

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They can reduce the possibility of running into upgrade failures that can lead to extended downtime.
- If there are incompatibilities, Amazon Aurora prevents the upgrade from proceeding and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to version 3 by resolving the incompatibilities. For detailed information about resolving incompatibilities, see [Preparing your installation for upgrade](#) in the MySQL documentation and [Upgrading to MySQL 8.0? Here is what you need to know...](#) on the MySQL Server Blog.

For more information about upgrading to MySQL 8.0, see [Upgrading MySQL](#) in the MySQL documentation.

The prechecks run before your DB cluster is taken offline for the major version upgrade. If the prechecks find an incompatibility, Aurora automatically cancels the upgrade before the DB instance is stopped. Aurora also generates an event for the incompatibility. For more information about Amazon Aurora events, see [Working with Amazon RDS event notification](#).

After the prechecks are completed, Aurora records detailed information about each incompatibility in the `upgrade-prechecks.log` file. In most cases, the log entry includes a link to the MySQL

documentation for correcting the incompatibility. For more information about viewing log files, see [Viewing and listing database log files](#).

### Note

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete. For more information on precheck performance considerations, see [Precheck process for Aurora MySQL](#).

  - [Errors, warnings, or notices](#)

## Precheck process for Aurora MySQL

As described previously, the Aurora MySQL upgrade process involves running compatibility checks (prechecks) on your database before the major version upgrade can proceed.

For in-place upgrades, the prechecks run on your writer DB instance while it's online. If the precheck succeeds, the upgrade proceeds. If errors are found, they're logged in the upgrade-

`prechecks.log` file and the upgrade is canceled. Before attempting the upgrade again, resolve any errors returned in the `upgrade-prechecks.log` file.

For snapshot-restore upgrades, the precheck runs during the restore process. If it succeeds, your database will upgrade to the new Aurora MySQL version. If errors are found, they're logged in the `upgrade-prechecks.log` file and the upgrade is canceled. Before attempting the upgrade again, resolve any errors returned in the `upgrade-prechecks.log` file.

For more information, see [Finding the reasons for Aurora MySQL major version upgrade failures](#) and [Precheck descriptions reference for Aurora MySQL](#).

To monitor precheck status, you can view the following events on your DB cluster.

Precheck status	Event message	Action
Started	Upgrade preparation in progress: Starting online upgrade prechecks.	None
Failed	Database cluster is in a state that cannot be upgraded: Upgrade prechecks failed. For more details, see the <code>upgrade-prechecks.log</code> file.  For more information on troubleshooting the cause of the upgrade failure, see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraMySQL.Upgrading.Troubleshooting.html">https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraMySQL.Upgrading.Troubleshooting.html</a>	Review <code>upgrade-prechecks.log</code> for errors.  Remediate errors.  Retry the upgrade.
Succeeded	Upgrade preparation in progress: Completed online upgrade prechecks.	Precheck succeeded with no errors returned.

Precheck status	Event message	Action
		Review upgrade-p rechecks.log for warnings and notices.

For more information on viewing events, see [Viewing Amazon RDS events](#).

## Precheck log format for Aurora MySQL

After the upgrade compatibility checks (prechecks) are complete, you can review the upgrade-prechecks.log file. The log file contains the results, affected objects, and remediation information for each precheck.

Errors block the upgrade. You must resolve them before retrying the upgrade.

Warnings and notices are less critical, but we still recommend that you review them carefully to make sure that there are no compatibility issues with the application workload. Address any identified issues soon.

The log file has the following format:

- `targetVersion` – The MySQL-compatible version of the Aurora MySQL upgrade.
- `auroraServerVersion` – The Aurora MySQL version on which the precheck was run.
- `auroraTargetVersion` – The Aurora MySQL version to which you're upgrading.
- `checksPerformed` – Contains the list of prechecks performed.
- `id` – The name of the precheck being run.
- `title` – A description of the precheck being run.
- `status` – This doesn't indicate whether the precheck succeeded or failed, but shows the status of the precheck query:
  - `OK` – The precheck query ran and completed successfully.
  - `ERROR` – The precheck query failed to run. This can occur because of issues such as resource constraints, unexpected instance restarts, or the compatibility precheck query being interrupted.

For more information, see [this example](#).

- `description` – A general description of the incompatibility, and how to remediate the issue.

- `documentationLink` – Where applicable, a link to relevant Aurora MySQL or MySQL documentation is noted here. For more information, see [Precheck descriptions reference for Aurora MySQL](#).
- `detectedProblems` – If the precheck returns an error, warning, or notice, this shows details of the incompatibility, and incompatible objects where applicable:
  - `level` – The level of the incompatibility detected by the precheck. Valid levels are the following:
    - `Error` – The upgrade can't proceed until you resolve the incompatibility.
    - `Warning` – The upgrade can proceed, but a deprecated object, syntax, or configuration was detected. Review warnings carefully, and resolve them soon to avoid issues in future releases.
    - `Notice` – The upgrade can proceed, but a deprecated object, syntax, or configuration was detected. Review notices carefully, and resolve them soon to avoid issues in future releases.
  - `dbObject` – The name of the database object in which the incompatibility was detected.
  - `description` – A detailed description of the incompatibility, and how to remediate the issue.
- `errorCount` – The number of incompatibility errors detected. These block the upgrade.
- `warningCount` – The number of incompatibility warnings detected. These don't block the upgrade, but address them soon to avoid problems in future releases.
- `noticeCount` – The number of incompatibility notices detected. These don't block the upgrade, address them soon to avoid problems in future releases.
- `Summary` – A summary of the precheck compatibility error, warning, and notice counts.

## Precheck log output examples for Aurora MySQL

The following examples show the precheck log output that you might see. For details of the prechecks that are run, see [Precheck descriptions reference for Aurora MySQL](#).

### Precheck status OK, no incompatibility detected

The precheck query completed successfully. No incompatibilities were detected.

```
{
  "id": "auroraUpgradeCheckIndexLengthLimitOnTinytext",
  "title": "Check for the tables with indexes defined with prefix length greater than 255 bytes on tiny text columns",
  "status": "OK",
```

```
"detectedProblems": []
},
```

## Precheck status OK, error detected

The precheck query completed successfully. One error was detected.

```
{
  "id": "auroraUpgradeCheckForPrefixIndexOnGeometryColumns",
  "title": "Check for geometry columns on prefix indexes",
  "status": "OK",
  "description": "Consider dropping the prefix indexes of geometry columns and restart the upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test25.sbtest1",
      "description": "Table `test25`.`sbtest1` has an index `idx_t1` on geometry column/s. Mysql 8.0 does not support this type of index on a geometry column https://dev.mysql.com/worklog/task/?id=11808. To upgrade to MySQL 8.0, Run 'DROP INDEX `idx_t1` ON `test25`.`sbtest1`;"
    }
  ],
}
```

## Precheck status OK, warning detected

Warnings can be returned when a precheck is successful or unsuccessful.

Here the precheck query completed successfully. Two warnings were detected.

```
{
  "id": "zeroDatesCheck",
  "title": "Zero Date, Datetime, and Timestamp values",
  "status": "OK",
  "description": "Warning: By default zero date/datetime/timestamp values are no longer allowed in MySQL, as of 5.7.8 NO_ZERO_IN_DATE and NO_ZERO_DATE are included in SQL_MODE by default. These modes should be used with strict mode as they will be merged with strict mode in a future release. If you do not include these modes in your SQL_MODE setting, you are able to insert date/datetime/timestamp values that contain zeros. It is strongly advised to replace zero values with valid ones, as they may not work correctly in the future.",
  "documentationLink": "https://lefred.be/content/mysql-8-0-and-wrong-dates/",
  "detectedProblems": [
```

```

    {
      "level": "Warning",
      "dbObject": "global.sql_mode",
      "description": "does not contain either NO_ZERO_DATE or NO_ZERO_IN_DATE
which allows insertion of zero dates"
    },
    {
      "level": "Warning",
      "dbObject": "session.sql_mode",
      "description": " of 10 session(s) does not contain either NO_ZERO_DATE or
NO_ZERO_IN_DATE which allows insertion of zero dates"
    }
  ]
}

```

## Precheck status ERROR, no incompatibilities reported

The precheck query failed with an error, so incompatibilities couldn't be verified.

```

{
  "id": "auroraUpgradeCheckForDatafilePathInconsistency",
  "title": "Check for inconsistency related to ibd file path.",
  "status": "ERROR",
  "description": "Can't connect to MySQL server on 'localhost:3306' (111) at
13/08/2024 12:22:20 UTC. This failure can occur due to low memory available on the
instance for executing upgrade prechecks. Please check 'FreeableMemory' Cloudwatch
metric to verify the available memory on the instance while executing prechecks. If
instance ran out of memory, we recommend to retry the upgrade on a higher instance
class."
}

```

This failure can occur because of an unexpected instance restart or a compatibility precheck query being interrupted on the database while running. For example, on smaller DB instance classes, you might experience this when the available memory on the instance runs low.

You can use the `FreeableMemory` Amazon CloudWatch metric to verify the available memory on the instance while running prechecks. If the instance ran out of memory, we recommend retrying the upgrade on a larger DB instance class. In some cases, you can use a [Blue/Green deployment](#). This allows prechecks and upgrades to run on the “green” DB cluster independent of the production workload, which also consumes system resources.

For more information, see [Troubleshooting memory usage issues for Aurora MySQL databases](#).

## Precheck summary, one error and three warnings detected

The compatibility prechecks also contain information on the source and target Aurora MySQL versions, and a summary of error, warning, and notice counts at the end of the precheck output.

For example, the following output shows that an attempt was made to upgrade from Aurora MySQL 2.11.6 to Aurora MySQL 3.07.1. The upgrade returned one error, three warnings, and no notices. Because upgrades can't proceed when an error is returned, you must resolve the [routineSyntaxCheck](#) compatibility issue and retry the upgrade.

```
{
  "serverAddress": "/tmp%2Fmysql.sock",
  "serverVersion": "5.7.12 - MySQL Community Server (GPL)",
  "targetVersion": "8.0.36",
  "auroraServerVersion": "2.11.6",
  "auroraTargetVersion": "3.07.1",
  "outfilePath": "/rdsdbdata/tmp/PreChecker.log",
  "checksPerformed": [{

avoid compatibility issues."
}

```

## Precheck performance for Aurora MySQL

The compatibility prechecks run before the DB instance is taken offline for the upgrade, so under regular circumstances they don't cause DB instance downtime while running. However, they can impact application workload running on the writer DB instance. The prechecks access the data dictionary through [information\\_schema](#) tables, which can be slow if there are many database objects. Consider the following factors:

- Precheck duration varies with the number of database objects such as tables, columns, routines, and constraints. DB clusters with a large number of objects can take longer to run.

For example, the [removedFunctionsCheck](#) can take longer and use more resources based on the number of [stored objects](#).

- For in-place upgrades, using a larger DB instance class (for example, db.r5.24xlarge or db.r6g.16xlarge) can help the upgrade complete faster by using more CPU. You can downsize after the upgrade.
- Queries on the `information_schema` across multiple databases can be slow, especially with many objects and on smaller DB instances. In such cases, consider using cloning, snapshot restore, or a [Blue/Green deployment](#) for upgrades.
- Precheck resource usage (CPU, memory) can increase with more objects, leading to longer run times on smaller DB instances. In such cases, consider testing using cloning, snapshot restore, or a Blue/Green deployment for upgrades.

If the prechecks fail due to lack of resources, you can detect this in the precheck log using the status output:

```
"status": "ERROR",
```

For more information, see [How the Aurora MySQL in-place major version upgrade works](#) and [Planning a major version upgrade for an Aurora MySQL cluster](#).

### Summary of Community MySQL upgrade prechecks

The following is a general list of incompatibilities between MySQL 5.7 and 8.0:

- Your MySQL 5.7-compatible DB cluster must not use features that aren't supported in MySQL 8.0.

For more information, see [Features removed in MySQL 8.0](#) in the MySQL documentation.

- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see [Keywords and reserved words](#) in the MySQL documentation.

- For improved Unicode support, consider converting objects that use the utf8mb3 charset to use the utf8mb4 charset. The utf8mb3 character set is deprecated. Also, consider using utf8mb4 for character set references instead of utf8, because currently utf8 is an alias for the utf8mb3 charset.

For more information, see [The utf8mb3 character set \(3-byte UTF-8 unicode encoding\)](#) in the MySQL documentation.

- There must be no InnoDB tables with a nondefault row format.
- There must be no ZEROFILL or display length type attributes.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no tables in the MySQL 5.7 mysql system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no tables that use obsolete data types or functions.
- There must be no foreign key constraint names longer than 64 characters.
- There must be no obsolete SQL modes defined in your sql\_mode system variable setting.
- There must be no tables or stored procedures with individual ENUM or SET column elements that exceed 255 characters in length.
- There must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no circular references in tablespace data file paths.
- There must be no queries and stored program definitions that use ASC or DESC qualifiers for GROUP BY clauses.
- There must be no removed system variables, and system variables must use the new default values for MySQL 8.0.
- There must be no zero (0) date, datetime, or timestamp values.
- There must be no schema inconsistencies resulting from file removal or corruption.
- There must be no table names that contain the FTS character string.
- There must be no InnoDB tables that belong to a different engine.

- There must be no table or schema names that are invalid for MySQL 5.7.

For details of the prechecks that are run, see [Precheck descriptions reference for Aurora MySQL](#).

For more information about upgrading to MySQL 8.0, see [Upgrading MySQL](#) in the MySQL documentation. For a general description of changes in MySQL 8.0, see [What is new in MySQL 8.0](#) in the MySQL documentation.

## Summary of Aurora MySQL upgrade prechecks

Aurora MySQL has its own specific requirements when upgrading from version 2 to version 3, including the following:

- There must be no deprecated SQL syntax, such as `SQL_CACHE`, `SQL_NO_CACHE`, and `QUERY_CACHE`, in views, routines, triggers, and events.
- There must be no `FTS_DOC_ID` column present on any table without the FTS index.
- There must be no column definition mismatch between the InnoDB data dictionary and the actual table definition.
- All database and table names must be lowercase when the `lower_case_table_names` parameter is set to 1.
- Events and triggers must not have a missing or empty definer or an invalid creation context.
- All trigger names in a database must be unique.
- DDL recovery and Fast DDL aren't supported in Aurora MySQL version 3. There must be no artifacts in databases related to these features.
- Tables with the `REDUNDANT` or `COMPACT` row format can't have indexes larger than 767 bytes.
- The prefix length of indexes defined on `tiny` text columns can't exceed 255 bytes. With the `utf8mb4` character set, this limits the prefix length supported to 63 characters.

A larger prefix length was allowed in MySQL 5.7 using the `innodb_large_prefix` parameter. This parameter is deprecated in MySQL 8.0.

- There must be no InnoDB metadata inconsistency in the `mysql.host` table.
- There must be no column data type mismatch in system tables.
- There must be no XA transactions in the prepared state.
- Column names in views can't be longer than 64 characters.
- Special characters in stored procedures can't be inconsistent.

- Tables can't have data file path inconsistency.

For details of the prechecks that are run, see [Precheck descriptions reference for Aurora MySQL](#).

## Precheck descriptions reference for Aurora MySQL

The upgrade prechecks for Aurora MySQL are described here in detail.

### Contents

- [Errors](#)
  - [MySQL prechecks that report errors](#)
  - [Aurora MySQL prechecks that report errors](#)
- [Warnings](#)
  - [MySQL prechecks that report warnings](#)
  - [Aurora MySQL prechecks that report warnings](#)
- [Notices](#)
- [Errors, warnings, or notices](#)

### Errors

The following prechecks generate errors when the precheck fails, and the upgrade can't proceed.

### Topics

- [MySQL prechecks that report errors](#)
- [Aurora MySQL prechecks that report errors](#)

### MySQL prechecks that report errors

The following prechecks are from Community MySQL:

- [checkTableMysqlSchema](#)
- [circularDirectoryCheck](#)
- [columnsWhichCannotHaveDefaultsCheck](#)
- [deprecatedSyntaxCheck](#)
- [engineMixupCheck](#)

- [enumSetElementLengthCheck](#)
- [foreignKeyLengthCheck](#)
- [getDuplicateTriggers](#)

- [partitionedTablesInSharedTablespaceCheck](#)
- [removedFunctionsCheck](#)
- [routineSyntaxCheck](#)
- [schemaInconsistencyCheck](#)

## checkTableMysqlSchema

**Precheck level: Error**

### Issues reported by the check table x for upgrade command for the mysql schema

Before starting the upgrade to Aurora MySQL version 3, `check table for upgrade` is run on each table in the `mysql` schema on the DB instance. The `check table for upgrade` command examines tables for any potential issues that might arise during an upgrade to a newer version of MySQL. Running this command before attempting an upgrade can help identify and resolve any incompatibilities ahead of time, making the actual upgrade process smoother.

This command performs various checks on each table, such as the following:

- Verifying that the table structure and metadata are compatible with the target MySQL version
- Checking for any deprecated or removed features used by the table
- Ensuring that the table can be properly upgraded without data loss

For more information, see [CHECK TABLE statement](#) in the MySQL documentation.

#### Example output:

```
{
  "id": "checkTableMysqlSchema",
  "title": "Issues reported by 'check table x for upgrade' command for mysql
schema.",
  "status": "OK",
  "detectedProblems": []
}
```

The output for this precheck depends on the error encountered, and when it's encountered, because `check table for upgrade` performs multiple checks.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

## circularDirectoryCheck

### Precheck level: Error

#### Circular directory references in tablespace data file paths

As of [MySQL 8.0.17](#), the `CREATE TABLESPACE ... ADD DATAFILE` clause no longer permits circular directory references. To avoid upgrade issues, remove any circular directory references from tablespace data file paths before upgrading to Aurora MySQL version 3.

#### Example output:

```
{
  "id": "circularDirectory",
  "title": "Circular directory references in tablespace data file paths",
  "status": "OK",
  "description": "Error: Following tablespaces contain circular directory references
(e.g. the reference './../') in data file paths which as of MySQL 8.0.17 are not
```

```
permitted by the CREATE TABLESPACE ... ADD DATAFILE clause. An exception to the
restriction exists on Linux, where a circular directory reference is permitted if
the preceding directory is a symbolic link. To avoid upgrade issues, remove any
circular directory references from tablespace data file paths before upgrading.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/upgrading-from-
previous-series.html#upgrade-innodb-changes",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "ts2",
      "description": "circular reference in datafile path: '/home/ec2-user/dbdata/
mysql_5_7_44/./ts2.ibd'",
      "dbObjectType": "Tablespace"
    }
  ]
}
```

If you receive this error, rebuild your tables using a [file-per-table tablespace](#). Use default file paths for all tablespace and table definitions.

### Note

Aurora MySQL doesn't support general tablespaces or CREATE TABLESPACE commands.

Before rebuilding tablespaces, see [Online DDL operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

After rebuilding, the precheck passes, allowing the upgrade to proceed.

```
{
  "id": "circularDirectoryCheck",
  "title": "Circular directory references in tablespace data file paths",
  "status": "OK",
  "detectedProblems": []
},
```

## columnsWhichCannotHaveDefaultsCheck

**Precheck level: Error**

**Columns that can't have default values**

Before MySQL 8.0.13, BLOB, TEXT, GEOMETRY, and JSON columns can't have [default values](#). Remove any default clauses on these columns before upgrading to Aurora MySQL version 3. For more information on changes to the default handling for these data types, see the [Data type default values](#) in the MySQL documentation.

### Example output:

```
{
  "id": "columnsWhichCannotHaveDefaultsCheck",
  "title": "Columns which cannot have default values",
  "status": "OK",
  "description": "Error: The following columns are defined as either BLOB, TEXT, GEOMETRY or JSON and have a default value set. These data types cannot have default values in MySQL versions prior to 8.0.13, while starting with 8.0.13, the default value must be specified as an expression. In order to fix this issue, please use the ALTER TABLE ... ALTER COLUMN ... DROP DEFAULT statement.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/data-type-defaults.html#data-type-defaults-explicit",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.test_blob_default.geo_col",
      "description": "geometry"
    }
  ]
},
```

The precheck returns an error because the `geo_col` column in the `test.test_blob_default` table is using a BLOB, TEXT, GEOMETRY, or JSON data type with a default value specified.

Looking at the table definition, we can see that the `geo_col` column is defined as `geo_col geometry NOT NULL default ''`.

```
mysql> show create table test_blob_default\G
***** 1. row *****
      Table: test_blob_default
Create Table: CREATE TABLE `test_blob_default` (
  `geo_col` geometry NOT NULL DEFAULT ''
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Removing this default clause to allow the precheck to pass.

**Note**

Before running ALTER TABLE statements or rebuilding tablespaces, see [Online DDL operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

```
mysql> ALTER TABLE test_blob_default modify COLUMN geo_col geometry NOT NULL;
Query OK, 0 rows affected (0.02 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> show create table test_blob_default\G
***** 1. row *****
      Table: test_blob_default
Create Table: CREATE TABLE `test_blob_default` (
  `geo_col` geometry NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

The precheck passes, and you can retry the upgrade.

```
{
  "id": "columnsWhichCannotHaveDefaultsCheck",
  "title": "Columns which cannot have default values",
  "status": "OK",
  "detectedProblems": []
},
```

**deprecatedSyntaxCheck****Precheck level: Error****Usage of deprecated keywords in definition**

MySQL 8.0 has removed the [query cache](#). As a result, some query cache-specific SQL syntax has been removed. If any of your database objects contain the QUERY CACHE, SQL\_CACHE, or SQL\_NO\_CACHE keywords, a precheck error is returned. To resolve this issue, re-create these objects, removing the mentioned keywords.

**Example output:**

```
{
  "id": "deprecatedSyntaxCheck",
  "title": "Usage of deprecated keywords in definition",
  "status": "OK",
  "description": "Error: The following DB objects contain keywords like 'QUERY
CACHE', 'SQL_CACHE', 'SQL_NO_CACHE' which are not supported in major version 8.0.
It is recommended to drop these DB objects or rebuild without any of the above
keywords before upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.no_query_cache_check",
      "description": "PROCEDURE uses deprecated words in definition"
    }
  ]
}
```

The precheck reports that the `test.no_query_cache_check` stored procedure is using one of the removed keywords. Looking at the procedure definition, we can see that it uses `SQL_NO_CACHE`.

```
mysql> show create procedure test.no_query_cache_check\G
***** 1. row *****
      Procedure: no_query_cache_check
      sql_mode:
      Create Procedure: CREATE DEFINER=`reinvent`@`%` PROCEDURE
`no_query_cache_check`()
BEGIN
      SELECT SQL_NO_CACHE k from sbtest1 where id > 10 and id < 20 group by k asc;
END
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
      Database Collation: latin1_swedish_ci
1 row in set (0.00 sec)
```

Remove the keyword.

```
mysql> drop procedure test.no_query_cache_check;
Query OK, 0 rows affected (0.01 sec)

mysql> delimiter //
```

```
mysql> CREATE DEFINER=`reinvent`@`%` PROCEDURE `no_query_cache_check`() BEGIN
  SELECT k from sbtest1 where id > 10 and id < 20 group by k asc; END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
```

After removing the keyword, the precheck completes successfully.

```
{
  "id": "deprecatedSyntaxCheck",
  "title": "Usage of deprecated keywords in definition",
  "status": "OK",
  "detectedProblems": []
}
```

## engineMixupCheck

### Precheck level: Error

#### Tables recognized by InnoDB that belong to a different engine

Similar to [schemaInconsistencyCheck](#), this precheck verifies that table metadata in MySQL is consistent before proceeding with the upgrade.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

### Example output:

```
{
  "id": "engineMixupCheck",
  "title": "Tables recognized by InnoDB that belong to a different engine",
  "status": "OK",
  "description": "Error: Following tables are recognized by InnoDB engine while the
SQL layer believes they belong to a different engine. Such situation may happen
when one removes InnoDB table files manually from the disk and creates e.g. a
MyISAM table with the same name.\n\nA possible way to solve this situation is to
e.g. in case of MyISAM table:\n\n1. Rename the MyISAM table to a temporary name
(RENAME TABLE).\n2. Create some dummy InnoDB table (its definition does not need to
match), then copy (copy, not move) and rename the dummy .frm and .ibd files to the
orphan name using OS file commands.\n3. The orphan table can be then dropped (DROP
```

```
TABLE), as well as the dummy table.\n4. Finally the MyISAM table can be renamed
back to its original name.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "mysql.general_log_backup",
      "description": "recognized by the InnoDB engine but belongs to CSV"
    }
  ]
}
```

## enumSetElementLengthCheck

### Precheck level: Error

### ENUM and SET column definitions containing elements longer than 255 characters

Tables and stored procedures must not have ENUM or SET column elements exceeding 255 characters or 1020 bytes. Before MySQL 8.0, the maximum combined length was 64K, but 8.0 limits individual elements to 255 characters or 1020 bytes (supporting multibyte). If you get a precheck failure for `enumSetElementLengthCheck`, modify any elements exceeding these new limits before retrying the upgrade.

### Example output:

```
{
  "id": "enumSetElementLengthCheck",
  "title": "ENUM/SET column definitions containing elements longer than 255
characters",
  "status": "OK",
  "description": "Error: The following columns are defined as either ENUM or SET and
contain at least one element longer that 255 characters. They need to be altered so
that all elements fit into the 255 characters limit.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/string-type-
overview.html",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.large_set.s",
      "description": "SET contains element longer than 255 characters"
    }
  ]
},
```

The precheck reports an error because the column `s` in the `test.large_set` table contains a SET element larger than 255 characters.

After reducing the SET size for this column, the precheck passes, allowing the upgrade to proceed.

```
{
  "id": "enumSetElementLengthCheck",
  "title": "ENUM/SET column definitions containing elements longer than 255
characters",
  "status": "OK",
  "detectedProblems": []
},
```

## foreignKeyLengthCheck

**Precheck level: Error**

### Foreign key constraint names longer than 64 characters

In MySQL, the length of identifiers is limited to 64 characters, as outlined in the [MySQL documentation](#). Due to [issues](#) identified where foreign key lengths could equal or exceed this value, leading to upgrade failures, this precheck was implemented. If you encounter errors with this precheck you should [alter or rename](#) your constraint so that it is less than 64 characters before retrying the upgrade.

**Example output:**

```
{
  "id": "foreignKeyLength",
  "title": "Foreign key constraint names longer than 64 characters",
  "status": "OK",
  "detectedProblems": []
}
```

## getDuplicateTriggers

**Precheck level: Error**

### All trigger names in a database must be unique.

Due to changes in the data dictionary implementation, MySQL 8.0 doesn't support case-sensitive triggers within a database. This precheck validates that your DB cluster doesn't have

one or more databases containing duplicate triggers. For more information, see [Identifier case sensitivity](#) in the MySQL documentation.

**Example output:**

```
{
  "id": "getDuplicateTriggers",
  "title": "MySQL pre-checks that all trigger names in a database are unique or not.",
  "status": "OK",
  "description": "Error: You have one or more database containing duplicate triggers. Mysql 8.0 does not support case sensitive triggers within a database https://dev.mysql.com/doc/refman/8.0/en/identifier-case-sensitivity.html. To upgrade to MySQL 8.0, drop the triggers with case-insensitive duplicate names and recreate with distinct names.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test",
      "description": "before_insert_product"
    },
    {
      "level": "Error",
      "dbObject": "test",
      "description": "before_insert_PRODUCT"
    }
  ]
}
```

The precheck reports an error that the database cluster has two triggers with the same name, but using different cases: `test.before_insert_product` and `test.before_insert_PRODUCT`.

Before upgrading, rename the triggers or drop and re-create them with a new name.

After renaming `test.before_insert_PRODUCT` to `test.before_insert_product_2`, the precheck succeeds.

```
{
  "id": "getDuplicateTriggers",
  "title": "MySQL pre-checks that all trigger names in a database are unique or not.",
  "status": "OK",
  "description": "Error: You have one or more database containing duplicate triggers. Mysql 8.0 does not support case sensitive triggers within a database https://dev.mysql.com/doc/refman/8.0/en/identifier-case-sensitivity.html. To upgrade to MySQL 8.0, drop the triggers with case-insensitive duplicate names and recreate with distinct names.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test",
      "description": "before_insert_product"
    },
    {
      "level": "Error",
      "dbObject": "test",
      "description": "before_insert_PRODUCT_2"
    }
  ]
}
```

```
"status": "OK",
"detectedProblems": []
}
```

## getEventsWithNullDefiner

### Precheck level: Error

#### The definer column for mysql.event can't be null or blank.

The DEFINER attribute specifies the MySQL account that owns a stored object definition, such as a trigger, stored procedure, or event. This attribute is particularly useful in situations where you want to control the security context under which the stored object runs. When creating a stored object, if a DEFINER isn't specified, the default is the user who created the object.

When upgrading to MySQL 8.0, you can't have any stored objects that have a null or blank definer in the MySQL data dictionary. If you have such stored objects, a precheck error is raised. You must fix it before the upgrade can proceed.

Example error:

```
{
  "id": "getEventsWithNullDefiner",
  "title": "The definer column for mysql.event cannot be null or blank.",
  "status": "OK",
  "description": "Error: Set definer column in mysql.event to a valid non-null definer.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.get_version",
      "description": "Set definer for event get_version in Schema test"
    }
  ]
}
```

The precheck returns an error for the `test.get_version` [event](#) because it has a null definer.

To resolve this you can check the event definition. As you can see, the definer is null or blank.

```
mysql> select db,name,definer from mysql.event where name='get_version';
+-----+-----+-----+
```

```
| db | name | definer |
+-----+-----+-----+
| test | get_version | |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Drop or re-create the event with a valid definer.

### Note

Before dropping or redefining a DEFINER, carefully review and check your application and privilege requirements. For more information, see [Stored object access control](#) in the MySQL documentation.

```
mysql> drop event test.get_version;
Query OK, 0 rows affected (0.00 sec)

mysql> DELIMITER ;
mysql> delimiter $$
mysql> CREATE EVENT get_version
->     ON SCHEDULE
->     EVERY 1 DAY
->     DO
->     ///DO SOMETHING //
-> $$
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> select db,name,definer from mysql.event where name='get_version';
+-----+-----+-----+
| db | name | definer |
+-----+-----+-----+
| test | get_version | reinvent@% |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Now the precheck passes.

```
{
```

```
"id": "getEventsWithNullDefiner",
"title": "The definer column for mysql.event cannot be null or blank.",
"status": "OK",
"detectedProblems": [],
```

## getMismatchedMetadata

### Precheck level: Error

#### Column definition mismatch between InnoDB data dictionary and actual table definition

Similar to [schemaInconsistencyCheck](#), this precheck verifies that table metadata in MySQL is consistent before proceeding with the upgrade. In this case, the precheck verifies that the column definitions match between the InnoDB data dictionary and the MySQL table definition. If a mismatch is detected, the upgrade doesn't proceed.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

#### Example output:

```
{
  "id": "getMismatchedMetadata",
  "title": "Column definition mismatch between InnoDB Data Dictionary and actual
table definition.",
  "status": "OK",
  "description": "Error: Your database has mismatched metadata. The upgrade to mysql
8.0 will not succeed until this is fixed.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.mismatchTable",
      "description": "Table `test/mismatchTable` column names mismatch with InnoDB
dictionary column names: iD <> id"
    }
  ]
}
```

The precheck reports a mismatch in the metadata for the `id` column in the `test.mismatchTable` table. Specifically, the MySQL metadata has the column name as `iD`, while InnoDB has it as `id`.

## getTriggersWithNullDefiner

### Precheck level: Error

The definer column for `information_schema.triggers` can't be null or blank.

The precheck validates that your database has no triggers defined with null or blank definers. For more information on definer requirements for stored objects, see [getEventsWithNullDefiner](#).

### Example output:

```
{
  "id": "getTriggersWithNullDefiner",
  "title": "The definer column for information_schema.triggers cannot be null or blank.",
  "status": "OK",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.example_trigger",
      "description": "Set definer for trigger example_trigger in Schema test"
    }
  ]
}
```

The precheck returns an error because the `example_trigger` trigger in the `test` schema has a null definer. To correct this issue, fix the definer by re-creating the trigger with a valid user, or drop the trigger. For more information, see the example in [getEventsWithNullDefiner](#).

#### Note

Before dropping or redefining a DEFINER, carefully review and check your application and privilege requirements. For more information, see [Stored object access control](#) in the MySQL documentation.

## getValueOfVariablelower\_case\_table\_names

### Precheck level: Error

**All database or table names must be lowercase when the `lower_case_table_names` parameter is set to 1.**

Before MySQL 8.0, database names, table names and other objects corresponded to files in the data directory, such as file-based metadata (.frm). The [lower\\_case\\_table\\_names](#) system variable allows users to control how the server handles identifier case sensitivity for database objects, and the storage of such metadata objects. This parameter could be changed on an already initialized server following a reboot.

However, in MySQL 8.0, while this parameter still controls how the server handles identifier case sensitivity, it can't be changed after the data dictionary is initialized. When upgrading or creating a MySQL 8.0 database, the value set for `lower_case_table_names` the first time the data dictionary is started on MySQL, is used for the lifetime of that database. This restriction was put in place as part of the implementation of the [Atomic Data Dictionary](#) implementation, where database objects are migrated from file-based metadata to internal InnoDB tables in the `mysql` schema.

For more information, see [Data dictionary changes](#) in the MySQL documentation.

To avoid issues during upgrade when updating file-based metadata to the new Atomic Data Dictionary, this precheck validates that when `lower_case_table_names = 1`, all tables are stored on disk in lower case. If they aren't, a precheck error is returned, and you must correct the metadata before proceeding with the upgrade.

**Example output:**

```
{
  "id": "getValueOfVariablelower_case_table_names",
  "title": "MySQL pre-checks that all database or table names are lowercase when the
lower_case_table_names parameter is set to 1.",
  "status": "OK",
  "description": "Error: You have one or more databases or tables with uppercase
letters in the names, but the lower_case_table_names parameter is set to 1. To
upgrade to MySQL 8.0, either change all database or table names to lowercase, or
set the parameter to 0.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.TEST",
      "description": "Table test.TEST contains one or more capital letters in name
while lower_case_table_names = 1"
```

```
    }  
  ]  
}
```

An error is returned because the table `test.TEST` contains uppercase letters, but `lower_case_table_names` is set to 1.

To resolve this issue, you can rename the table to use lowercase, or modify the `lower_case_table_names` parameter on the DB cluster before starting the upgrade.

### Note

Carefully test and review the documentation on [case sensitivity](#) in MySQL, and how any such changes might affect your application.

Also review the MySQL 8.0 documentation on how [lower\\_case\\_table\\_names](#) are handled differently in MySQL 8.0.

## groupByAscSyntaxCheck

**Precheck level: Error**

### Usage of removed GROUP BY ASC/DESC syntax

As of MySQL 8.0.13, the deprecated ASC or DESC syntax for GROUP BY clauses has been removed. Queries relying on GROUP BY sorting might now produce different results. To get a specific sort order, use an ORDER BY clause instead. If any objects exist in your database using this syntax, you must re-create them using an ORDER BY clause before retrying the upgrade. For more information, see [SQL changes](#) in the MySQL documentation.

### Example output:

```
{  
  "id": "groupByAscSyntaxCheck",  
  "title": "Usage of removed GROUP BY ASC/DESC syntax",  
  "status": "OK",  
  "description": "Error: The following DB objects use removed GROUP BY ASC/DESC  
syntax. They need to be altered so that ASC/DESC keyword is removed from GROUP BY  
clause and placed in appropriate ORDER BY clause.",  
  "documentationLink": "https://dev.mysql.com/doc/relnotes/mysql/8.0/en/  
news-8-0-13.html#mysqld-8-0-13-sql-syntax",
```

```

"detectedProblems": [
  {
    "level": "Error",
    "dbObject": "test.groupbyasc",
    "description": "PROCEDURE uses removed GROUP BY ASC syntax",
    "dbObjectType": "Routine"
  }
]
}

```

## mysqlEmptyDotTableSyntaxCheck

### Precheck level: Error

### Check for deprecated .<table> syntax used in routines.

In MySQL 8.0, routines can no longer contain the deprecated identifier syntax (\". <table>\"). If any stored routines or triggers contain such identifiers, the upgrade fails. For example, the following .dot\_table reference is no longer permitted:

```

mysql> show create procedure incorrect_procedure\G
***** 1. row *****
      Procedure: incorrect_procedure
      sql_mode:
      Create Procedure: CREATE DEFINER=`reinvent`@`%` PROCEDURE
`incorrect_procedure`()
BEGIN delete FROM .dot_table; select * from .dot_table where 1=1; END
character_set_client: utf8mb4
collation_connection: utf8mb4_0900_ai_ci
      Database Collation: latin1_swedish_ci
1 row in set (0.00 sec)

```

After you re-create the routines and triggers to use the correct identifier syntax and escaping, the precheck passes, and the upgrade can proceed. For more information on identifiers, see [Schema object names](#) in the MySQL documentation.

### Example output:

```

{
  "id": "mysqlEmptyDotTableSyntaxCheck",
  "title": "Check for deprecated '<table>' syntax used in routines.",
  "status": "OK",

```

```

    "description": "Error: The following routines contain identifiers in deprecated
    identifier syntax (\".<table>\"), and should be corrected before upgrade:\n",
    "detectedProblems": [
      {
        "level": "Error",
        "dbObject": "test.incorrect_procedure",
        "description": " routine body contains deprecated identifiers."
      }
    ]
  }
}

```

The precheck returns an error for the `incorrect_procedure` routine in the test database because it contains deprecated syntax.

After you correct the routine, the precheck succeeds, and you can retry the upgrade.

## mysqlIndexTooLargeCheck

### Precheck level: Error

### Check for indexes that are too large to work on MySQL versions higher than 5.7

For compact or redundant row formats, it shouldn't be possible to create an index with a prefix larger than 767 bytes. However, before MySQL version 5.7.35 this was possible. For more information, see the [MySQL 5.7.35 release notes](#).

Any indexes that were affected by this bug will become inaccessible after upgrading to MySQL 8.0. This precheck identifies offending indexes that have to be rebuilt before the upgrade is allowed to proceed.

```

{
  "id": "mysqlIndexTooLargeCheck",
  "title": "Check for indexes that are too large to work on higher versions of MySQL
  Server than 5.7",
  "status": "OK",
  "description": "Error: The following indexes were made too large for their format
  in an older version of MySQL (older than 5.7.34). Normally those indexes within
  tables with compact or redundant row formats shouldn't be larger than 767 bytes. To
  fix this problem those indexes should be dropped before upgrading or those tables
  will be inaccessible.",
  "detectedProblems": [
    {
      "level": "Error",

```

```

    "dbObject": "test.table_with_large_idx",
    "description": "IDX_2"
  }
]
}

```

The precheck returns an error because the `test.table_with_large_idx` table contains an index on a table using a compact or redundant row format that's larger than 767 bytes. These tables would become inaccessible after upgrading to MySQL 8.0. Before proceeding with the upgrade, do one of the following:

- Drop the index mentioned in the precheck.
- Add an index mentioned in the precheck.
- Change the row format used by the table.

Here we rebuild the table to resolve the precheck failure. Before rebuilding the table, make sure that the [innodb\\_file\\_format](#) is set to Barracuda, and the [innodb\\_default\\_row\\_format](#) is set to dynamic. These are the defaults in MySQL 5.7. For more information, see [InnoDB row formats](#) and [InnoDB file-format management](#) in the MySQL documentation.

### Note

Before rebuilding tablespaces, see [Online DDL operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

```

mysql > select @@innodb_file_format,@@innodb_default_row_format;
+-----+-----+
| @@innodb_file_format | @@innodb_default_row_format |
+-----+-----+
| Barracuda           | dynamic                     |
+-----+-----+
1 row in set (0.00 sec)

mysql> optimize table table_with_large_idx;
+-----+-----+-----+
| Table                | Op      | Msg_type | Msg_text
+-----+-----+-----+
|                      |         |          |
+-----+-----+-----+

```

```

| test.table_with_large_idx | optimize | note      | Table does not support optimize,
doing recreate + analyze instead |
| test.table_with_large_idx | optimize | status    | OK
|
+-----+-----+-----+
+-----+
2 rows in set (0.02 sec)

# Verify FILE_FORMAT and ROW_FORMAT
mysql> select * from information_schema.innodb_sys_tables where name like 'test/
table_with_large_idx';
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
| TABLE_ID | NAME                               | FLAG | N_COLS | SPACE | FILE_FORMAT |
ROW_FORMAT | ZIP_PAGE_SIZE | SPACE_TYPE |
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
|      43 | test/table_with_large_idx | 33 | 4 | 26 | Barracuda |
Dynamic   | 0 | Single   |
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+
1 row in set (0.00 sec)

```

After rebuilding the table, the precheck passes, and the upgrade can proceed.

```

{
  "id": "mysqlIndexTooLargeCheck",
  "title": "Check for indexes that are too large to work on higher versions of MySQL
Server than 5.7",
  "status": "OK",
  "detectedProblems": []
},

```

## mysqlInvalid57NamesCheck

### Precheck level: Error

### Check for invalid table and schema names used in MySQL 5.7

When migrating to the new data dictionary in MySQL 8.0, your database instance can't contain schemas or tables prefixed with `#mysql150#`. If any such objects exist, the upgrade fails. To resolve this issue, run [mysqlcheck](#) against the returned schemas and tables.

**Note**

Make sure that you use a [MySQL 5.7 version](#) of `mysqlcheck`, because [--fix-db-names](#) and [--fix-table-names](#) have been removed from [MySQL 8.0](#).

**Example output:**

```
{
  "id": "mysqlInvalid57NamesCheck",
  "title": "Check for invalid table names and schema names used in 5.7",
  "status": "OK",
  "description": "The following tables and/or schemas have invalid names. In order
to fix them use the mysqlcheck utility as follows:\n\n $ mysqlcheck --check-
upgrade --all-databases\n $ mysqlcheck --fix-db-names --fix-table-names --all-
databases\n\nOR via mysql client, for eg:\n\n ALTER DATABASE `#mysql50#lost+found`
UPGRADE DATA DIRECTORY NAME;",
  "documentationLink": "https://dev.mysql.com/doc/refman/5.7/en/identifier-
mapping.html https://dev.mysql.com/doc/refman/5.7/en/alter-database.html https://
dev.mysql.com/doc/refman/8.0/en/mysql-nutshell.html#mysql-nutshell-removals",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "#mysql50#fix_db_names",
      "description": "Schema name"
    }
  ]
}
```

The precheck reports that the schema `#mysql50#fix_db_names` has an invalid name.

After fixing the schema name, the precheck passes, allowing the upgrade to proceed.

```
{
  "id": "mysqlInvalid57NamesCheck",
  "title": "Check for invalid table names and schema names used in 5.7",
  "status": "OK",
  "detectedProblems": [],
},
```

## mysqlOrphanedRoutinesCheck

### Precheck level: Error

### Check for orphaned routines in 5.7

When migrating to the new data dictionary in MySQL 8.0, if there are any stored procedures in the database where the schema no longer exists, the upgrade fails. This precheck verifies that all schemas referenced in stored procedures on your DB instance still exist. To allow the upgrade to proceed, drop these stored procedures.

### Example output:

```
{
  "id": "mysqlOrphanedRoutinesCheck",
  "title": "Check for orphaned routines in 5.7",
  "status": "OK",
  "description": "Error: The following routines have been orphaned. Schemas that they are referencing no longer exists.\nThey have to be cleaned up or the upgrade will fail.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "dropped_db.get_version",
      "description": "is orphaned"
    }
  ]
},
```

The precheck reports that the `get_version` stored procedure in the `dropped_db` database is orphaned.

To clean up this procedure, you can re-create the missing schema.

```
mysql> create database dropped_db;
Query OK, 1 row affected (0.01 sec)
```

After the schema is re-created, you can drop the procedure to allow the upgrade to proceed.

```
{
  "id": "mysqlOrphanedRoutinesCheck",
  "title": "Check for orphaned routines in 5.7",
  "status": "OK",
```

```
"detectedProblems": []
},
```

## mysqlSchemaCheck

### Precheck level: Error

#### Table names in the mysql schema conflicting with new tables in MySQL 8.0

The new [Atomic Data Dictionary](#) introduced in MySQL 8.0 stores all metadata in a set of internal InnoDB tables in the mysql schema. During the upgrade, the new [internal data dictionary tables](#) are created in the mysql schema. To avoid naming collisions, which would result in upgrade failures, the precheck examines all table names in the mysql schema to ensure that none of the new table names are already in use. If they are, an error is returned, and the upgrade isn't allowed to proceed.

#### Example output:

```
{
  "id": "mysqlSchema",
  "title": "Table names in the mysql schema conflicting with new tables in the latest MySQL.",
  "status": "OK",
  "description": "Error: The following tables in mysql schema have names that will conflict with the ones introduced in the latest version. They must be renamed or removed before upgrading (use RENAME TABLE command). This may also entail changes to applications that use the affected tables.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/upgrade-before-you-begin.html",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "mysql.tablespaces",
      "description": "Table name used in mysql schema.",
      "dbObjectType": "Table"
    }
  ]
}
```

An error is returned because there is a table named `tablespaces` in the mysql schema. This is one of the new internal data dictionary table names in MySQL 8.0. You must rename or remove any such tables before upgrading, by using the `RENAME TABLE` command.

## nonNativePartitioningCheck

### Precheck level: Error

#### Partitioned tables using engines with non-native partitioning

According to the [MySQL 8.0 documentation](#), two storage engines currently provide native partitioning support: [InnoDB](#) and [NDB](#). Of these, only InnoDB is supported in Aurora MySQL version 3, compatible with MySQL 8.0. Any attempt to create partitioned tables in MySQL 8.0 using any other storage engine fails. This precheck looks for tables in your DB cluster that are using non-native partitioning. If any are returned, you must remove the partitioning or convert the storage engine to InnoDB.

#### Example output:

```
{
  "id": "nonNativePartitioning",
  "title": "Partitioned tables using engines with non native partitioning",
  "status": "OK",
  "description": "Error: In the latest MySQL storage engine is responsible for providing its own partitioning handler, and the MySQL server no longer provides generic partitioning support. InnoDB and NDB are the only storage engines that provide a native partitioning handler that is supported in the latest MySQL. A partitioned table using any other storage engine must be altered—either to convert it to InnoDB or NDB, or to remove its partitioning—before upgrading the server, else it cannot be used afterwards.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/upgrading-from-previous-series.html#upgrade-configuration-changes",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.partMyisamTable",
      "description": "MyISAM engine does not support native partitioning",
      "dbObjectType": "Table"
    }
  ]
}
```

Here a MyISAM table is using partitioning, which requires action before the upgrade can proceed.

## oldTemporalCheck

**Precheck level: Error**

### Usage of old temporal type

"Old temporals" refer to the temporal type columns (such as `TIMESTAMP` and `DATETIME`) created in MySQL versions 5.5 and lower. In MySQL 8.0, support for these old temporal data types is removed, meaning that in-place upgrades from MySQL 5.7 to 8.0 aren't possible if the database contains these old temporal types. To fix this, you must [rebuild](#) any tables containing such old temporal date types, before proceeding with the upgrade.

For more information on the deprecation of old temporal data types in MySQL 5.7, see this [blog](#). For more information on the removal of old temporal data types in MySQL 8.0, see this [blog](#).

#### Note

Before rebuilding tablespaces, see [Online DDL operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

### Example output:

```
{
  "id": "oldTemporalCheck",
  "title": "Usage of old temporal type",
  "status": "OK",
  "description": "Error: Following table columns use a deprecated and no longer supported temporal disk storage format. They must be converted to the new format before upgrading. It can be done by rebuilding the table using 'ALTER TABLE <table_name> FORCE' command",
  "documentationLink": "https://dev.mysql.com/blog-archive/mysql-8-0-removing-support-for-old-temporal-datatypes/",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.55_temporal_table.timestamp_column",
      "description": "timestamp /* 5.5 binary format */",
      "dbObjectType": "Column"
    }
  ]
}
```

```
]
},
```

An error is reported for the column `timestamp_column` in the table `test.55_temporal_table`, because it uses an old temporal disk storage format that's no longer supported.

To resolve this issue and allow the upgrade to proceed, rebuild the table to convert the old temporal disk storage format to the new one introduced in MySQL 5.6. For more information and prerequisites before doing so, see [Converting between 3-byte and 4-byte Unicode character sets](#) in the MySQL documentation.

Running the following command to rebuild the tables mentioned in this precheck converts the old temporal types to the newer format with fractional-second precision.

```
ALTER TABLE ... ENGINE=InnoDB;
```

For more information on rebuilding tables, see [ALTER TABLE statement](#) in the MySQL documentation.

After rebuilding the table in question and restarting the upgrade, the compatibility check passes, allowing the upgrade to proceed.

```
{
  "id": "oldTemporalCheck",
  "title": "Usage of old temporal type",
  "status": "OK",
  "detectedProblems": []
}
```

## partitionedTablesInSharedTablespaceCheck

### Precheck level: Error

### Usage of partitioned tables in shared tablespaces

As of [MySQL 8.0.13](#), support for placing table partitions in shared tablespaces is removed. Before upgrading, move any such tables from shared tablespaces to file-per-table tablespaces.

**Note**

Before rebuilding tablespaces, see [Partitioning operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

**Example output:**

```
{
  "id": "partitionedTablesInSharedTablespaceCheck",
  "title": "Usage of partitioned tables in shared tablespaces",
  "status": "OK",
  "description": "Error: The following tables have partitions in shared tablespaces. They need to be moved to file-per-table tablespace before upgrading. You can do this by running query like 'ALTER TABLE table_name REORGANIZE PARTITION X INTO (PARTITION X VALUES LESS THAN (30) TABLESPACE=innodb_file_per_table);'",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/mysql-nutshell.html#mysql-nutshell-removals",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.partInnoDBTable",
      "description": "Partition p1 is in shared tablespace innodb",
      "dbObjectType": "Table"
    }
  ]
}
```

The precheck fails because partition p1 from table `test.partInnoDBTable` is in the system tablespace.

To resolve this issue, rebuild the `test.partInnoDBTable` table, placing the offending partition p1 in a file-per-table tablespace.

```
mysql > ALTER TABLE partInnoDBTable REORGANIZE PARTITION p1
-> INTO (PARTITION p1 VALUES LESS THAN ('2014-01-01')
TABLESPACE=innodb_file_per_table);
Query OK, 0 rows affected, 1 warning (0.02 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

After doing so, the precheck passes.

```
{
  "id": "partitionedTablesInSharedTablespaceCheck",
  "title": "Usage of partitioned tables in shared tablespaces",
  "status": "OK",
  "detectedProblems": []
}
```

## removedFunctionsCheck

### Precheck level: Error

### Usage of functions that were removed from the latest MySQL version

In MySQL 8.0, a number of built-in functions have been removed. This precheck examines your database for objects that might use these functions. If they're found, an error is returned. You must resolve the issues before retrying the upgrade.

The majority of functions removed are [spatial functions](#), which have been replaced with equivalent ST\_\* functions. In these cases, you modify the database objects to use the new procedure naming. For more information, see [Features removed in MySQL 8.0](#) in the MySQL documentation.

### Example output:

```
{
  "id": "removedFunctionsCheck",
  "title": "Usage of removed functions",
  "status": "OK",
  "description": "Error: The following DB objects use functions that were removed in the latest MySQL version. Please make sure to update them to use supported alternatives before upgrade.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/mysql-nutshell.html#mysql-nutshell-removals",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.GetLocationsInPolygon",
      "description": "PROCEDURE uses removed function POLYGONFROMTEXT (consider using ST_POLYGONFROMTEXT instead)",
      "dbObjectType": "Routine"
    },
    {
```

```

    "level": "Error",
    "dbObject": "test.InsertLocation",
    "description": "PROCEDURE uses removed function POINTFROMTEXT (consider
using ST_POINTFROMTEXT instead)",
    "dbObjectType": "Routine"
  }
]
},

```

The precheck reports that the `test.GetLocationsInPolygon` stored procedure is using two removed functions: [POLYGONFROMTEXT](#) and [POINTFROMTEXT](#). It also suggests that you use the new [ST\\_POLYGONFROMTEXT](#) and [ST\\_POINTFROMTEXT](#) as replacements. After re-creating the procedure using the suggestions, the precheck completes successfully.

```

{
  "id": "removedFunctionsCheck",
  "title": "Usage of removed functions",
  "status": "OK",
  "detectedProblems": []
},

```

### Note

While in most cases the deprecated functions have direct replacements, make sure that you test your application and review the documentation for any changes in behavior as a result of the change.

## routineSyntaxCheck

### Precheck level: Error

### MySQL syntax check for routine-like objects

MySQL 8.0 introduced [reserved keywords](#) that were not reserved previously. The upgrade prechecker evaluates the usage of reserved keywords in the names of database objects and in their definitions and body. If it detects reserved keywords being used in database objects, such as stored procedures, functions, events, and triggers, the upgrade fails and an error is published to the `upgrade-prechecks.log` file. To resolve the issue, you must update these object definitions and enclose any such references in single quotes (') before upgrading. For

more information on escaping reserved words in MySQL, see [String literals](#) in the MySQL documentation.

Alternatively, you can change the name to a different name, which may require application changes.

### Example output:

```
{
  "id": "routineSyntaxCheck",
  "title": "MySQL syntax check for routine-like objects",
  "status": "OK",
  "description": "The following objects did not pass a syntax check with the latest MySQL grammar. A common reason is that they reference names that conflict with new reserved keywords. You must update these routine definitions and `quote` any such references before upgrading.",
  "documentationLink": "https://dev.mysql.com/doc/refman/en/keywords.html",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.select_res_word",
      "description": "at line 2,18: unexpected token 'except'",
      "dbObjectType": "Routine"
    }
  ]
}
```

To fix this issue, check the routine definition.

```
SHOW CREATE PROCEDURE test.select_res_word\G

***** 1. row *****
      Procedure: select_res_word
      sql_mode:
ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_Z
      Create Procedure: CREATE PROCEDURE 'select_res_word'()
BEGIN
      SELECT * FROM except;
END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

```
1 row in set (0.00 sec)
```

The procedure uses a table named `except`, which is a new keyword in MySQL 8.0. Re-create the procedure by escaping the string literal.

```
> drop procedure if exists select_res_word;
Query OK, 0 rows affected (0.00 sec)

> DELIMITER $$
> CREATE PROCEDURE select_res_word()
  -> BEGIN
  ->     SELECT * FROM 'except';
  -> END$$
Query OK, 0 rows affected (0.00 sec)

> DELIMITER ;
```

The precheck now passes.

```
{
  "id": "routineSyntaxCheck",
  "title": "MySQL syntax check for routine-like objects",
  "status": "OK",
  "detectedProblems": []
}
```

## schemaInconsistencyCheck

### Precheck level: Error

#### Schema inconsistencies resulting from file removal or corruption

As described previously, MySQL 8.0 introduced the [Atomic Data Dictionary](#), which stores all metadata in a set of internal InnoDB tables in the `mysql` schema. This new architecture provides a transactional, [ACID](#)-compliant way to manage database metadata, solving the "atomic DDL" problem from the old file-based approach. Before MySQL 8.0, it was possible for schema objects to become orphaned if a DDL operation was unexpectedly interrupted. The migration of file-based metadata to the new Atomic Data Dictionary tables during upgrade ensures that there are no such orphaned schema objects in the DB instance. If any orphaned objects are encountered, the upgrade fails.

To help detect these orphaned objects before initiating the upgrade, the `schemaInconsistencyCheck` precheck is run to ensure that all data dictionary metadata objects are in sync. If any orphaned metadata objects are detected, the upgrade doesn't proceed. To proceed with the upgrade, clean up these orphaned metadata objects.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

### Example output:

```
{
  "id": "schemaInconsistencyCheck",
  "title": "Schema inconsistencies resulting from file removal or corruption",
  "status": "OK",
  "description": "Error: Following tables show signs that either table datadir
  directory or frm file was removed/corrupted. Please check server logs, examine
  datadir to detect the issue and fix it before upgrade",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.schemaInconsistencyCheck_failure",
      "description": "present in INFORMATION_SCHEMA's INNODB_SYS_TABLES table but
  missing from TABLES table"
    }
  ]
}
```

The precheck reports that the `test.schemaInconsistencyCheck_failure` table has inconsistent metadata. In this case, the table exists in the InnoDB storage engine metadata (`information_schema.INNODB_SYS_TABLES`), but not in the MySQL metadata (`information_schema.TABLES`).

## Aurora MySQL prechecks that report errors

The following prechecks are specific to Aurora MySQL:

- [auroraCheckDDLRecovery](#)
- [auroraCheckRdsUpgradePrechecksTable](#)
- [auroraFODUpgradeCheck](#)

- [auroraGetDanglingFulltextIndex](#)
- [auroraUpgradeCheckForDatafilePathInconsistency](#)
- [auroraUpgradeCheckForFtsSpaceIdZero](#)
- [auroraUpgradeCheckForIncompleteXATransactions](#)
- [auroraUpgradeCheckForInstanceLimit](#)
- [auroraUpgradeCheckForInternalUsers](#)
- [auroraUpgradeCheckForInvalidUtf8mb3CharacterStringInViews](#)
- [auroraUpgradeCheckForInvalidUtf8mb3ColumnComments](#)
- [auroraUpgradeCheckForInvalidUtf8mb3IndexComments](#)
- [auroraUpgradeCheckForInvalidUtf8mb3TableComments](#)
- [auroraUpgradeCheckForMasterUser](#)
- [auroraUpgradeCheckForPrefixIndexOnGeometryColumns](#)
- [auroraUpgradeCheckForSpecialCharactersInProcedures](#)
- [auroraUpgradeCheckForSysSchemaObjectTypeMismatch](#)
- [auroraUpgradeCheckForViewColumnNameLength](#)
- [auroraUpgradeCheckIndexLengthLimitOnTinyColumns](#)
- [auroraUpgradeCheckMissingInnoDBMetadataForMySQLHostTable](#)

## auroraCheckDDLRecovery

### Precheck level: Error

#### Check for artifacts related to Aurora DDL recovery feature

As part of the Data Definition Language (DDL) recovery implementation in Aurora MySQL, metadata on inflight DDL statements is maintained in the `ddl_log_md_table` and `ddl_log_table` tables in the `mysql` schema. Aurora's implementation of DDL recovery isn't supported for version 3 onward, because the functionality is part of the new [Atomic Data Dictionary](#) implementation in MySQL 8.0. If you have any DDL statements running during the compatibility checks, this precheck might fail. We recommend that you try the upgrade while no DDL statements are running.

If this precheck fails without any running DDL statements, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

If any DDL statements are running, the precheck output prints the following message:

```
"There are DDL statements in process. Please allow DDL statements to finish before upgrading."
```

### Example output:

```
{
  "id": "auroraCheckDDLRecovery",
  "title": "Check for artifacts related to Aurora DDL recovery feature",
  "status": "OK",
  "description": "Aurora implementation of DDL recovery is not supported from 3.x onwards. This check verifies that the database do not have artifacts related to the feature",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "mysql.ddl_log_md_table",
      "description": "Table mysql.ddl_log_md_table is not empty. Your database has pending DDL recovery operations. Reachout to AWS support for assistance."
    },
    {
      "level": "Error",
      "dbObject": "mysql.ddl_log_table",
      "description": "Table mysql.ddl_log_table is not empty. Your database has pending DDL recovery operations. Reachout to AWS support for assistance."
    },
    {
      "level": "Error",
      "dbObject": "information_schema.processlist",
      "description": "There are DDL statements in process. Please allow DDL statements to finish before upgrading."
    }
  ]
}
```

The precheck returned an error due to an inflight DDL running concurrently with the compatibility checks. We recommend that you retry the upgrade without any DDLs running.

### **auroraCheckRdsUpgradePrechecksTable**

#### **Precheck level: Error**

## Check existence of `mysql.rds_upgrade_prechecks` table

This is an internal-only precheck carried out by the RDS service. Any errors will be automatically handled on upgrade and can be safely ignored.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

```
{
  "id": "auroraCheckRdsUpgradePrechecksTable",
  "title": "Check existence of mysql.rds_upgrade_prechecks table",
  "status": "OK",
  "detectedProblems": []
}
```

## auroraFODUpgradeCheck

### Precheck level: Error

### Check for artifacts related to Aurora fast DDL feature

The [Fast DDL](#) optimization was introduced in [lab mode](#) on Aurora MySQL version 2 to improve the efficiency of some DDL operations. In Aurora MySQL version 3, lab mode has been removed, and the Fast DDL implementation has been superseded by the MySQL 8.0 feature called [Instant DDL](#).

Before upgrading to Aurora MySQL version 3, any tables that use Fast DDL in lab mode will have to be rebuilt by running the `OPTIMIZE TABLE` or `ALTER TABLE ... ENGINE=InnoDB` command to ensure compatibility with Aurora MySQL version 3.

This precheck returns a list of any such tables. After the returned tables have been rebuilt, you can retry the upgrade.

### Example output:

```
{
  "id": "auroraFODUpgradeCheck",
  "title": "Check for artifacts related to Aurora fast DDL feature",
  "status": "OK",
  "description": "Aurora fast DDL is not supported from 3.x onwards. This check verifies that the database does not have artifacts related to the feature",
}
```

```

"documentationLink": "https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraMySQL.Managing.FastDDL.html#AuroraMySQL.Managing.FastDDL-v2",
"detectedProblems": [
  {
    "level": "Error",
    "dbObject": "test.test",
    "description": "Your table has pending Aurora fast DDL operations. Run 'OPTIMIZE TABLE <table name>' for the table to apply all the pending DDL updates. Then try the upgrade again."
  }
]
}

```

The precheck reports that the table `test.test` has pending Fast DDL operations.

To allow the upgrade to proceed, you can rebuild the table, then retry the upgrade.

#### Note

Before rebuilding tablespaces, see [Online DDL operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

```

mysql> optimize table test.test;
+-----+-----+-----+
+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text
|           |         |          |
+-----+-----+-----+
+-----+-----+-----+
| test.test | optimize | note     | Table does not support optimize, doing recreate
+ analyze instead |
| test.test | optimize | status   | OK
|           |         |          |
+-----+-----+-----+
+-----+-----+-----+
2 rows in set (0.04 sec)

```

After rebuilding the table, the precheck succeeds.

```
{
```

```

    "id": "auroraFODUpgradeCheck",
    "title": "Check for artifacts related to Aurora fast DDL feature",
    "status": "OK",
    "detectedProblems": []
  }

```

## auroraGetDanglingFulltextIndex

### Precheck level: Error

### Tables with dangling FULLTEXT index reference

Before MySQL 5.6.26, it was possible that after dropping a full-text search index, the hidden FTS\_DOC\_ID and FTS\_DOC\_ID\_INDEX columns would become orphaned. For more information, see [Bug #76012](#).

If you have any tables created on earlier versions of MySQL where this has occurred, it can cause upgrades to Aurora MySQL version 3 to fail. This precheck verifies that no such orphaned, or “dangling” full-text indexes exist on your DB cluster before upgrading to MySQL 8.0. If this precheck fails, rebuild any tables that contain such dangling full-text indexes.

### Example output:

```

{
  "id": "auroraGetDanglingFulltextIndex",
  "title": "Tables with dangling FULLTEXT index reference",
  "status": "OK",
  "description": "Error: The following tables contain dangling FULLTEXT index which is not supported. It is recommended to rebuild the table before upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.table_with_fts_index",
      "description": "Table `test.table_with_fts_index` contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
    }
  ]
},

```

The precheck reports an error for the `test.table_with_fts_index` table because it contains a dangling full-text index. To allow the upgrade to proceed, rebuild the table to clean up the

full-text index auxiliary tables. Use `OPTIMIZE TABLE test.table_with_fts_index` or `ALTER TABLE test.table_with_fts_index, ENGINE=INNODB`.

After rebuilding the table, the precheck passes.

```
{
  "id": "auroraGetDanglingFulltextIndex",
  "title": "Tables with dangling FULLTEXT index reference",
  "status": "OK",
  "detectedProblems": []
},
```

### **auroraUpgradeCheckForDatafilePathInconsistency**

**Precheck level: Error**

#### **Check for inconsistency related to ibd file path**

This precheck applies only to Aurora MySQL version 3.03.0 and lower. If you encounter an error with this precheck, upgrade to Aurora MySQL version 3.04 or higher.

#### **Example output:**

```
{
  "id": "auroraUpgradeCheckForDatafilePathInconsistency",
  "title": "Check for inconsistency related to ibd file path.",
  "status": "OK",
  "detectedProblems": []
}
```

### **auroraUpgradeCheckForFtsSpaceIdZero**

**Precheck level: Error**

#### **Check for full-text index with space ID as zero**

In MySQL, when you add a [full-text index](#) to an InnoDB table, a number of auxiliary index tablespaces are created. Due to a [bug](#) in earlier versions of MySQL, which was fixed in version 5.6.20, it was possible that these auxiliary index tables were created in the [system tablespace](#), rather than their own InnoDB tablespace.

If any such auxiliary tablespaces exist, the upgrade will fail. Re-create the full-text indexes mentioned in the precheck error, then retry the upgrade.

**Example output:**

```
{
  "id": "auroraUpgradeCheckForFtsSpaceIdZero",
  "title": "Check for fulltext index with space id as zero",
  "status": "OK",
  "description": "The auxiliary tables of FTS indexes on the table are created
in system table-space. Due to this DDL queries executed on MySQL8.0 shall cause
database unavailability. To avoid that, drop and recreate all the FTS indexes on
the table or rebuild the table using ALTER TABLE query before the upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.fts_space_zero_check",
      "description": " The auxiliary tables of FTS indexes on the table
'test.fts_space_zero_check' are created in system table-space due to https://
bugs.mysql.com/bug.php?id=72132. In MySQL8.0, DDL queries executed on this table
shall cause database unavailability. To avoid that, drop and recreate all the
FTS indexes on the table or rebuild the table using ALTER TABLE query before the
upgrade."
    }
  ]
},
```

The precheck reports an error for the `test.fts_space_zero_check` table, because it has auxiliary full-text search (FTS) tables in the system tablespace.

After you drop and re-create the FTS indexes associated with this table, the precheck succeeds.

**Note**

Before rebuilding tablespaces, see [Partitioning operations](#) in the MySQL documentation to understand the effects of locking and data movement on foreground transactions.

```
{
  "id": "auroraUpgradeCheckForFtsSpaceIdZero",
  "title": "Check for fulltext index with space id as zero",
  "status": "OK",
  "detectedProblems": []
}
```

## auroraUpgradeCheckForIncompleteXATransactions

### Precheck level: Error

#### Check for XA transactions in prepared state

While running the major version upgrade process, it is essential that the Aurora MySQL version 2 DB instance undergo a [clean shutdown](#). This ensures that all transactions are committed or rolled back, and that InnoDB has purged all undo log records. Because transaction rollback is necessary, if your database has any [XA transactions](#) in a prepared state, it can block the clean shutdown from proceeding. For this reason, if any prepared XA transactions are detected, the upgrade will be unable to proceed until you take action to commit or roll them back.

For more information on finding XA transactions in a prepared state using XA RECOVER, see [XA transaction SQL statements](#) in the MySQL documentation. For more information on XA transaction states, see [XA transaction states](#) in the MySQL documentation.

#### Example output:

```
{
  "id": "auroraUpgradeCheckForIncompleteXATransactions",
  "title": "Pre-checks for XA Transactions in prepared state.",
  "status": "OK",
  "description": "Your cluster currently has XA transactions in the prepared state. To proceed with the upgrade, commit or rollback these transactions.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "all",
      "description": "Your cluster currently has XA transactions in the prepared state. To proceed with the upgrade, commit or rollback these transactions."
    }
  ]
}
```

This precheck reports an error because there are transactions in a prepared state that should be committed or rolled back.

After logging into the database, you can check the [information\\_schema.innodb\\_trx](#) table and the XA RECOVER output for more information.

**⚠ Important**

Before committing or rolling back a transaction, we recommend that you review the [MySQL documentation](#) and your application requirements.

```
mysql> select trx_started,
  trx_mysql_thread_id,
  trx_id, trx_state,
  trx_operation_state,
  trx_rows_modified,
  trx_rows_locked
from
  information_schema.innodb_trx;
+-----+-----+-----+-----+
+-----+-----+-----+-----+
| trx_started          | trx_mysql_thread_id | trx_id | trx_state |
| trx_operation_state | trx_rows_modified   | trx_rows_locked |
+-----+-----+-----+-----+
| 2024-08-12 01:09:39 |                    | 0      | RUNNING   | NULL
|                    | 1                  | 0      |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> xa recover;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data    |
+-----+-----+-----+-----+
| 1        | 6            | 0            | xatest  |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

In this case, we roll back the prepared transaction.

```
mysql> XA ROLLBACK 'xatest';
Query OK, 0 rows affected (0.00 sec)
v
mysql> xa recover;
Empty set (0.00 sec)
```

After the XA transaction is rolled back, the precheck succeeds.

```
{
  "id": "auroraUpgradeCheckForIncompleteXATransactions",
  "title": "Pre-checks for XA Transactions in prepared state.",
  "status": "OK",
  "detectedProblems": []
}
```

## auroraUpgradeCheckForInstanceLimit

### Precheck level: Error

#### Check whether upgrade is supported on the current instance class

Running an in-place upgrade from Aurora MySQL version 2.12.0 or 2.12.1, where the writer [DB instance class](#) is db.r6i.32xlarge, is currently not supported. In this case, the precheck returns an error. To allow the upgrade to proceed, you can either change your DB instance class to db.r6i.24xlarge or smaller. Or you can upgrade to Aurora MySQL version 2.12.2 or higher, where in-place upgrade to Aurora MySQL version 3 is supported on db.r6i.32xlarge.

#### Example output:

```
{
  "id": "auroraUpgradeCheckForInstanceLimit",
  "title": "Checks if upgrade is supported on the current instance class",
  "status": "OK",
  "description": "Upgrade from Aurora Version 2.12.0 and 2.12.1 may fail for 32.xl and above instance class.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "all",
      "description": "Upgrade is not supported on this instance size for Aurora MySQL Version 2.12.1. Before upgrading to Aurora MySQL 3, please consider either: 1. Changing the instance class to 24.xl or lower. -or- 2. Upgrading to patch version 2.12.2 or higher."
    }
  ]
},
```

The precheck returns an error because the writer DB instance is using the db.r6i.32xlarge instance class, and is running on Aurora MySQL version 2.12.1.

## **auroraUpgradeCheckForInternalUsers**

**Precheck level: Error**

### **Check for 8.0 internal users**

This precheck applies only to Aurora MySQL version 3.03.0 and lower. If you encounter an error with this precheck, upgrade to Aurora MySQL version 3.04 or higher.

**Example output:**

```
{
  "id": "auroraUpgradeCheckForInternalUsers",
  "title": "Check for 8.0 internal users.",
  "status": "OK",
  "detectedProblems": []
}
```

## **auroraUpgradeCheckForInvalidUtf8mb3CharacterStringInViews**

**Precheck level: Error**

### **Check for invalid utf8mb3 characters in view definition**

This precheck identifies views that contain comments with invalid utf8mb3 character encoding. In MySQL 8.0, stricter validation is applied to character encoding in metadata, including view comments. If any view definition contains characters that are not valid in the utf8mb3 character set, the upgrade fails.

To resolve this issue, modify the view definition to remove or replace any non-BMP characters before you attempt the upgrade.

**Example output:**

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3CharacterStringInViews",
  "title": "Check for invalid utf8mb3 character string.",
  "status": "OK",
  "description": "Definition of following view(s) has/have invalid utf8mb3 character string.",
  "detectedProblems": [
```

```

    {
      "level": "Error",
      "dbObject": "precheck.utf8mb3_invalid_char_view",
      "description": "Definition of view precheck.utf8mb3_invalid_char_view
contains an invalid utf8mb3 character string. This is due to https://
bugs.mysql.com/bug.php?id=110177. To fix the inconsistency, we recommend you to
modify the view definition to not use non-BMP characters and try the upgrade
again."
    }
  ]
},

```

The precheck reports that the `utf8mb3_invalid_char_view` view definition contains invalid `utf8mb3` characters in its definition.

To resolve this issue, identify the view that contains the unsupported characters and update the comments. First, examine the view structure and identify comments.

```

MySQL> SHOW CREATE VIEW precheck.utf8mb3_invalid_char_view\G
***** 1. row *****
          View: utf8mb3_invalid_char_view
          Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`admin`@`%` SQL SECURITY
DEFINER VIEW `utf8mb3_invalid_char_view` AS select 'This row contains a dolphin #'
AS `message`
character_set_client: utf8
collation_connection: utf8_general_ci
1 row in set, 1 warning (0.00 sec)

```

Once you've identified the view that contains the error, replace the view with the `CREATE OR REPLACE VIEW` statement.

```

MySQL> CREATE OR REPLACE VIEW precheck.utf8mb3_invalid_char_view AS select 'This
view definition to not use non-BMP characters' AS message;

```

After updating all view definitions that contain unsupported characters, the precheck passes and the upgrade can proceed.

```

{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3ColumnComments",
  "title": "Check for invalid utf8mb3 column comments.",
  "status": "OK",
  "detectedProblems": []
}

```

```
}
```

## auroraUpgradeCheckForInvalidUtf8mb3ColumnComments

### Precheck level: Error

#### Check for invalid utf8mb3 column comments

This precheck identifies tables that contain column comments with invalid utf8mb3 character encoding. In MySQL 8.0, stricter validation is applied to character encoding in metadata, including column comments. If any column comments contain characters that are not valid in the utf8mb3 character set, the upgrade will fail.

To resolve this issue, you must modify the column comments to remove or replace any non-BMP characters before attempting the upgrade. You can use the ALTER TABLE statement to update the column comments.

#### Example output:

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3ColumnComments",
  "title": "Check for invalid utf8mb3 column comments.",
  "status": "OK",
  "description": "Following table(s) has/have invalid utf8mb3 comments on the
column/columns.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.t2",
      "description": "Table test.t2 has invalid utf8mb3 comments in it's column/
columns. This is due to non-BMP characters in the comment field. To fix the
inconsistency, we recommend you to modify comment fields to not use non-BMP
characters and try the upgrade again."
    }
  ]
}
```

The precheck reports that the test.t2 table contains invalid utf8mb3 characters in one or more column comments, specifically due to the presence of non-BMP characters.

To resolve this issue, you can identify the problematic columns and update their comments. First, examine the table structure to identify columns with comments:

```
mysql> SHOW CREATE TABLE test.t2\G
```

Once you've identified the columns with problematic comments, update them using the ALTER TABLE statement. For example:

```
mysql> ALTER TABLE test.t2 MODIFY COLUMN column_name data_type COMMENT 'Updated comment without non-BMP characters';
```

Alternatively, you can remove the comment entirely:

```
mysql> ALTER TABLE test.t2 MODIFY COLUMN column_name data_type COMMENT '';
```

After updating all problematic column comments, the precheck will pass and the upgrade can proceed:

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3ColumnComments",
  "title": "Check for invalid utf8mb3 column comments.",
  "status": "OK",
  "detectedProblems": []
}
```

### Note

Before modifying column comments, ensure that any application code or documentation that relies on these comments is updated accordingly. Consider migrating to the utf8mb4 character set for better Unicode support if your application requires non-BMP characters.

## **auroraUpgradeCheckForInvalidUtf8mb3IndexComments**

**Precheck level: Error**

### **Check for invalid utf8mb3 index comments**

This precheck identifies tables that contain index comments with invalid utf8mb3 character encoding. In MySQL 8.0, stricter validation is applied to character encoding in metadata,

including index comments. If any index comments contain characters that are not valid in the utf8mb3 character set, the upgrade fails.

To resolve this issue, you must modify the index comments to remove or replace any non-BMP characters before attempting the upgrade.

### Example output:

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3IndexComments",
  "title": "Check for invalid utf8mb3 index comments.",
  "status": "OK",
  "description": "Following table(s) has/have invalid utf8mb3 comments on the
index.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "precheck.utf8mb3_tab_index_comment",
      "description": "Table precheck.utf8mb3_tab_index_comment has invalid
utf8mb3 comments in it's index. This is due to https://bugs.mysql.com/bug.php?
id=110177. To fix the inconsistency, we recommend you to modify comment fields to
not use non-BMP characters and try the upgrade again."
    }
  ]
},
```

The precheck reports that the utf8mb3\_tab\_index\_comment table contains invalid utf8mb3 characters in one or more column comments, specifically due to the presence of non-BMP characters.

To resolve this issue, first, examine the table structure to identify the index with problematic comments.

```
MySQL> SHOW CREATE TABLE precheck.utf8mb3_tab_index_comment\G
***** 1. row *****
      Table: utf8mb3_tab_index_comment
Create Table: CREATE TABLE `utf8mb3_tab_index_comment` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(100) DEFAULT NULL,
  KEY `idx_name` (`name`) COMMENT 'Name index #'
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.01 sec)
```

Once you identify the index that contains comments that use unsupported characters, drop and recreate the index.

**Note**

Dropping and recreating a table index can lead to downtime. We recommend that you plan and schedule this operation during maintenance.

```
MySQL> ALTER TABLE precheck.utf8mb3_tab_index_comment DROP INDEX idx_name;
MySQL> ALTER TABLE precheck.utf8mb3_tab_index_comment ADD INDEX idx_name(name);
```

The following example shows another way to recreate the index.

```
MySQL> ALTER TABLE utf8mb3_tab_index_comment DROP INDEX idx_name, ADD INDEX idx_name
(name) COMMENT 'Updated comment without non-BMP characters';
```

After you remove or update all unsupported index comments, the precheck passes and the upgrade can proceed.

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3IndexComments",
  "title": "Check for invalid utf8mb3 index comments.",
  "status": "OK",
  "detectedProblems": [],
},
```

## auroraUpgradeCheckForInvalidUtf8mb3TableComments

### Precheck level: Error

#### Check for invalid utf8mb3 characters in table definition

This precheck identifies tables that contain comments with invalid utf8mb3 character encoding. In MySQL 8.0, stricter validation is applied to character encoding in metadata, including table comments. If any table comments contain characters that are not valid in the utf8mb3 character set, the upgrade fails.

To resolve this issue, you must modify the table comments to remove or replace any non-BMP characters before attempting the upgrade.

**Example output:**

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3TableComments",
  "title": "Check for invalid utf8mb3 table comments.",
  "status": "OK",
  "description": "Following table(s) has/have invalid utf8mb3 comments.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "precheck.utf8mb3_table_with_comment",
      "description": "Table precheck.utf8mb3_table_with_comment has invalid
utf8mb3 comments. This is due to https://bugs.mysql.com/bug.php?id=110177. To fix
the inconsistency, we recommend you to modify comment fields to not use non-BMP
characters and try the upgrade again."
    }
  ]
},
```

The precheck reports invalid utf8mb3 comments defined for the `utf8mb3_table_with_comment` tables in the test database.

To resolve this issue, identify the table that contains unsupported characters and update the comments. First, examine the table structure and identify the comments.

```
MySQL> SHOW CREATE TABLE precheck.utf8mb3_table_with_comment\G
***** 1. row *****
      Table: utf8mb3_table_with_comment
Create Table: CREATE TABLE `utf8mb3_table_with_comment` (
  `id` int(11) NOT NULL,
  `name` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COMMENT='This table comment contains flag ##'
1 row in set (0.00 sec)
```

Once you've identified table comments that contain unsupported characters, update the comments with the `ALTER TABLE` statement.

```
MySQL> ALTER TABLE precheck.utf8mb3_table_with_comment COMMENT='Updated comment
without non-BMP characters';
```

Alternatively, you can remove the comment.

```
MySQL> ALTER TABLE precheck.utf8mb3_table_with_comment COMMENT='';
```

After you remove all unsupported characters from all table comments, the precheck succeeds.

```
{
  "id": "auroraUpgradeCheckForInvalidUtf8mb3TableComments",
  "title": "Check for invalid utf8mb3 table comments.",
  "status": "OK",
  "detectedProblems": [],
},
```

## auroraUpgradeCheckForMasterUser

### Precheck level: Error

#### Check whether RDS master user exists

MySQL 8 has added a new privilege model with support for [role](#) and [dynamic privileges](#) to make privilege management easier and more fine grained. As part of this change, Aurora MySQL has introduced the new `rds_superuser_role`, which is automatically granted to the database's master user on upgrade from Aurora MySQL version 2 to version 3.

For more information on the roles and privileges assigned to the master user in Aurora MySQL, see [Master user account privileges](#). For more information on the role-based privilege model in Aurora MySQL version 3, see [Role-based privilege model](#).

This precheck verifies that the master user exists in the database. If the master user doesn't exist, the precheck fails. To allow the upgrade to proceed, re-create the master user by resetting the master user password, or by manually creating the user. Then retry the upgrade. For more information on resetting the master user password, see [Changing the password for the database master user](#).

#### Example output:

```
{
  "id": "auroraUpgradeCheckForMasterUser",
  "title": "Check if master user exists",
  "status": "OK",
  "description": "Throws error if master user has been dropped!",
}
```

```

  "documentationLink": "https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/UsingWithRDS.MasterAccounts.html",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "all",
      "description": "Your Master User on host '%' has been dropped. To proceed with the upgrade, recreate the master user `reinvent` on default host '%"
    }
  ]
}

```

After you reset your master user password, the precheck will pass, and you can retry the upgrade.

The following example uses the Amazon CLI to reset the password. Password changes are applied immediately.

```

aws rds modify-db-cluster \
  --db-cluster-identifier my-db-cluster \
  --master-user-password my-new-password

```

Then the precheck succeeds.

```

{
  "id": "auroraUpgradeCheckForMasterUser",
  "title": "Check if master user exists",
  "status": "OK",
  "detectedProblems": []
}

```

## auroraUpgradeCheckForPrefixIndexOnGeometryColumns

### Precheck level: Error

#### Check for geometry columns on prefix indexes

As of [MySQL 8.0.12](#), you can no longer create a [prefixed](#) index on a column using the [GEOMETRY](#) data type. For more information, see [WL#11808](#).

If any such indexes exist, your upgrade will fail. To resolve the issue, drop the prefixed GEOMETRY indexes on the tables mentioned in the precheck failure.

**Example output:**

```
{
  "id": "auroraUpgradeCheckForPrefixIndexOnGeometryColumns",
  "title": "Check for geometry columns on prefix indexes",
  "status": "OK",
  "description": "Consider dropping the prefix Indexes of geometry columns and
restart the upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.geom_index_prefix",
      "description": "Table `test`.`geom_index_prefix` has an index `LatLon` on
geometry column/s. Mysql 8.0 does not support this type of index on a geometry
column https://dev.mysql.com/worklog/task/?id=11808. To upgrade to MySQL 8.0, Run
'DROP INDEX `LatLon` ON `test`.`geom_index_prefix`;"
    }
  ]
}
```

The precheck reports an error because the `test.geom_index_prefix` table contains an index with a prefix on a GEOMETRY column.

After you drop this index, the precheck succeeds.

```
{
  "id": "auroraUpgradeCheckForPrefixIndexOnGeometryColumns",
  "title": "Check for geometry columns on prefix indexes",
  "status": "OK",
  "detectedProblems": []
}
```

**auroraUpgradeCheckForSpecialCharactersInProcedures****Precheck level: Error****Check for inconsistency related to special characters in stored procedures**

Before MySQL 8.0, database names, table names, and other objects corresponded to files in the data directory, that is, file-based metadata. As part of the upgrade to MySQL 8.0, all database objects are migrated to the new internal data dictionary tables that are stored in the `mysql` schema to support the newly implemented [Atomic Data Dictionary](#). As part of migrating stored

procedures, the procedure definition and body for each procedure is validated as it's ingested into the new data dictionary.

Before MySQL 8, in some cases it was possible to create stored routines, or insert directly into the `mysql.proc` table, procedures that contained special characters. For example, you could create a stored procedure that contained a comment with the noncompliant, [non-breaking space character](#) `\xa0`. If any such procedures are encountered, the upgrade fails.

This precheck validates that the bodies and definitions of your stored procedures don't contain any such characters. To allow the upgrade to proceed, re-create these stored procedures without any hidden or special characters.

### Example output:

```
{
  "id": "auroraUpgradeCheckForSpecialCharactersInProcedures",
  "title": "Check for inconsistency related to special characters in stored
procedures.",
  "status": "OK",
  "description": "Following procedure(s) has special characters inconsistency.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "information_schema.routines",
      "description": "Data Dictionary Metadata is inconsistent for the procedure
`get_version_proc` in the database `test` due to usage of special characters in
procedure body. To avoid that, drop and recreate the procedure without any special
characters before proceeding with the Upgrade."
    }
  ]
}
```

The precheck reports that the DB cluster contains a procedure called `get_version_proc` in the `test` database that contains special characters in the procedure body.

After dropping and re-creating the stored procedure, the precheck succeeds, allowing the upgrade to proceed.

```
{
  "id": "auroraUpgradeCheckForSpecialCharactersInProcedures",
  "title": "Check for inconsistency related to special characters in stored
procedures.",
```

```
"status": "OK",
"detectedProblems": []
},
```

## auroraUpgradeCheckForSysSchemaObjectTypeMismatch

**Precheck level: Error**

### Check object type mismatch for sys schema

The [sys schema](#) is a set of objects and views in a MySQL database that helps users troubleshoot, optimize, and monitor their DB instances. When performing a major version upgrade from Aurora MySQL version 2 to version 3, the sys schema views are re-created and updated to the new Aurora MySQL version 3 definitions.

As part of the upgrade, if any objects in the sys schema are defined using storage engines (sys\_config/BASE TABLE in [INFORMATION\\_SCHEMA.TABLES](#)), rather than views, the upgrade will fail. Such tables can be found in the `information_schema.tables` table. This is not an expected behavior, but in some cases can occur due to user error.

This precheck validates all sys schema objects to ensure that they use the correct table definitions, and that views aren't mistakenly defined as InnoDB or MyISAM tables. To resolve the issue, manually fix any returned objects by renaming or dropping them. Then retry the upgrade.

### Example output:

```
{
  "id": "auroraUpgradeCheckForSysSchemaObjectTypeMismatch",
  "title": "Check object type mismatch for sys schema.",
  "status": "OK",
  "description": "Database contains objects with type mismatch for sys schema.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "sys.waits_global_by_latency",
      "description": "Your object sys.waits_global_by_latency has a type mismatch.
To fix the inconsistency we recommend to rename or remove the object before
upgrading (use RENAME TABLE command). "
    }
  ]
}
```

The precheck reports that the [sys.waits\\_global\\_by\\_latency](#) view in the sys schema has a type mismatch that is blocking the upgrade from proceeding.

After logging into the DB instance, you can see that this object is defined as a InnoDB table, when it should be a view.

```
mysql> show create table sys.waits_global_by_latency\G
***** 1. row *****
      Table: waits_global_by_latency
Create Table: CREATE TABLE `waits_global_by_latency` (
  `events` varchar(128) DEFAULT NULL,
  `total` bigint(20) unsigned DEFAULT NULL,
  `total_latency` text,
  `avg_latency` text,
  `max_latency` text
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)
```

To resolve this issue we can either drop and re-create the view with the [correct definition](#) or rename it. During the upgrade process, it will be automatically created with the correct table definition.

```
mysql> RENAME TABLE sys.waits_global_by_latency to sys.waits_global_by_latency_old;
Query OK, 0 rows affected (0.01 sec)
```

After doing this, the precheck passes.

```
{
  "id": "auroraUpgradeCheckForSysSchemaObjectTypeMismatch",
  "title": "Check object type mismatch for sys schema.",
  "status": "OK",
  "detectedProblems": []
}
```

## auroraUpgradeCheckForViewColumnNameLength

**Precheck level: Error**

**Check upper limit for column name in view**

The [maximum permitted length of a column name](#) in MySQL is 64 characters. Before MySQL 8.0, in some cases it was possible to create a view with a column name larger than 64

```
2 rows in set (0.00 sec)
```

To allow the upgrade to proceed, re-create the view, making sure that the column length doesn't exceed 64 characters.

```
mysql> drop view `test`.`colname_view_test`;
Query OK, 0 rows affected (0.01 sec)

mysql> create view `test`.`colname_view_test`(col1, col2_nopad) as select inf,
  fodcol from test;
Query OK, 0 rows affected (0.01 sec)

mysql> desc `test`.`colname_view_test`;
+-----+-----+-----+-----+-----+-----+
| Field      | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| col1       | varchar(20)  | YES  |     | NULL    |      |
| col2_nopad | int(11)       | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

After doing this, the precheck succeeds.

```
{
  "id": "auroraUpgradeCheckForViewColumnNameLength",
  "title": "Check for upperbound limit related to column name in view.",
  "status": "OK",
  "detectedProblems": []
}
```

## auroraUpgradeCheckIndexLengthLimitOnTinyColumns

### Precheck level: Error

#### Check for tables with indexes defined with a prefix length greater than 255 bytes on tiny columns

When creating an index on a column using a [binary data type](#) in MySQL, you must add a [prefix length](#) in the index definition. Before MySQL 8.0, in some cases it was possible to specify a prefix length larger than the maximum allowed size of such data types. An example is TINYTEXT and TINYBLOB columns, where the maximum permitted data size is 255 bytes, but

index prefixes larger than this were permitted. For more information, see [InnoDB limits](#) in the MySQL documentation.

If this precheck fails, drop the offending index or reduce the prefix length of TINYTEXT and TINYBLOB columns of the index to less than 255 bytes. Then retry the upgrade.

### Example output:

```
{
  "id": "auroraUpgradeCheckIndexLengthLimitOnTinyColumns",
  "title": "Check for the tables with indexes defined with prefix length greater than 255 bytes on tiny columns",
  "status": "OK",
  "description": "Prefix length of the indexes defined on tiny columns cannot exceed 255 bytes. With utf8mb4 char set, this limits the prefix length supported upto 63 characters only. A larger prefix length was allowed in MySQL5.7 using innodb_large_prefix parameter. This parameter is deprecated in MySQL 8.0.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/innodb-limits.html, https://dev.mysql.com/doc/refman/8.0/en/storage-requirements.html",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.tintxt_prefixed_index.col1",
      "description": "Index 'PRIMARY' on tinytext/tinyblob column `col1` of table `test.tintxt_prefixed_index` is defined with prefix length exceeding 255 bytes. Reduce the prefix length to <=255 bytes depending on character set used. For utf8mb4, it should be <=63."
    }
  ]
}
```

The precheck reports an error for the `test.tintxt_prefixed_index` table, because it has an Index PRIMARY that has a prefix larger than 255 bytes on a TINYTEXT or TINYBLOB column.

Looking at the definition for this table, we can see that the primary key has a prefix of 65 on the TINYTEXT column `col1`. Because the table is defined using the `utf8mb4` character set, which stores 4 bytes per character, the prefix exceeds the 255-byte limit.

```
mysql> show create table `test`.`tintxt_prefixed_index`\G
***** 1. row *****
      Table: tintxt_prefixed_index
Create Table: CREATE TABLE `tintxt_prefixed_index` (
```

```

`col1` tinytext NOT NULL,
`col2` tinytext,
`col_id` tinytext,
PRIMARY KEY (`col1`(65))
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 ROW_FORMAT=DYNAMIC
1 row in set (0.00 sec)

```

Modifying the index prefix to 63 while using the utf8mb4 character set will allow the upgrade to proceed.

```

mysql> alter table `test`.`tintxt_prefixed_index` drop PRIMARY KEY, ADD PRIMARY KEY
(`col1`(63));
Query OK, 0 rows affected (0.04 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

After doing this, the precheck succeeds.

```

{
  "id": "auroraUpgradeCheckIndexLengthLimitOnTinyColumns",
  "title": "Check for the tables with indexes defined with prefix length greater
than 255 bytes on tiny columns",
  "status": "OK",
  "detectedProblems": []
}

```

## auroraUpgradeCheckMissingInnodbMetadataForMysqlHostTable

**Precheck level: Error**

### Check missing InnoDB metadata inconsistency for the mysql.host table

This is an internal-only precheck carried out by the RDS service. Any errors will be automatically handled on upgrade and can be safely ignored.

If you encounter any errors with this precheck, open a case with [Amazon Support](#) to request that the metadata inconsistency be resolved. Alternatively, you can retry the upgrade by performing a logical dump, then restoring to a new Aurora MySQL version 3 DB cluster.

## Warnings

The following prechecks generate warnings when the precheck fails, but the upgrade can proceed.

## Topics

- [MySQL prechecks that report warnings](#)
- [Aurora MySQL prechecks that report warnings](#)

### MySQL prechecks that report warnings

The following prechecks are from Community MySQL:

- [defaultAuthenticationPlugin](#)
- [maxdbFlagCheck](#)
- [mysqlDollarSignNameCheck](#)
- [reservedKeywordsCheck](#)
- [utf8mb3Check](#)
- [zeroDatesCheck](#)

#### defaultAuthenticationPlugin

**Precheck level: Warning**

##### New default authentication plugin considerations

In MySQL 8.0, the `caching_sha2_password` authentication plugin was introduced, providing more secure password encryption and better performance than the deprecated `mysql_native_password` plugin. For Aurora MySQL version 3, the default authentication plugin used for database users is the `mysql_native_password` plugin.

This precheck warns that this plugin will be removed and the default changed in a future major version release. Consider evaluating the compatibility of your application clients and users ahead of this change.

For more information, see [caching\\_sha2\\_password compatibility issues and solutions](#) in the MySQL documentation.

##### Example output:

```
{
  "id": "defaultAuthenticationPlugin",
  "title": "New default authentication plugin considerations",
```

```

    "description": "Warning: The new default authentication plugin
    'caching_sha2_password' offers more secure password hashing than previously
    used 'mysql_native_password' (and consequent improved client connection
    authentication). However, it also has compatibility implications that
    may affect existing MySQL installations. If your MySQL installation
    must serve pre-8.0 clients and you encounter compatibility issues after
    upgrading, the simplest way to address those issues is to reconfigure
    the server to revert to the previous default authentication plugin
    (mysql_native_password). For example, use these lines in the server option file:
    \n\n[mysqld]\ndefault_authentication_plugin=mysql_native_password\n\nHowever, the
    setting should be viewed as temporary, not as a long term or permanent solution,
    because it causes new accounts created with the setting in effect to forego the
    improved authentication security.\nIf you are using replication please take time to
    understand how the authentication plugin changes may impact you.",
    "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/upgrading-from-
    previous-series.html#upgrade-caching-sha2-password-compatibility-issues\nhttps://
    dev.mysql.com/doc/refman/8.0/en/upgrading-from-previous-series.html#upgrade-caching-
    sha2-password-replication"
  },

```

## maxdbFlagCheck

### Precheck level: Warning

### Usage of obsolete MAXDB sql\_mode flag

In MySQL 8.0, a number of deprecated [sql\\_mode](#) system variable options were [removed](#), one of which was MAXDB. This precheck examines all currently connected sessions, along with routines and triggers, to ensure that none have sql\_mode set to any combination that includes MAXDB.

### Example output:

```

{
  "id": "maxdbFlagCheck",
  "title": "Usage of obsolete MAXDB sql_mode flag",
  "status": "OK",
  "description": "Warning: The following DB objects have the obsolete MAXDB
  option persisted for sql_mode, which will be cleared during the upgrade. It can
  potentially change the datatype DATETIME into TIMESTAMP if it is used inside
  object's definition, and this in turn can change the behavior in case of dates
  earlier than 1970 or later than 2037. If this is a concern, please redefine these
  objects so that they do not rely on the MAXDB flag before running the upgrade.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/mysql-
  nutshell.html#mysql-nutshell-removals",

```

```

"detectedProblems": [
  {
    "level": "Warning",
    "dbObject": "test.maxdb_stored_routine",
    "description": "PROCEDURE uses obsolete MAXDB sql_mode",
    "dbObjectType": "Routine"
  }
]
}

```

The precheck reports that the `test.maxdb_stored_routine` routine contains a unsupported `sql_mode` option.

After logging into the database, you can see in the routine definition that `sql_mode` contains `MAXDB`.

```

> SHOW CREATE PROCEDURE test.maxdb_stored_routine\G

***** 1. row *****
      Procedure: maxdb_stored_routine
      sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,MAXDB,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPT
      Create Procedure: CREATE DEFINER="msandbox"@localhost PROCEDURE
"maxdb_stored_routine"()
BEGIN
  SELECT * FROM test;
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
1 row in set (0.00 sec)

```

To resolve the issue, re-create the procedure after setting the correct `sql_mode` on the client.

### Note

According to the [MySQL documentation](#), MySQL stores the `sql_mode` setting that's in effect when a routine is created or altered. It always runs the routine with this setting, regardless of the `sql_mode` setting when the routine starts.

Before changing `sql_mode`, see [Server SQL modes](#) in the MySQL documentation. Carefully evaluate any potential impact of doing so on your application.

## Re-create the procedure without the unsupported `sql_mode`.

```
mysql > set sql_mode='PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE';
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql > DROP PROCEDURE test.maxdb_stored_routine\G
Query OK, 0 rows affected (0.00 sec)

mysql >
mysql > DELIMITER $$
mysql >
mysql > CREATE PROCEDURE test.maxdb_stored_routine()
  -> SQL SECURITY DEFINER
  -> BEGIN
  ->     SELECT * FROM test;
  -> END$$
Query OK, 0 rows affected (0.00 sec)

mysql >
mysql > DELIMITER ;
mysql > show create procedure test.maxdb_stored_routine\G
***** 1. row *****
      Procedure: maxdb_stored_routine
      sql_mode: PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE
      Create Procedure: CREATE DEFINER="msandbox"@"localhost" PROCEDURE
      "maxdb_stored_routine"()
      BEGIN
      SELECT * FROM test;
      END
      character_set_client: utf8
      collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
      1 row in set (0.00 sec)
```

## The precheck succeeds.

```
{
  "id": "maxdbFlagCheck",
  "title": "Usage of obsolete MAXDB sql_mode flag",
  "status": "OK",
  "detectedProblems": []
}
```

## mysqlDollarSignNameCheck

### Precheck level: Warning

#### Check for deprecated usage of single dollar signs in object names

As of [MySQL 8.0.32](#), use of the dollar sign (\$) as the first character of an unquoted identifier is deprecated. If you have any schemas, tables, views, columns, or routines containing a \$ as the first character, this precheck returns a warning. While this warning doesn't block the upgrade from proceeding, we recommend that you take action soon to resolve this. From [MySQL 8.4](#) any such identifiers will return a syntax error rather than a warning.

#### Example output:

```
{
  "id": "mysqlDollarSignNameCheck",
  "title": "Check for deprecated usage of single dollar signs in object names",
  "status": "OK",
  "description": "Warning: The following objects have names with deprecated usage of dollar sign ($) at the begining of the identifier. To correct this warning, ensure, that names starting with dollar sign, also end with it, similiary to quotes ($example$). ",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "test.$deprecated_syntx",
      "description": " name starts with $ sign."
    }
  ]
},
```

The precheck reports a warning because the \$deprecated\_syntx table in the test schema contains a \$ as the first character.

## reservedKeywordsCheck

### Precheck level: Warning

#### Usage of database objects with names conflicting with new reserved keywords

This check is similar to the [routineSyntaxCheck](#), in that it checks for usage of database objects with names conflicting with new reserved keywords. While they don't block upgrades, you need to evaluate warnings carefully.

## Example output:

Using the previous example with the table named `except`, the precheck returns a warning:

```
{
  "id": "reservedKeywordsCheck",
  "title": "Usage of db objects with names conflicting with new reserved keywords",
  "status": "OK",
  "description": "Warning: The following objects have names that conflict with new reserved keywords. Ensure queries sent by your applications use `quotes` when referring to them or they will result in errors.",
  "documentationLink": "https://dev.mysql.com/doc/refman/en/keywords.html",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "test.except",
      "description": "Table name",
      "dbObjectType": "Table"
    }
  ]
}
```

This warning lets you know that there might be some application queries to review. If your application queries aren't correctly [escaping string literals](#), they might experience errors after upgrading to MySQL 8.0. Review your applications to confirm, testing against a clone or snapshot of your Aurora MySQL DB cluster running on version 3.

Example of a non-escaped application query that will fail after upgrading:

```
SELECT * FROM escape;
```

Example of a correctly escaped application query that will succeed after upgrading:

```
SELECT * FROM 'escape';
```

## utf8mb3Check

**Precheck level: Warning**

**Usage of utf8mb3 character set**

In MySQL 8.0 the `utf8mb3` character set is deprecated, and will be removed in a future MySQL major version. This precheck is implemented to raise a warning if any database objects using this character set are detected. While this won't block an upgrade from proceeding, we highly recommend that you think about migrating tables to the `utf8mb4` character set, which is the default as of MySQL 8.0. For more information on [utf8mb3](#) and [utf8mb4](#), see [Converting between 3-byte and 4-byte Unicode character sets](#) in the MySQL documentation.

### Example output:

```
{
  "id": "utf8mb3",
  "title": "Usage of utf8mb3 charset",
  "status": "OK",
  "description": "Warning: The following objects use the deprecated utf8mb3
character set. It is recommended to convert them to use utf8mb4 instead, for
improved Unicode support. The utf8mb3 character is subject to removal in the
future.",
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/charset-unicode-
utf8mb3.html",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "test.t1.col1",
      "description": "column's default character set: utf8",
      "dbObjectType": "Column"
    },
    {
      "level": "Warning",
      "dbObject": "test.t1.col2",
      "description": "column's default character set: utf8",
      "dbObjectType": "Column"
    }
  ]
}
```

To resolve this issue, you rebuild the objects and tables referenced. For more information and prerequisites before doing so, see [Converting between 3-byte and 4-byte Unicode character sets](#) in the MySQL documentation.

## zeroDatesCheck

### Precheck level: Warning

## Zero date, datetime, and timestamp values

MySQL now enforces stricter rules regarding the use of zero values in date, datetime, and timestamp columns. We recommend that you use the `NO_ZERO_IN_DATE` and `NO_ZERO_DATE` SQL modes in conjunction with `strict` mode, as they will be merged with `strict` mode in a future MySQL release.

If the `sql_mode` setting for any of your database connections, at the time of running the precheck, doesn't include these modes, a warning is raised in the precheck. Users might still be able to insert date, datetime, and timestamp values containing zero values. However, we strongly advise replacing any zero values with valid ones, as their behavior might change in the future and they might not function correctly. As this is a warning, it won't block upgrades, but we recommend that you start planning to take action.

### Example output:

```
{
  "id": "zeroDatesCheck",
  "title": "Zero Date, Datetime, and Timestamp values",
  "status": "OK",
  "description": "Warning: By default zero date/datetime/timestamp values are no longer allowed in MySQL, as of 5.7.8 NO_ZERO_IN_DATE and NO_ZERO_DATE are included in SQL_MODE by default. These modes should be used with strict mode as they will be merged with strict mode in a future release. If you do not include these modes in your SQL_MODE setting, you are able to insert date/datetime/timestamp values that contain zeros. It is strongly advised to replace zero values with valid ones, as they may not work correctly in the future.",
  "documentationLink": "https://lefred.be/content/mysql-8-0-and-wrong-dates/",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "global.sql_mode",
      "description": "does not contain either NO_ZERO_DATE or NO_ZERO_IN_DATE which allows insertion of zero dates"
    },
    {
      "level": "Warning",
      "dbObject": "session.sql_mode",
      "description": " of 10 session(s) does not contain either NO_ZERO_DATE or NO_ZERO_IN_DATE which allows insertion of zero dates"
    }
  ]
}
```

```
}
```

## Aurora MySQL prechecks that report warnings

The following prechecks are specific to Aurora MySQL:

- [auroraUpgradeCheckForRollbackSegmentHistoryLength](#)
- [auroraUpgradeCheckForUncommittedRowModifications](#)

### auroraUpgradeCheckForRollbackSegmentHistoryLength

#### Precheck level: Warning

#### Checks whether the rollback segment history list length for the cluster is high

As mentioned in [auroraUpgradeCheckForIncompleteXATransactions](#), while running the major version upgrade process, it is essential that the Aurora MySQL version 2 DB instance undergo a [clean shutdown](#). This ensures that all transactions are committed or rolled back, and that InnoDB has purged all undo log records.

If your DB cluster has a high rollback segment history list length (HLL), it can prolong the amount of time that InnoDB takes to complete its purge of undo log records, leading to extended downtime during the major version upgrade process. If the precheck detects that the HLL on your DB cluster is high, it raises a warning. While this doesn't block your upgrade from proceeding, we recommend that you closely monitor the HLL on your DB cluster. Keeping it at low levels reduces the downtime required during a major version upgrade. For more information on monitoring HLL, see [The InnoDB history list length increased significantly](#).

#### Example output:

```
{
  "id": "auroraUpgradeCheckForRollbackSegmentHistoryLength",
  "title": "Checks if the rollback segment history length for the cluster is high",
  "status": "OK",
  "description": "Rollback Segment History length is greater than 1M. Upgrade may take longer time.",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "information_schema.innodb_metrics",
```

```
    "description": "The InnoDB undo history list length('trx_rseg_history_len')
is 82989114. Upgrade may take longer due to purging of undo information for old row
versions."
  }
]
}
```

The precheck returns a warning because it detected the InnoDB undo HLL was high on the database cluster (82989114). Although the upgrade proceeds, depending on the amount of undo to purge, it can extend the downtime required during the upgrade process.

We recommend that you [investigate open transactions](#) on your DB cluster before running the upgrade in production, to make sure your HLL is kept at a manageable size.

### **auroraUpgradeCheckForUncommittedRowModifications**

#### **Precheck level: Warning**

#### **Checks whether there are many uncommitted row modifications**

As mentioned in [auroraUpgradeCheckForIncompleteXATransactions](#), while running the major version upgrade process, it is essential that the Aurora MySQL version 2 DB instance undergo a [clean shutdown](#). This ensures that all transactions are committed or rolled back, and that InnoDB has purged all undo log records.

If your DB cluster has transactions that have modified a large number of rows, it can prolong the amount of time InnoDB takes to complete a rollback of this transaction as part of the clean shutdown process. If the precheck finds long-running transactions, with a large number of modified rows on your DB cluster, it raises a warning. While this doesn't block your upgrade from proceeding, we recommend that you closely monitor the size of active transactions on your DB cluster. Keeping it at low levels reduces the downtime required during a major version upgrade.

#### **Example output:**

```
{
  "id": "auroraUpgradeCheckForUncommittedRowModifications",
  "title": "Checks if there are many uncommitted modifications to rows",
  "status": "OK",
  "description": "Database contains uncommitted row changes greater than 10M.
Upgrade may take longer time.",
  "detectedProblems": [
```

```

    {
      "level": "Warning",
      "dbObject": "information_schema.innodb_trx",
      "description": "The database contains 11000000 uncommitted row change(s) in
1 transaction(s). Upgrade may take longer due to transaction rollback."
    }
  ]
},

```

The precheck reports that the DB cluster contains a transaction with 11,000,000 uncommitted row changes that will need to be rolled back during the clean shutdown process. The upgrade will proceed, but to reduce downtime during the upgrade process, we recommend that you monitor and investigate this before running the upgrade on your production clusters.

To view active transactions on your writer DB instance, you can use the [information\\_schema.innodb\\_trx](#) table. The following query on the writer DB instance shows current transactions, run time, state, and modified rows for the DB cluster.

```

# Example of uncommitted transaction
mysql> SELECT trx_started,
      TIME_TO_SEC(TIMEDIFF(now(), trx_started)) AS seconds_trx_has_been_running,
      trx_mysql_thread_id AS show_processlist_connection_id,
      trx_id,
      trx_state,
      trx_rows_modified AS rows_modified
FROM information_schema.innodb_trx;
+-----+-----+-----+-----+
+-----+-----+-----+-----+
| trx_started          | seconds_trx_has_been_running |
show_processlist_connection_id | trx_id    | trx_state | rows_modified |
+-----+-----+-----+-----+
+-----+-----+-----+-----+
| 2024-08-12 18:32:52 |                               | 1592 |
20041 | 52866130 | RUNNING  |      11000000 |
+-----+-----+-----+-----+
+-----+-----+-----+-----+
1 row in set (0.01 sec)

# Example of transaction rolling back
mysql> SELECT trx_started,
      TIME_TO_SEC(TIMEDIFF(now(), trx_started)) AS seconds_trx_has_been_running,
      trx_mysql_thread_id AS show_processlist_connection_id,
      trx_id,

```

```

    trx_state,
    trx_rows_modified AS rows_modified
FROM information_schema.innodb_trx;
+-----+-----+-----+-----+
+-----+-----+-----+-----+
| trx_started          | seconds_trx_has_been_running |
show_processlist_connection_id | trx_id   | trx_state   | rows_modified |
+-----+-----+-----+-----+
+-----+-----+-----+-----+
| 2024-08-12 18:32:52 |          1719 |
20041 | 52866130 | ROLLING BACK | 10680479 |
+-----+-----+-----+-----+
+-----+-----+-----+-----+
1 row in set (0.01 sec)

```

After the transaction is committed or rolled back, the precheck no longer returns a warning. Consult the MySQL documentation and your application team before rolling back any large transactions, as rollback can take some time to complete, depending on transaction size.

```

{
  "id": "auroraUpgradeCheckForUncommittedRowModifications",
  "title": "Checks if there are many uncommitted modifications to rows",
  "status": "OK",
  "detectedProblems": []
},

```

For more information on optimizing InnoDB transaction management, and the potential impact of running and rolling back large transactions on MySQL database instances, see [Optimizing InnoDB transaction management](#) in the MySQL documentation.

## Notices

The following precheck generates a notice when the precheck fails, but the upgrade can proceed.

### sqlModeFlagCheck

#### Precheck level: Notice

#### Usage of obsolete sql\_mode flags

In addition to MAXDB, a number of other sql\_mode options have been [removed](#): DB2, MSSQL, MYSQL323, MYSQL40, ORACLE, POSTGRESQL, NO\_FIELD\_OPTIONS, NO\_KEY\_OPTIONS, and

NO\_TABLE\_OPTIONS. As of MySQL 8.0, none of these values can be assigned to the `sql_mode` system variable. If this precheck finds any open sessions using these `sql_mode` settings, make sure that your DB instance and DB cluster parameter groups, and client applications and configurations, are updated to disable them.- For more information, see the [MySQL documentation](#).

### Example output:

```
{
  "id": "sqlModeFlagCheck",
  "title": "Usage of obsolete sql_mode flags",
  "status": "OK",
  "detectedProblems": []
}
```

To resolve any of these precheck failures, see [maxdbFlagCheck](#).

## Errors, warnings, or notices

The following precheck can return an error, warning, or notice depending on the precheck output.

### checkTableOutput

#### Precheck level: Error, Warning, or Notice

#### Issues reported by the check `table x for upgrade` command

Before starting the upgrade to Aurora MySQL version 3, `check table for upgrade` is run on each table in the user schemas in your DB cluster. This precheck isn't the same as [checkTableMysqlSchema](#).

The `check table for upgrade` command examines tables for any potential issues that might arise during an upgrade to a newer version of MySQL. Running this command before attempting an upgrade can help identify and resolve any incompatibilities ahead of time, making the actual upgrade process smoother.

This command performs various checks on each table, such as the following:

- Verifying that the table structure and metadata are compatible with the target MySQL version
- Checking for any deprecated or removed features used by the table

- Ensuring that the table can be properly upgraded without data loss

Unlike other prechecks, it can return an error, warning, or notice depending on the check table output. If this precheck returns any tables, review them carefully, along with the return code and message before initiating the upgrade. For more information, see [CHECK TABLE statement](#) in the MySQL documentation.

Here we provide an error example and a warning example.

### Error example:

```
{
  "id": "checkTableOutput",
  "title": "Issues reported by 'check table x for upgrade' command",
  "status": "OK",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "test.parent",
      "description": "Table 'test.parent' doesn't exist"
    }
  ]
},
```

The precheck reports an error that the `test.parent` table doesn't exist.

The `mysql-error.log` file for the writer DB instance shows that there is a foreign key error.

```
2024-08-13T15:32:10.676893Z 62 [Warning] InnoDB: Load table `test`.`parent` failed,
the table has missing foreign key indexes. Turn off 'foreign_key_checks' and try
again.
2024-08-13T15:32:10.676905Z 62 [Warning] InnoDB: Cannot open table test/parent from
the internal data dictionary of InnoDB though the .frm file for the table exists.
Please refer to http://dev.mysql.com/doc/refman/5.7/en/innodb-troubleshooting.html
for how to resolve the issue.
```

Log into the writer DB instance and run `show engine innodb status\G` to get more information on the foreign key error.

```
mysql> show engine innodb status\G
***** 1. row *****
Type: InnoDB
```

```

Name:
Status:
=====
2024-08-13 15:33:33 0x14ef7b8a1700 INNODB MONITOR OUTPUT
=====
.
.
.
-----
LATEST FOREIGN KEY ERROR
-----
2024-08-13 15:32:10 0x14ef6dbbb700 Error in foreign key constraint of table test/
child:
there is no index in referenced table which would contain
the columns as the first columns, or the data types in the
referenced table do not match the ones in table. Constraint:
'
  CONSTRAINT `fk_pname` FOREIGN KEY (`p_name`) REFERENCES `parent` (`name`)
The index in the foreign key in table is p_name_idx
Please refer to http://dev.mysql.com/doc/refman/5.7/en/innodb-foreign-key-
constraints.html for correct foreign key definition.
.
.

```

The LATEST FOREIGN KEY ERROR message reports that the `fk_pname` foreign key constraint in the `test.child` table, which references the `test.parent` table, has either a missing index or data type mismatch. The MySQL documentation on [foreign key constraints](https://dev.mysql.com/doc/refman/5.7/en/innodb-foreign-key-constraints.html) states that columns referenced in a foreign key must have an associated index, and the parent/child columns must use the same data type.

To verify whether this is related to a missing index or data type mismatch, log into the database and check the table definitions by temporarily disabling the session variable [foreign\\_key\\_checks](#). After doing so, we can see that the child constraint in question (`fk_pname`) uses `p_name varchar(20) CHARACTER SET latin1 DEFAULT NULL` to reference the parent table `name varchar(20) NOT NULL`. The parent table uses `DEFAULT CHARSET=utf8`, but the child table's `p_name` column uses `latin1`, so the data type mismatch error is thrown.

```

mysql> show create table parent\G
ERROR 1146 (42S02): Table 'test.parent' doesn't exist

```

```

mysql> show create table child\G
***** 1. row *****
      Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) NOT NULL,
  `p_name` varchar(20) CHARACTER SET latin1 DEFAULT NULL,
  PRIMARY KEY (`id`),
  KEY `p_name_idx` (`p_name`),
  CONSTRAINT `fk_pname` FOREIGN KEY (`p_name`) REFERENCES `parent` (`name`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> set foreign_key_checks=0;
Query OK, 0 rows affected (0.00 sec)

mysql> show create table parent\G
***** 1. row *****
      Table: parent
Create Table: CREATE TABLE `parent` (
  `name` varchar(20) NOT NULL,
  PRIMARY KEY (`name`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> show create table child\G
***** 1. row *****
      Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) NOT NULL,
  `p_name` varchar(20) CHARACTER SET latin1 DEFAULT NULL,
  PRIMARY KEY (`id`),
  KEY `p_name_idx` (`p_name`),
  CONSTRAINT `fk_pname` FOREIGN KEY (`p_name`) REFERENCES `parent` (`name`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

```

To resolve this issue, we can either change the child table to use the same character set as the parent, or change the parent to use the same character set as the child table. Here, because the child table explicitly uses `latin1` in the `p_name` column definition, we run `ALTER TABLE` to modify the character set to `utf8`.

```

mysql> alter table child modify p_name varchar(20) character set utf8 DEFAULT NULL;
Query OK, 0 rows affected (0.06 sec)

```

```
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> flush tables;  
Query OK, 0 rows affected (0.01 sec)
```

After doing so, the precheck passes, and the upgrade can proceed.

### Warning example:

```
{  
  "id": "checkTableOutput",  
  "title": "Issues reported by 'check table x for upgrade' command",  
  "status": "OK",  
  "detectedProblems": [  
    {  
      "level": "Warning",  
      "dbObject": "test.orders",  
      "description": "Trigger test.orders.delete_audit_trigg does not have CREATED  
attribute."  
    }  
  ]  
}
```

The precheck reports a warning for the `delete_audit_trigg` trigger on the `test.orders` table because it doesn't have a `CREATED` attribute. According to [Checking version compatibility](#) in the MySQL documentation, this message is informational, and is printed for triggers created before MySQL 5.7.2.

Because this is a warning, it doesn't block the upgrade from proceeding. However, if you wish to resolve the issue, you can re-create the trigger in question, and the precheck succeeds with no warnings.

```
{  
  "id": "checkTableOutput",  
  "title": "Issues reported by 'check table x for upgrade' command",  
  "status": "OK",  
  "detectedProblems": []  
},
```

## How to perform an in-place upgrade

We recommend that you review the background material in [How the Aurora MySQL in-place major version upgrade works](#).

Perform any preupgrade planning and testing, as described in [Planning a major version upgrade for an Aurora MySQL cluster](#).

### Console

The following example upgrades the `mydbcluster-cluster` DB cluster to Aurora MySQL version 3.04.1.

### To upgrade the major version of an Aurora MySQL DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. If you used a custom parameter group for the original DB cluster, create a corresponding parameter group compatible with the new major version. Make any necessary adjustments to the configuration parameters in that new parameter group. For more information, see [How in-place upgrades affect the parameter groups for a cluster](#).
3. In the navigation pane, choose **Databases**.
4. In the list, choose the DB cluster that you want to modify.
5. Choose **Modify**.
6. For **Version**, choose a new Aurora MySQL major version.

We generally recommend using the latest minor version of the major version. Here, we choose the current default version.

RDS > Databases > Modify DB cluster: aurora-mysql-v2-to-v3

## Modify DB cluster: aurora-mysql-v2-to-v3

### Settings

**Engine version** [Info](#)  
View the engine versions that support the following database features.

► [Show filters](#)

**Version** [Info](#)

Aurora (MySQL 5.7) 2.10.2	▲
Aurora (MySQL 5.7) 2.10.2	
Aurora MySQL 3.01.1 (compatible with MySQL 8.0.23)	
Aurora MySQL 3.02.0 (compatible with MySQL 8.0.23)	
<a href="#">more</a> <a href="#">↗</a>	

**DB cluster identifier** [Info](#)  
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your  account in the current  Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

7. Choose **Continue**.
8. On the next page, specify when to perform the upgrade. Choose **During the next scheduled maintenance window** or **Immediately**.
9. (Optional) Periodically examine the **Events** page in the RDS console during the upgrade. Doing so helps you to monitor the progress of the upgrade and identify any issues. If the upgrade encounters any issues, consult [Troubleshooting for Aurora MySQL in-place upgrade](#) for the steps to take.
10. If you created a new parameter group at the start of this procedure, associate the custom parameter group with your upgraded cluster. For more information, see [How in-place upgrades affect the parameter groups for a cluster](#).

#### **Note**

Performing this step requires you to restart the cluster again to apply the new parameter group.

11. (Optional) After you complete any post-upgrade testing, delete the manual snapshot that Aurora created at the beginning of the upgrade.

## Amazon CLI

To upgrade the major version of an Aurora MySQL DB cluster, use the Amazon CLI [modify-db-cluster](#) command with the following required parameters:

- `--db-cluster-identifier`
- `--engine-version`
- `--allow-major-version-upgrade`
- `--apply-immediately` or `--no-apply-immediately`

If your cluster uses any custom parameter groups, also include one or both of the following options:

- `--db-cluster-parameter-group-name`, if the cluster uses a custom cluster parameter group
- `--db-instance-parameter-group-name`, if any instances in the cluster use a custom DB parameter group

The following example upgrades the `sample-cluster` DB cluster to Aurora MySQL version 3.04.1. The upgrade happens immediately, instead of waiting for the next maintenance window.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
    --db-cluster-identifier sample-cluster \  
    --engine-version 8.0.mysql_aurora.3.04.1 \  
    --allow-major-version-upgrade \  
    --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
    --db-cluster-identifier sample-cluster ^  
    --engine-version 8.0.mysql_aurora.3.04.1 ^  
    --allow-major-version-upgrade ^  
    --apply-immediately
```

You can combine other CLI commands with `modify-db-cluster` to create an automated end-to-end process for performing and verifying upgrades. For more information and examples, see [Aurora MySQL in-place upgrade tutorial](#).

### Note

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the [modify-global-cluster](#) command operation instead of `modify-db-cluster`. For more information, see [In-place major upgrades for global databases](#).

## RDS API

To upgrade the major version of an Aurora MySQL DB cluster, use the RDS API operation [ModifyDBCluster](#) with the following required parameters:

- `DBClusterIdentifier`
- `Engine`
- `EngineVersion`
- `AllowMajorVersionUpgrade`
- `ApplyImmediately` (set to `true` or `false`)

### Note

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the [ModifyGlobalCluster](#) operation instead of `ModifyDBCluster`. For more information, see [In-place major upgrades for global databases](#).

## How in-place upgrades affect the parameter groups for a cluster

Aurora parameter groups have different sets of configuration settings for clusters that are compatible with MySQL 5.7 or 8.0. When you perform an in-place upgrade, the upgraded cluster and all its instances must use the corresponding cluster and instance parameter groups:

Your cluster and instances might use the default 5.7-compatible parameter groups. If so, the upgraded cluster and instance start with the default 8.0-compatible parameter groups. If your cluster and instances use any custom parameter groups, make sure to create corresponding or 8.0-compatible parameter groups. Also make sure to specify those during the upgrade process.

### Note

For most parameter settings, you can choose the custom parameter group at two points. These are when you create the cluster or associate the parameter group with the cluster later.

However, if you use a nondefault setting for the `lower_case_table_names` parameter, you must set up the custom parameter group with this setting in advance. Then specify the parameter group when you perform the snapshot restore to create the cluster. Any change to the `lower_case_table_names` parameter has no effect after the cluster is created.

We recommend that you use the same setting for `lower_case_table_names` when you upgrade from Aurora MySQL version 2 to version 3.

With an Aurora global database based on Aurora MySQL, you can perform an in-place upgrade from Aurora MySQL version 2 to version 3 only if you set the `lower_case_table_names` parameter to default and reboot your global database. For more information on the methods that you can use, see [Major version upgrades](#).

## Changes to cluster properties between Aurora MySQL versions

When you upgrade from Aurora MySQL version 2 to version 3, make sure to check any applications or scripts that you use to set up or manage Aurora MySQL clusters and DB instances.

Also, change your code that manipulates parameter groups to account for the fact that the default parameter group names are different for 5.7- and 8.0-compatible clusters. The default parameter group names for Aurora MySQL version 2 and 3 clusters are `default.aurora-mysql5.7` and `default.aurora-mysql8.0`, respectively.

For example, you might have code like the following that applies to your cluster before an upgrade.

```
# Check the default parameter values for MySQL 5.7-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql5.7 --
region us-east-1
```

After upgrading the major version of the cluster, modify that code as follows.

```
# Check the default parameter values for MySQL 8.0-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql8.0 --
region us-east-1
```

## In-place major upgrades for global databases

For an Aurora global database, you upgrade the global database cluster. Aurora automatically upgrades all of the clusters at the same time and makes sure that they all run the same engine version. This requirement is because any changes to system tables, data file formats, and so on, are automatically replicated to all the secondary clusters.

Follow the instructions in [How the Aurora MySQL in-place major version upgrade works](#). When you specify what to upgrade, make sure to choose the global database cluster instead of one of the clusters it contains.

If you use the Amazon Web Services Management Console, choose the item with the role **Global database**.

<input type="checkbox"/>	DB identifier	Role	Engine	Engine version
<input checked="" type="radio"/>	global-cluster	Global database	Aurora MySQL	5.7.mysql_aurora.2.09.2
<input type="radio"/>	cluster1	Primary cluster	Aurora MySQL	5.7.mysql_aurora.2.09.2
<input type="radio"/>	dbinstance-1	Writer instance	Aurora MySQL	5.7.mysql_aurora.2.09.2
<input type="radio"/>	cluster-2	Secondary cluster	Aurora MySQL	5.7.mysql_aurora.2.09.2
<input type="radio"/>	dbinstance-2	Reader instance	Aurora MySQL	5.7.mysql_aurora.2.09.2

If you use the Amazon CLI or RDS API, start the upgrade process by calling the [modify-global-cluster](#) command or [ModifyGlobalCluster](#) operation. You use one of these instead of `modify-db-cluster` or `ModifyDBCluster`.

### Note

You can't specify a custom parameter group for the global database cluster while you're performing a major version upgrade of that Aurora global database. Create your custom parameter groups in each Region of the global cluster. Then apply them manually to the Regional clusters after the upgrade.

To upgrade the major version of an Aurora MySQL global database cluster by using the Amazon CLI, use the [modify-global-cluster](#) command with the following required parameters:

- `--global-cluster-identifier`
- `--engine aurora-mysql`
- `--engine-version`
- `--allow-major-version-upgrade`

The following example upgrades the global database cluster to Aurora MySQL version 3.04.2.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-global-cluster \  
  --global-cluster-identifier global_cluster_identifier \  
  --engine aurora-mysql \  
  --engine-version 8.0.mysql_aurora.3.04.2 \  
  --allow-major-version-upgrade
```

For Windows:

```
aws rds modify-global-cluster ^  
  --global-cluster-identifier global_cluster_identifier ^  
  --engine aurora-mysql ^  
  --engine-version 8.0.mysql_aurora.3.04.2 ^  
  --allow-major-version-upgrade
```

### In-place upgrades for DB clusters with cross-Region read replicas

You can upgrade an Aurora DB cluster that has a cross-Region read replica using the in-place upgrade procedure, but there are certain considerations:

- You must upgrade the read replica DB cluster first. If you try to upgrade the primary cluster first, you will receive an error message such as the following:

Unable to upgrade DB cluster test-xr-primary-cluster because the associated Aurora cross-Region replica test-xr-replica-cluster isn't patched yet. Upgrade the Aurora cross-Region replica and try again.

This means that the primary DB cluster can't have a higher DB engine version than the replica cluster.

- Before you upgrade the primary DB cluster, stop the write workload and disable any new connection requests to the writer DB instance of the primary cluster.
- When you upgrade the primary cluster, choose a custom DB cluster parameter group with the `binlog_format` parameter set to a value that supports binary logging replication, such as `MIXED`.

For more information about using binary logging with Aurora MySQL, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#). For more information about modifying Aurora MySQL configuration parameters, see [Aurora MySQL configuration parameters](#) and [Parameter groups for Amazon Aurora](#).

- Don't wait a long time to upgrade the primary DB cluster after you upgrade the replica cluster. We recommend not waiting longer than the next maintenance window.
- After you upgrade the primary DB cluster, reboot its writer DB instance. The custom DB cluster parameter group that enables binlog replication doesn't take effect until the writer DB instance is rebooted.
- Don't resume the write workload or enable connections to the writer DB instance until you confirm that cross-Region replication has restarted, and that the replica lag in the secondary Amazon Web Services Region is 0.

## Aurora MySQL in-place upgrade tutorial

The following Linux examples show how you might perform the general steps of the in-place upgrade procedure using the Amazon CLI.

This first example creates an Aurora DB cluster that's running a 2.x version of Aurora MySQL. The cluster includes a writer DB instance and a reader DB instance. The `wait db-instance-available` command pauses until the writer DB instance is available. That's the point when the cluster is ready to be upgraded.

```
aws rds create-db-cluster --db-cluster-identifier mynewdbcluster --engine aurora-mysql \
  \
  --db-cluster-version 5.7.mysql_aurora.2.11.2
...
aws rds create-db-instance --db-instance-identifier mynewdbcluster-instance1 \
```

```
--db-cluster-identifier mynewdbcluster --db-instance-class db.t4g.medium --engine
aurora-mysql
...
aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1
```

The Aurora MySQL 3.x versions that you can upgrade the cluster to depend on the 2.x version that the cluster is currently running and on the Amazon Web Services Region where the cluster is located. The first command, with `--output text`, just shows the available target version. The second command shows the full JSON output of the response. In that response, you can see details such as the `aurora-mysql` value that you use for the engine parameter. You can also see the fact that upgrading to 3.04.0 represents a major version upgrade.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
  --query '*[].[EngineVersion:EngineVersion]' --output text
5.7.mysql_aurora.2.11.2

aws rds describe-db-engine-versions --engine aurora-mysql --engine-version
5.7.mysql_aurora.2.11.2 \
  --query '*[].[ValidUpgradeTarget]'
...
{
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.04.0",
  "Description": "Aurora MySQL 3.04.0 (compatible with MySQL 8.0.28)",
  "AutoUpgrade": false,
  "IsMajorVersionUpgrade": true,
  "SupportedEngineModes": [
    "provisioned"
  ],
  "SupportsParallelQuery": true,
  "SupportsGlobalDatabases": true,
  "SupportsBabelfish": false,
  "SupportsIntegrations": false
},
...
```

This example shows how if you enter a target version number that isn't a valid upgrade target for the cluster, Aurora doesn't perform the upgrade. Aurora also doesn't perform a major version upgrade unless you include the `--allow-major-version-upgrade` parameter. That way, you can't accidentally perform an upgrade that has the potential to require extensive testing and changes to your application code.

```
aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
  --engine-version 5.7.mysql_aurora.2.09.2 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster
operation: Cannot find upgrade target from 5.7.mysql_aurora.2.11.2 with requested
version 5.7.mysql_aurora.2.09.2.

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
  --engine-version 8.0.mysql_aurora.3.04.0 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster
operation: The AllowMajorVersionUpgrade flag must be present when upgrading to a new
major version.

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
  --engine-version 8.0.mysql_aurora.3.04.0 --apply-immediately --allow-major-version-
upgrade
{
  "DBClusterIdentifier": "mynewdbcluster",
  "Status": "available",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.11.2"
}
```

It takes a few moments for the status of the cluster and associated DB instances to change to upgrading. The version numbers for the cluster and DB instances only change when the upgrade is finished. Again, you can use the `wait db-instance-available` command for the writer DB instance to wait until the upgrade is finished before proceeding.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
  --query '*[].[Status,EngineVersion]' --output text
upgrading 5.7.mysql_aurora.2.11.2

aws rds describe-db-instances --db-instance-identifier mynewdbcluster-instance1 \
  --query '*[.]'.
{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceStatus:DBInstanceStatus} | [0]'
{
  "DBInstanceIdentifier": "mynewdbcluster-instance1",
  "DBInstanceStatus": "upgrading"
}

aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1
```

At this point, the version number for the cluster matches the one that was specified for the upgrade.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \  
  --query '*[].[EngineVersion]' --output text  
  
8.0.mysql_aurora.3.04.0
```

The preceding example did an immediate upgrade by specifying the `--apply-immediately` parameter. To let the upgrade happen at a convenient time when the cluster isn't expected to be busy, you can specify the `--no-apply-immediately` parameter. Doing so makes the upgrade start during the next maintenance window for the cluster. The maintenance window defines the period during which maintenance operations can start. A long-running operation might not finish during the maintenance window. Thus, you don't need to define a larger maintenance window even if you expect that the upgrade might take a long time.

The following example upgrades a cluster that's initially running Aurora MySQL version 2.11.2. In the `describe-db-engine-versions` output, the `False` and `True` values represent the `IsMajorVersionUpgrade` property. From version 2.11.2, you can upgrade to some other 2.\* versions. Those upgrades aren't considered major version upgrades and so don't require an in-place upgrade. In-place upgrade is only available for upgrades to the 3.\* versions that are shown in the list.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \  
  --query '*[].[EngineVersion:EngineVersion]' --output text  
5.7.mysql_aurora.2.11.2  
  
aws rds describe-db-engine-versions --engine aurora-mysql --engine-version  
5.7.mysql_aurora.2.10.2 \  
  --query '*[].[ValidUpgradeTarget][[0][0]][*].[EngineVersion,IsMajorVersionUpgrade]'  
  --output text  
  
5.7.mysql_aurora.2.11.3 False  
5.7.mysql_aurora.2.11.4 False  
5.7.mysql_aurora.2.11.5 False  
5.7.mysql_aurora.2.11.6 False  
5.7.mysql_aurora.2.12.0 False  
5.7.mysql_aurora.2.12.1 False  
5.7.mysql_aurora.2.12.2 False  
5.7.mysql_aurora.2.12.3 False  
8.0.mysql_aurora.3.04.0 True
```

```

8.0.mysql_aurora.3.04.1 True
8.0.mysql_aurora.3.04.2 True
8.0.mysql_aurora.3.04.3 True
8.0.mysql_aurora.3.05.2 True
8.0.mysql_aurora.3.06.0 True
8.0.mysql_aurora.3.06.1 True
8.0.mysql_aurora.3.07.1 True

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
  --engine-version 8.0.mysql_aurora.3.04.0 --no-apply-immediately --allow-major-
  version-upgrade
...

```

When a cluster is created without a specified maintenance window, Aurora picks a random day of the week. In this case, the `modify-db-cluster` command is submitted on a Monday. Thus, we change the maintenance window to be Tuesday morning. All times are represented in the UTC time zone. The `tue:10:00-tue:10:30` window corresponds to 2:00-2:30 AM Pacific time. The change in the maintenance window takes effect immediately.

```

aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster --query '*[].[
  PreferredMaintenanceWindow]'
[
  [
    "sat:08:20-sat:08:50"
  ]
]

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster --preferred-
  maintenance-window tue:10:00-tue:10:30"
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster --query '*[].[
  PreferredMaintenanceWindow]'
[
  [
    "tue:10:00-tue:10:30"
  ]
]

```

The following example shows how to get a report of the events generated by the upgrade. The `--duration` argument represents the number of minutes to retrieve the event information. This argument is needed, because by default `describe-events` only returns events from the last hour.

```
aws rds describe-events --source-type db-cluster --source-identifier mynewdbcluster --
duration 20160
{
  "Events": [
    {
      "SourceIdentifier": "mynewdbcluster",
      "SourceType": "db-cluster",
      "Message": "DB cluster created",
      "EventCategories": [
        "creation"
      ],
      "Date": "2022-11-17T01:24:11.093000+00:00",

    }
  ]
}

```

## Finding the reasons for Aurora MySQL major version upgrade failures

In the [tutorial](#), the upgrade from Aurora MySQL version 2 to version 3 succeeded. But if the upgrade had failed, you would want to know why.

You can start by using the `describe-events` Amazon CLI command to look at the DB cluster events. This example shows the events for `mydbcluster` for the last 10 hours.

```

aws rds describe-events \
  --source-type db-cluster \
  --source-identifier mydbcluster \
  --duration 600

```

In this case, we had an upgrade precheck failure.

```

{
  "Events": [
    {
      "SourceIdentifier": "mydbcluster",
      "SourceType": "db-cluster",
      "Message": "Database cluster engine version upgrade started.",
      "EventCategories": [
        "maintenance"
      ],
      "Date": "2024-04-11T13:23:22.846000+00:00",
      "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster"
    },
    {
      "SourceIdentifier": "mydbcluster",
      "SourceType": "db-cluster",

```

```

    "Message": "Database cluster is in a state that cannot be upgraded: Upgrade
prechecks failed. For more details, see the
        upgrade-prechecks.log file. For more information on troubleshooting the
cause of the upgrade failure, see
        https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/
AuroraMySQL.Updating.Troubleshooting.html",
    "EventCategories": [
        "maintenance"
    ],
    "Date": "2024-04-11T13:23:24.373000+00:00",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster"
}
]
}

```

To diagnose the exact cause of the problem, examine the database logs for the writer DB instance. When an upgrade to Aurora MySQL version 3 fails, the writer instance contains a log file with the name `upgrade-prechecks.log`. This example shows how to detect the presence of that log and then download it to a local file for examination.

```

aws rds describe-db-log-files --db-instance-identifier mydbcluster-instance \
    --query '*[][LogFileName]' --output text

error/mysql-error-running.log
error/mysql-error-running.log.2024-04-11.20
error/mysql-error-running.log.2024-04-11.21
error/mysql-error.log
external/mysql-external.log
upgrade-prechecks.log

aws rds download-db-log-file-portion --db-instance-identifier mydbcluster-instance \
    --log-file-name upgrade-prechecks.log \
    --starting-token 0 \
    --output text >upgrade_prechecks.log

```

The `upgrade-prechecks.log` file is in JSON format. We download it using the `--output text` option to avoid encoding JSON output within another JSON wrapper. For Aurora MySQL version 3 upgrades, this log always includes certain informational and warning messages. It only includes error messages if the upgrade fails. If the upgrade succeeds, the log file isn't produced at all.

To summarize all of the errors and display the associated object and description fields, you can run the command `grep -A 2 '"level": "Error"'` on the contents of the `upgrade-`

prechecks.log file. Doing so displays each error line and the two lines after it. These contain the name of the corresponding database object and guidance about how to correct the problem.

```
$ cat upgrade-prechecks.log | grep -A 2 '"level": "Error"'

"level": "Error",
"dbObject": "problematic_upgrade.dangling_fulltext_index",
"description": "Table `problematic_upgrade.dangling_fulltext_index` contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
```

In this example, you can run the following SQL command on the offending table to try to fix the issue, or you can re-create the table without the dangling index.

```
OPTIMIZE TABLE problematic_upgrade.dangling_fulltext_index;
```

Then retry the upgrade.

### Troubleshooting for Aurora MySQL in-place upgrade

Use the following tips to help troubleshoot problems with Aurora MySQL in-place upgrades. These tips don't apply to Aurora Serverless DB clusters.

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
Associated Aurora cross-Region replica isn't patched yet	Aurora cancels the upgrade.	Upgrade the Aurora cross-Region replica and try again.
Cluster has XA transactions in the prepared state	Aurora cancels the upgrade.	Commit or roll back all prepared XA transactions.
Cluster is processing any data definition language (DDL) statements	Aurora cancels the upgrade.	Consider waiting and performing the upgrade after all DDL statements are finished.
Cluster has uncommitted changes for many rows	Upgrade might take a long time.	The upgrade process rolls back the uncommitted changes. The indicator for this condition is the value of TRX_ROWS_MODIFIED in the

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
Cluster has high number of undo records	Upgrade might take a long time.	<p data-bbox="829 260 1386 338">INFORMATION_SCHEMA.INNODB_TRX table.</p> <p data-bbox="829 386 1484 512">Consider performing the upgrade only after all large transactions are committed or rolled back.</p> <p data-bbox="829 560 1487 978">Even if the uncommitted transactions don't affect a large number of rows, they might involve a large volume of data. For example, you might be inserting large BLOBs. Aurora doesn't automatically detect or generate an event for this kind of transaction activity. The indicator for this condition is the history list length (HLL). The upgrade process rolls back the uncommitted changes.</p> <p data-bbox="829 1026 1468 1199">You can check the HLL in the output from the <code>SHOW ENGINE INNODB STATUS SQL</code> command, or directly by using the following SQL query:</p> <pre data-bbox="829 1241 1507 1398">SELECT count FROM information_schema .innodb_metrics WHERE name = 'trx_rseg_history_len';</pre> <p data-bbox="829 1436 1463 1562">You can also monitor the <code>RollbackSegmentHistoryListLength</code> metric in Amazon CloudWatch.</p> <p data-bbox="829 1610 1463 1688">Consider performing the upgrade only after the HLL is smaller.</p>

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
Cluster is in the process of committing a large binary log transaction	Upgrade might take a long time.	<p>The upgrade process waits until the binary log changes are applied. More transactions or DDL statements could start during this period, further slowing down the upgrade process.</p> <p>Schedule the upgrade process when the cluster isn't busy with generating binary log replication changes. Aurora doesn't automatically detect or generate an event for this condition.</p>
Schema inconsistencies resulting from file removal or corruption	Aurora cancels the upgrade.	<p>Change the default storage engine for temporary tables from MyISAM to InnoDB. Perform the following steps:</p> <ol style="list-style-type: none"><li>1. Modify the <code>default_tmp_storage_engine</code> DB parameter to InnoDB.</li><li>2. Reboot the DB cluster.</li><li>3. After rebooting, confirm that the <code>default_tmp_storage_engine</code> DB parameter is set to InnoDB. Use the following command: <pre>show global variables like 'default_tmp_storage_engine';</pre></li><li>4. Make sure not to create any temporary tables that use the MyISAM storage engine. We recommend that you pause any database workload and not create any new database connections, because you're upgrading soon.</li><li>5. Try the in-place upgrade again.</li></ol>

Reason for in-place upgrade being canceled or slow	Effect	Solution to allow in-place upgrade to complete within maintenance window
Master user was deleted	Aurora cancels the upgrade.	<div data-bbox="829 275 1507 443" style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; margin-bottom: 10px;"> <p><b>⚠ Important</b></p> <p>Don't delete the master user.</p> </div> <p>However, if for some reason you should happen to delete the master user, restore it using the following SQL commands:</p> <div data-bbox="829 680 1507 1430" style="border: 1px solid #ccc; border-radius: 10px; padding: 10px; margin-top: 10px;"> <pre>CREATE USER '<i>master_username</i>' '@'%'   IDENTIFIED BY '<i>master_user_password</i>' REQUIRE NONE PASSWORD EXPIRE   DEFAULT ACCOUNT UNLOCK;  GRANT SELECT, INSERT, UPDATE, DELETE,   CREATE, DROP, RELOAD, PROCESS,   REFERENCES, INDEX, ALTER, SHOW   DATABASES, CREATE TEMPORARY TABLES,   LOCK TABLES, EXECUTE, REPLICATION   SLAVE, REPLICATION CLIENT, CREATE   VIEW, SHOW VIEW, CREATE ROUTINE, ALTER   ROUTINE, CREATE USER, EVENT,   TRIGGER, LOAD FROM S3, SELECT INTO   S3, INVOKE LAMBDA, INVOKE SAGEMAKER   , INVOKE COMPREHEND ON *.* TO   '<i>master_username</i>' '@'%' WITH GRANT   OPTION;</pre> </div>

For more details on troubleshooting issues that cause upgrade prechecks to fail, see the following blogs:

- [Amazon Aurora MySQL version 2 \(with MySQL 5.7 compatibility\) to version 3 \(with MySQL 8.0 compatibility\) upgrade checklist, Part 1](#)
- [Amazon Aurora MySQL version 2 \(with MySQL 5.7 compatibility\) to version 3 \(with MySQL 8.0 compatibility\) upgrade checklist, Part 2](#)

You can use the following steps to perform your own checks for some of the conditions in the preceding table. That way, you can schedule the upgrade at a time when you know the database is in a state where the upgrade can complete successfully and quickly.

- You can check for open XA transactions by executing the `XA RECOVER` statement. You can then commit or roll back the XA transactions before starting the upgrade.
- You can check for DDL statements by executing a `SHOW PROCESSLIST` statement and looking for `CREATE`, `DROP`, `ALTER`, `RENAME`, and `TRUNCATE` statements in the output. Allow all DDL statements to finish before starting the upgrade.
- You can check the total number of uncommitted rows by querying the `INFORMATION_SCHEMA.INNODB_TRX` table. The table contains one row for each transaction. The `TRX_ROWS_MODIFIED` column contains the number of rows modified or inserted by the transaction.
- You can check the length of the InnoDB history list by executing the `SHOW ENGINE INNODB STATUS SQL` statement and looking for the `History list length` in the output. You can also check the value directly by running the following query:

```
SELECT count FROM information_schema.innodb_metrics WHERE name =  
'trx_rseg_history_len';
```

The length of the history list corresponds to the amount of undo information stored by the database to implement multi-version concurrency control (MVCC).

### Post-upgrade cleanup for Aurora MySQL version 3

After you finish upgrading any Aurora MySQL version 2 clusters to Aurora MySQL version 3, you can perform these other cleanup actions:

- Create new MySQL 8.0–compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups.
- Update any CloudWatch alarms, setup scripts, and so on to use the new names for any metrics whose names were affected by inclusive language changes. For a list of such metrics, see [Inclusive language changes for Aurora MySQL version 3](#).
- Update any Amazon CloudFormation templates to use the new names for any configuration parameters whose names were affected by inclusive language changes. For a list of such parameters, see [Inclusive language changes for Aurora MySQL version 3](#).

## Spatial indexes

After upgrading to Aurora MySQL version 3, check if you need to drop or recreate objects and indexes related to spatial indexes. Before MySQL 8.0, Aurora could optimize spatial queries using indexes that didn't contain a spatial resource identifier (SRID). Aurora MySQL version 3 only uses spatial indexes containing SRIDs. During an upgrade, Aurora automatically drops any spatial indexes without SRIDs and prints warning messages in the database log. If you observe such warning messages, create new spatial indexes with SRIDs after the upgrade. For more information about changes to spatial functions and data types in MySQL 8.0, see [Changes in MySQL 8.0](#) in the *MySQL Reference Manual*.

## Database engine updates and fixes for Amazon Aurora MySQL

You can find the following information in the *Release notes for Amazon Aurora MySQL-Compatible Edition*:

- [Database engine updates for Amazon Aurora MySQL version 3](#)
- [Database engine updates for Amazon Aurora MySQL version 2](#)
- [Database engine updates for Amazon Aurora MySQL version 1 \(Deprecated\)](#)

- [Security vulnerabilities fixed in Amazon Aurora MySQL](#)

# Working with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed, reliability, and manageability of Amazon Aurora with the simplicity and cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. To learn more about Aurora in general, see [What is Amazon Aurora?](#).

In addition to the benefits of Aurora, Aurora PostgreSQL offers a convenient migration pathway from Amazon RDS into Aurora, with push-button migration tools that convert your existing RDS for PostgreSQL applications to Aurora PostgreSQL. Routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair are also easy to manage with Aurora PostgreSQL.

Aurora PostgreSQL can work with many industry standards. For example, you can use Aurora PostgreSQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI), under a completed Business Associate Agreement (BAA) with Amazon.

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about Amazon and compliance efforts, see [Amazon services in scope by compliance program](#).

## Important

If you encounter an issue with your Aurora PostgreSQL DB cluster, your Amazon support agent might need more information about the health of your databases. The goal is to ensure that Amazon Support gets as much of the required information as possible in the shortest possible time.

You can use PG Collector to help gather valuable database information in a consolidated HTML file. For more information on PG Collector, how to run it, and how to download the HTML report, see [PG Collector](#).

Upon successful completion, and unless otherwise noted, the script returns output in a readable HTML format. The script is designed to exclude any data or security details from the HTML that might compromise your business. It also makes no modifications to your database or its environment. However, if you find any information in the HTML that you are uncomfortable sharing, feel free to remove the problematic information before uploading

the HTML. When the HTML is acceptable, upload it using the attachments section in the case details of your support case.

## Working with the database preview environment

The PostgreSQL community releases new major version of PostgreSQL annually. Similarly, Amazon Aurora makes PostgreSQL major versions available as Preview releases. This allows you to create DB cluster using the Preview version and test out its features in the Database Preview Environment.

Aurora PostgreSQL DB clusters in the Database Preview Environment are functionally similar to other Aurora PostgreSQL DB clusters. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances and DB clusters are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using r5, r6g, r6i, r7g, r7i, r8g, x2g, t3 and t4g instance types only. For more information about instance classes, see [Amazon Aurora DB instance classes](#).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

## Supported DB instance class types

Amazon Aurora PostgreSQL supports the following DB instance classes in the preview region:

### Memory Optimized Classes

- db.r5 – memory-optimized instance classes
- db.r6g – memory-optimized instance classes powered by Amazon Graviton2 processors
- db.r6i – memory-optimized instance classes
- db.r7g – memory-optimized instance classes powered by Amazon Graviton3 processors
- db.r7i – memory-optimized instance classes
- db.r8g – memory-optimized instance classes powered by Amazon Graviton4 processors

- db.x2g – memory-optimized instance classes powered by Amazon Graviton2 processors

 **Note**

For more information on the list of instance classes, see [DB instance class types](#).

### Burstable classes

- db.t3.medium
- db.t3.large
- db.t4g.medium
- db.t4g.large

## Unsupported features in the preview environment

The following features aren't available in the preview environment:

- Aurora Serverless v1 and v2
- Major version upgrades (MVU)
- No new minor versions will be released in preview region
- RDS for PostgreSQL to Aurora PostgreSQL inbound replication
- Amazon RDS Blue/Green deployment
- Cross-Region snapshot copy
- Aurora global database
- Database activity streams (DAS), RDS Proxy, and Amazon DMS
- Auto scaling read replicas
- Amazon Bedrock
- RDS export
- Performance Insights
- Custom endpoints
- Snapshot copy
- Zero-ETL

- Babelfish
- All extensions

## PostgreSQL version 17 in the Database Preview environment

**⚠ This is preview documentation for Aurora PostgreSQL version 17. It is subject to change.**

PostgreSQL version 17.0 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 17 contains several improvements that are described in the following PostgreSQL documentation:

- [PostgreSQL 17 Released](#)

For information on the Database Preview Environment, see [Working with the database preview environment](#). To access the Preview Environment from the console, select <https://console.amazonaws.cn/rds-preview/>.

## Security with Amazon Aurora PostgreSQL

For a general overview of Aurora security, see [Security in Amazon Aurora](#). You can manage security for Amazon Aurora PostgreSQL at a few different levels:

- To control who can perform Amazon RDS management actions on Aurora PostgreSQL DB clusters and DB instances, use Amazon Identity and Access Management (IAM). IAM handles the authentication of user identity before the user can access the service. It also handles authorization, that is, whether the user is allowed to do what they're trying to do. IAM database authentication is an additional authentication method that you can choose when you create your Aurora PostgreSQL DB cluster. For more information, see [Identity and access management for Amazon Aurora](#).

If you do use IAM with your Aurora PostgreSQL DB cluster, sign in to the Amazon Web Services Management Console with your IAM credentials first, before opening the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

- Make sure to create Aurora DB clusters in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the

endpoint and port of the DB instance for Aurora DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see [Amazon VPC and Amazon Aurora](#).

The supported VPC tenancy depends on the DB instance class used by your Aurora PostgreSQL DB clusters. With default VPC tenancy, the DB cluster runs on shared hardware. With dedicated VPC tenancy, the DB cluster runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t3 and db.t4g DB instance classes. All other Aurora PostgreSQL DB instance classes support both default and dedicated VPC tenancy.

For more information about instance classes, see [Amazon Aurora DB instance classes](#). For more information about default and dedicated VPC tenancy, see [Dedicated instances](#) in the *Amazon Elastic Compute Cloud User Guide*.

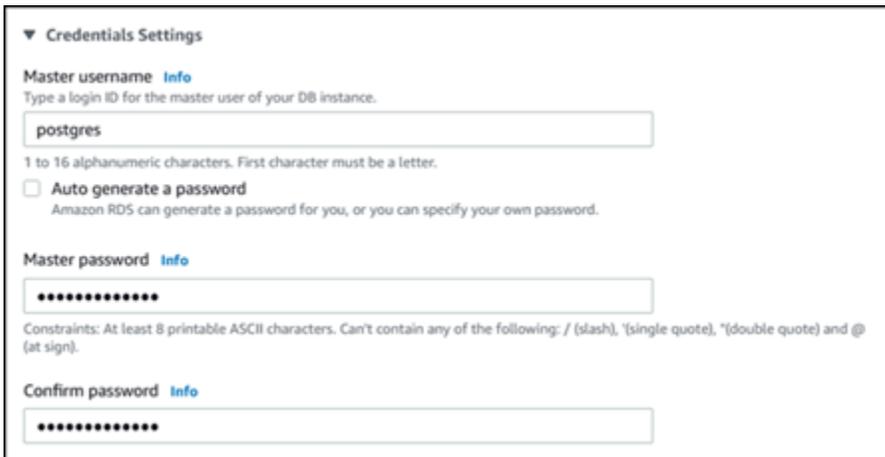

- To grant permissions to the PostgreSQL databases running on your Amazon Aurora DB cluster, you can take the same general approach as with stand-alone instances of PostgreSQL. Commands such as CREATE ROLE, ALTER ROLE, GRANT, and REVOKE work just as they do in on-premises databases, as does directly modifying databases, schemas, and tables.

PostgreSQL manages privileges by using *roles*. The `rds_superuser` role is the most privileged role on an Aurora PostgreSQL DB cluster. This role is created automatically, and it's granted to the user that creates the DB cluster (the master user account, `postgres` by default). To learn more, see [Understanding PostgreSQL roles and permissions](#).

All available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, 14, and higher releases support the Salted Challenge Response Authentication Mechanism (SCRAM) for passwords as an alternative to message digest (MD5). We recommend that you use SCRAM because it's more secure than MD5. For more information, including how to migrate database user passwords from MD5 to SCRAM, see [Using SCRAM for PostgreSQL password encryption](#).

## Understanding PostgreSQL roles and permissions

When you create an Aurora PostgreSQL DB cluster using the Amazon Web Services Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:

▼ Credentials Settings

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

postgres

1 to 16 alphanumeric characters. First character must be a letter.

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

\*\*\*\*\*

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), ' (single quote), " (double quote) and @ (at sign).

**Confirm password** [Info](#)

\*\*\*\*\*

You can choose another name rather than accept the default (`postgres`). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (`postgres`) throughout this guide.

If you use the `create-db-cluster` Amazon CLI rather than the Amazon Web Services Management Console, you create the user name by passing it with the `master-username` parameter. For more information, see [Step 2: Create an Aurora PostgreSQL DB cluster](#).

Whether you use the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

## Topics

- [Understanding the `rds\_superuser` role](#)
- [Controlling user access to the PostgreSQL database](#)
- [Delegating and controlling user password management](#)
- [Using SCRAM for PostgreSQL password encryption](#)

## Understanding the `rds_superuser` role

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the `LOGIN` privilege.

**Note**

The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see [Database Roles](#) in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your Aurora PostgreSQL DB cluster. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION
VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for `CREATE ROLE`, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Aurora PostgreSQL. For more information, see [Working with extensions and foreign data wrappers](#).
- Create roles for users and grant privileges to users. For more information, see [CREATE ROLE](#) and [GRANT](#) in the PostgreSQL documentation.
- Create databases. For more information, see [CREATE DATABASE](#) in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`.

In the `CREATE ROLE postgres . . .` statement, you can see that the `postgres` user role specifically disallows PostgreSQL `superuser` permissions. Aurora PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL `superuser` account. Many of the tasks that require `superuser` access on a stand-alone PostgreSQL are managed automatically by Aurora.

For more information about granting privileges, see [GRANT](#) in the PostgreSQL documentation.

The `rds_superuser` role is one of several *predefined* roles in an Aurora PostgreSQL DB cluster.

#### Note

In PostgreSQL 13 and earlier releases, *predefined* roles are known as *default* roles.

In the following list, you find some of the other predefined roles that are created automatically for a new Aurora PostgreSQL DB cluster. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds\_password** – A role that can change passwords and set up password constraints for database users. The `rds_superuser` role is granted with this role by default, and can grant the role to database users. For more information, see [Controlling user access to the PostgreSQL database](#).
  - For RDS for PostgreSQL versions older than 14, `rds_password` role can change passwords and set up password constraints for database users and users with `rds_superuser` role. From RDS for PostgreSQL version 14 and later, `rds_password` role can change passwords and set up password constraints only for database users. Only users with `rds_superuser` role can perform these actions on other users with `rds_superuser` role.
- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone PostgreSQL database. This role is used internally by Aurora PostgreSQL for many management tasks.

## Viewing roles and their privileges

You can view predefined roles and their privileges in your RDS for PostgreSQL DB instance using different commands depending on your PostgreSQL version. To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and run following commands using the `psql`.

## For psql 15 and earlier versions

Connect to your RDS for PostgreSQL DB instance and use the `\du` command in psql:

```
postgres=> \du
```

		List of roles	
Role name	Member of	Attributes	
postgres	{rds_superuser}	Create role, Create DB	+
		Password valid until infinity	
rds_ad		Cannot login	{}
rds_iam		Cannot login	{}
rds_password		Cannot login	{}
rds_replication		Cannot login	{}
rds_superuser		Cannot login	
	{pg_monitor,pg_signal_backend,rds_password,rds_replication}		
rdsadmin		Superuser, Create role, Create DB, Replication, Bypass RLS+	{}
		Password valid until infinity	

## For psql 16 and later versions

```
postgres=> \drg+
```

List of role grants			
Role name	Member of	Options	Grantor
postgres	rds_superuser	INHERIT, SET	rdsadmin
rds_superuser	pg_checkpoint	ADMIN, INHERIT, SET	rdsadmin
rds_superuser	pg_monitor	ADMIN, INHERIT, SET	rdsadmin
rds_superuser	pg_signal_backend	ADMIN, INHERIT, SET	rdsadmin
rds_superuser	pg_use_reserved_connections	ADMIN, INHERIT, SET	rdsadmin
rds_superuser	rds_password	ADMIN, INHERIT, SET	rdsadmin
rds_superuser	rds_replication	ADMIN, INHERIT, SET	rdsadmin

To check role membership without version dependency, you can use the following SQL query:

```
SELECT m.rolname AS "Role name", r.rolname AS "Member of"
FROM pg_catalog.pg_roles m
JOIN pg_catalog.pg_auth_members pam ON (pam.member = m.oid)
LEFT JOIN pg_catalog.pg_roles r ON (pam.roleid = r.oid)
```

```
LEFT JOIN pg_catalog.pg_roles g ON (pam.grantor = g.oid)
WHERE m.rolname !~ '^pg_'
ORDER BY 1, 2;
```

In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

### Note

Aurora PostgreSQL versions 15.2 and 14.7 introduced restrictive behavior of the `rds_superuser` role. An Aurora PostgreSQL user needs to be granted the `CONNECT` privilege on the corresponding database to connect even if the user is granted the `rds_superuser` role. Prior to Aurora PostgreSQL versions 14.7 and 15.2, a user was able to connect to any database and system table if the user was granted the `rds_superuser` role. This restrictive behavior aligns with the Amazon and Amazon Aurora commitments to the continuous improvement of security.

Please update the respective logic in your applications if the above enhancement has an impact.

## Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's `public` schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your Aurora PostgreSQL DB cluster primary node, we recommend that you revoke these default `public` privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

### To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created Aurora PostgreSQL DB cluster for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or `pgAdmin`) to connect to the primary DB instance on your Aurora PostgreSQL DB cluster:

```
psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the `public` schema, do the following:

```
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;
CREATE DATABASE
```

4. Revoke all privileges from the `PUBLIC` schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
REVOKE
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
CREATE ROLE
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
GRANT
```

7. Grant all users with the `lab_tech` role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
GRANT
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
```

```
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab\_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, lab\_user1 and lab\_user2 can connect to the lab\_db database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see [Managing PostgreSQL Users and Roles](#).

For more information about privileges in PostgreSQL databases, see the [GRANT](#) command in the PostgreSQL documentation.

## Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the rds\_password role can manage passwords.

### Note

To use restricted password management, your Aurora PostgreSQL DB cluster must be running Amazon Aurora PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
 rds.restrict_password_commands
-----
off
```

```
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds_restrict_password_commands` to 1. Be sure to reboot your Aurora PostgreSQL's primary DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (`ALTER ROLE myrole RENAME TO newname`) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

## Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see [Password Authentication](#) in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your Aurora PostgreSQL DB cluster. SCRAM is supported in Aurora PostgreSQL version 10 and all higher

major and minor versions. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see [PostgreSQL JDBC Driver](#) in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see [List of drivers](#) in the PostgreSQL documentation.

Aurora PostgreSQL version 14 and higher support scram-sha-256 for password encryption by default for new DB clusters. For these versions, the default DB cluster parameter group (`default.aurora-postgresql14`) has its `password_encryption` value set to `scram-sha-256`. SCRAM isn't supported for Aurora Serverless v1.

### Setting up Aurora PostgreSQL DB cluster to require SCRAM

For Aurora PostgreSQL 14.3 and higher versions, you can require the Aurora PostgreSQL DB cluster to accept only passwords that use the scram-sha-256 algorithm.

#### Important

For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your Aurora PostgreSQL DB cluster for the parameters that control password encryption.
- If your Aurora PostgreSQL DB cluster uses a default parameter group, you need to create a custom DB cluster parameter group and apply it to your Aurora PostgreSQL DB cluster so that you can modify parameters when needed. If your Aurora PostgreSQL DB cluster uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.

- Change the `password_encryption` parameter to `scram-sha-256`.
- Notify all database users that they need to update their passwords. Do the same for your `postgres` account. The new passwords are encrypted and stored using the `scram-sha-256` algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use `scram-sha-256`, you can change the `rds.accepted_password_auth_method` parameter from `md5+scram` to `scram-sha-256`.

### Warning

After you change `rds.accepted_password_auth_method` to `scram-sha-256` alone, any users (roles) with `md5`-encrypted passwords can't connect.

## Getting ready to require SCRAM for your Aurora PostgreSQL DB cluster

Before making any changes to your Aurora PostgreSQL DB cluster, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. To see which PostgreSQL versions support `rds_tools`, see [Extension versions for Amazon RDS for PostgreSQL](#).

### To get a list of database users (roles) and password encryption methods

1. Use `psql` to connect to the primary instance of your Aurora PostgreSQL DB cluster , as shown in the following.

```
psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Install the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools;  
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM  
    rds_tools.role_password_encryption_type();
```

You see output similar to the following.

```
      rolname          | encryption_type
-----+-----
 pg_monitor           |
 pg_read_all_settings |
 pg_read_all_stats    |
 pg_stat_scan_tables  |
 pg_signal_backend    |
 lab_tester           | md5
 user_465             | md5
 postgres             | md5
(8 rows)
```

## Creating a custom DB cluster parameter group

### Note

If your Aurora PostgreSQL DB cluster already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Aurora, see [Creating a DB cluster parameter group in Amazon Aurora](#).

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the Aurora PostgreSQL DB cluster allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB cluster parameter group and apply it to your cluster.

You can also use the Amazon Web Services Management Console or the RDS API to create a custom DB cluster parameter group. For more information, see [Creating a DB cluster parameter group in Amazon Aurora](#).

You can now associate the custom parameter group with your DB instance.

## To create a custom DB cluster parameter group

1. Use the [create-db-cluster-parameter-group](#) CLI command to create the custom parameter group for the cluster. The following example uses `aurora-postgresql13` as the source for this custom parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-  
lab-scam-passwords' \  
  --db-parameter-group-family aurora-postgresql13 --description 'Custom DB cluster  
parameter group for SCRAM'
```

For Windows:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-  
lab-scam-passwords" ^  
  --db-parameter-group-family aurora-postgresql13 --description "Custom DB cluster  
parameter group for SCRAM"
```

You can now associate the custom parameter group with your cluster.

2. Use the [modify-db-cluster](#) CLI command to apply this custom parameter group to your Aurora PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier 'your-instance-name' \  
  --db-cluster-parameter-group-name "docs-lab-scam-passwords"
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier "your-instance-name" ^  
  --db-cluster-parameter-group-name "docs-lab-scam-passwords"
```

To resynchronize your Aurora PostgreSQL DB cluster with your custom DB cluster parameter group, reboot the primary and all other instances of the cluster.

## Configuring password encryption to use SCRAM

The password encryption mechanism used by an Aurora PostgreSQL DB cluster is set in the DB cluster parameter group in the `password_encryption` parameter. Allowed values are `unset`, `md5`, or `scram-sha-256`. The default value depends on the Aurora PostgreSQL version, as follows:

- Aurora PostgreSQL 14 – Default is `scram-sha-256`
- Aurora PostgreSQL 13 – Default is `md5`

With a custom DB cluster parameter group attached to your Aurora PostgreSQL DB cluster, you can modify values for the password encryption parameter.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable	Source	Apply type
<input type="checkbox"/>	<code>password_encryption</code>	<code>scram-sha-256</code>	<code>md5, scram-sha-256</code>	true	system	dynamic
<input type="checkbox"/>	<code>rds.accepted_password_auth_method</code>	<code>md5+scram</code>	<code>md5+scram, scram</code>	true	system	dynamic

### To change password encryption setting to scram-sha-256

- Change the value of the password encryption to `scram-sha-256`, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name \
  'docs-lab-scram-passwords' --parameters
  'ParameterName=password_encryption,ParameterValue=scram-
  sha-256,ApplyMethod=immediate'
```

For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name ^
  "docs-lab-scram-passwords" --parameters
  "ParameterName=password_encryption,ParameterValue=scram-
  sha-256,ApplyMethod=immediate"
```

## Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

### To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.

```
psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Check the setting of the password\_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

```
postgres=> SHOW password_encryption;
password_encryption
-----
md5
(1 row)
```

3. Change the value of this parameter to scram-sha-256. For more information, see [Configuring password encryption to use SCRAM](#).
4. Check the value again to make sure that it's now set to scram-sha-256, as follows.

```
postgres=> SHOW password_encryption;
password_encryption
-----
scram-sha-256
(1 row)
```

5. Notify all database users to change their passwords. Be sure to also change your own password for account postgres (the database user with rds\_superuser privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

6. Repeat the process for all databases on your Aurora PostgreSQL DB cluster.

## Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can't log in to the Aurora PostgreSQL DB cluster.

The `rds.accepted_password_auth_method` specifies the encryption method that the Aurora PostgreSQL DB cluster accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable	Source	Apply type
<input type="checkbox"/>	<code>password_encryption</code>	<code>scram-sha-256</code>	<code>md5, scram-sha-256</code>	true	system	dynamic
<input type="checkbox"/>	<code>rds.accepted_password_auth_method</code>	<code>md5+scram</code>	<code>md5+scram, scram</code>	true	system	dynamic

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

### To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your Aurora PostgreSQL DB cluster use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
 rolname          | encryption_type
-----+-----
 pg_monitor       |
 pg_read_all_settings |
 pg_read_all_stats  |
 pg_stat_scan_tables |
 pg_signal_backend  |
 lab_tester       | scram-sha-256
 user_465         | scram-sha-256
 postgres         | scram-sha-256
( rows)
```

2. Repeat the query across all DB instances in your Aurora PostgreSQL DB cluster.

If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-  
lab-scram-passwords' \  
  --parameters  
  'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

For Windows:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-  
lab-scram-passwords" ^  
  --parameters  
  "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

## Securing Aurora PostgreSQL data with SSL/TLS

Amazon RDS supports Secure Socket Layer (SSL) and Transport Layer Security (TLS) encryption for Aurora PostgreSQL DB clusters. Using SSL/TLS, you can encrypt a connection between your applications and your Aurora PostgreSQL DB clusters. You can also force all connections to your Aurora PostgreSQL DB cluster to use SSL/TLS. Amazon Aurora PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2. We recommend using TLS 1.2 for encrypted connections. We have added support for TLSv1.3 from the following versions of Aurora PostgreSQL:

- 15.3 and all higher versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
- 12.15 and higher 12 versions
- 11.20 and higher 11 versions

For general information about SSL/TLS support and PostgreSQL databases, see [SSL support](#) in the PostgreSQL documentation. For information about using an SSL/TLS connection over JDBC, see [Configuring the client](#) in the PostgreSQL documentation.

## Topics

- [Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster](#)
- [Determining the SSL/TLS connection status](#)
- [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters](#)

SSL/TLS support is available in all Amazon Regions for Aurora PostgreSQL. Amazon RDS creates an SSL/TLS certificate for your Aurora PostgreSQL DB cluster when the DB cluster is created. If you enable SSL/TLS certificate verification, then the SSL/TLS certificate includes the DB cluster endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

### To connect to an Aurora PostgreSQL DB cluster over SSL/TLS

1. Download the certificate.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

2. Import the certificate into your operating system.
3. Connect to your Aurora PostgreSQL DB cluster over SSL/TLS.

When you connect using SSL/TLS, your client can choose to verify the certificate chain or not. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as `psql` or `JDBC`, is configured with SSL/TLS support, the client first tries to connect to the database with SSL/TLS by default. If the client can't connect with SSL/TLS, it reverts to connecting without SSL/TLS. By default, the `sslmode` option for `JDBC` and `libpq`-based clients is set to `prefer`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using `psql` to connect to an Aurora PostgreSQL DB cluster.

```
$ psql -h testpg.cdhuqifdpib.us-east-1.rds.amazonaws.com -p 5432 \  
"dbname=testpg user=testuser sslrootcert=rds-ca-2015-root.pem sslmode=verify-full"
```

## Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster

To require SSL/TLS connections to your Aurora PostgreSQL DB cluster, use `rds.force_ssl` parameter.

- To require SSL/TLS connections, set the `rds.force_ssl` parameter value to 1 (on).
- To turn off required SSL/TLS connections, set the `rds.force_ssl` parameter value to 0 (off).

The default value of this parameter depends on the Aurora PostgreSQL version:

- For Aurora PostgreSQL versions 17 and later: The default value is 1 (on).
- For Aurora PostgreSQL versions 16 and older: The default value is 0 (off).

### Note

When you perform a major version upgrade from Aurora PostgreSQL version 16 or earlier to version 17 or later, the default value of the parameter changes from 0 (off) to 1 (on). This change may cause connectivity failures for applications that are not configured for SSL. You can revert to the previous default behavior by setting this parameter to 0 (off).

For more information on handling parameters, see [Parameter groups for Amazon Aurora](#).

Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB cluster's `pg_hba.conf` file to support the new SSL/TLS configuration.

When the `rds.force_ssl` parameter is set to 1 for a DB cluster, you see output similar to the following when you connect, indicating that SSL/TLS is now required:

```
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql (9.3.12, server 9.4.4)
WARNING: psql major version 9.3, server major version 9.4.
Some psql features might not work.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

## Determining the SSL/TLS connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB cluster.

```
Password for user master:
psql (9.3.12)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL/TLS is being used. The function returns `t` if the connection is using SSL/TLS, otherwise it returns `f`.

```
postgres=> create extension sslinfo;
CREATE EXTENSION

postgres=> select ssl_is_used();
 ssl_is_used
-----
t
(1 row)
```

You can use the `select ssl_cipher()` command to determine the SSL/TLS cipher:

```
postgres=> select ssl_cipher();
ssl_cipher
-----
DHE-RSA-AES256-SHA
(1 row)
```

If you enable `set rds.force_ssl` and restart your DB cluster, non-SSL connections are refused with the following message:

```
$ export PGSSLMODE=disable
```

```
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database
"postgres", SSL off
$
```

For information about the `sslmode` option, see [Database connection control functions](#) in the PostgreSQL documentation.

## Configuring cipher suites for connections to Aurora PostgreSQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client SSL/TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this helps prevent the use of insecure or deprecated ciphers.

Configurable cipher suites is supported in Aurora PostgreSQL versions 11.8 and higher.

To specify the list of permissible ciphers for encrypting connections, modify the `ssl_ciphers` cluster parameter. Set the `ssl_ciphers` parameter to a string of comma-separated cipher values in a cluster parameter group using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API. To set cluster parameters, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

The following table shows the supported ciphers for the valid Aurora PostgreSQL engine versions.

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
9.6, 10.20 and lower, 11.15 and lower, 12.10 and lower, 13.6 and lower	DHE-RSA-AES128-SHA	Yes	No	No
	DHE-RSA-AES128-SHA	No	Yes	No
	DHE-RSA-AES128-SHA256	No	Yes	No
	DHE-RSA-AES128-GCM-SHA256	No	Yes	No
	DHE-RSA-AES256-SHA	No	Yes	No

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
	DHE-RSA-AES256-SHA256	Yes	Yes	No
	DHE-RSA-AES256-GCM-SHA384	No	Yes	No
	ECDHE-ECDSA-AES256-SHA	Yes	Yes	No
	ECDHE-ECDSA-AES256-GCM-SHA384	No	Yes	No
	ECDHE-RSA-AES256-SHA384	No	Yes	No
	ECDHE-RSA-AES128-SHA			
	ECDHE-RSA-AES128-SHA256			
	ECDHE-RSA-AES128-GCM-SHA256			
	ECDHE-RSA-AES256-SHA			
	ECDHE-RSA-AES256-GCM-SHA384			

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
10.21, 11.16, 12.11, 13.7, 14.3 and 14.4	ECDHE-RSA-AES128-SHA	Yes	Yes	No
	ECDHE-RSA-WITH-AES128-SHA	No	Yes	No
	ECDHE-RSA-WITH-AES256-SHA	Yes	Yes	No
	ECDHE-RSA-WITH-AES256-SHA256	No	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	Yes	Yes	No
	ECDHE-RSA-WITH-AES256-GCM-SHA384	No	Yes	No
	ECDHE-RSA-WITH-AES256-GCM-SHA384	Yes	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	No	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	Yes	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	No	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	Yes	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	No	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	Yes	Yes	No
	ECDHE-RSA-WITH-AES128-GCM-SHA256	No	Yes	No

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
	_AES_256_ GCM_SHA384  TLS_RSA_W ITH_AES_2 56_GCM_SHA384  TLS_RSA_W ITH_AES_2 56_CBC_SHA  TLS_RSA_W ITH_AES_1 28_GCM_SHA256  TLS_RSA_W ITH_AES_1 28_CBC_SHA  TLS_ECDHE _RSA_WITH _CHACHA20 _POLY1305_SHA256			

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
10.22 , 11.17 , 12.12 , 13.8 , 14.5 , and 15.2	TLS_ECDHE	Yes	Yes	No
	_RSA_WITH _AES_128_CBC_SHA	No	Yes	No
	TLS_ECDHE	No	Yes	No
	_RSA_WITH _AES_128_	Yes	Yes	No
	CBC_SHA256	No	Yes	No

11.20, 12.15, 13.11, 14.8, 15.3, 16.1 and higher	TLS_ECDHE	Yes	Yes	No
	_RSA_WITH _AES_128_CBC_SHA	No	Yes	No
	TLS_ECDHE	No	Yes	No
	_RSA_WITH _AES_128_	Yes	Yes	No
	CBC_SHA256	No	Yes	No
	TLS_ECDHE	Yes	Yes	No
	_RSA_WITH _AES_128_	No	Yes	No
	GCM_SHA256	No	Yes	No
	TLS_ECDHE	Yes	Yes	No
	_RSA_WITH _AES_256_CBC_SHA	No	Yes	No
	TLS_ECDHE	No	Yes	No
	_RSA_WITH _AES_256_	Yes	Yes	No
	GCM_SHA384	No	Yes	No
	TLS_ECDHE	Yes	Yes	No
	_RSA_WITH _AES_128_CBC_SHA	Yes	Yes	No
	TLS_ECDHE	No	Yes	No
_RSA_WITH _AES_128_	No	No	Yes	
CBC_SHA256	No	No	Yes	
TLS_ECDHE				
_RSA_WITH _AES_128_				
GCM_SHA256				

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
	TLS_ECDHE _RSA_WITH _AES_256_CBC_SHA			
	TLS_ECDHE _RSA_WITH _AES_256_ GCM_SHA384			
	TLS_RSA_W ITH_AES_2 56_GCM_SHA384			
	TLS_RSA_W ITH_AES_2 56_CBC_SHA			
	TLS_RSA_W ITH_AES_1 28_GCM_SHA256			
	TLS_RSA_W ITH_AES_1 28_CBC_SHA256			
	TLS_RSA_W ITH_AES_1 28_CBC_SHA			
	TLS_ECDHE _RSA_WITH _CHACHA20 _POLY1305_SHA256			
	TLS_AES_1 28_GCM_SHA256			

Aurora PostgreSQL engine versions	Supported ciphers	TLS 1.1	TLS 1.2	TLS 1.3
	TLS_AES_256_GCM_SHA384			

You can also use the [describe-engine-default-cluster-parameters](#) CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora PostgreSQL 11.

```
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-postgresql11

...some output truncated...
{
  "ParameterName": "ssl_ciphers",
  "Description": "Sets the list of allowed TLS ciphers to be used on secure connections.",
  "Source": "engine-default",
  "ApplyType": "dynamic",
  "DataType": "list",
  "AllowedValues": "DHE-RSA-AES128-SHA,DHE-RSA-AES128-SHA256,DHE-RSA-AES128-GCM-SHA256,DHE-RSA-AES256-SHA,DHE-RSA-AES256-SHA256,DHE-RSA-AES256-GCM-SHA384,
  ECDHE-RSA-AES128-SHA,ECDHE-RSA-AES128-SHA256,ECDHE-RSA-AES128-GCM-SHA256,ECDHE-RSA-AES256-SHA,ECDHE-RSA-AES256-SHA384,ECDHE-RSA-AES256-GCM-SHA384,TLS_RSA_WITH_AES_256_GCM_SHA384,
  TLS_RSA_WITH_AES_256_CBC_SHA,TLS_RSA_WITH_AES_128_GCM_SHA256,TLS_RSA_WITH_AES_128_CBC_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA",
  "IsModifiable": true,
  "MinimumEngineVersion": "11.8",
  "SupportedEngineModes": [
    "provisioned"
  ]
},
...some output truncated...
```

The `ssl_ciphers` parameter defaults to all allowed cipher suites. For more information about ciphers, see the [ssl\\_ciphers](#) variable in the PostgreSQL documentation.

## Using dynamic masking with Aurora PostgreSQL

Dynamic data masking is a security feature that protects sensitive data in Aurora PostgreSQL databases by controlling how data appears to users at query time. Aurora implements it through the `pg_columnmask` extension. `pg_columnmask` provides column-level data protection that complements PostgreSQL's native row-level security and granular access control mechanisms.

With `pg_columnmask`, you create masking policies that determine data visibility based on user roles. When users query tables with masking policies, Aurora PostgreSQL applies the appropriate masking function at query time based on the user's role and policy weight. The underlying data remains unchanged in storage.

`pg_columnmask` supports the following capabilities:

- **Built-in and custom masking functions** – Use pre-built functions for common patterns like email and text masking, or create your own custom functions to protect sensitive data (PII) through SQL-based masking policies.
- **Multiple masking strategies** – Completely hide information, replace partial values with wildcards, or define custom masking approaches.
- **Policy prioritization** – Define multiple policies for a single column. Use weights to determine which masking policy should be used when multiple policies apply to a column. Aurora PostgreSQL applies policies based on weight and user role membership.

`pg_columnmask` is available on Aurora PostgreSQL version 16.10 and higher, and version 17.6 and higher. It is available at no additional cost.

### Getting started with dynamic masking

To dynamically mask data, you install the `pg_columnmask` extension in your database and create masking policies for your tables. The setup process involves prerequisite verification, extension installation, role configuration, policy creation, and validation testing.

#### Extension installation and configuration

Connect to your Aurora PostgreSQL cluster using the RDS Console Query Editor or a PostgreSQL client such as `psql` with `rds_superuser` (master user) credentials.

Execute the extension creation command to enable `pg_columnmask` functionality:

```
CREATE EXTENSION pg_columnmask;
```

This command installs the `pg_columnmask` extension, creates the necessary catalog tables, and registers the built-in masking functions. The extension installation is database-specific, meaning you must install it separately in each database where the functionality is required.

 **Note**

Connections made before installing this extension will still show unmasked data. Close and reconnect to fix this.

Verify the extension installation by checking the available masking functions:

```
SELECT proname FROM pg_proc
   WHERE pronamespace = 'pgcolumnmask'::regnamespace AND proname LIKE 'mask_%';
   proname
-----Output -----
mask_email
mask_text
mask_timestamp
(3 rows)
```

## Procedures for managing data masking policies

You can manage masking policies using procedures provided by the `pg_columnmask` extension. To create, modify, or drop masking policies, you must have one of the following privileges:

- Owner of the table on which you are creating the `pg_columnmask` policy.
- Member of `rds_superuser`.
- Member of `pg_columnmask` policy manager role set by the `pgcolumnmask.policy_admin_role` parameter.

The following command creates a table that is used in subsequent sections:

```
CREATE TABLE public.customers (
  id SERIAL PRIMARY KEY,
  name TEXT,
```

```

phone TEXT,
address TEXT,
email TEXT
);

```

## CREATE\_MASKING\_POLICY

The following procedure creates a new masking policy for a user table:

### Syntax

```

create_masking_policy(
  policy_name,
  table_name,
  masking_expressions,
  roles,
  weight)

```

### Arguments

Parameter	Datatype	Description
policy_name	NAME	The name of the masking policy. Must be unique per table.
table_name	REGCLASS	The qualified/unqualified name or oid of the table to apply masking policy.
masking_expressions	JSONB	JSON object containing column name and masking function pairs. Each key is a column name and its value is the masking expression to be applied on that column.
roles	NAME[]	The roles to which this masking policy applies. Default is PUBLIC.

Parameter	Datatype	Description
weight	INT	Weight of the masking policy. When multiple policies are applicable to a given user's query, the policy with the highest weight (higher integer number) will be applied to each masked column.  Default is 0. No two masking policies on the table can have the same weight.

### Return type

None

### Example of creating a masking policy that masks the email column for the test\_user role:

```
CALL pgcolumnmask.create_masking_policy(  
    'customer_mask',  
    'public.customers',  
    JSON_OBJECT('{  
        "email", "pgcolumnmask.mask_email(email)"  
    }')::JSONB,  
    ARRAY['test_user'],  
    100  
);
```

### ALTER\_MASKING\_POLICY

This procedure modifies an existing masking policy. ALTER\_MASKING\_POLICY can modify the policy masking expressions, set of roles to which the policy applies and the weight of the masking policy. When one of those parameters is omitted, the corresponding part of the policy is unchanged.

### Syntax

```
alter_masking_policy(  

```

```
policy_name,
table_name,
masking_expressions,
roles,
weight)
```

## Arguments

Parameter	Datatype	Description
policy_name	NAME	Existing name of the masking policy.
table_name	REGCLASS	The qualified/unqualified name oid of the table containing the masking policy.
masking_expressions	JSONB	New JSON object containing column name and masking function pairs or NULL otherwise.
roles	NAME[]	The list of new roles to which this masking policy applies or NULL otherwise.
weight	INT	New weight for the masking policy or NULL otherwise.

## Return type

None

**Example of adding the analyst role to an existing masking policy without changing other policy attributes.**

```
CALL pgcolumnmask.alter_masking_policy(
    'customer_mask',
```

```
'public.customers',
NULL,
ARRAY['test_user', 'analyst'],
NULL
);

-- Alter the weight of the policy without altering other details
CALL pgcolumnmask.alter_masking_policy(
    'customer_mask',
    'customers',
    NULL,
    NULL,
    4
);
```

## DROP\_MASKING\_POLICY

This procedure removes an existing masking policy.

### Syntax

```
drop_masking_policy(
    policy_name,
    table_name)
```

### Arguments

Parameter	Datatype	Description
policy_name	NAME	Existing name of the masking policy.
table_name	REGCLASS	The qualified/unqualified name oid of the table containing the masking policy.

### Return type

None

## Example of dropping the masking policy `customer_mask`

```
-- Drop a masking policy
CALL pgcolumnmask.drop_masking_policy(
    'customer_mask',
    'public.customers',
);
```

## Escaping identifiers in masking policy DDL procedure

When creating data masking policies with quoted identifiers, proper escaping is required to ensure correct object references and policy application. To use quoted identifiers inside the `pg_columnmask` masking policy management procedures:

- **Policy name** – Must be enclosed in double quotes.
- **Table name** – Both schema name and table name must be enclosed in double quotes individually when required.
- **Masking expressions** – Column and function names in masking expressions must be enclosed in double quotes and the quotes themselves must be escaped using a backslash.
- **Roles** – The array of role names is automatically quoted. The role name should exactly match the name as seen in `pg_roles` including case sensitivity.

## Example of escaping and quoting syntax

This example shows the proper escaping and quoting syntax when creating masking policies for tables, columns, functions, and roles that use mixed-case names or require quoted identifiers in Aurora PostgreSQL.

```
-- Create a table and columns with mixed case name
CREATE TABLE public."Employees" (
    "Name" TEXT,
    "Email" TEXT,
    ssn VARCHAR(20)
);

-- Create a role with mixed case name
CREATE ROLE "Masked_user";

-- Create a function with mixed case name
```

```

CREATE OR REPLACE FUNCTION public."MaskEmail"(text)
  RETURNS character varying
  LANGUAGE plpgsql
  IMMUTABLE PARALLEL SAFE
  AS $$ BEGIN
    RETURN 'XXXXXXXX'::text;
  END $$;

-- Now use these objects with mixed case names in
-- masking policy management procedures
CALL pgcolumnmask.create_masking_policy(
  "Policy1", -- policy name should be surrounded with double quotes for quoting
  'public."Employees"', -- table and schema name should be individually
                    -- surrounded with double quotes for quoting
  JSON_OBJECT('{
    "\"Email\"", "\"MaskEmail\"(\"Email\")"
  }')::JSONB, -- masking expression should have double quotes around function names
              -- and columns names etc when needed. Also the double quotes itself
              -- should be escaped using \ (backslash) since this is a JSON string
  ARRAY['Masked_user'], -- Rolename do not need quoting
                    -- (this behaviour may change in future release)

  100
);

SELECT * FROM pgcolumnmask.pg_columnmask_policies
  WHERE tablename = 'Employees';
-[ RECORD 1 ]-----+-----
schemaname      | public
tablename       | Employees
policyname     | Policy1
roles           | {Masked_user}
masked_columns  | {Email}
masking_functions | {"(\"MaskEmail\"(\"Email\"))::text"}
weight         | 100

```

## Administrative views

You can review all the `pg_columnmask` policy using the publicly accessible `pgcolumnmask.pg_columnmask_policies` administrative view. Following information is available using this view. The view only returns the masking policies owned by current user.

Column name	Data type	Description
schemaname	NAME	Schema of the relation to which the policy is attached
tablename	NAME	Name of the relation to which the policy is attached
policyname	NAME	Name of the masking policy, all masking policies have unique names
roles	TEXT[]	Role to which policy applies.
masked_columns	TEXT[]	Masked columns
masking_functions	TEXT[]	Masking functions
weight	INT	Weight of the attached policy

## Pre-defined data masking functions

`pg_columnmask` extension provides built-in utility functions written in C language (for faster execution) which can be used as masking expression for `pg_columnmask` policies.

### `mask_text`

A function to mask text data with configurable visibility options.

### Arguments

Parameter	Datatype	Description
input	TEXT	The original text string to be masked
mask_char	CHAR(1)	Character used for masking (default: 'X')

Parameter	Datatype	Description
<code>visible_prefix</code>	INT	Number of characters at the beginning of input text that will remain unmasked (default: 0)
<code>visible_suffix</code>	INT	Number of characters at the end of input text that will remain unmasked (default: 0)
<code>use_hash_mask</code>	BOOLEAN	If TRUE, uses a hash-based masking instead of <code>mask_char</code> (default: FALSE)

### Example of using different masking options

Mask the entire input string with the default 'X' character

```
postgres=> SELECT pgcolumnmask.mask_text('Hello World');
 mask_text
-----
XXXXXXXXXXXX
```

Use the `mask_char` argument to mask text input using a different character

```
postgres=> SELECT pgcolumnmask.mask_text('Hello World', '*');
 mask_text
-----
*****
```

Use `visible_prefix` and `visible_suffix` parameters to control how many characters remain unmasked at the start and end of the text

```
postgres=> SELECT pgcolumnmask.mask_text('Hello World', '*', 5, 1);
 mask_text
-----
Hello*****d
```

When `use_hash_mask` is true the input string is masked using random characters `mask_char` argument is ignored but `visible_prefix` and `visible_suffix` are still honored

```
postgres=> SELECT pgcolumnmask.mask_text('Hello World', '*', 2, 2, true);
 mask_text
-----
Hex36d0Hild
```

## mask\_timestamp

Parameter	Datatype	Description
<code>ts_to_mask</code>	TIMESTAMP	The original timestamp to be masked
<code>mask_part</code>	TEXT	Specifies which part of the timestamp to mask (default: 'all') Valid values: 'year', 'month', 'day', 'hour', 'minute', 'second', 'all'
<code>mask_value</code>	TIMESTAMP	The timestamp value to use for masking (default: '1900-01-01 00:00:00')

### Example of using mask\_timestamps

These examples demonstrate complete timestamp masking to a default value, partial masking of specific timestamp components (year only), and masking with a custom replacement value.

Completely mask input value to the default timestamp

```
postgres=> SELECT pgcolumnmask.mask_timestamp('2023-06-15 14:30:00');
 mask_timestamp
-----
1900-01-01 00:00:00
```

To mask only one part of the timestamp from example only the year

```
postgres=> SELECT pgcolumnmask.mask_timestamp('2023-06-15 14:30:00', 'year');
           mask_timestamp
-----
1900-06-15 14:30:00
```

To change the masked value for timestamp use the `mask_value` argument

```
postgres=> SELECT pgcolumnmask.mask_timestamp('2023-06-15 14:30:00', 'all', '2012-12-12
           12:12:12');
           mask_timestamp
-----
2012-12-12 12:12:12
```

## mask\_timestamp

A function to mask email addresses while preserving email structure.

Parameter	Datatype	Description
input	TEXT	The original email address to be masked
mask_char	CHAR(1)	Character used for masking (default: 'X')
mask_local	BOOLEAN	If TRUE, masks the local part of email (before @) (default: TRUE)
mask_domain	BOOLEAN	If TRUE, masks the domain part of email (after @) (default: TRUE)

## Example of using mask\_email

These examples demonstrate complete email masking, custom mask characters, and selective masking of either the local part or domain part of the email address.

### Complete masking

```
postgres=> SELECT pgcolumnmask.mask_email('user@example.com');
      mask_email
-----
XXXX@XXXXXXX.com
```

### Use `mask_char` to change the character used for masking

```
postgres=> SELECT pgcolumnmask.mask_email('user@example.com', '*');
      mask_email
-----
****@*****.com
```

### Use `mask_local` and `mask_domain` to control masking on local and domain

```
postgres=> SELECT pgcolumnmask.mask_email('user@example.com', '*', true, false);
      mask_email
-----
****@example.com

postgres=> SELECT pgcolumnmask.mask_email('user@example.com', '*', false, true);
      mask_email
-----
user@*****.com
```

## Implementing `pg_columnmask` in an end-to-end workflow

This section demonstrates a complete implementation of `pg_columnmask` using a sample employee table with sensitive data. You'll learn how to create custom masking functions, define multiple masking policies with different weight levels for various roles (intern, support, analyst), and observe how users with single or multiple role memberships see different levels of masked data. The examples also cover masking behavior in DML statements with `RETURNING` clauses, triggers on tables versus views, and policy management operations including renaming, altering weights, and cleanup.

#### 1. Create a sample table with some sensitive data:

```
CREATE SCHEMA hr;

CREATE TABLE hr.employees (
  id INT PRIMARY KEY,
```

```

name TEXT NOT NULL,
email TEXT,
ssn TEXT,
salary NUMERIC(10,2)
);

INSERT INTO hr.employees VALUES
(1, 'John Doe', 'john.doe@example.com', '123-45-6789', 50000.00),
(2, 'Jane Smith', 'jane.smith@example.com', '987-65-4321', 60000.00);

```

## 2. Create custom masking functions:

```

CREATE OR REPLACE FUNCTION public.mask_ssn(ssn TEXT)
RETURNS TEXT AS $$
BEGIN
    RETURN 'XXX-XX-' || RIGHT(ssn, 4);
END;
$$ LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION public.mask_salary(salary NUMERIC, multiplier NUMERIC
DEFAULT 0.0)
RETURNS NUMERIC AS $$
BEGIN
    RETURN salary * multiplier;
END;
$$ LANGUAGE plpgsql;

```

## 3. Create multiple policies with different masking levels based on user roles:

```

-- Create different roles
CREATE ROLE analyst_role;
CREATE ROLE support_role;
CREATE ROLE intern_role;

GRANT USAGE ON SCHEMA hr TO analyst_role, support_role, intern_role;
GRANT SELECT ON hr.employees TO analyst_role, support_role, intern_role;
-----

-- Low-Weight Policy (Intern)
CALL pgcolumnmask.create_masking_policy(
    'employee_mask_strict',
    'hr.employees',
    JSON_BUILD_OBJECT('name', 'pgcolumnmask.mask_text(name, '*'')',

```

```

        'email', 'pgcolumnmask.mask_email(email)',
        'ssn', 'pgcolumnmask.mask_text(ssn, '*'')',
        'salary', 'public.mask_salary(salary)::JSONB,
ARRAY['intern_role'],
10 -- Lowest weight
);

-----

-- Medium-Weight Policy (Support)
CALL pgcolumnmask.create_masking_policy(
    'employee_mask_moderate',
    'hr.employees',
    JSON_BUILD_OBJECT('email', 'pgcolumnmask.mask_email(email, '#'')',
        'ssn', 'public.mask_ssn(ssn)',
        'salary', 'public.mask_salary(salary)::JSONB,
    ARRAY['support_role'],
    50 -- Medium weight
);

-----

-- High-Weight Policy (Analyst)
CALL pgcolumnmask.create_masking_policy(
    'employee_mask_light',
    'hr.employees',
    JSON_BUILD_OBJECT('ssn', 'public.mask_ssn(ssn)',
        'salary', 'public.mask_salary(salary, 0.9)::JSONB,
    ARRAY['analyst_role'],
    100 -- Highest weight
);

```

4. The following examples demonstrate how different users see data based on their role membership and policy weights.

```

-- Create users
CREATE USER sarah_intern;
GRANT intern_role TO sarah_intern;

CREATE USER lisa_support;
GRANT support_role TO lisa_support;

CREATE USER mike_analyst;
GRANT analyst_role TO mike_analyst;

```

```
CREATE USER ethan_support_intern;
GRANT support_role, intern_role TO ethan_support_intern;

CREATE USER john_analyst_intern;
GRANT analyst_role, intern_role TO john_analyst_intern;
```

As an intern (strictest masking):

```
SET ROLE sarah_intern;

SELECT * FROM hr.employees;
 id | name | email | ssn | salary
----+-----+-----+-----+-----
  1 | ***** | XXXXXXXX@XXXXXXX.com | ***** | 0.00
  2 | ***** | XXXXXXXXXX@XXXXXXX.com | ***** | 0.00
```

As a support user (moderate masking):

```
SET ROLE lisa_support;

SELECT * FROM hr.employees;
 id | name | email | ssn | salary
----+-----+-----+-----+-----
  1 | John Doe | #####@#####.com | XXX-XX-6789 | 0.00
  2 | Jane Smith | #####@#####.com | XXX-XX-4321 | 0.00
```

As an analyst (lightest masking):

```
SET ROLE mike_analyst;

SELECT * FROM hr.employees;
 id | name | email | ssn | salary
----+-----+-----+-----+-----
  1 | John Doe | john.doe@example.com | XXX-XX-6789 | 45000.00
  2 | Jane Smith | jane.smith@example.com | XXX-XX-4321 | 54000.00
```

As ethan\_support\_intern user which is both intern and support user:

```
SET ROLE ethan_support_intern;
```

```
-- masking policies applicable to this user: employee_mask_strict and
employee_mask_moderate
-- id : unmasked because no masking policy applicable on ethan_support_intern
--           masks these columns
-- name : masked because of employee_mask_strict policy
-- email, ssn, salary : both employee_mask_strict and employee_mask_moderate mask
these columns
--
--           but employee_mask_moderate will be use because of higher
weight
```

```
SELECT * FROM hr.employees;
```

id	name	email	ssn	salary
1	*****	#####@#####.com	XXX-XX-6789	0.00
2	*****	#####@#####.com	XXX-XX-4321	0.00

As a john\_analyst\_intern which is both intern and analyst:

```
SET ROLE john_analyst_intern;
```

```
-- masking policies applicable to this user: employee_mask_strict and
employee_mask_light
-- id : unmasked because no masking policy applicable on john_analyst_intern
--           masks these columns
-- name, email : masked because of employee_mask_strict
-- ssn, salary : both employee_mask_strict and employee_mask_light mask these
columns
--
--           but employee_mask_light will be use because of higher weight
```

```
SELECT * FROM hr.employees;
```

id	name	email	ssn	salary
1	*****	XXXXXXXX@XXXXXXX.com	XXX-XX-6789	45000.00
2	*****	XXXXXXXXXX@XXXXXXX.com	XXX-XX-4321	54000.00

## Understanding masking behavior in DML operations

pg\_columnmask applies consistently across all DML operations, including INSERT, UPDATE, DELETE, and MERGE statements. When you execute these operations, Aurora PostgreSQL masks data according to a core principle – any data read from storage is masked according to the current user's applicable policies.

Masking affects some of the following query components like:

- WHERE clauses
- JOIN conditions
- Subqueries
- RETURNING clauses

All of these components operate on masked values, not the original data. While data is written to storage unmasked, users only see their masked view when reading it back.

Aurora PostgreSQL enforces all database constraints (NOT NULL, UNIQUE, CHECK, FOREIGN KEY) on the actual stored values, not masked values. This can occasionally create apparent inconsistencies if masking functions aren't carefully designed.

Masking works alongside column-level permissions:

- Users without SELECT privileges cannot read columns
- Users with SELECT privileges see masked values according to their applicable policies

## Understanding masking behavior in trigger functions

When `pg_columnmask` policies are applied to tables, it's important to understand how masking interacts with trigger functions. Triggers are database functions that execute automatically in response to certain events on a table, such as INSERT, UPDATE, or DELETE operations.

By default, DDM applies different masking rules depending on the type of trigger:

### Table triggers

**Transition tables are unmasked** – Trigger functions on tables have access to unmasked data in their transition tables for both old and new row versions

Table owners create triggers and own the data, so they have full access to manage their tables effectively

### View Triggers (INSTEAD OF Triggers)

**Transition tables are masked** – Trigger functions on views see masked data according to the current user's permissions

View owners may differ from base table owners and should respect masking policies on underlying tables

Two server-level configuration parameters control trigger behavior with masked tables. These can only be set by `rds_superuser`:

- **Restrict Triggers on Masked Tables** – Prevents trigger execution when a masked user performs DML operations on tables with applicable masking policies.
- **Restrict Triggers on Views with Masked Tables:** – Prevents trigger execution on views when the view definition includes tables with masking policies applicable to the current user.

### Example of differences between function application to table and view

The following example creates a trigger function that prints old and new row values, then demonstrates how the same function behaves differently when attached to a table versus a view.

```
-- Create trigger function
CREATE OR REPLACE FUNCTION print_changes()
  RETURNS TRIGGER AS
  $$
    BEGIN
      RAISE NOTICE 'Old row: name=%, email=%, ssn=%, salary=%',
        OLD.name, OLD.email, OLD.ssn, OLD.salary;

      RAISE NOTICE 'New row: name=%, email=%, ssn=%, salary=%',
        NEW.name, NEW.email, NEW.ssn, NEW.salary;

      RETURN NEW;
    END;
  $$ LANGUAGE plpgsql;

-- Create trigger
CREATE TRIGGER print_changes_trigger
  BEFORE UPDATE ON hr.employees
  FOR EACH ROW
  EXECUTE FUNCTION print_changes();

-- Grant update to analyst role
GRANT UPDATE ON hr.employees TO analyst_role;

-- Unmasked data must be seen inside trigger even for masked user for the OLD and NEW
```

```
-- row passed to trigger function
BEGIN;
SET ROLE mike_analyst;
UPDATE hr.employees SET id = id + 10 RETURNING *;
NOTICE:  Old row: name=John Doe, email=john.doe@example.com, ssn=123-45-6789,
  salary=50000.00
NOTICE:  New row: name=John Doe, email=john.doe@example.com, ssn=123-45-6789,
  salary=50000.00
NOTICE:  Old row: name=Jane Smith, email=jane.smith@example.com, ssn=987-65-4321,
  salary=60000.00
NOTICE:  New row: name=Jane Smith, email=jane.smith@example.com, ssn=987-65-4321,
  salary=60000.00
 id |   name   |      email      |      ssn      | salary
-----+-----+-----+-----+-----
 11 | John Doe  | john.doe@example.com | XXX-XX-6789 | 45000.00
 12 | Jane Smith | jane.smith@example.com | XXX-XX-4321 | 54000.00
(2 rows)

ROLLBACK;

-- Triggers on views (which are supposed to see masked data for new/old row)
CREATE VIEW hr.view_over_employees AS SELECT * FROM hr.employees;
GRANT UPDATE, SELECT ON hr.view_over_employees TO analyst_role;

-- Create trigger for this view
CREATE TRIGGER print_changes_trigger
  INSTEAD OF UPDATE ON hr.view_over_employees
  FOR EACH ROW
  EXECUTE FUNCTION print_changes();

-- Masked new and old rows should be passed to trigger if trigger is on view
BEGIN;
SET ROLE mike_analyst;
UPDATE hr.view_over_employees SET id = id + 10 RETURNING *;
NOTICE:  Old row: name=John Doe, email=john.doe@example.com, ssn=XXX-XX-6789,
  salary=45000.00
NOTICE:  New row: name=John Doe, email=john.doe@example.com, ssn=XXX-XX-6789,
  salary=45000.00
NOTICE:  Old row: name=Jane Smith, email=jane.smith@example.com, ssn=XXX-XX-4321,
  salary=54000.00
NOTICE:  New row: name=Jane Smith, email=jane.smith@example.com, ssn=XXX-XX-4321,
  salary=54000.00
 id |   name   |      email      |      ssn      | salary
```

```

-----+-----+-----+-----+-----
 11 | John Doe   | john.doe@example.com | XXX-XX-6789 | 45000.00
 12 | Jane Smith | jane.smith@example.com | XXX-XX-4321 | 54000.00
(2 rows)
ROLLBACK;

```

We recommend reviewing trigger behavior before implementing triggers on masked tables. Table triggers have access to unmasked data in transition tables, while view triggers see masked data.

### Example of renaming masking policy

The following example demonstrates how to rename existing policies using the `rename_masking_policy` procedure.

```

-- Rename the strict policy
CALL pgcolumnmask.rename_masking_policy(
    'employee_mask_strict',
    'hr.employees',
    'intern_protection_policy'
);

-- Verify the rename
SELECT policyname, roles, weight
   FROM pgcolumnmask.pg_columnmask_policies
   WHERE tablename = 'employees'
   ORDER BY weight DESC;

```

policyname	roles	weight
employee_mask_light	{analyst_role}	100
employee_mask_moderate	{support_role}	50
intern_protection_policy	{intern_role}	10

### Example of altering policy weight

The following example demonstrates how to alter policy weights to change their weight.

```

-- Change weight of moderate policy
CALL pgcolumnmask.alter_masking_policy(
    'employee_mask_moderate'::NAME,
    'hr.employees'::REGCLASS,
    NULL, -- Keep existing masking expressions

```

```

NULL,    -- Keep existing roles
75       -- New weight
);

-- Verify the changes
SELECT policyname, roles, weight
   FROM pgcolumnmask.pg_columnmask_policies
   WHERE tablename = 'employees'
   ORDER BY weight DESC;

```

policyname	roles	weight
employee_mask_light	{analyst_role}	100
employee_mask_moderate	{support_role}	75
intern_protection_policy	{intern_role}	10

### Example of cleaning up

The following example demonstrates how to drop all policies, tables and users.

```

-- Drop policies
CALL pgcolumnmask.drop_masking_policy(
    'intern_protection_policy',
    'hr.employees'
);

CALL pgcolumnmask.drop_masking_policy(
    'employee_mask_moderate',
    'hr.employees'
);

CALL pgcolumnmask.drop_masking_policy(
    'employee_mask_light',
    'hr.employees'
);

-- Drop table and functions
DROP VIEW IF EXISTS hr.view_over_employees;
DROP TABLE IF EXISTS hr.employees;
DROP SCHEMA IF EXISTS hr;
DROP FUNCTION IF EXISTS public.mask_ssn(text);
DROP FUNCTION IF EXISTS public.mask_salary(numeric, numeric);

-- Drop users
DROP USER sarah_intern, lisa_support, mike_analyst,

```

```
ethan_support_intern, john_analyst_intern;  
DROP ROLE intern_role, support_role, analyst_role;
```

## Configuring masking policy management role

The PostgreSQL column masking extension, `pg_columnmask`, allows you to delegate the management of masking policies to a specific role, rather than requiring `rds_superuser` or table owner privileges. This provides more granular control over who can create, alter, and drop masking policies.

To configure the role that will have masking policy management privileges, follow these steps:

1. Create the policy admin role – As an `rds_superuser`, create a new role responsible for managing masking policies:

```
CREATE ROLE mask_admin NOLOGIN;
```

2. Configure the PostgreSQL parameter – In your custom DB cluster parameter group, set the `pgcolumnmask.policy_admin_role_name` engine configuration parameter to the name of the role you created:

```
pgcolumnmask.policy_admin_role_name = mask_admin
```

This engine configuration parameters can be set in a DB cluster parameter group and it does not require an instance reboot. For details on updating parameter, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

3. Grant the role to users As an `rds_superuser`, grant the `mask_admin` role to the users who should be able to manage masking policies:

```
CREATE USER alice LOGIN;  
CREATE USER bob LOGIN;  
GRANT mask_admin TO alice, bob;
```

Additionally, ensure that the users have `USAGE` privilege on the schemas where they will be managing masking policies:

```
GRANT USAGE ON SCHEMA hr TO alice, bob;
```

Now, when users `alice` and `bob` connect to the database, they can use the standard `pg_columnmask` extension functions to create, alter, and drop masking policies on all tables in all the schemas where they have `USAGE` privilege on the schema.

## Best practices for secure `pg_columnmask` implementation

The following section provides security best practices for implementing `pg_columnmask` in your Aurora PostgreSQL environment. Follow these recommendations to:

- Establish a secure role-based access control architecture
- Develop masking functions that prevent security vulnerabilities
- Understand and control trigger behavior with masked data

### Role-based security architecture

Define a role hierarchy to implement access controls in your database. Aurora PostgreSQL `pg_columnmask` augments these controls by providing an additional layer for fine-grained data masking within those roles.

Create dedicated roles that align with organizational functions rather than granting permissions to individual users. This approach provides better auditability and simplifies permission management as your organizational structure evolves.

### Example of creating an organizational role hierarchy

The following example creates an organizational role hierarchy with dedicated roles for different functions, then assigns individual users to the appropriate roles. In this example, organizational roles (`analyst_role`, `support_role`) are created first, then individual users are granted membership in these roles. This structure allows you to manage permissions at the role level rather than for each individual user.

```
-- Create organizational role hierarchy
CREATE ROLE data_admin_role;
CREATE ROLE security_admin_role;
CREATE ROLE analyst_role;
CREATE ROLE support_role;
CREATE ROLE developer_role;

-- Specify security_admin_role as masking policy manager in the DB cluster parameter
-- group pgcolumnmask.policy_admin_rolname = 'security_admin_role'
```

```
-- Create specific users and assign to appropriate roles
CREATE USER security_manager;
CREATE USER data_analyst1, data_analyst2;
CREATE USER support_agent1, support_agent2;

GRANT security_admin_role TO security_manager;
GRANT analyst_role TO data_analyst1, data_analyst2;
GRANT support_role TO support_agent1, support_agent2;
```

Implement the principle of least privilege by granting only the minimum permissions necessary for each role. Avoid granting broad permissions that could be exploited if credentials are compromised.

```
-- Grant specific table permissions rather than schema-wide access
GRANT SELECT ON sensitive_data.customers TO analyst_role;
GRANT SELECT ON sensitive_data.transactions TO analyst_role;
-- Do not grant: GRANT ALL ON SCHEMA sensitive_data TO analyst_role;
```

Policy administrators require USAGE privileges on schemas where they manage masking policies. Grant these privileges selectively, following the principle of least privilege. Conduct regular reviews of schema access permissions to ensure only authorized personnel maintain policy management capabilities.

The policy admin role parameter configuration is restricted to database administrators only. This parameter cannot be modified at the database or session level, preventing unprivileged users from overriding policy admin assignments. This restriction ensures that masking policy control remains centralized and secure.

Assign the policy admin role to specific individuals rather than groups. This targeted approach ensures selective access to masking policy management, as policy administrators have the ability to mask all tables within the database.

### Secure masking function development

Develop masking functions using early binding semantics to ensure proper dependency tracking and prevent late binding vulnerabilities such as search path modification during runtime. It is recommended to use BEGIN ATOMIC syntax for SQL functions to enable compile-time validation (i.e. early binding) and dependency management.

```
-- Example - Secure masking function with early binding
```

```

CREATE OR REPLACE FUNCTION secure_mask_ssn(input_ssn TEXT)
  RETURNS TEXT
  LANGUAGE SQL
  IMMUTABLE PARALLEL SAFE STRICT
  BEGIN ATOMIC
    SELECT CASE
      WHEN input_ssn IS NULL THEN NULL
      WHEN length(input_ssn) < 4 THEN repeat('X', length(input_ssn))
      ELSE repeat('X', length(input_ssn) - 4) || right(input_ssn, 4)
    END;
  END;

```

Alternatively, create functions that are immune to search path changes by explicitly schema qualifying all object references, ensuring consistent behavior across different user sessions.

```

-- Function immune to search path changes
CREATE OR REPLACE FUNCTION data_masking.secure_phone_mask(phone_number TEXT)
  RETURNS TEXT
  LANGUAGE SQL
  IMMUTABLE PARALLEL SAFE STRICT
  AS $$
  SELECT CASE
    WHEN phone_number IS NULL THEN NULL
    WHEN public.length(public.regexp_replace(phone_number, '^[^0-9]', '', 'g')) < 10
  THEN 'XXX-XXX-XXXX'
    ELSE public.regexp_replace(
      phone_number,
      '([0-9]{3})[0-9]{3}([0-9]{4})',
      public.concat('\1-XXX-\2')
    )
  END;
$$;

```

Implement input validation within masking functions to handle edge cases and prevent unexpected behavior. Always include NULL handling and validate input formats to ensure consistent masking behavior.

```

-- Robust masking function with comprehensive input validation
CREATE OR REPLACE FUNCTION secure_mask_phone(phone_number TEXT)
  RETURNS TEXT
  LANGUAGE SQL
  IMMUTABLE PARALLEL SAFE STRICT

```

```

BEGIN ATOMIC
  SELECT CASE
    WHEN phone_number IS NULL THEN NULL
    WHEN length(trim(phone_number)) = 0 THEN phone_number
    WHEN length(regex_replace(phone_number, '^[0-9]', '', 'g')) < 10 THEN
'XXX-XXX-XXXX'
    ELSE regex_replace(phone_number, '([0-9]{3})[0-9]{3}([0-9]{4})', '\1-XXX-
\2')
  END;
END;

```

## DML Triggers behavior with pg\_columnmask

For table triggers, transition tables will be fully unmasked. For view triggers(IOT), transition tables will be masked according to the current user's view permissions.

### Table triggers with pg\_columnmask

Triggers are passed a transition table which contains the old and new version of the rows modified by the firing DML query. Depending upon when the trigger is fired, Aurora PostgreSQL populates the old and new rows. For example, a BEFORE INSERT trigger only has new versions of the rows and empty old versions because there is no old version to refer.

pg\_columnmask does not mask transition tables inside triggers on tables. Triggers can use masked columns inside their body and it sees unmasked data. The trigger creator should make sure how the trigger gets executed for an user. The following example works correctly in this case.

```

-- Example for table trigger uses masked column in its definition
-- Create a table and insert some rows
CREATE TABLE public.credit_card_table (
  name TEXT,
  credit_card_no VARCHAR(16),
  is_fraud BOOL
);

INSERT INTO public.credit_card_table (name, credit_card_no, is_fraud)
VALUES
('John Doe', '4532015112830366', false),
('Jane Smith', '5410000000000000', true),
('Brad Smith', '1234567891234567', true);

```

```
-- Create a role which will see masked data and grant it privileges
CREATE ROLE intern_user;
GRANT SELECT, DELETE ON public.credit_card_table TO intern_user;

-- Trigger which will silently skip delete of non fraudulent credit cards
CREATE OR REPLACE FUNCTION prevent_non_fraud_delete()
  RETURNS TRIGGER AS
  $$
  BEGIN
    IF OLD.is_fraud = false THEN
      RETURN NULL;
    END IF;
    RETURN OLD;
  END;
  $$ LANGUAGE plpgsql;

CREATE TRIGGER prevent_non_fraud_delete
  BEFORE DELETE ON credit_card_table
  FOR EACH ROW
  EXECUTE FUNCTION prevent_non_fraud_delete();

CREATE OR REPLACE FUNCTION public.return_false()
  RETURNS BOOLEAN
  LANGUAGE SQL
  IMMUTABLE PARALLEL SAFE STRICT
  BEGIN ATOMIC
    SELECT false;
  END;

-- A masking policy that masks both credit card number and is_fraud column.
-- If we apply masking inside trigger then prevent_non_fraud_delete trigger will
-- allow deleting more rows to masked user (even non fraud ones).
CALL pgcolumnmask.create_masking_policy(
  'mask_credit_card_no_&_is_fraud'::NAME,
  'public.credit_card_table'::REGCLASS,
  JSON_BUILD_OBJECT('credit_card_no', 'pgcolumnmask.mask_text(credit_card_no)',
                    'is_fraud', 'public.return_false()')::JSONB,
  ARRAY['intern_user']::NAME[],
  10::INT
);

-- Test trigger behaviour using intern_user
BEGIN;
SET ROLE intern_user;
```

```

-- credit card number & is_fraud is completely masked from intern_user
SELECT * FROM public.credit_card_table;
  name      | credit_card_no | is_fraud
-----+-----+-----
John Doe   | XXXXXXXXXXXXXXX | f
Jane Smith | XXXXXXXXXXXXXXX | f
Brad Smith | XXXXXXXXXXXXXXX | f
(3 rows)

-- The delete trigger lets the intern user delete rows for Jane and Brad even though
-- intern_user sees their is_fraud = false, but the table trigger works with
original
-- unmasked value
DELETE FROM public.credit_card_table RETURNING *;
  name      | credit_card_no | is_fraud
-----+-----+-----
Jane Smith | XXXXXXXXXXXXXXX | f
Brad Smith | XXXXXXXXXXXXXXX | f
(2 rows)

COMMIT;

```

Trigger creator leaks unmasked data to user if they are not careful about the statements they use in their trigger body. For example using a `RAISE NOTICE '%', masked_column;` prints the column to current user.

```

-- Example showing table trigger leaking column value to current user
CREATE OR REPLACE FUNCTION leaky_trigger_func()
  RETURNS TRIGGER AS
  $$
  BEGIN
    RAISE NOTICE 'Old credit card number was: %', OLD.credit_card_no;
    RAISE NOTICE 'New credit card number is %', NEW.credit_card_no;
    RETURN NEW;
  END;
  $$ LANGUAGE plpgsql;

CREATE TRIGGER leaky_trigger
  AFTER UPDATE ON public.credit_card_table
  FOR EACH ROW
  EXECUTE FUNCTION leaky_trigger_func();

```

```

-- Grant update on column is_fraud to auditor role
-- auditor will NOT HAVE PERMISSION TO READ DATA
CREATE ROLE auditor;
GRANT UPDATE (is_fraud) ON public.credit_card_table TO auditor;

-- Also add auditor role to existing masking policy on credit card table
CALL pgcolumnmask.alter_masking_policy(
    'mask_credit_card_no_&is_fraud'::NAME,
    'public.credit_card_table'::REGCLASS,
    NULL::JSONB,
    ARRAY['intern_user', 'auditor']::NAME[],
    NULL::INT
);

-- Log in as auditor
-- [auditor]
-- Update will fail if trying to read data from the table
UPDATE public.credit_card_table
    SET is_fraud = true
    WHERE credit_card_no = '4532015112830366';
ERROR:  permission denied for table cc_table

-- [auditor]
-- But leaky update trigger will still print the entire row even though
-- current user does not have permission to select from public.credit_card_table
UPDATE public.credit_card_table SET is_fraud = true;
NOTICE:  Old credit_card_no was: 4532015112830366
NOTICE:  New credit_card_no is 4532015112830366

```

## Triggers on views with pg\_columnmask (Instead of triggers)

Triggers can only be created on views in PostgreSQL. They are used for running DML statements on views that are not updatable. Transit tables are always masked inside instead of trigger (IOT), because the view and the base tables used inside the view query could have different owners. In which case, base tables might have some masking policies applicable on the view owner and the view owner must always see masked data from base tables inside its triggers. This is different from triggers on tables because in that case the trigger creator and the data inside the tables are owned by the same user which is not the case here.

```

-- Create a view over credit card table
CREATE OR REPLACE VIEW public.credit_card_view
AS

```

```
SELECT * FROM public.credit_card_table;

-- Truncate credit card table and insert fresh data
TRUNCATE TABLE public.credit_card_table;
INSERT INTO public.credit_card_table (name, credit_card_no, is_fraud)
VALUES
('John Doe', '4532015112830366', false),
('Jane Smith', '5410000000000000', true),
('Brad Smith', '1234567891234567', true);

CREATE OR REPLACE FUNCTION public.print_changes()
RETURNS TRIGGER AS
$$
BEGIN
    RAISE NOTICE 'Old row: name=%, credit card number=%, is fraud=%',
        OLD.name, OLD.credit_card_no, OLD.is_fraud;

    RAISE NOTICE 'New row: name=%, credit card number=%, is fraud=%',
        NEW.name, NEW.credit_card_no, NEW.is_fraud;

RETURN NEW;
END;
$$ LANGUAGE plpgsql;

CREATE TRIGGER print_changes_trigger
INSTEAD OF UPDATE ON public.credit_card_view
FOR EACH ROW
EXECUTE FUNCTION public.print_changes();

GRANT SELECT, UPDATE ON public.credit_card_view TO auditor;

-- [auditor]
-- Login as auditor role
BEGIN;

-- Any data coming out from the table will be masked in instead of triggers
-- according to masking policies applicable to current user
UPDATE public.credit_card_view
SET name = CONCAT(name, '_new_name')
RETURNING *;

```

## Database/User level GuCs to control triggers behavior

Two configuration parameters control trigger execution behavior for users with applicable masking policies. Use these parameters to prevent triggers from executing on masked tables or views when additional security restrictions are required. Both parameters are disabled by default, allowing triggers to execute normally.

### First GUC: Trigger firing restriction on masked tables

Specifications:

- Name: `pgcolumnmask.restrict_dml_triggers_for_masked_users`
- Type: `boolean`

- Default: false (triggers are allowed to be executed)

Prevents trigger execution on masked tables for masked users when set to TRUE. `pg_columnmask` runs through the error.

### **Second GUC: Trigger firing restriction on views with masked tables**

Specifications:

- Name: `pgcolumnmask.restrict_iot_triggers_for_masked_users`
- Type: boolean
- Default: false (triggers are allowed to be executed)

Prevents trigger execution on views that include masked tables in their definition for masked users when set to TRUE.

These parameters operate independently and are configurable like standard database configuration parameters.

## **Aurora PostgreSQL `pg_columnmask` data movement scenarios**

`pg_columnmask` behavior varies across different data movement operations depending on whether the operation occurs at the storage, logical, or application layer. Storage-level operations (such as cloning) behave differently from logical operations (such as `pg_dump`) and application-level operations (such as FDW queries). This section describes masking behavior for common scenarios including replication, backups, exports, and migrations, and explains the security implications for each.

### **Topics**

- [Aurora Global Database and Read Replicas](#)
- [Database clone and snapshot restore](#)
- [Logical replication](#)
- [Blue/Green deployments](#)
- [Zero-ETL and CDC streams](#)
- [Amazon Database Migration Service](#)
- [Data exports](#)
- [Views and materialized views](#)

- [Data dump and restore](#)
- [Foreign data wrapper](#)

## Aurora Global Database and Read Replicas

Aurora `pg_columnmask` policies are stored in database system tables within the cluster volume. All replicas access the same policies and return consistently masked results. For Aurora Global Database deployments, `pg_columnmask` policies replicate to secondary Amazon Web Services Regions along with other database system tables, ensuring consistent data protection across regions. During failover scenarios, all `pg_columnmask` policies remain intact and functional.

## Database clone and snapshot restore

Aurora Fast Clone and snapshot restore operations preserve all `pg_columnmask` policies, roles, and configurations as part of the database system tables. The cloned or restored database inherits all existing policies from the source cluster. After cloning or restoration, each database cluster maintains independent `pg_columnmask` policies.

## Logical replication

During initial synchronization, logical replication uses standard SQL COPY operations, and `pg_columnmask` policies are enforced based on the replication user's permissions. During ongoing CDC (change data capture), masking policies are not applied and unmasked data is replicated through WAL records. Users with `pg_create_subscription` privileges can potentially exfiltrate unmasked data by setting up replication to a system they control.

## Blue/Green deployments

During snapshot restoration, `pg_columnmask` policies are automatically included. The green environment starts with an identical copy of all policies from the blue environment. During replication from blue to green, data is not masked. Subsequent masking policy changes (DDL commands) on the blue cluster do not replicate to the green cluster and invalidate RDS blue/green deployments.

## Zero-ETL and CDC streams

Data replication is not affected by `pg_columnmask` policies. Zero-ETL supports DDL replication but doesn't replicate `pg_columnmask` or RLS policies. No masking policies are applied to replicated data in Zero-ETL.

## Amazon Database Migration Service

Initial data sync is masked or unmasked based on the user selected for the DMS task. CDC data is always unmasked. While `pg_columnmask` related internal RLS policies may be migrated, they won't function on non-`pg_columnmask`-enabled targets.

### Data exports

`pg_columnmask` treats exports like any other query operation—masking is applied based on the executing user's permissions. This applies to SQL commands like `COPY`, `SELECT INTO`, `CREATE TABLE AS`, and Aurora PostgreSQL's S3 export functionality.

#### Note

When masked users export data, the resulting files contain masked values that may violate database constraints when restored.

### Views and materialized views

Keep the following considerations in mind when using views:

- **Regular views** – Always use `INVOKER` semantics. The current user's masking policies apply when querying the view, regardless of who created the view.
- **Materialized views** – When refreshed, the masking policies of the materialized view owner apply, not the policies of the user performing the refresh. If the owner has masking policies, the materialized view always contains masked data.

### Data dump and restore

`pg_dump` operates as a regular database user and applies masking policies based on the connecting user's permissions. If a masked user performs a dump, the backup file contains masked data.

`pg_columnmask` policies are included in the dump as part of the database schema. Successful restoration requires that all referenced roles exist in the target database and that the target has the `pg_columnmask` extension installed.

**Note**

Starting with PostgreSQL 18, `pg_dump` supports the `--no-policies` option which excludes both Row Level Security (RLS) and `pg_columnmask` masking policies from database dumps. For more information, see [pg\\_dump](#).

## Foreign data wrapper

When using foreign data wrappers, masking policies on remote tables are applied based on the mapped user's permissions on the source server, not the local querying user's permissions, and while you can access masked remote data through FDW, you cannot create DDM or RLS policies directly on foreign tables in your local database.

## Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to Aurora PostgreSQL DB clusters only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster](#). For information about using SSL/TLS with PostgreSQL DB clusters, see [Securing Aurora PostgreSQL data with SSL/TLS](#).

## Topics

- [Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL](#)
- [Determining whether a client requires certificate verification in order to connect](#)
- [Updating your application trust store](#)
- [Using SSL/TLS connections for different types of applications](#)

## Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL

Check the DB cluster configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see [Parameter groups for Amazon Aurora](#).

If `rds.force_ssl` isn't set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
select datname, username, ssl, client_addr from pg_stat_ssl inner join pg_stat_activity
on pg_stat_ssl.pid = pg_stat_activity.pid where ssl is true and username<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
datname | username | ssl | client_addr
-----+-----+-----+-----
benchdb | pgadmin  | t   | 53.95.6.13
postgres | pgadmin  | t   | 53.95.6.13
(2 rows)
```

The preceding query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

## Determining whether a client requires certificate verification in order to connect

When a client, such as `psql` or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used for both libpq-based clients (such as `psql`) and JDBC is set to `prefer`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLRROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLRROOTCERT=/fullpath/ssl-cert.pem psql -h  
pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U primaryuser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full`.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full  
sslrootcert=/full/path/ssl-cert.pem user=primaryuser dbname=postgres"
```

For example, in the preceding case, if you use an invalid root certificate, you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

## Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](#) in the PostgreSQL documentation.

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

## Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

## Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

For the complete list of options, see [Parameter key words](#) in the PostgreSQL documentation. For the complete list of environment variables, see [Environment variables](#) in the PostgreSQL documentation.

- **pgAdmin**

This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

For information about configuring connections, see the [pgAdmin documentation](#).

- **JDBC**

JDBC enables database connections with Java applications.

For general information about connecting to a PostgreSQL database with JDBC, see [Connecting to the database](#) in the PostgreSQL documentation. For information about connecting with SSL/TLS, see [Configuring the client](#) in the PostgreSQL documentation.

- **Python**

A popular Python library for connecting to PostgreSQL databases is `psycopg2`.

For information about using `psycopg2`, see the [psycopg2 documentation](#). For a short tutorial on how to connect to a PostgreSQL database, see [Psycopg2 tutorial](#). You can find information about the options the `connect` command accepts in [The psycopg2 module content](#).

**⚠ Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the `rds-ca-rsa2048-g1` certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance](#).

## Using Kerberos authentication with Aurora PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB cluster running PostgreSQL. To do so, configure your DB cluster to use Amazon Directory Service for Microsoft Active Directory for Kerberos authentication. Amazon Directory Service for Microsoft Active Directory is also called Amazon Managed Microsoft AD. It's a feature available with Amazon Directory Service. To learn more, see [What is Amazon Directory Service?](#) in the *Amazon Directory Service Administration Guide*.

To start, create an Amazon Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB cluster the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB cluster, authentication requests are forwarded to the Amazon Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the Amazon Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, Amazon Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, because Kerberos and IAM authentication provide different authentication methods, a specific database user can log in to a database using only one or the other authentication method but not both. For more information about IAM authentication, see [IAM database authentication](#).

**Note**

RDS for PostgreSQL doesn't support Kerberos authentication for Active Directory groups.

## Topics

- [Region and version availability](#)
- [Overview of Kerberos authentication for PostgreSQL DB clusters](#)
- [Setting up Kerberos authentication for PostgreSQL DB clusters](#)
- [Managing an Aurora PostgreSQL DB cluster in an Active Directory domain](#)
- [Connecting to PostgreSQL with Kerberos authentication](#)
- [Using AD security groups for Aurora PostgreSQL access control](#)

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across Amazon Web Services Regions. For more information on version and Region availability of Aurora PostgreSQL with Kerberos authentication, see [Kerberos authentication with Aurora PostgreSQL](#).

## Overview of Kerberos authentication for PostgreSQL DB clusters

To set up Kerberos authentication for a PostgreSQL DB cluster, take the following steps, described in more detail later:

1. Use Amazon Managed Microsoft AD to create an Amazon Managed Microsoft AD directory. You can use the Amazon Web Services Management Console, the Amazon CLI, or the Amazon Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the cluster.
2. Create a role that provides Amazon Aurora access to make calls to your Amazon Managed Microsoft AD directory. To do so, create an Amazon Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For the IAM role to allow access, the Amazon Security Token Service (Amazon STS) endpoint must be activated in the correct Amazon Region for your Amazon account. Amazon STS endpoints are active by default in all Amazon Web Services Regions, and you can use them without any further actions. For more information, see [Activating and deactivating Amazon STS in an Amazon Region](#) in the *IAM User Guide*.

3. Create and configure users in the Amazon Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in Amazon Managed Microsoft AD](#) in the *Amazon Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different Amazon accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see [What is VPC peering?](#) in the *Amazon VPC Peering Guide*.
5. Create or modify a PostgreSQL DB cluster either from the console, CLI, or RDS API using one of the following methods:
  - [Creating and connecting to an Aurora PostgreSQL DB cluster](#)
  - [Modifying an Amazon Aurora DB cluster](#)
  - [Restoring from a DB cluster snapshot](#)
  - [Restoring a DB cluster to a specified time](#)

You can locate the cluster in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different Amazon account or VPC. When you create or modify the PostgreSQL DB cluster, do the following:

- Provide the domain identifier (d- \* identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB cluster. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB cluster using Kerberos authentication.

## Setting up Kerberos authentication for PostgreSQL DB clusters

You use Amazon Directory Service for Microsoft Active Directory (Amazon Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB cluster. To set up Kerberos authentication, take the following steps.

### Topics

- [Step 1: Create a directory using Amazon Managed Microsoft AD](#)
- [Step 2: \(Optional\) Create a trust relationship between your on-premises Active Directory and Amazon Directory Service](#)
- [Step 3: Create an IAM role for Amazon Aurora to access the Amazon Directory Service](#)
- [Step 4: Create and configure users](#)
- [Step 5: Enable cross-VPC traffic between the directory and the DB instance](#)
- [Step 6: Create or modify a PostgreSQL DB cluster](#)
- [Step 7: Create PostgreSQL users for your Kerberos principals](#)
- [Step 8: Configure a PostgreSQL client](#)

### Step 1: Create a directory using Amazon Managed Microsoft AD

Amazon Directory Service creates a fully managed Active Directory in the Amazon Cloud. When you create an Amazon Managed Microsoft AD directory, Amazon Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an Amazon Managed Microsoft AD directory, Amazon Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

**⚠ Important**

Make sure to save this password. Amazon Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB cluster.

When you launch Amazon Directory Service for Microsoft Active Directory, Amazon creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by Amazon.

The Admin account that was created with your Amazon Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

**To create a directory with Amazon Managed Microsoft AD**

1. In the [Amazon Directory Service console](#) navigation pane, choose **Directories**, and then choose **Set up directory**.

2. Choose **Amazon Managed Microsoft AD**. Amazon Managed Microsoft AD is the only option currently supported for use with Amazon Aurora.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

### **Edition**

Choose the edition that meets your requirements.

### **Directory DNS name**

The fully qualified name for the directory, such as **corp.example.com**.

### **Directory NetBIOS name**

An optional short name for the directory, such as CORP.

### **Directory description**

An optional description for the directory.

### **Admin password**

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#\$%^&\* \_-+= `| \(){}[];:"'<>.,?/)

### **Confirm password**

Retype the administrator password.

#### **Important**

Make sure that you save this password. Amazon Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

### **VPC**

Choose the VPC for the directory. You can create the PostgreSQL DB cluster in this same VPC or in a different VPC.

### **Subnets**

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

## Review & create

### Review

Directory type	VPC
Microsoft AD	vpc-8b6b78e9 ( )
Directory DNS name	Subnets
corp.example.com	subnet-75128d10 ( , us-east-1a)
Directory NetBIOS name	subnet-f51665dd ( , us-east-1b)
CORP	
Directory description	
My directory	

### Pricing

Edition	Free trial eligible <a href="#">Learn more</a>
Standard	30-day limited trial
~USD ( ) *	
* Includes two domain controllers, USD ( )/mo for each additional domain controller.	

Cancel Previous **Create directory**

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

Directory Service > Directories > d-90670a8d36

My directory		

[Application management](#) | [Scale & share](#) | [Networking & security](#) | [Maintenance](#)

## Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and Amazon Directory Service

If you don't plan to use your own on-premises Microsoft Active Directory, skip to [Step 3: Create an IAM role for Amazon Aurora to access the Amazon Directory Service](#).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the Amazon Managed Microsoft AD directory (created in [Step 1: Create a directory using Amazon Managed Microsoft AD](#)). The trust can be one-way, where the Amazon Managed

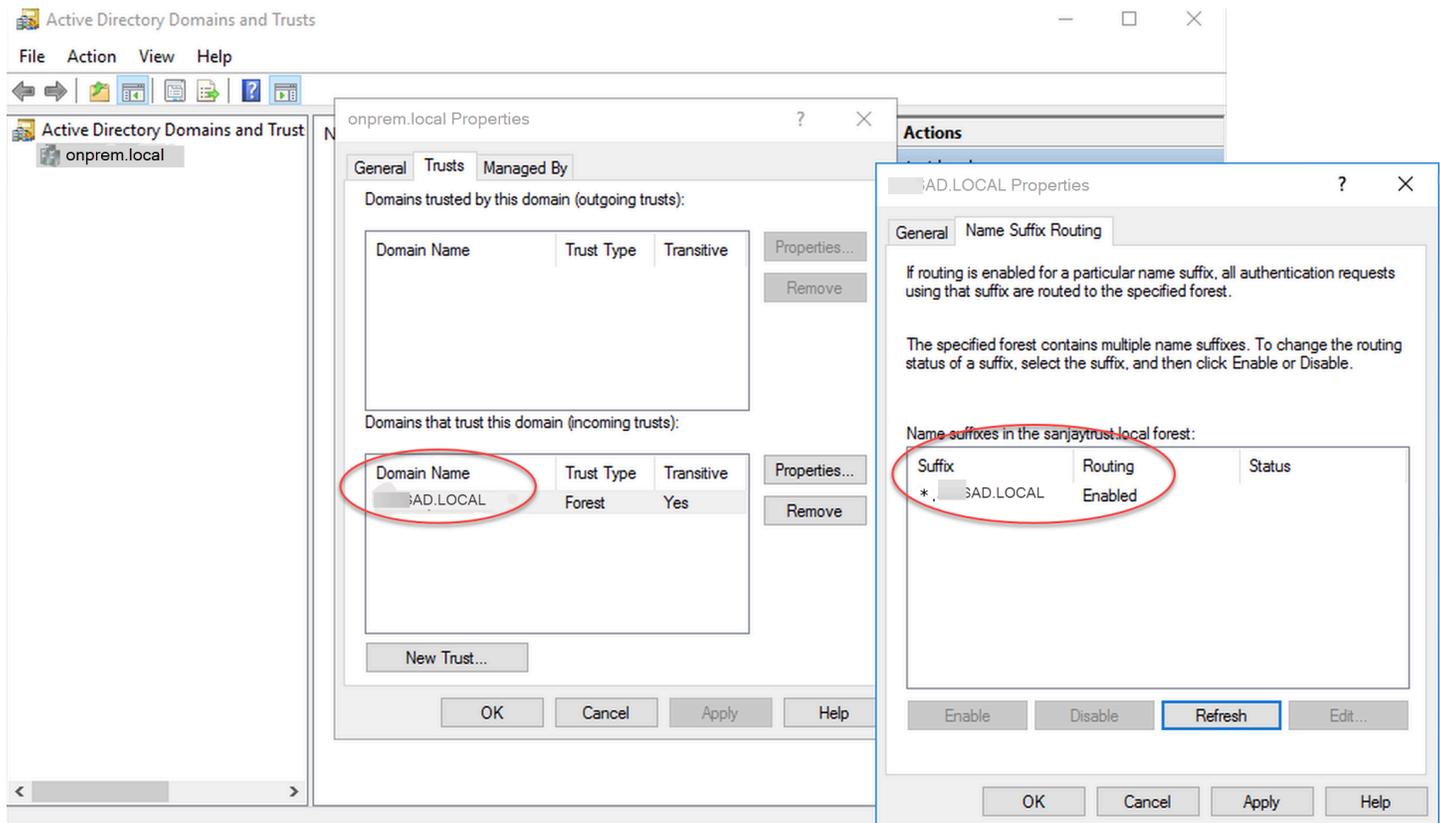

Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using Amazon Directory Service, see [When to create a trust relationship](#) in the *Amazon Directory Service Administration Guide*.

 **Note**

If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using the domain name of the Amazon Directory Service in the endpoint rather than `rds.amazonaws.com`. For more information, see [Connecting to PostgreSQL with Kerberos authentication](#).
- Windows clients can't connect using Aurora custom endpoints. To learn more, see [Amazon Aurora endpoint connections](#).
- For [global databases](#):
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary Amazon Web Services Region of the global database only.
  - Windows clients can't connect using cluster endpoints in secondary Amazon Web Services Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

### Step 3: Create an IAM role for Amazon Aurora to access the Amazon Directory Service

For Amazon Aurora to call Amazon Directory Service for you, your Amazon account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon Aurora to make calls to Amazon Directory Service. (Note that this IAM role to access the Amazon Directory Service is different than the IAM role used for [IAM database authentication](#).)

When you create a DB instance using the Amazon Web Services Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the Amazon managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an Amazon service](#) in the *IAM User Guide*.

**Note**

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon Aurora.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",

```

```
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
    ],
    "Effect": "Allow",
    "Resource": "*"
  }
]
```

For opt-in Amazon Web Services Regions, use Region-specific service principals in IAM role trust policies. When you create a trust policy for services in these Regions, specify the Region code in the service principal.

The following example shows a trust policy that includes Region-specific service principals:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.REGION-CODE.amazonaws.com",
          "rds.REGION-CODE.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Replace REGION-CODE with the code for your specific Region. For example, use the following service principals for the Asia Pacific (Melbourne) Region:

```
"Service": [  
  "directoryservice.rds.ap-southeast-4.amazonaws.com",  
  "rds.ap-southeast-4.amazonaws.com"  
]
```

## Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see [Add Users and Computers to the Active Directory domain](#) in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an Amazon Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the Amazon Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see [Create a user](#) in the *Amazon Directory Service Administration Guide*.

## Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB cluster in the same VPC, skip this step and move on to [Step 6: Create or modify a PostgreSQL DB cluster](#).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or [Amazon Transit Gateway](#).

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](#) in the *Amazon Virtual Private Cloud Peering Guide*.

### To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different Amazon account owns the directory, you must share the directory.

## To share the directory between Amazon accounts

1. Start sharing the directory with the Amazon account that the DB instance will be created in by following the instructions in [Tutorial: Sharing your Amazon Managed Microsoft AD directory for seamless EC2 Domain-join](#) in the *Amazon Directory Service Administration Guide*.
2. Sign in to the Amazon Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the Amazon Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

## Step 6: Create or modify a PostgreSQL DB cluster

Create or modify a PostgreSQL DB cluster for use with your directory. You can use the console, CLI, or RDS API to associate a DB cluster with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB cluster using the console, the [create-db-cluster](#) CLI command, or the [CreateDBCluster](#) RDS API operation. For instructions, see [Creating and connecting to an Aurora PostgreSQL DB cluster](#).
- Modify an existing PostgreSQL DB cluster using the console, the [modify-db-cluster](#) CLI command, or the [ModifyDBCluster](#) RDS API operation. For instructions, see [Modifying an Amazon Aurora DB cluster](#).
- Restore a PostgreSQL DB cluster from a DB snapshot using the console, the [restore-db-cluster-from-db-snapshot](#) CLI command, or the [RestoreDBClusterFromDBSnapshot](#) RDS API operation. For instructions, see [Restoring from a DB cluster snapshot](#).
- Restore a PostgreSQL DB cluster to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBClusterToPointInTime](#) RDS API operation. For instructions, see [Restoring a DB cluster to a specified time](#).

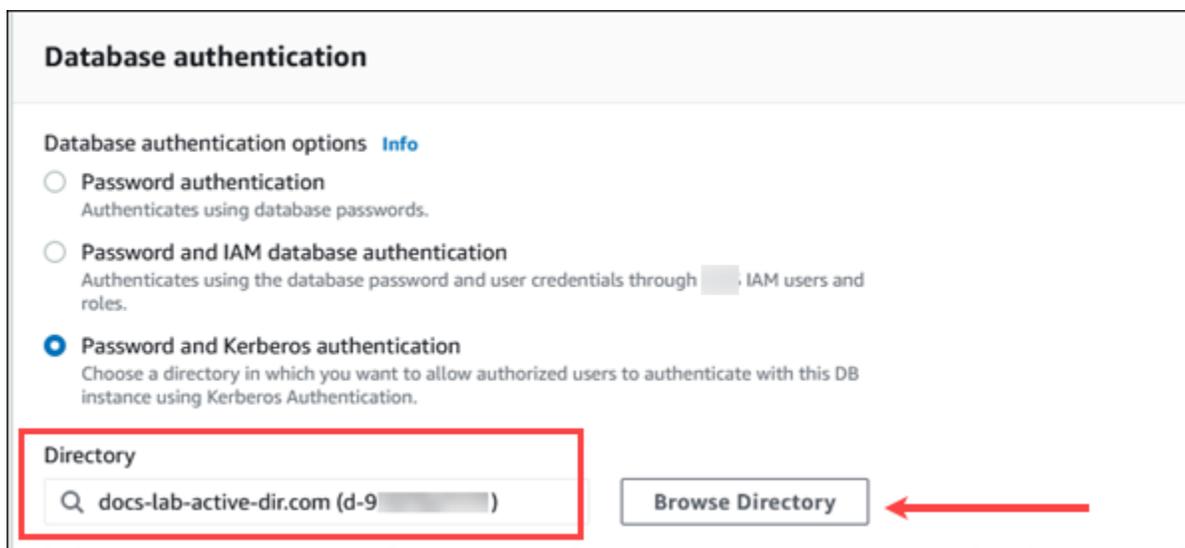

Kerberos authentication is only supported for PostgreSQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster must use a security group that allows ingress and egress within the directory's VPC so the DB cluster can communicate with the directory.

**Note**

Enabling Kerberos authentication isn't currently supported on Aurora PostgreSQL DB cluster during migration from RDS for PostgreSQL. You can enable Kerberos authentication only on a standalone Aurora PostgreSQL DB cluster.

**Console**

When you use the console to create, modify, or restore a DB cluster, choose **Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.

**Amazon CLI**

When you use the Amazon CLI, the following parameters are required for the DB cluster to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB cluster to use a directory.

```
aws rds modify-db-cluster --db-cluster-identifier mydbinstance --domain d-Directory-ID
--domain-iam-role-name role-name
```

### Important

If you modify a DB cluster to enable Kerberos authentication, reboot the DB cluster after making the change.

## Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your Aurora PostgreSQL DB cluster is joined to the Amazon Managed Microsoft AD domain. The users that you created in the directory in [Step 4: Create and configure users](#) need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your Aurora PostgreSQL DB cluster, you use `postgres`, as shown in the following steps.

### To create PostgreSQL database users for Kerberos principals

1. Use `psql` to connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
port=5432 --username=postgres --password
```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case `alias` (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

```
postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
CREATE ROLE
```

3. Grant the `rds_ad` role to the database user.

```
postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
GRANT ROLE
```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the Aurora PostgreSQL DB cluster by using their Kerberos credentials.

It's required that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see [IAM database authentication](#).

### Configuring your Aurora PostgreSQL DB cluster for case-insensitive user names

Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 support the `krb_caseins_users` PostgreSQL parameter. This parameter supports case-insensitive Active Directory user names. By default, this parameter is set to `false`, so user names are interpreted case-sensitively by Aurora PostgreSQL. That's the default behavior in all older versions of Aurora PostgreSQL. However, you can set this parameter to `true` in your custom DB cluster parameter group and allow your Aurora PostgreSQL DB cluster to interpret user names, case-insensitively. Consider doing this as a convenience for your database users, who might sometimes mis-type the casing of their user name when authenticating using Active Directory.

To change the `krb_caseins_users` parameter, your Aurora PostgreSQL DB cluster must be using a custom DB cluster parameter group. For information about working with a custom DB cluster parameter group, see [Parameter groups for Amazon Aurora](#).

You can use the Amazon CLI or the Amazon Web Services Management Console to change the setting. For more information, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

## Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a `krb5.conf` file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and Amazon Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for Amazon Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use `psql` to connect and access the database.

The following is sample krb5.conf content for Amazon Managed Microsoft AD.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
  EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
  }
[domain_realm]
  .example.com = EXAMPLE.COM
  example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
  EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
  }
  ONPREM.COM = {
    kdc = onprem.com
    admin_server = onprem.com
  }
[domain_realm]
  .example.com = EXAMPLE.COM
  example.com = EXAMPLE.COM
  .onprem.com = ONPREM.COM
  onprem.com = ONPREM.COM
  .rds.amazonaws.com = EXAMPLE.COM
  .amazonaws.com.cn = EXAMPLE.COM
  .amazon.com = EXAMPLE.COM
```

## Managing an Aurora PostgreSQL DB cluster in an Active Directory domain

You can use the console, the CLI, or the RDS API to manage your DB cluster and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable

Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the [modify-db-cluster](#) CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the [modify-db-cluster](#) CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the [modify-db-cluster](#) CLI command. Specify the domain identifier of the new domain for the `--domain` option.

## Understanding Domain membership

After you create or modify your DB cluster, the DB instances become members of the domain. You can view the status of the domain membership in the console or by running the [describe-db-instances](#) CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – Amazon is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – Amazon will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – Amazon will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented Amazon from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – Amazon is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB cluster. If so, make sure that you are using the correct IAM role, then modify the DB cluster to join the domain.

## Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see [Connecting to an Amazon Aurora PostgreSQL DB cluster](#). For information about obtaining the endpoint, port number, and other details needed for connection, see [Viewing the endpoints for an Aurora cluster](#).

### Note

GSSAPI authentication and encryption in PostgreSQL are implemented by the Kerberos library `libkrb5.so`. Features such as `postgres_fdw` and `dblink` also rely on this same library for outbound connections with Kerberos authentication or encryption.

### pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your Aurora PostgreSQL database.
  - For **Host**, enter the endpoint for the Writer instance of your Aurora PostgreSQL DB cluster. An endpoint looks similar to the following:

```
AUR-cluster-instance.11122223333.aws-region.rds.amazonaws.com
```

To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the Amazon Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the Amazon Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

```
AUR-cluster-instance.111122223333.aws-region.corp.example.com
```

- For **Port**, enter the assigned port.
- For **Maintenance database**, enter the name of the initial database to which the client will connect.
- For **Username**, enter the user name that you entered for Kerberos authentication in [Step 7: Create PostgreSQL users for your Kerberos principals](#).

5. Choose **Save**.

## Psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

```
kinit username
```

Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB cluster is using a publicly accessible VPC, put IP address for your DB cluster endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

```
% dig +short PostgreSQL-endpoint.Amazon-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.Amazon-Region.compute.amazonaws.com.
34.210.197.118

% echo " 34.210.197.118 PostgreSQL-endpoint.Amazon-Region.rds.amazonaws.com" >> /
etc/hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the Amazon Managed Active Directory.

For example, suppose that the domain name for your Amazon Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.Amazon-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```
% echo " 34.210.197.118 PostgreSQL-endpoint.Amazon-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB cluster that is integrated with Active Directory. Use a cluster or instance endpoint.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.Amazon-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.Amazon-Region.corp.example.com postgres
```

## Using AD security groups for Aurora PostgreSQL access control

From Aurora PostgreSQL 14.10 and 15.5 versions, Aurora PostgreSQL access control can be managed using Amazon Directory Service for Microsoft Active Directory (AD) security groups. Earlier versions of Aurora PostgreSQL support Kerberos based authentication with AD only for individual users. Each AD user had to be explicitly provisioned to DB cluster to get access.

Instead of explicitly provisioning each AD user to DB cluster based on business needs, you can leverage AD security groups as explained below:

- AD users are members of various AD security groups in an Active Directory. These are not dictated by DB cluster administrator, but are based on business requirements, and are handled by an AD administrator.
- DB cluster administrators create DB roles in DB instances based on business requirements. These DB roles may have different permissions or privileges.
- DB cluster administrators configure a mapping from AD security groups to DB roles on a per DB cluster basis.
- DB users can access DB clusters using their AD credentials. Access is based on AD security group membership. AD users gain or lose access automatically based on their AD group memberships.

### Prerequisites

Ensure that you have the following before setting up the extension for AD Security groups:

- Set up Kerberos authentication for PostgreSQL DB clusters. For more information, see [Setting up Kerberos authentication for PostgreSQL DB clusters](#).

#### Note

For AD security groups, skip Step 7: Create PostgreSQL users for your Kerberos principals in this setup procedure.

#### Important

If you enable AD security groups on an Aurora PostgreSQL cluster that already has Kerberos authentication enabled, you might encounter authentication issues. This occurs

when you add `pg_ad_mapping` to the `shared_preload_libraries` parameter and restart your database. When using cluster endpoints, login attempts using an AD user that isn't a database user with the `rds_ad` role can fail. This can also potentially cause engine crashes. To resolve this issue, disable and then re-enable Kerberos authentication on your cluster. This workaround is required for existing instances but doesn't affect instances created after April 2025.

- Managing a DB cluster in a Domain. For more information, see [Managing a DB cluster in a Domain](#).

## Setting up the `pg_ad_mapping` extension

Aurora PostgreSQL is now providing `pg_ad_mapping` extension to manage the mapping between AD security groups and DB roles in Aurora PostgreSQL cluster. For more information about the functions provided by `pg_ad_mapping`, see [Using functions from the `pg\_ad\_mapping` extension](#).

To set up the `pg_ad_mapping` extension on your Aurora PostgreSQL DB cluster, you first add `pg_ad_mapping` to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. For information about creating a custom DB cluster parameter group, see [Parameter groups for Amazon Aurora](#). Next, you install the `pg_ad_mapping` extension. The procedures in this section show you how. You can use the Amazon Web Services Management Console or the Amazon CLI.

You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group.

### Console

#### To set up the `pg_ad_mapping` extension

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.

4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pg_ad_mapping` to the list in the **Values** field. Use a comma to separate items in the list of values.

RDS > Parameter groups > Modify parameter group: dblab-custom-db-parameter

**Modifiable parameters (370)**

Q shared\_pre X 1 match

<input type="checkbox"/>	Name	Value
<input type="checkbox"/>	shared_preload_libraries	Allowed values auto_explain,orafce,pgaudit,pg_similarity,pg_stat_statements,pg_tle,pg_hint_plan,pg_prewarm,plprofiler,pglogical,pg_cron,pg_ad_mapping <input type="text" value="pg_ad_mapping, pg_stat_statements"/>

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_ad_mapping` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pg_ad_mapping
(1 row)
```

10. With `pg_ad_mapping` initialized, you can now create the extension. You need to create the extension after initializing the library to start using the functions provided by this extension.

```
CREATE EXTENSION pg_ad_mapping;
```

11. Close the `psql` session.

```
labdb=> \q
```

## Amazon CLI

### To setup `pg_ad_mapping`

To setup `pg_ad_mapping` using the Amazon CLI, you call the [modify-db-parameter-group](#) operation to add this parameter in your custom parameter group, as shown in the following procedure.

1. Use the following Amazon CLI command to add `pg_ad_mapping` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=shared_preload_libraries,ParameterValue=pg_ad_mapping,ApplyMethod=pending-  
reboot" \  
  --region aws-region
```

2. Use the following Amazon CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the `pg_ad_mapping` is initialized.

```
aws rds reboot-db-instance \  
  --db-instance-identifier writer-instance \  
  --region aws-region
```

3. When the instance is available, you can verify that `pg_ad_mapping` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;  
shared_preload_libraries  
-----  
rdsutils,pg_ad_mapping  
(1 row)
```

With `pg_ad_mapping` initialized, you can now create the extension.

```
CREATE EXTENSION pg_ad_mapping;
```

4. Close the `psql` session so that you can use the Amazon CLI.

```
labdb=> \q
```

## Retrieving Active Directory Group SID in PowerShell

A security identifier (SID) is used to uniquely identify a security principal or security group. Whenever a security group or account is created in Active Directory a SID is assigned to it. To fetch the AD security group SID from the active directory, you can use the Get-ADGroup cmdlet from windows client machine which is joined with that Active Directory domain. The Identity parameter specifies the Active Directory group name to get the corresponding SID.

The following example returns the SID of AD group *adgroup1*.

```
C:\Users\Admin> Get-ADGroup -Identity adgroup1 | select SID  
  
SID  
-----  
S-1-5-21-3168537779-1985441202-1799118680-1612
```

## Mapping DB role with AD security group

You need to explicitly provision the AD security groups in the database as a PostgreSQL DB role. An AD user, who is part of at least one provisioned AD security group will get access to the database. You shouldn't grant `rds_ad_role` to AD group security based DB role. Kerberos authentication for security group will get triggered by using the domain name suffix like *user1@example.com*. This DB role can't use Password or IAM authentication to gain access to database.

### Note

AD users who have a corresponding DB role in the database with `rds_ad_role` granted to them, can't login as part of the AD security group. They will get access through DB role as an individual user.

For example, `accounts-group` is a security group in AD where you would like to provision this security group in the Aurora PostgreSQL as `accounts-role`.

AD Security Group	PosgreSQL DB role
accounts-group	accounts-role

When mapping the DB role with the AD security group, you must ensure that DB role has the LOGIN attribute set and it has CONNECT privilege to the required login database.

```
postgres => alter role accounts-role login;

ALTER ROLE
postgres => grant connect on database accounts-db to accounts-role;
```

Admin can now proceed to create the mapping between AD security group and PostgreSQL DB role.

```
admin=>select pgadmap_set_mapping('accounts-group', 'accounts-role', <SID>, <Weight>);
```

For information on retrieving SID of AD security group, see [Retrieving Active Directory Group SID in PowerShell](#).

There might be cases where an AD user belongs to multiple groups, in that case, AD user will inherit the privileges of the DB role, which was provisioned with the highest weight. If the two roles have the same weight, AD user will inherit the privileges of the DB role corresponding to the mapping that was added recently. The recommendation is to specify weights that reflect the relative permissions/privileges of individual DB roles. Higher the permissions or privileges of a DB role, higher the weight that should be associated with the mapping entry. This will avoid the ambiguity of two mappings having the same weight.

The following table shows a sample mapping from AD security groups to Aurora PostgreSQL DB roles.

AD Security Group	PosgreSQL DB role	Weight
accounts-group	accounts-role	7
sales-group	sales-role	10

AD Security Group	PosgreSQL DB role	Weight
dev-group	dev-role	7

In the following example, `user1` will inherit the privileges of `sales-role` since it has the higher weight while `user2` will inherit the privileges of `dev-role` as the mapping for this role was created after `accounts-role`, which share the same weight as `accounts-role`.

Username	Security Group membership
user1	accounts-group sales-group
user2	accounts-group dev-group

The `psql` commands to establish, list, and clear the mappings are shown below. Currently, it isn't possible to modify a single mapping entry. The existing entry needs to be deleted and the mapping recreated.

```
admin=>select pgadmap_set_mapping('accounts-group', 'accounts-role', 'S-1-5-67-890',
7);
admin=>select pgadmap_set_mapping('sales-group', 'sales-role', 'S-1-2-34-560', 10);
admin=>select pgadmap_set_mapping('dev-group', 'dev-role', 'S-1-8-43-612', 7);

admin=>select * from pgadmap_read_mapping();

 ad_sid      | pg_role      | weight | ad_grp
-----+-----+-----+-----
S-1-5-67-890 | accounts-role | 7      | accounts-group
S-1-2-34-560 | sales-role   | 10     | sales-group
S-1-8-43-612 | dev-role     | 7      | dev-group
(3 rows)
```

## AD user identity logging/auditing

Use the following command to determine the database role inherited by current or session user:

```
postgres=>select session_user, current_user;
```

```
session_user | current_user
-----+-----
dev-role    | dev-role
```

```
(1 row)
```

To determine the AD security principal identity, use the following command:

```
postgres=>select principal from pg_stat_gssapi where pid = pg_backend_pid();
```

```
principal
-----
user1@example.com
```

```
(1 row)
```

Currently, AD user identity isn't visible in the audit logs. The `log_connections` parameter can be enabled to log DB session establishment. For more information, see [log\\_connections](#). The output for this includes the AD user identity, as shown below. The backend PID associated with this output can then help attribute actions back to the actual AD user.

```
pgrole1@postgres:[615]:LOG: connection authorized: user=pgrole1
database=postgres application_name=psql GSS (authenticated=yes, encrypted=yes,
principal=Admin@EXAMPLE.COM)
```

## Limitations

- Microsoft Entra ID known as Azure Active Directory isn't supported.

## Using functions from the `pg_ad_mapping` extension

`pg_ad_mapping` extension provided support to the following functions:

## pgadmap\_set\_mapping

This function establishes the mapping between AD security group and Database role with an associated weight.

### Syntax

```
pgadmap_set_mapping(  
ad_group,  
db_role,  
ad_group_sid,  
weight)
```

### Arguments

Parameter	Description
ad_group	Name of AD Group. Value cannot be null or empty string.
db_role	Database role to be mapped to the specified AD Group. Value cannot be null or empty string.
ad_group_sid	Security identifier that is used to uniquely identify the AD group. Value starts with 'S-1-' and cannot be null or empty string. For more information, see <a href="#">Retrieving Active Directory Group SID in PowerShell</a> .
weight	Weight associated with the database role. The role with highest weight gets precedence when user is a member of multiple groups. Default value of weight is 1.

### Return type

None

### Usage notes

This function adds a new mapping from AD security group to database role. It can only be executed on the primary DB instance of the DB cluster by a user having rds\_superuser privilege.

## Examples

```
postgres=> select pgadmap_set_mapping('accounts-group', 'accounts-
role', 'S-1-2-33-12345-67890-12345-678', 10);
```

```
pgadmap_set_mapping
```

```
(1 row)
```

## pgadmap\_read\_mapping

This function lists the mappings between AD security group and DB role that were set using `pgadmap_set_mapping` function.

## Syntax

```
pgadmap_read_mapping()
```

## Arguments

None

## Return type

Parameter	Description
<code>ad_group_sid</code>	Security identifier that is used to uniquely identify the AD group. Value starts with 'S-1-' and cannot be null or empty string. For more information, see <a href="#">Retrieving Active Directory Group SID in PowerShell</a> .accounts-role@example.com
<code>db_role</code>	Database role to be mapped to the specified AD Group. Value cannot be null or empty string.
<code>weight</code>	Weight associated with the database role. The role with highest weight gets precedence when user is a member of multiple groups. Default value of weight is 1.
<code>ad_group</code>	Name of AD Group. Value cannot be null or empty string.

## Usage notes

Call this function to list all the available mappings between AD security group and DB role.

## Examples

```
postgres=> select * from pgadmap_read_mapping();
```

```

ad_sid                | pg_role      | weight | ad_grp
-----+-----+-----+-----
S-1-2-33-12345-67890-12345-678 | accounts-role | 10     | accounts-group
(1 row)

(1 row)

```

## pgadmap\_reset\_mapping

This function resets one or all the mappings that were set using `pgadmap_set_mapping` function.

## Syntax

```
pgadmap_reset_mapping(
  ad_group_sid,
  db_role,
  weight)
```

## Arguments

Parameter	Description
<code>ad_group_sid</code>	Security identifier that is used to uniquely identify the AD group.
<code>db_role</code>	Database role to be mapped to the specified AD Group.
<code>weight</code>	Weight associated with the database role.

If no arguments are provided, all AD group to DB role mappings are reset. Either all arguments need to be provided or none.

## Return type

None

## Usage notes

Call this function to delete a specific AD group to DB role mapping or to reset all mappings. This function can only be executed on the primary DB instance of the DB cluster by a user having `rds_superuser` privilege.

## Examples

```
postgres=> select * from pgadmap_read_mapping();
```

ad_sid	pg_role	weight	ad_grp
S-1-2-33-12345-67890-12345-678	accounts-role	10	accounts-group
S-1-2-33-12345-67890-12345-666	sales-role	10	sales-group

(2 rows)

```
postgres=> select pgadmap_reset_mapping('S-1-2-33-12345-67890-12345-678', 'accounts-  
role', 10);
```

```
pgadmap_reset_mapping
```

(1 row)

```
postgres=> select * from pgadmap_read_mapping();
```

ad_sid	pg_role	weight	ad_grp
S-1-2-33-12345-67890-12345-666	sales-role	10	sales-group

(1 row)

```
postgres=> select pgadmap_reset_mapping();
```

```
pgadmap_reset_mapping
```

(1 row)

```
postgres=> select * from pgadmap_read_mapping();
```

ad_sid	pg_role	weight	ad_grp
--------	---------	--------	--------

(0 rows)

# Migrating data to Amazon Aurora with PostgreSQL compatibility

You have several options for migrating data from your existing database to an Amazon Aurora PostgreSQL-Compatible Edition DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating. Following are your options:

## [Migrating an RDS for PostgreSQL DB instance using a snapshot](#)

You can migrate data directly from an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster.

## [Migrating an RDS for PostgreSQL DB instance using an Aurora read replica](#)

You can also migrate from an RDS for PostgreSQL DB instance by creating an Aurora PostgreSQL read replica of an RDS for PostgreSQL DB instance. When the replica lag between the RDS for PostgreSQL DB instance and the Aurora PostgreSQL read replica is zero, you can stop replication. At this point, you can make the Aurora read replica a standalone Aurora PostgreSQL DB cluster for reading and writing.

## [Importing data from Amazon S3 into Aurora PostgreSQL](#)

You can migrate data by importing it from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster.

## **Migrating from a database that is not PostgreSQL-compatible**

You can use Amazon Database Migration Service (Amazon DMS) to migrate data from a database that is not PostgreSQL-compatible. For more information on Amazon DMS, see [What is Amazon Database Migration Service?](#) in the *Amazon Database Migration Service User Guide*.

### Note

Enabling Kerberos authentication isn't currently supported on Aurora PostgreSQL DB cluster during migration from RDS for PostgreSQL. You can enable Kerberos authentication only on a standalone Aurora PostgreSQL DB cluster.

For a list of Amazon Web Services Regions where Aurora is available, see [Amazon Aurora](#) in the *Amazon Web Services General Reference*.

### Important

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you turn off auto minor version upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL.

For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).

## Migrating a snapshot of an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster

To create an Aurora PostgreSQL DB cluster, you can migrate a DB snapshot of an RDS for PostgreSQL DB instance. The new Aurora PostgreSQL DB cluster is populated with the data from the original RDS for PostgreSQL DB instance. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

In some cases, the DB snapshot might not be in the Amazon Web Services Region where you want to locate your data. If so, use the Amazon RDS console to copy the DB snapshot to that Amazon Web Services Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

You can migrate RDS for PostgreSQL snapshots that are compatible with the Aurora PostgreSQL versions available in the given Amazon Web Services Region. For example, you can migrate a snapshot from an RDS for PostgreSQL 11.1 DB instance to Aurora PostgreSQL version 11.4, 11.7, 11.8, or 11.9 in the US West (N. California) Region. You can migrate RDS for PostgreSQL 10.11 snapshot to Aurora PostgreSQL 10.11, 10.12, 10.13, and 10.14. In other words, the RDS for PostgreSQL snapshot must use the same or a lower minor version as the Aurora PostgreSQL.

You can also choose for your new Aurora PostgreSQL DB cluster to be encrypted at rest by using an Amazon KMS key. This option is available only for unencrypted DB snapshots.

To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster, you can use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API. When you use

the Amazon Web Services Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

## Console

### To migrate a PostgreSQL DB snapshot by using the RDS console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Snapshots**.
3. On the **Snapshots** page, choose the RDS for PostgreSQL snapshot that you want to migrate into an Aurora PostgreSQL DB cluster.
4. Choose **Actions** then choose **Migrate snapshot**.
5. Set the following values on the **Migrate database** page:
  - **DB engine version:** Choose a DB engine version you want to use for the new migrated instance.
  - **DB instance identifier:** Enter a name for the DB cluster that is unique for your account in the Amazon Web Services Region that you chose. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the Amazon Web Services Region and DB engine that you chose, for example **aurora-cluster1**.

The DB instance identifier has the following constraints:

- It must contain 1–63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It can't end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB instances per Amazon account, per Amazon Web Services Region.
- **DB instance class:** Choose a DB instance class that has the required storage and capacity for your database, for example `db.r6g.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. So you only need to choose a DB instance class that meets your current storage requirements. For more information, see [Overview of Amazon Aurora storage](#).
- **Virtual private cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora PostgreSQL DB cluster by choosing your VPC identifier, for example `vpc-`

a464d1c1. For information about creating a VPC, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

Otherwise, you can choose to have Amazon RDS create a VPC for you by choosing **Create new VPC**.

- **DB subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora PostgreSQL DB cluster by choosing your subnet group identifier, for example `gs-subnet-group1`.
- **Public access:** Choose **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Choose **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network.

 **Note**

Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Public access** to **No**.

- **VPC security group:** Choose a VPC security group to allow access to your database.
- **Availability Zone:** Choose the Availability Zone to host the primary instance for your Aurora PostgreSQL DB cluster. To have Amazon RDS choose an Availability Zone for you, choose **No preference**.
- **Database port:** Enter the default port to be used when connecting to instances in the Aurora PostgreSQL DB cluster. The default is 5432.

 **Note**

You might be behind a corporate firewall that doesn't allow access to default ports such as the PostgreSQL default port, 5432. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora PostgreSQL DB cluster.

- **Enable Encryption:** Choose **Enable Encryption** for your new Aurora PostgreSQL DB cluster to be encrypted at rest. Also choose a KMS key as the **Amazon KMS key** value.
- **Auto minor version upgrade:** Choose **Enable auto minor version upgrade** to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.

The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.

6. Choose **Migrate** to migrate your DB snapshot.
7. Choose **Databases** to see the new DB cluster. Choose the new DB cluster to monitor the progress of the migration. When the migration completes, the Status for the cluster is **Available**. On the **Connectivity & security** tab, you can find the cluster endpoint to use for connecting to the primary writer instance of the DB cluster. For more information on connecting to an Aurora PostgreSQL DB cluster, see [Connecting to an Amazon Aurora DB cluster](#).

## Amazon CLI

Using the Amazon CLI to migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL involves two separate Amazon CLI commands. First, you use the `restore-db-cluster-from-snapshot` Amazon CLI command create a new Aurora PostgreSQL DB cluster. You then use the `create-db-instance` command to create the primary DB instance in the new cluster to complete the migration. The following procedure creates an Aurora PostgreSQL DB cluster with primary DB instance that has the same configuration as the DB instance used to create the snapshot.

### To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster

1. Use the [describe-db-snapshots](#) command to obtain information about the DB snapshot you want to migrate. You can specify either the `--db-instance-identifier` parameter or the `--db-snapshot-identifier` in the command. If you don't specify one of these parameters, you get all snapshots.

```
aws rds describe-db-snapshots --db-instance-identifier <your-db-instance-name>
```

2. The command returns all configuration details for any snapshots created from the DB instance specified. In the output, find the snapshot that you want to migrate and locate its Amazon Resource Name (ARN). To learn more about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#). An ARN looks similar to the output following.

```
"DBSnapshotArn": "arn:aws:rds:aws-region:111122223333:snapshot:<snapshot_name>"
```

Also in the output you can find configuration details for the RDS for PostgreSQL DB instance, such as the engine version, allocated storage, whether or not the DB instance is encrypted, and so on.

3. Use the [restore-db-cluster-from-snapshot](#) command to start the migration. Specify the following parameters:
  - `--db-cluster-identifier` – The name that you want to give to the Aurora PostgreSQL DB cluster. This Aurora DB cluster is the target for your DB snapshot migration.
  - `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate.
  - `--engine` – Specify `aurora-postgresql` for the Aurora DB cluster engine.
  - `--kms-key-id` – This optional parameter lets you create an encrypted Aurora PostgreSQL DB cluster from an unencrypted DB snapshot. It also lets you choose a different encryption key for the DB cluster than the key used for the DB snapshot.

 **Note**

You can't create an unencrypted Aurora PostgreSQL DB cluster from an encrypted DB snapshot.

Without the `--kms-key-id` parameter specified as shown following, the [restore-db-cluster-from-snapshot](#) Amazon CLI command creates an empty Aurora PostgreSQL DB cluster that's either encrypted using the same key as the DB snapshot or is unencrypted if the source DB snapshot isn't encrypted.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier cluster-name \  
  --snapshot-identifier arn:aws:rds:aws-region:111122223333:snapshot:your-  
snapshot-name \  
  --engine aurora-postgresql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
```

```
--db-cluster-identifier new_cluster ^  
--snapshot-identifier arn:aws:rds:aws-region:111122223333:snapshot:your-  
snapshot-name ^  
--engine aurora-postgresql
```

- The command returns details about the Aurora PostgreSQL DB cluster that's being created for the migration. You can check the status of the Aurora PostgreSQL DB cluster by using the [describe-db-clusters](#) Amazon CLI command.

```
aws rds describe-db-clusters --db-cluster-identifier cluster-name
```

- When the DB cluster becomes "available", you use [create-db-instance](#) command to populate the Aurora PostgreSQL DB cluster with the DB instance based on your Amazon RDS DB snapshot. Specify the following parameters:
  - `--db-cluster-identifier` – The name of the new Aurora PostgreSQL DB cluster that you created in the previous step.
  - `--db-instance-identifier` – The name you want to give to the DB instance. This instance becomes the primary node in your Aurora PostgreSQL DB cluster.
  - `----db-instance-class` – Specify the DB instance class to use. Choose from among the DB instance classes supported by the Aurora PostgreSQL version to which you're migrating. For more information, see [DB instance class types](#) and [Supported DB engines for DB instance classes](#).
  - `--engine` – Specify `aurora-postgresql` for the DB instance.

You can also create the DB instance with a different configuration than the source DB snapshot, by passing in the appropriate options in the `create-db-instance` Amazon CLI command. For more information, see the [create-db-instance](#) command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
--db-cluster-identifier cluster-name \  
--db-instance-identifier --db-instance-class db.instance.class \  
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier cluster-name ^  
  --db-instance-identifier --db-instance-class db.instance.class ^  
  --engine aurora-postgresql
```

When the migration process completes, the Aurora PostgreSQL cluster has a populated primary DB instance.

# Migrating data from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster using an Aurora read replica

You can use an RDS for PostgreSQL DB instance as the basis for a new Aurora PostgreSQL DB cluster by using an Aurora read replica for the migration process. The Aurora read replica option is available only for migrating within the same Amazon Web Services Region and account, and it's available only if the Region offers a compatible version of Aurora PostgreSQL for your RDS for PostgreSQL DB instance. By *compatible*, we mean that the Aurora PostgreSQL version is the same as the RDS for PostgreSQL version, or that it is a higher minor version in the same major version family.

For example, to use this technique to migrate an RDS for PostgreSQL 11.14 DB instance, the Region must offer Aurora PostgreSQL version 11.14 or a higher minor version in the PostgreSQL version 11 family.

## Topics

- [Overview of migrating data by using an Aurora read replica](#)
- [Preparing to migrate data by using an Aurora read replica](#)
- [Creating an Aurora read replica](#)
- [Promoting an Aurora read replica](#)

## Overview of migrating data by using an Aurora read replica

Migrating from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster is a multistep procedure. First, you create an Aurora read replica of your source RDS for PostgreSQL DB instance. That starts a replication process from your RDS for PostgreSQL DB instance to a special-purpose DB cluster known as a Replica *cluster*. The Replica cluster consists solely of an Aurora read replica (a reader instance).

### Note

It can take several hours per terabyte of data for the migration to complete.

## Promoting an Aurora PostgreSQL Replica

After you create an Aurora PostgreSQL DB cluster, follow these steps to promote the Aurora Replica:

1. Stop all database write workload on the source RDS for PostgreSQL DB instance.
2. Get the current WAL LSN from the source RDS for PostgreSQL DB instance:

```
SELECT pg_current_wal_lsn();
pg_current_wal_lsn
-----
0/F0000318
(1 row)
```

3. On the Aurora PostgreSQL Replica cluster, check that the replayed LSN is greater than the LSN from step 2:

```
SELECT pg_last_wal_replay_lsn();
pg_last_wal_replay_lsn
-----
0/F0000400
(1 row)
```

Alternatively, you can use the following query on the source RDS for PostgreSQL DB instance:

```
SELECT restart_lsn FROM pg_replication_slots;
```

4. Promote the Aurora PostgreSQL Replica cluster.

When the replication stops, the replica cluster is promoted to a standalone Aurora PostgreSQL DB cluster, and the reader is promoted to writer instance for the cluster. At this point, you can add instances to the Aurora PostgreSQL DB cluster to size it according to your use case. If you no longer need the original RDS for PostgreSQL DB instance, you can delete it.

You can't create an Aurora read replica if your RDS for PostgreSQL DB instance already has an Aurora read replica or if it has a cross-Region read replica.

## Preparing to migrate data by using an Aurora read replica

### Note

When preparing to migrate data to Aurora PostgreSQL, it's important to identify and handle unlogged tables appropriately. For more information, see [Handling unlogged tables during migration](#).

During the migration process using Aurora read replica, updates made to the source RDS for PostgreSQL DB instance are asynchronously replicated to the Aurora read replica of the Replica cluster. The process uses PostgreSQL's native streaming replication functionality which stores write-ahead logs (WAL) segments on the source instance. Before starting this migration process, make sure that your instance has sufficient storage capacity by checking values for the metrics listed in the table.

Metric	Description
FreeStorageSpace	The available storage space.  Units: Bytes
OldestReplicationSlotLag	The size of the lag for WAL data in the replica that is lagging the most.  Units: Megabytes
RDSToAuroraPostgreSQLReplicaLag	The amount of time in seconds that an Aurora PostgreSQL DB cluster lags behind the source RDS DB instance.
TransactionLogsDiskUsage	The disk space used by the transaction logs.  Units: Megabytes

For more information about monitoring your RDS instance, see [Monitoring](#) in the *Amazon RDS User Guide*.

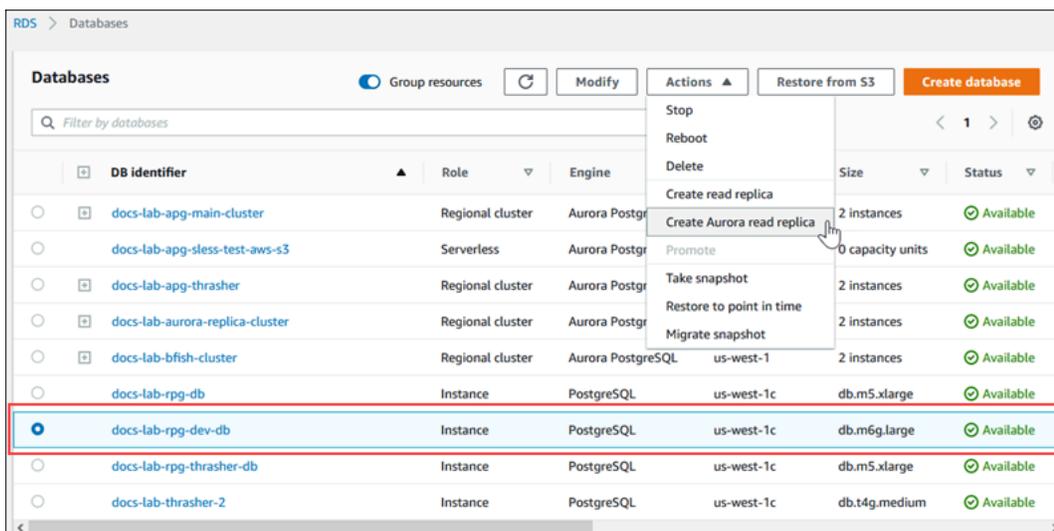

## Creating an Aurora read replica

You can create an Aurora read replica for an RDS for PostgreSQL DB instance by using the Amazon Web Services Management Console or the Amazon CLI. The option to create an Aurora read replica using the Amazon Web Services Management Console is available only if the Amazon Web Services Region offers a compatible Aurora PostgreSQL version. That is, it's available only if there's an Aurora PostgreSQL version that is the same as the RDS for PostgreSQL version or a higher minor version in the same major version family.

### Console

#### To create an Aurora read replica from a source PostgreSQL DB instance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the RDS for PostgreSQL DB instance that you want to use as the source for your Aurora read replica. For **Actions**, choose **Create Aurora read replica**. If this choice doesn't display, it means that a compatible Aurora PostgreSQL version isn't available in the Region.

4. On the Create Aurora read replica settings page, you configure the properties for the Aurora PostgreSQL DB cluster as shown in the following table. The Replica DB cluster is created from a snapshot of the source DB instance using the same 'master' user name and password as the source, so you can't change these at this time.

Option	Description
<b>DB instance class</b>	Choose a DB instance class that meets the processing and memory requirements primary instance in the DB cluster. For more information, see <a href="#">Amazon Aurora DB instance classes</a> .
<b>Multi-AZ deployment</b>	Not available during the migration
<b>DB instance identifier</b>	<p>Enter the name that you want to give to the DB instance. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</p> <p>The DB instance identifier has the following constraints:</p> <ul style="list-style-type: none"><li>• It must contain 1–63 alphanumeric characters or hyphens.</li><li>• Its first character must be a letter.</li><li>• It can't end with a hyphen or contain two consecutive hyphens.</li><li>• It must be unique for all DB instances for each Amazon account, for each Amazon Web Services Region.</li></ul>
<b>Virtual Private Cloud (VPC)</b>	Choose the VPC to host the DB cluster. Choose <b>Create new VPC</b> to have Amazon RDS create a VPC for you. For more information, see <a href="#">DB cluster prerequisites</a> .
<b>DB subnet group</b>	Choose the DB subnet group to use for the DB cluster. Choose <b>Create new DB Subnet Group</b> to have Amazon RDS create a DB subnet group for you. For more information, see <a href="#">DB cluster prerequisites</a> .

Option	Description
<b>Public accessibility</b>	Choose <b>Yes</b> to give the DB cluster a public IP address; otherwise, choose <b>No</b> . The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see <a href="#">Hiding a DB cluster in a VPC from the internet</a> .
<b>Availability zone</b>	Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see <a href="#">Regions and Availability Zones</a> .
<b>VPC security groups</b>	Choose one or more VPC security groups to secure network access to the DB cluster. Choose <b>Create new VPC security group</b> to have Amazon RDS create a VPC security group for you. For more information, see <a href="#">DB cluster prerequisites</a> .
<b>Database port</b>	Specify the port for applications and utilities to use to access the database. Aurora PostgreSQL DB clusters default to the default PostgreSQL port, 5432. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.
<b>DB parameter group</b>	Choose a DB parameter group for the Aurora PostgreSQL DB cluster. Aurora has a default DB parameter group you can use, or you can create your own DB parameter group. For more information about DB parameter groups, see <a href="#">Parameter groups for Amazon Aurora</a> .

Option	Description
<b>DB cluster parameter group</b>	Choose a DB cluster parameter group for the Aurora PostgreSQL DB cluster. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see <a href="#">Parameter groups for Amazon Aurora</a> .
<b>Encryption</b>	Choose <b>Enable encryption</b> for your new Aurora DB cluster to be encrypted at rest. If you choose <b>Enable encryption</b> , also choose a KMS key as the <b>Amazon KMS key</b> value.
<b>Priority</b>	Choose a failover priority for the DB cluster. If you don't choose a value, the default is <b>tier-1</b> . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a> .
<b>Backup retention period</b>	Choose the length of time, 1–35 days, for Aurora to retain backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.
<b>Enhanced monitoring</b>	Choose <b>Enable enhanced monitoring</b> to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .
<b>Monitoring Role</b>	Only available if you chose <b>Enable enhanced monitoring</b> . The Amazon Identity and Access Management (IAM) role to use for Enhanced Monitoring. For more information, see <a href="#">Setting up and enabling Enhanced Monitoring</a> .

Option	Description
<b>Granularity</b>	Only available if you chose <b>Enable enhanced monitoring</b> . Set the interval, in seconds, between when metrics are collected for your DB cluster.
<b>Auto minor version upgrade</b>	<p>Choose <b>Yes</b> to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.</p> <p>The <b>Auto minor version upgrade</b> option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.</p>
<b>Maintenance window</b>	Choose the weekly time range during which system maintenance can occur.

## 5. Choose **Create read replica**.

### Amazon CLI

To create an Aurora read replica from a source RDS for PostgreSQL DB instance by using the Amazon CLI, you first use the [create-db-cluster](#) CLI command to create an empty Aurora DB cluster. Once the DB cluster exists, you then use the [create-db-instance](#) command to create the primary instance for your DB cluster. The primary instance is the first instance that's created in an Aurora DB cluster. In this case, it's created initially as an Aurora read replica of your RDS for PostgreSQL DB instance. When the process concludes, your RDS for PostgreSQL DB instance has effectively been migrated to an Aurora PostgreSQL DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance that you identify when you invoke the Amazon CLI commands.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption

for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

The following examples create an Aurora PostgreSQL DB cluster named `my-new-aurora-cluster` that's going to use an unencrypted RDS DB source instance. You first create the Aurora PostgreSQL DB cluster by calling the [create-db-cluster](#) CLI command. The example shows how to use the optional `--storage-encrypted` parameter to specify that the DB cluster should be encrypted. Because the source DB isn't encrypted, the `--kms-key-id` is used to specify the key to use. For more information about required and optional parameters, see the list following the example.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
  --db-cluster-identifier my-new-aurora-cluster \
  --db-subnet-group-name my-db-subnet \
  --vpc-security-group-ids sg-11111111 \
  --engine aurora-postgresql \
  --engine-version same-as-your-rds-instance-version \
  --replication-source-identifier arn:aws:rds:aws-region:111122223333:db/rpg-source-
db \
  --storage-encrypted \
  --kms-key-id arn:aws:kms:aws-
region:111122223333:key/11111111-2222-3333-444444444444
```

For Windows:

```
aws rds create-db-cluster ^
  --db-cluster-identifier my-new-aurora-cluster ^
  --db-subnet-group-name my-db-subnet ^
  --vpc-security-group-ids sg-11111111 ^
  --engine aurora-postgresql ^
  --engine-version same-as-your-rds-instance-version ^
  --replication-source-identifier arn:aws:rds:aws-region:111122223333:db/rpg-source-
db ^
  --storage-encrypted ^
  --kms-key-id arn:aws:kms:aws-
region:111122223333:key/11111111-2222-3333-444444444444
```

In the following list you can find more information about some of the options shown in the example. Unless otherwise specified, these parameters are required.

- `--db-cluster-identifier` – You need to give your new Aurora PostgreSQL DB cluster a name.
- `--db-subnet-group-name` – Create your Aurora PostgreSQL DB cluster in the same DB subnet as the source DB instance.
- `--vpc-security-group-ids` – Specify the security group for your Aurora PostgreSQL DB cluster.
- `--engine-version` – Specify the version to use for the Aurora PostgreSQL DB cluster. This should be the same as or a higher minor version than the version used by your source RDS for PostgreSQL DB instance.
- `--replication-source-identifier` – Identify your RDS for PostgreSQL DB instance using its Amazon Resource Name (ARN). For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#) in the *Amazon Web Services General Reference*. of your DB cluster.
- `--storage-encrypted` – Optional. Use only when needed to specify encryption as follows:
  - Use this parameter when the source DB instance has encrypted storage. The call to [create-db-cluster](#) fails if you don't use this parameter with a source DB instance that has encrypted storage. If you want to use a different key for the Aurora PostgreSQL DB cluster than the key used by the source DB instance, you need to also specify the `--kms-key-id`.
  - Use if the source DB instance's storage is unencrypted but you want the Aurora PostgreSQL DB cluster to use encryption. If so, you also need to identify the encryption key to use with the `--kms-key-id` parameter.
- `--kms-key-id` – Optional. When used, you can specify the key to use for storage encryption (`--storage-encrypted`) by using the key's ARN, ID, alias ARN, or its alias name. This parameter is needed only for the following situations:
  - To choose a different key for the Aurora PostgreSQL DB cluster than that used by the source DB instance.
  - To create an encrypted cluster from an unencrypted source. In this case, you need to specify the key that Aurora PostgreSQL should use for encryption.

After creating the Aurora PostgreSQL DB cluster, you then create the primary instance by using the [create-db-instance](#) CLI command, as shown in the following:

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
```

```
--db-cluster-identifier my-new-aurora-cluster \  
--db-instance-class db.x2g.16xlarge \  
--db-instance-identifier rpg-for-migration \  
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier my-new-aurora-cluster ^  
  --db-instance-class db.x2g.16xlarge ^  
  --db-instance-identifier rpg-for-migration ^  
  --engine aurora-postgresql
```

In the following list, you can find more information about some of the options shown in the example.

- `--db-cluster-identifier` – Specify the name of the Aurora PostgreSQL DB cluster that you created with the [create-db-instance](#) command in the previous steps.
- `--db-instance-class` – The name of the DB instance class to use for your primary instance, such as `db.r4.xlarge`, `db.t4g.medium`, `db.x2g.16xlarge`, and so on. For a list of available DB instance classes, see [DB instance class types](#).
- `--db-instance-identifier` – Specify the name to give your primary instance.
- `--engine aurora-postgresql` – Specify `aurora-postgresql` for the engine.

## RDS API

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, first use the RDS API operation [CreateDBCluster](#) to create a new Aurora DB cluster for the Aurora read replica that gets created from your source RDS for PostgreSQL DB instance. When the Aurora PostgreSQL DB cluster is available, you then use the [CreateDBInstance](#) to create the primary instance for the Aurora DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance specified with `ReplicationSourceIdentifier`.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance.

If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

To create the Aurora DB cluster for the Aurora read replica, use the RDS API operation [CreateDBCluster](#) with the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster to create.
- `DBSubnetGroupName` – The name of the DB subnet group to associate with this DB cluster.
- `Engine=aurora-postgresql` – The name of the engine to use.
- `ReplicationSourceIdentifier` – The Amazon Resource Name (ARN) for the source PostgreSQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#) in the *Amazon Web Services General Reference*. If `ReplicationSourceIdentifier` identifies an encrypted source, Amazon RDS uses your default KMS key unless you specify a different key using the `KmsKeyId` option.
- `VpcSecurityGroupIds` – The list of Amazon EC2 VPC security groups to associate with this DB cluster.
- `StorageEncrypted` – Indicates that the DB cluster is encrypted. When you use this parameter without also specifying the `ReplicationSourceIdentifier`, Amazon RDS uses your default KMS key.
- `KmsKeyId` – The key for an encrypted cluster. When used, you can specify the key to use for storage encryption by using the key's ARN, ID, alias ARN, or its alias name.

For more information, see [CreateDBCluster](#) in the *Amazon RDS API Reference*.

Once the Aurora DB cluster is available, you can then create a primary instance for it by using the RDS API operation [CreateDBInstance](#) with the following parameters:

- `DBClusterIdentifier` – The name of your DB cluster.
- `DBInstanceClass` – The name of the DB instance class to use for your primary instance.
- `DBInstanceIdentifier` – The name of your primary instance.
- `Engine=aurora-postgresql` – The name of the engine to use.

For more information, see [CreateDBInstance](#) in the *Amazon RDS API Reference*.

## Promoting an Aurora read replica

The migration to Aurora PostgreSQL isn't complete until you promote the Replica cluster, so don't delete the RDS for PostgreSQL source DB instance just yet.

Before promoting the Replica cluster, make sure that the RDS for PostgreSQL DB instance doesn't have any in-process transactions or other activity writing to the database. When the replica lag on the Aurora read replica reaches zero (0), you can promote the Replica cluster. For more information about monitoring replica lag, see [Monitoring Aurora PostgreSQL replication](#) and [Instance-level metrics for Amazon Aurora](#).

### Console

#### To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Replica cluster.

The screenshot shows the Amazon RDS console 'Databases' page. A table lists various database instances and clusters. The 'docs-lab-app-dev-db-replica-cluster' is selected, and its context menu is open, showing the 'Promote' option highlighted. The table has columns for DB identifier, Role, Engine, Status, and CPU. The 'docs-lab-rpg-dev-db' instance is also highlighted with a red box.

DB identifier	Role	Engine	Status	CPU
docs-lab-app-dev-db-replica-cluster	Replica cluster	Aurora PostgreSQL	Available	-
docs-lab-app-dev-db-replica	Writer instance	Aurora PostgreSQL	Available	-
docs-lab-app-main-cluster	Regional cluster	Aurora PostgreSQL	Available	-
docs-lab-app-sless-test-aws-s3	Serverless	Aurora PostgreSQL	Available	-
docs-lab-app-thrasher	Regional cluster	Aurora PostgreSQL	Available	-
docs-lab-bfish-cluster	Regional cluster	Aurora PostgreSQL	Available	-
docs-lab-rpg-db	Instance	PostgreSQL	Available	-
docs-lab-rpg-dev-db	Primary	PostgreSQL	Available	-
docs-lab-rpg-thrasher-db	Instance	PostgreSQL	Available	-
docs-lab-thrasher-2	Instance	PostgreSQL	Available	-

4. For **Actions**, choose **Promote**. This may take a few minutes and can cause downtime.

When the process completes, the Aurora Replica cluster is a Regional Aurora PostgreSQL DB cluster, with a Writer instance containing the data from the RDS for PostgreSQL DB instance.

## Amazon CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the [promote-read-replica-db-cluster](#) Amazon CLI command.

### Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \  
  --db-cluster-identifier myreadreplicaccluster
```

For Windows:

```
aws rds promote-read-replica-db-cluster ^  
  --db-cluster-identifier myreadreplicaccluster
```

## RDS API

To promote an Aurora read replica to a stand-alone DB cluster, use the RDS API operation [PromoteReadReplicaDBCluster](#).

After you promote the Replica cluster, you can confirm that the promotion has completed by checking the event log, as follows.

### To confirm that the Aurora Replica cluster was promoted

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Events**.
3. On the **Events** page, find the name of your cluster in the **Source** list. Each event has a source, type, time, and message. You can see all events that have occurred in your Amazon Web Services Region for your account. A successful promotion generates the following message.

```
Promoted Read Replica cluster to a stand-alone database cluster.
```

After promotion is complete, the source RDS for PostgreSQL DB instance and the Aurora PostgreSQL DB cluster are unlinked. You can direct your client applications to the endpoint for the

Aurora read replica. For more information on the Aurora endpoints, see [Amazon Aurora endpoint connections](#). At this point, you can safely delete the DB instance.

## Optimizing query performance in Aurora PostgreSQL

Optimizing query performance is crucial because it helps databases run faster and more efficiently while using fewer resources, which results in better user experience and lower operating costs. Amazon Aurora PostgreSQL provides several features to help optimize query performance for PostgreSQL workloads.

### Topics

- [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#)
- [Optimizing correlated subqueries in Aurora PostgreSQL](#)
- [Improving query performance using adaptive join](#)
- [Using shared plan cache](#)

## Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads

You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. An Aurora PostgreSQL DB instance that uses Aurora Optimized Reads delivers up to 8x improved query latency and up to 30% cost savings for applications with large datasets, that exceed the memory capacity of a DB instance.

### Topics

- [Overview of Aurora Optimized Reads in PostgreSQL](#)
- [Using Aurora Optimized Reads](#)
- [Use cases for Aurora Optimized Reads](#)
- [Monitoring DB instances that use Aurora Optimized Reads](#)
- [Best practices for Aurora Optimized Reads](#)

## Overview of Aurora Optimized Reads in PostgreSQL

Aurora Optimized Reads is available by default when you create a DB cluster that uses Graviton-based R6gd, R8gd, and Intel-based R6id instances with non-volatile memory express (NVMe) storage. It is available from the following PostgreSQL versions:

- 14.12 and higher versions, 15.7 and higher versions, 16.3 and higher versions, 17.4 and higher versions for R8gd instances
- 14.9 and higher versions, 15.4 and higher versions, 16.1 and all higher versions for R6gd and R6id instances

Aurora Optimized Reads supports two capabilities: tiered cache and temporary objects.

**Optimized Reads-enabled tiered cache** - Using tiered cache, you can extend your DB instance caching capacity by up to 5x the instance memory. This automatically maintains the cache to contain the most recent, transactionally consistent data, freeing applications from the overhead of managing the data currency of external result-set based caching solutions. It offers up to 8x better latency for queries that were previously fetching data from Aurora storage.

In Aurora, the value for `shared_buffers` in the default parameter group is usually set to around 75% of the available memory. However, for the r8gd, r6gd, and r6id instance types, Aurora reduces the `shared_buffers` space by 4.5% to host the metadata for the Optimized Reads cache.

**Optimized Reads-enabled temporary objects** - Using temporary objects, you can achieve faster query processing by placing the temporary files that are generated by PostgreSQL on the local NVMe storage. This reduces the traffic to Elastic Block Storage (EBS) over the network. It offers up to 2x better latency and throughput for advanced queries that sort, join, or merge large volumes of data that do not fit within the memory capacity available on a DB instance.

On an Aurora I/O-Optimized cluster, Optimized Reads makes use of both tiered cache and temporary objects on NVMe storage. With Optimized Reads-enabled tiered cache capability, Aurora allocates 2x the instance memory for temporary objects, approximately 10% of the storage for internal operations and the remaining storage as tiered cache. On an Aurora Standard cluster, Optimized Reads makes use of only temporary objects.

Aurora I/O-Optimized clusters allows you to resize the allocated space for Optimized Reads-enabled temporary objects using the dynamic parameter `aurora_temp_space_size` at the instance level. This resizing feature is available from the following PostgreSQL versions:

- 16.8 and all higher versions
- 15.12 and higher 15 versions
- 14.17 and higher 14 versions

With this parameter, you can resize the capacity from 2x up to 6x of instance memory without requiring database engine restart. When you expand temporary object space, the change takes effect immediately, regardless of concurrent workloads. However, when you reduce the space, the adjustment completes only after there is sufficient unused space in temporary objects to accommodate the new size request. After you resize Optimized Reads-enabled temporary objects, the tiered cache automatically adjusts to use any available space.

Engine	Cluster storage configuration	Optimized Reads-enabled temporary objects	Optimized Reads-enabled tiered cache	Versions supported
Aurora PostgreSQL-Compatible Edition	Standard	Yes	No	<ul style="list-style-type: none"> <li>• 14.9 and higher versions, 15.4 and higher versions, 16.1 and all higher versions for r6gd and r6id instances</li> <li>• 14.12 and higher versions, 15.7 and higher versions, 16.3 and higher versions, 17.4 and higher versions for r8gd instances</li> </ul>
	I/O-Optimized	Yes	Yes	

**Note**

A switch between IO-Optimized and Standard clusters on a NVMe-based DB instance class causes an immediate database engine restart.

In Aurora PostgreSQL, use the `temp_tablespaces` parameter to configure the table space where the temporary objects are stored.

To check whether the temporary objects are configured, use the following command:

```
postgres=> show temp_tablespaces;
temp_tablespaces
-----
aurora_temp_tablespace
(1 row)
```

The `aurora_temp_tablespace` is a tablespace configured by Aurora that points to the NVMe local storage. You can't modify this parameter or switch back to Amazon EBS storage.

To check whether optimized reads cache is turned on, use the following command:

```
postgres=> show shared_preload_libraries;
          shared_preload_libraries
-----
rdsutils,pg_stat_statements,aurora_optimized_reads_cache
```

## Using Aurora Optimized Reads

When you provision an Aurora PostgreSQL DB instance with one of the NVMe-based DB instances, the DB instance automatically uses Aurora Optimized Reads.

To turn on Aurora Optimized Reads, do one of the following:

- Create an Aurora PostgreSQL DB cluster using one of the NVMe-based DB instance classes. For more information, see [Creating an Amazon Aurora DB cluster](#).
- Modify an existing Aurora PostgreSQL DB cluster to use one of the NVMe-based DB instance classes. For more information, see [Modifying an Amazon Aurora DB cluster](#).

Aurora Optimized Reads is available in all Amazon Web Services Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see [Amazon Aurora DB instance classes](#).

To switch back to a non-optimized reads Aurora instance, modify the DB instance class of your Aurora instance to the similar instance class without NVMe ephemeral storage for your database workloads. For example, if the current DB instance class is `db.r6gd.4xlarge`, choose `db.r6g.4xlarge` to switch back. For more information, see [Modifying an Aurora DB instance](#).

## Use cases for Aurora Optimized Reads

### Optimized Reads-enabled tiered cache

The following are some use cases that can benefit from Optimized Reads with tiered cache:

- Internet scale applications such as payments processing, billing, e-commerce with strict performance SLAs.
- Real-time reporting dashboards that run hundreds of point queries for metrics/data collection.
- Generative AI applications with the `pgvector` extension to search exact or nearest neighbors across millions of vector embeddings.

### Optimized Reads-enabled temporary objects

The following are some use cases that can benefit from Optimized Reads with temporary objects:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as `GROUP BY` and `ORDER BY` that can't always use appropriate indexes.
- `CREATE INDEX` or `REINDEX` operations for sorting.
- Other workloads that use internal temporary tables.

## Monitoring DB instances that use Aurora Optimized Reads

You can monitor your queries that use Optimized Reads-enabled tiered cache with the `EXPLAIN` command as shown in the following example:

```
Postgres=> EXPLAIN (ANALYZE, BUFFERS) SELECT c FROM sbtest15 WHERE id=100000000
```

#### QUERY PLAN

```
-----
Index Scan using sbtest15_pkey on sbtest15 (cost=0.57..8.59 rows=1 width=121) (actual
time=0.287..0.288 rows=1 loops=1)
  Index Cond: (id = 100000000)
  Buffers: shared hit=3 read=2 aurora_orcache_hit=2
  I/O Timings: shared/local read=0.264
Planning:
  Buffers: shared hit=33 read=6 aurora_orcache_hit=6
  I/O Timings: shared/local read=0.607
Planning Time: 0.929 ms
Execution Time: 0.303 ms
(9 rows)
Time: 2.028 ms
```

#### Note

`aurora_orcache_hit` and `aurora_storage_read` fields in the `Buffers` section of the explain plan are shown only when `Optimized Reads` is turned on and their values are greater than zero. The `read` field is the total of the `aurora_orcache_hit` and `aurora_storage_read` fields.

You can monitor DB instances that use Aurora Optimized Reads using the following CloudWatch metrics:

- `AuroraOptimizedReadsCacheHitRatio`
- `FreeEphemeralStorage`
- `ReadIOPSEphemeralStorage`
- `ReadLatencyEphemeralStorage`
- `ReadThroughputEphemeralStorage`
- `WriteIOPSEphemeralStorage`
- `WriteLatencyEphemeralStorage`

- `WriteThroughputEphemeralStorage`

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see [Instance-level metrics for Amazon Aurora](#).

You can also use the `pg_proctab` extension to monitor NVMe storage.

```
postgres=>select * from pg_diskusage();
```

```
major | minor |          devname          | reads_completed | reads_merged | sectors_read |
readtime | writes_completed | writes_merged | sectors_written | writetime | current_io
| iotime | totaliotime
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
          |          | rdstemp          |          23264 |          0 |          191450 |
11670 |          1750892 |          0 |          24540576 |          819350 |          0 |
3847580 |          831020
          |          | rdsephemeralstorage |          23271 |          0 |          193098 |
2620 |          114961 |          0 |          13845120 |          130770 |          0 |
215010 |          133410
(2 rows)
```

## Best practices for Aurora Optimized Reads

Use the following best practices for Aurora Optimized Reads:

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeEphemeralStorage`. If the instance store is reaching its limit because of the workload on the DB instance, tune the concurrency and queries which heavily use temporary objects or modify it to use a larger DB instance class.
- Monitor the CloudWatch metric for the Optimized Reads cache hit rate. Operations like `VACUUM` modify large numbers of blocks very quickly. This can cause a temporary drop in the hit ratio. The `pg_prewarm` extension can be used to load data into the buffer cache that allows Aurora to proactively write some of those blocks to the Optimized Reads cache.
- You can enable cluster cache management (CCM) to warm up the buffer cache and tiered cache on a tier-0 reader, which will be used as a failover target. When CCM is enabled, the buffer cache is periodically scanned to write pages eligible for eviction in tiered cache. For more information on CCM, see [Fast recovery after failover with cluster cache management for Aurora PostgreSQL](#).

## Optimizing correlated subqueries in Aurora PostgreSQL

A correlated subquery references table columns from the outer query. It is evaluated once for every row returned by the outer query. In the following example, the subquery references a column from table `ot`. This table is not included in the subquery's `FROM` clause, but it is referenced in the outer query's `FROM` clause. If table `ot` has 1 million rows, the subquery needs to be evaluated 1 million times.

```
SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT AVG(it.b) FROM it WHERE it.a = ot.a);
```

### Note

- Subquery transformation and subquery cache are available in Aurora PostgreSQL beginning with version 16.8, while Babelfish for Aurora PostgreSQL supports these features from 4.2.0.
- Starting with Babelfish for Aurora PostgreSQL versions 4.6.0 and 5.2.0, the following parameters control these features:
  - `babelfishpg_tsq.apg_enable_correlated_scalar_transform`
  - `babelfishpg_tsq.apg_enable_subquery_cache`

By default, both parameters are turned on.

## Improving Aurora PostgreSQL query performance using subquery transformation

Aurora PostgreSQL can accelerate correlated subqueries by transforming them into equivalent outer joins. This optimization applies to the following two types of correlated subqueries:

- Subqueries that return a single aggregate value and appear in the `SELECT` list.

```
SELECT ot.a, ot.b, (SELECT AVG(it.b) FROM it WHERE it.a = ot.a) FROM ot;
```

- Subqueries that return a single aggregate value and appear in a `WHERE` clause.

```
SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT AVG(it.b) FROM it WHERE it.a = ot.a);
```

## Enabling transformation in the subquery

To enable the transformation of correlated subqueries into equivalent outer joins, set the `apg_enable_correlated_scalar_transform` parameter to `ON`. The default value of this parameter is `OFF`.

You can modify the cluster or instance parameter group to set the parameters. To learn more, see [Parameter groups for Amazon Aurora](#).

Alternatively, you can configure the setting for just the current session by the following command:

```
SET apg_enable_correlated_scalar_transform TO ON;
```

## Verifying the transformation

Use the `EXPLAIN` command to verify if the correlated subquery has been transformed into an outer join in the query plan.

When the transformation is enabled, the applicable correlated subquery part will be transformed into outer join. For example:

```
postgres=> CREATE TABLE ot (a INT, b INT);
CREATE TABLE
postgres=> CREATE TABLE it (a INT, b INT);
CREATE TABLE

postgres=> SET apg_enable_correlated_scalar_transform TO ON;
SET
postgres=> EXPLAIN (COSTS FALSE) SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT
AVG(it.b) FROM it WHERE it.a = ot.a);
```

### QUERY PLAN

```
-----
Hash Join
  Hash Cond: (ot.a = apg_scalar_subquery.scalar_output)
  Join Filter: ((ot.b)::numeric < apg_scalar_subquery.avg)
  -> Seq Scan on ot
  -> Hash
        -> Subquery Scan on apg_scalar_subquery
              -> HashAggregate
                    Group Key: it.a
                          -> Seq Scan on it
```

The same query is not transformed when the GUC parameter is turned OFF. The plan will not have outer join but subplan instead.

```
postgres=> SET apg_enable_correlated_scalar_transform TO OFF;
SET
postgres=> EXPLAIN (COSTS FALSE) SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT
  AVG(it.b) FROM it WHERE it.a = ot.a);
      QUERY PLAN
-----
Seq Scan on ot
  Filter: ((b)::numeric < (SubPlan 1))
  SubPlan 1
    -> Aggregate
        -> Seq Scan on it
            Filter: (a = ot.a)
```

## Limitations

- The subquery must be in the SELECT list or in one of the conditions in the where clause. Otherwise, it won't be transformed.
- The subquery must return an aggregate function. User-defined aggregate functions aren't supported for transformation.
- A subquery whose return expression isn't a simple aggregate function won't be transformed.
- The correlated condition in subquery WHERE clauses should be a simple column reference. Otherwise, it won't be transformed.
- The correlated condition in subquery where clauses must be a plain equality predicate.
- The subquery can't contain either a HAVING or a GROUP BY clause.
- The where clause in the subquery may contain one or more predicates combined with AND.

### Note

The performance impact of transformation varies depending on your schema, data, and workload. Correlated subquery execution with transformation can significantly improve performance as the number of rows produced by the outer query increases. We strongly recommend that you test this feature in a non-production environment with your actual schema, data, and workload before enabling it in a production environment.

## Using subquery cache to improve Aurora PostgreSQL query performance

Aurora PostgreSQL supports subquery cache to store the results of correlated subqueries. This feature skips repeated correlated subquery executions when subquery results are already in the cache.

### Understanding subquery cache

PostgreSQL's Memoize node is the key part of subquery cache. The Memoize node maintains a hash table in local cache to map from input parameter values to query result rows. The memory limit for the hash table is the product of `work_mem` and `hash_mem_multiplier`. To learn more, see [Resource Consumption](#).

During query execution, subquery cache uses Cache Hit Rate (CHR) to estimate whether the cache is improving query performance and to decide at query runtime whether to continue using the cache. CHR is the ratio of the number of cache hits to the total number of requests. For example, if a correlated subquery needs to be executed 100 times, and 70 of those execution results can be retrieved from the cache, the CHR is 0.7.

For every `apg_subquery_cache_check_interval` number of cache misses, the benefit of subquery cache is evaluated by checking whether the CHR is larger than `apg_subquery_cache_hit_rate_threshold`. If not, the cache will be deleted from memory, and the query execution will return to the original, uncached subquery re-execution.

### Parameters that control subquery cache behavior

The following table lists the parameters that control the behavior of the subquery cache.

Parameter	Description	Default	Allowed
<code>apg_enable_subquery_cache</code>	Enables the use of cache for correlated scalar subqueries.	OFF	ON, OFF
<code>apg_subquery_cache_check_interval</code>	Sets the frequency, in number of cache misses, to evaluate subquery cache hit rate.	500	0–2147483647

Parameter	Description	Default	Allowed
apg_subquery_cache_hit_rate_threshold	Sets the threshold for subquery cache hit rate.	0.3	0.0–1.0

### Note

- Larger values of `apg_subquery_cache_check_interval` may improve the accuracy of the CHR-based cache benefit estimation, but will increase the cache overhead, since CHR won't get evaluated until the cache table has `apg_subquery_cache_check_interval` rows.
- Larger values of `apg_subquery_cache_hit_rate_threshold` bias towards abandoning subquery cache and returning back to the original, uncached subquery re-execution.

You can modify the cluster or instance parameter group to set the parameters. To learn more, see [Parameter groups for Amazon Aurora](#).

Alternatively, you can configure the setting for just the current session by the following command:

```
SET apg_enable_subquery_cache TO ON;
```

## Turning on subquery cache in Aurora PostgreSQL

When subquery cache is enabled, Aurora PostgreSQL applies cache to save subquery results. The query plan will then have a Memoize node under SubPlan.

For example, the following command sequence shows the estimated query execution plan of a simple correlated subquery without subquery cache.

```
postgres=> SET apg_enable_subquery_cache TO OFF;
SET
postgres=> EXPLAIN (COSTS FALSE) SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT it.b
FROM it WHERE it.a = ot.a);
```

QUERY PLAN

```
-----
Seq Scan on ot
  Filter: (b < (SubPlan 1))
  SubPlan 1
    -> Seq Scan on it
        Filter: (a = ot.a)
```

After turning on `apg_enable_subquery_cache`, the query plan will contain a Memoize node under the SubPlan node, indicating that the subquery is planning to use cache.

```
postgres=> SET apg_enable_subquery_cache TO ON;
SET
postgres=> EXPLAIN (COSTS FALSE) SELECT ot.a, ot.b FROM ot WHERE ot.b < (SELECT it.b
  FROM it WHERE it.a = ot.a);
```

#### QUERY PLAN

```
-----
Seq Scan on ot
  Filter: (b < (SubPlan 1))
  SubPlan 1
    -> Memoize
        Cache Key: ot.a
        Cache Mode: binary
    -> Seq Scan on it
        Filter: (a = ot.a)
```

The actual query execution plan contains more details of the subquery cache, including cache hits and cache misses. The following output shows the actual query execution plan of the above example query after inserting some values to the tables.

```
postgres=> EXPLAIN (COSTS FALSE, TIMING FALSE, ANALYZE TRUE) SELECT ot.a, ot.b FROM ot
  WHERE ot.b < (SELECT it.b FROM it WHERE it.a = ot.a);
```

#### QUERY PLAN

```
-----
Seq Scan on ot (actual rows=2 loops=1)
  Filter: (b < (SubPlan 1))
  Rows Removed by Filter: 8
  SubPlan 1
    -> Memoize (actual rows=0 loops=10)
        Cache Key: ot.a
        Cache Mode: binary
        Hits: 4 Misses: 6 Evictions: 0 Overflows: 0 Memory Usage: 1kB
```

```
-> Seq Scan on it (actual rows=0 loops=6)
    Filter: (a = ot.a)
    Rows Removed by Filter: 4
```

The total cache hit number is 4, and the total cache miss number is 6. If the total number of hits and misses is less than the number of loops in the Memoize node, it means that the CHR evaluation did not pass and the cache was cleaned up and abandoned at some point. The subquery execution then returned back to the original uncached re-execution.

## Limitations

Subquery cache does not support certain patterns of correlated subqueries. Those types of queries will be run without cache, even if subquery cache is turned on:

- IN/EXISTS/ANY/ALL correlated subqueries
- Correlated subqueries containing nondeterministic functions.
- Correlated subqueries that reference outer table columns with datatypes that don't support hashing or equality operations.

## Improving query performance using adaptive join

### Overview

Adaptive join is a preview feature in Aurora PostgreSQL 17.4 that helps improve query performance. This feature is disabled by default, but you can enable it using Global User Configuration (GUC) parameters. Since this is a preview feature, the default parameter values might change. When enabled, adaptive join helps optimize query performance by dynamically switching from a nested loop join to a hash join at runtime. This switch occurs when the PostgreSQL optimizer has incorrectly chosen a nested loop join due to inaccurate cardinality estimates.

### Configuring adaptive join

You can control adaptive join using these three GUC parameters:

## Adaptive join configuration parameters

GUC parameter	Description	Default and configuration options
apg_adaptive_join_crossover_multiplier	This multiplier works with the <i>row crossover point</i> to determine when to switch from a nested loop to a hash join. The row crossover point is where the SQL optimizer estimates that nested loop and hash join operations have equal cost. A higher multiplier value reduces the likelihood of adaptive join switching to a hash join.	Controls whether Adaptive Join is enabled <ul style="list-style-type: none"> <li>• Default value: -1 (disabled)</li> <li>• Valid range: -1 to DBL_MAX</li> <li>• To enable: Set to <math>\geq 1</math></li> </ul>
apg_adaptive_join_cost_threshold	This parameter sets a minimum query cost threshold. Adaptive join automatically disables itself for queries below this threshold. This prevents performance overhead in simple queries where the cost of planning an adaptive join could exceed the benefits of switching from nested loop to hash join.	Sets minimum cost threshold for the query <ul style="list-style-type: none"> <li>• Default value: 100</li> <li>• Valid range: 0 to DBL_MAX</li> </ul>
apg_enable_parameterized_adaptive_join	This parameter extends adaptive join functionality to parameterized nested loop joins when enabled. By default, adaptive join works only with unparameterized nested loop joins, as these are more likely to benefit from switching to hash join. Parameterized nested loop joins typically perform better, making the switch to hash join less critical.	Controls adaptive join behavior for nested loop joins <ul style="list-style-type: none"> <li>• Default value: false</li> <li>• Valid values: true/false               <ul style="list-style-type: none"> <li>• When false: Works only with unparameterized nested loop joins</li> <li>• When true: Works with both parameter</li> </ul> </li> </ul>

GUC parameter	Description	Default and configuration options
		<p>ized and unparamet erized nested loop joins</p> <div data-bbox="1117 464 1507 873" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p><b>Note</b></p> <p>Requires apg_adapt ive_join_ crossover _multiplier to be enabled first</p> </div>

## Using shared plan cache

### Overview

Aurora PostgreSQL uses a process-per-user model where each client connection creates a dedicated backend process. Each backend process maintains its own local plan cache for prepared statements. Because these caches can't be shared between processes, applications that use many prepared statements might create duplicate caches across different backend processes, which leads to increased memory usage.

Aurora PostgreSQL versions 17.6 and later and 16.10 and later introduce shared plan cache functionality. When you enable this feature, backend processes can share generic plans, which reduces memory usage and improves performance by eliminating duplicate plan generation.

The shared plan cache uses the following components as its cache key:

- Query string (including comments)
- Planner-related GUC parameters (including `search_path`)
- User ID
- Database ID

Instance restarts reset the shared cache.

## Parameters

The following table describes the parameters that control the shared plan cache feature:

Parameter	Description	Default	Allowed
<code>apg_shared_plan_cache.enable</code>	Turns shared plan cache on or off	0 (OFF)	0, 1
<code>apg_shared_plan_cache.max</code>	The maximum number of cache entries	200–1000 (instance size dependent)	100–50000
<code>apg_shared_plan_cache.min_size_per_entry</code>	The minimum plan size to store in shared cache. Smaller plans use local cache to optimize OLTP performance.	16 KB	0–32768 (KB)
<code>apg_shared_plan_cache.max_size_per_entry</code>	The maximum plan size for shared cache. Larger plans store only cost information.	256 KB–4 MB (instance size dependent)	0–32768 (KB)
<code>apg_shared_plan_cache.idle_generic_plan_release_timeout</code>	The time after which idle sessions release local generic plans. Lower values save memory; higher values might improve performance.	10 seconds	0–2147483647 (ms)

**Note**

You can modify all parameters without restarting.

## Monitoring views and functions

- `apg_shared_plan_cache()` – Shows detailed cache entry information (hits, validity, timestamps)
- `apg_shared_plan_cache_stat()` – Displays instance-level statistics (evictions, invalidations)
- `apg_shared_plan_cache_reset()` – Removes all entries in `apg_shared_plan_cache()` and `apg_shared_plan_cache_stat()`
- `apg_shared_plan_cache_remove(cache_key)` – Removes an entry from `apg_shared_plan_cache()` where the entry matches the `cache_key`

## Limitations

- Only works with prepared statements and doesn't cache PL/pgSQL statements
- Doesn't cache a query that contains temporary tables or catalog tables
- Doesn't cache a query that depends on RLS (Row-Level Security)
- Each replica maintains its own cache (no cross-replica sharing)

## Working with unlogged tables in Aurora PostgreSQL

Amazon Aurora PostgreSQL supports unlogged tables that are crash-safe and maintain data integrity even after writer instance failures or failovers. In standard PostgreSQL, unlogged tables bypass the Write-Ahead Log (WAL) during write operations, resulting in faster write speeds. However, this comes at the cost of reduced durability, as unlogged tables are not crash-safe and can lose data after a system failure or unclean shutdown. These unlogged tables are automatically truncated after a crash or unclean shutdown. Their contents and indexes are also not replicated to standby servers.

In contrast, Aurora PostgreSQL handles unlogged tables differently due to its distributed storage architecture. This is because Aurora's storage system does not rely on the traditional PostgreSQL WAL for durability. However, the performance benefits typically associated with unlogged tables

in standard PostgreSQL may not be as significant in Aurora. This is due to Aurora's distributed storage architecture, which can introduce additional overhead compared to the local storage used in standard PostgreSQL.

When using unlogged tables in Aurora PostgreSQL, consider the following:

- You can access unlogged tables only from the writer node in the Aurora DB cluster.
- Reader nodes can access unlogged tables only when promoted to writer status.
- When you try to access unlogged tables from a reader node, it will result in the following error:  

```
cannot access temporary or unlogged relations during recovery.
```

## Creating unlogged tables

To create an unlogged table in Aurora PostgreSQL, add the `UNLOGGED` keyword in your `CREATE TABLE` statement:

```
CREATE UNLOGGED TABLE staging_sales_data (  
    transaction_id bigint,  
    customer_id bigint,  
    product_id bigint,  
    transaction_date date,  
    amount NUMERIC  
);
```

## Handling unlogged tables during migration

When preparing to migrate data to Aurora PostgreSQL, it's important to identify and handle unlogged tables appropriately. Unlogged tables are not WAL-logged and are excluded from the replication stream, meaning they will not be replicated to an Aurora read replica.

Convert unlogged tables to logged tables or drop them if they are not being used before creating an Aurora read replica.

To verify the presence of unlogged tables in each database within the instance, use the following command:

```
SELECT oid, relfilenode, relname, relpersistence, relkind
FROM pg_class
WHERE relpersistence = 'u';
```

To convert an unlogged table back to a logged table, use the following command:

```
ALTER TABLE table_name SET LOGGED;
```

This operation rewrites the entire table and places an exclusive lock on it until completion. For large tables, this may result in significant downtime.

## Converting unlogged tables to logged tables

When you need to convert an unlogged table back to a logged table, you can use the following command:

```
ALTER TABLE table_name SET LOGGED;
```

This operation rewrites the entire table and places an exclusive lock on it until the operation completes. For large tables, this can result in significant downtime.

## Unlogged tables and logical replication

Unlogged tables are generally not included in logical replication because logical replication relies on the WAL to capture and transfer changes. By default, changes to unlogged tables are not WAL-logged and excluded from the replication stream, making them unsuitable for use cases where logical replication is required. However, Aurora PostgreSQL provides a parameter called `rds.logically_replicate_unlogged_tables` that allows you to control this behavior:

- When `rds.logically_replicate_unlogged_tables` is set to 0 (off) the unlogged tables are excluded from logical replication.
- When `rds.logically_replicate_unlogged_tables` is set to 1 (on) the unlogged tables are included in logical replication.

**Note**

In Aurora PostgreSQL, the `rds.logically_replicate_unlogged_tables` parameter is set by default to 1 (on) in versions 14 and earlier, and to 0 (off) in versions 15 and later.

## Working with PostgreSQL autovacuum on Amazon Aurora PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Aurora PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your Aurora PostgreSQL DB instance.

- [Identify and resolve aggressive vacuum blockers in Aurora PostgreSQL](#)

## Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the [autovacuum\\_work\\_mem](#) parameter. In Aurora PostgreSQL versions 14 and prior, the `autovacuum_work_mem` parameter is set to `-1`, indicating that the setting of `maintenance_work_mem` is used instead. For all other versions, `autovacuum_work_mem` is determined by `GREATEST({DBInstanceClassMemory/32768}, 65536)`.

Manual vacuum operations always use the `maintenance_work_mem` setting, with a default setting of `GREATEST({DBInstanceClassMemory/63963136*1024}, 65536)`, and it can also be adjusted at the session level using the `SET` command for more targeted manual `VACUUM` operations.

The `autovacuum_work_mem` determines memory for autovacuum to hold identifiers of dead tuples (`pg_stat_all_tables.n_dead_tup`) for vacuuming indexes.

When doing calculations to determine the `autovacuum_work_mem` parameter's value, be aware of the following:

- If you set the parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance. For larger instances, setting `maintenance_work_mem` or `autovacuum_work_mem` to at least 1 GB can improve the performance of vacuuming tables with a high number of dead tuples. However, in PostgreSQL versions 16 and prior, vacuum's memory usage is capped at 1 GB, which is sufficient to process approximately 179 million dead tuples in a single pass. If a table has more dead tuples than this, vacuum will need to make multiple passes through the table's indexes, significantly increasing the time required. Starting with PostgreSQL version 17, there isn't a limit of 1 GB, and autovacuum can process more than 179 million tuples by using radix trees.

A tuple identifier is 6 bytes in size. To estimate the memory needed for vacuuming an index of a table, query `pg_stat_all_tables.n_dead_tup` to find the number of dead tuples, then multiply this number by 6 to determine the memory required for vacuuming the index in a single pass. You may use the following query:

```
SELECT
    relname AS table_name,
    n_dead_tup,
    pg_size_pretty(n_dead_tup * 6) AS estimated_memory
FROM
    pg_stat_all_tables
WHERE
    relname = 'name_of_the_table';
```

- The `autovacuum_work_mem` parameter works in conjunction with the `autovacuum_max_workers` parameter. Each worker among `autovacuum_max_workers` can use the memory that you allocate. If you have many small tables, allocate more `autovacuum_max_workers` and less `autovacuum_work_mem`. If you have large tables (larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Thus, make sure that the combination of worker processes and memory equals the total memory that you want to allocate.

## Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, Aurora PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. *Adaptive autovacuum* is a feature for Aurora PostgreSQL. A detailed explanation of [TransactionID wraparound](#) is found in the PostgreSQL documentation.

Adaptive autovacuum is turned on by default for Aurora PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Aurora Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post [Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL](#) on the Amazon Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- [autovacuum\\_vacuum\\_cost\\_delay](#)
- [autovacuum\\_vacuum\\_cost\\_limit](#)
- [autovacuum\\_work\\_mem](#)
- [autovacuum\\_naptime](#)

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL [SHOW](#) SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the Amazon Web Services Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

## Determining if the tables in your database need vacuuming

You can use the following query to show the number of unfrozen transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc
limit 20;
```

For example, the results of running the preceding query might be the following.

datname	age
mydb	1771757888
template0	1721757888
template1	1721757888
rdsadmin	1694008527
postgres	1693881061

(5 rows)

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 ([autovacuum\\_freeze\\_max\\_age](#)).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unfrozen transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using `VACUUM` manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

For information on creating a process that warns you about transaction ID wraparound, see the Amazon Database Blog post [Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL](#).

- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](#).

## Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The [autovacuum threshold](#) is defined as:

$$\text{Vacuum-threshold} = \text{vacuum-base-threshold} + \text{vacuum-scale-factor} * \text{number-of-tuples}$$

where the vacuum base threshold is `autovacuum_vacuum_threshold`, the vacuum scale factor is `autovacuum_vacuum_scale_factor`, and the number of tuples is `pg_class.reltuples`.

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM
pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM
pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name =
'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param,
split_part(setting, '=', 2) as value from (select oid opt_oid, unnest(reloptions)
setting from pg_class) opt)
SELECT '''||ns.nspname||'".'''||c.relname||'""" as relation,
pg_size_pretty(pg_table_size(c.oid)) as table_size,
age(relfrozenxid) as xid_age,
coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
autovacuum_freeze_max_age,
(coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples)
AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples FROM
pg_class c join pg_namespace ns on ns.oid = c.relnamespace
join pg_stat_all_tables stat on stat.relid = c.oid join vbt on (1=1) join vsf on (1=1)
join fma on (1=1)
left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid =
cvbt.opt_oid
left join sto cvsf on cvsf.param = 'autovacuum_vacuum_scale_factor' and c.oid =
cvsf.opt_oid
```

```

left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
WHERE c.relkind = 'r' and nspname <> 'pg_catalog'
AND (age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
OR coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) *
c.reltuples <= n_dead_tup)
ORDER BY age(relfrozenxid) DESC LIMIT 50;

```

## Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```

SELECT datname, username, pid, state, wait_event, current_timestamp - xact_start AS
   xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;

```

After running the query, you should see output similar to the following.

```

datname | username | pid | state | wait_event |          xact_runtime          | query
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
mydb    | rdsadmin | 16473 | active |             | 33 days 16:32:11.600656 |
autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)

autovacuum: VACUUM ANALYZE public.mytable3
mydb    | rdsadmin | 618 | active |             | 00:00:00 |
SELECT datname, username, pid, state, wait_event, current_timestamp - xact_start AS
xact_runtime, query+
          |          |          |          |          |          | FROM
pg_stat_activity
          +

```

```
query like '%VACUUM%'
+
xact_start;
+
| WHERE
| ORDER BY
```

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your [maintenance\\_work\\_mem](#) parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```
GREATEST({DBInstanceClassMemory/63963136*1024}, 65536)
```

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual vacuum `freeze verbose table` to see the exact cause.

## Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the [maintenance\\_work\\_mem](#) parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

## To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

```
SELECT datname, username, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY
xact_start;
```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set [maintenance\\_work\\_mem](#) for the current session to 2 GB.

```
SET maintenance_work_mem='2 GB';
SET
```

4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

```
\timing on
Timing is on.
vacuum freeze verbose pgbench_branches;
```

```
INFO: vacuuming "public.pgbench_branches"
INFO: index "pgbench_branches_pkey" now contains 50 row versions in 2 pages
DETAIL: 0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO: index "pgbench_branches_test_index" now contains 50 row versions in 2 pages
DETAIL: 0 index row versions were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
INFO: "pgbench_branches": found 0 removable, 50 nonremovable row versions
      in 43 out of 43 pages
DETAIL: 0 dead row versions cannot be removed yet.
```

```
There were 9347 unused item pointers.
0 pages are entirely empty.
CPU 0.00s/0.00u sec elapsed 0.00 sec.
VACUUM
Time: 2.765 ms
```

- In session one, if autovacuum was blocking the vacuum session, `pg_stat_activity` shows that waiting is T for your vacuum session. In this case, end the autovacuum process as follows.

```
SELECT pg_terminate_backend('the_pid');
```

### Note

Some lower versions of Amazon Aurora can't terminate an autovacuum process using the preceding command and fail with the following error: `ERROR: 42501: must be a superuser to terminate superuser process LOCATION: pg_terminate_backend, signalfuncs.c:227`. To find the PostgreSQL versions that have been patched, search for the following bullet in [Amazon Aurora PostgreSQL updates](#):

```
Allow rds_superuser to terminate backends which are not explicitly
associated with a role
```

At this point, your session begins. Autovacuum restarts immediately because this table is probably the highest on its list of work.

- Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

## Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=> vacuum freeze pgbench_branches;
ERROR: index "pgbench_branches_test_index" contains unexpected
zero page at block 30521
```

HINT: Please REINDEX it.

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a [REINDEX](#) command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

### To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

```
SELECT datname, username, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY
xact_start;
```

3. In session two, issue the reindex command.

```
\timing on
Timing is on.
reindex index pgbench_branches_test_index;
REINDEX
Time: 9.966 ms
```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

```
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.

## Managing autovacuum with large indexes

As part of its operation, *autovacuum* performs several [vacuum phases](#) while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

### To check the size of the table and its indexes

```
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)
```

```
postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
```

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

### To check for unused indexes

Using the [pg\\_stat\\_user\\_indexes](#) view, you can check how frequently an index is used with the `idx_scan` column. In the following example, the unused indexes have the `idx_scan` value of 0.

```
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order
by idx_scan desc;
```

relid	indexrelid	schemaname	relname	indexrelname	idx_scan
idx_tup_read	idx_tup_fetch				
16433	16454	public	pgbench_accounts	index_f	6
6	0				

```

16433 | 16450 | public | pgbench_accounts | index_b | 3
| 199999 | 0
16433 | 16447 | public | pgbench_accounts | pgbench_accounts_pkey | 0
| 0 | 0
16433 | 16452 | public | pgbench_accounts | index_d | 0
| 0 | 0
16433 | 16453 | public | pgbench_accounts | index_e | 0
| 0 | 0
16433 | 16451 | public | pgbench_accounts | index_c | 0
| 0 | 0
16433 | 16449 | public | pgbench_accounts | index_a | 0
| 0 | 0
(7 rows)

```

```

postgres=> select schemaname, relname, indexrelname, idx_scan from pg_stat_user_indexes
where relname = 'pgbench_accounts' order by idx_scan desc;

```

```

schemaname | relname          | indexrelname          | idx_scan
-----+-----+-----+-----
public     | pgbench_accounts | index_f               | 6
public     | pgbench_accounts | index_b               | 3
public     | pgbench_accounts | pgbench_accounts_pkey | 0
public     | pgbench_accounts | index_d               | 0
public     | pgbench_accounts | index_e               | 0
public     | pgbench_accounts | index_c               | 0
public     | pgbench_accounts | index_a               | 0
(7 rows)

```

### Note

These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see [Statistics Functions](#). Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use [pg\\_stat\\_database](#)

```
postgres=> select datname, stats_reset from pg_stat_database where datname =
'postgres';
```

```
datname | stats_reset
-----+-----
postgres | 2022-11-17 08:58:11.427224+00
(1 row)
```

## Vacuuming a table as quickly as possible

### RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use `VACUUM` with the [INDEX\\_CLEANUP](#) clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) pgbench_accounts;

INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out
of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet, oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.
```

If an autovacuum session is already running, you must terminate it to begin the manual `VACUUM`. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](#)

#### Note

Skipping index cleanup regularly causes index bloat, which degrades scan performance. The index retains dead rows, and the table retains dead line pointers. As a result, `pg_stat_all_tables.n_dead_tup` increases until autovacuum or a manual `VACUUM` with index cleanup runs. As a best practice, use this procedure only to prevent transaction ID wraparound.

## RDS for PostgreSQL 11 and older

However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

## Other parameters that affect autovacuum

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The [autovacuum parameters](#) are described fully in the PostgreSQL documentation.

```
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
  'autovacuum_max_workers',
  'autovacuum_analyze_scale_factor',
  'autovacuum_naptime',
  'autovacuum_analyze_threshold',
  'autovacuum_analyze_scale_factor',
  'autovacuum_vacuum_threshold',
  'autovacuum_vacuum_scale_factor',
  'autovacuum_vacuum_threshold',
  'autovacuum_vacuum_cost_delay',
  'autovacuum_vacuum_cost_limit',
  'vacuum_cost_limit',
  'autovacuum_freeze_max_age',
  'maintenance_work_mem',
  'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- [maintenance\\_work\\_mem](#)
- [autovacuum\\_freeze\\_max\\_age](#)
- [autovacuum\\_max\\_workers](#)
- [autovacuum\\_vacuum\\_cost\\_delay](#)
- [autovacuum\\_vacuum\\_cost\\_limit](#)

## Setting table-level autovacuum parameters

You can set autovacuum-related [storage parameters](#) at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about [cost-based vacuuming](#).

## Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- `disabled` (PostgreSQL 10, PostgreSQL 9.6)
- `debug5`, `debug4`, `debug3`, `debug2`, `debug1`
- `info` (PostgreSQL 12, PostgreSQL 11)
- `notice`
- `warning` (PostgreSQL 13 and above)
- `error`, `log`, `fatal`, `panic`

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of `-1` logs nothing, while a setting of `0` logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- `10000` ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to `WARNING`. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than `-1` also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see [Automatic Vacuuming](#) in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from `debug1` up to `debug5` for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see [When to log](#) in the PostgreSQL documentation.

### Note

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

## Understanding the behavior of autovacuum with invalid databases

A new value `-2` is introduced into the `datconnlimit` column in the `pg_database` catalog to indicate databases that have been interrupted in the middle of the `DROP DATABASE` operation as invalid.

This new value is available from the following Aurora PostgreSQL versions:

- 15.4 and all higher versions
- 14.9 and higher versions
- 13.12 and higher versions
- 12.16 and higher versions
- 11.21 and higher versions

Invalid databases do not affect autovacuum's ability to freeze functionality for valid databases. Autovacuum ignores invalid databases. Consequently, regular vacuum operations will continue to function properly and efficiently for all valid databases in your PostgreSQL environment.

## Topics

- [Monitoring transaction ID](#)
- [Adjusting the monitoring query](#)
- [Resolving invalid database issue](#)

## Monitoring transaction ID

The `age(datfrozenxid)` function is commonly used to monitor the transaction ID (XID) age of databases to prevent transaction ID wraparound.

Since invalid databases are excluded from autovacuum, their transaction ID (XID) counter can reach the maximum value of 2 billion, wrap around to - 2 billion, and continue this cycle indefinitely. A typical query to monitor Transaction ID wraparound might look like:

```
SELECT max(age(datfrozenxid)) FROM pg_database;
```

However, with the introduction of the -2 value for `datconnlimit`, invalid databases can skew the results of this query. Since these databases are not valid and should not be part of regular maintenance checks, they can cause false positives, leading you to believe that the `age(datfrozenxid)` is higher than it actually is.

## Adjusting the monitoring query

To ensure accurate monitoring, you should adjust your monitoring query to exclude invalid databases. Follow this recommended query:

```
SELECT
    max(age(datfrozenxid))
FROM
    pg_database
WHERE
    datconlimit <> -2;
```

This query ensures that only valid databases are considered in the `age(datfrozenxid)` calculation, providing a true reflection of the transaction ID age across your PostgreSQL environment.

## Resolving invalid database issue

When attempting to connect to an invalid database, you may encounter an error message similar to the following:

```
postgres=> \c db1
connection to server at "mydb.xxxxxxxxxx.us-west-2.rds.amazonaws.com" (xx.xx.xx.xxx),
port xxxx failed: FATAL:  cannot connect to invalid database "db1"
HINT:  Use DROP DATABASE to drop invalid databases.
Previous connection kept
```

Additionally, if the `log_min_messages` parameter is set to `DEBUG2` or higher, you may notice the following log entries indicating that the autovacuum process is skipping the invalid database:

```
2024-07-30 05:59:00 UTC::@[32000]:DEBUG:  autovacuum: skipping invalid database "db6"
2024-07-30 05:59:00 UTC::@[32000]:DEBUG:  autovacuum: skipping invalid database "db1"
```

To resolve the issue, follow the HINT provided during the connection attempt. Connect to any valid database using your RDS master account or a database account with the `rds_superuser` role, and drop invalid database(s).

```
SELECT
    'DROP DATABASE ' || quote_ident(datname) || ';'
FROM
    pg_database
WHERE
    datconlimit = -2 \gexec
```

## Identify and resolve aggressive vacuum blockers in Aurora PostgreSQL

In PostgreSQL, vacuuming is vital for ensuring database health as it reclaims storage and prevents [transaction ID wraparound](#) issues. However, there are times when vacuuming can be prevented from operating as desired, which can result in performance degradation, storage bloat, and even impact availability of your DB instance by transaction ID wraparound. Therefore, identifying and resolving these issues are essential for optimal database performance and availability. Read [Understanding autovacuum in Amazon RDS for PostgreSQL environments](#) to learn more about autovacuum.

The `postgres_get_av_diag()` function helps identify issues that either prevent or delay the aggressive vacuum progress. Suggestions are provided, which may include commands to resolve the issue where it is identifiable or guidance for further diagnostics where the issue is not identifiable. Aggressive vacuum blockers are reported when the age exceeds RDS' [adaptive autovacuum](#) threshold of 500 million transaction IDs.

### What is the age of the transaction ID?

The `age()` function for transaction IDs calculates the number of transactions that have occurred since the oldest unfrozen transaction ID for a database (`pg_database.datfrozenxid`) or table (`pg_class.relfrozenxid`). This value indicates database activity since the last aggressive vacuum operation and highlights the likely workload for upcoming VACUUM processes.

### What is an aggressive vacuum?

An aggressive VACUUM operation conducts a comprehensive scan of all pages within a table, including those typically skipped during regular VACUUMs. This thorough scan aims to "freeze" transaction IDs approaching their maximum age, effectively preventing a situation known as [transaction ID wraparound](#).

For `postgres_get_av_diag()` to report blockers, the blocker must be at least 500 million transactions old.

## Topics

## Installing autovacuum monitoring and diagnostic tools in Aurora PostgreSQL

The `postgres_get_av_diag()` function is currently available in the following Aurora PostgreSQL versions:

- 17.4 and higher 17 versions
- 16.7 and higher 16 versions
- 15.11 and higher 15 versions
- 14.16 and higher 14 versions
- 13.19 and higher 13 versions

In order to use `postgres_get_av_diag()`, create the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools ;
CREATE EXTENSION
```

Verify that the extension is installed.

```
postgres=> \dx rds_tools
           List of installed extensions
  Name      | Version | Schema  | Description
-----+-----+-----+-----
+-----+-----+-----+-----
rds_tools | 1.9    | rds_tools | miscellaneous administrative functions for RDS
PostgreSQL
1 row
```

Verify that the function is created.

```

postgres=> SELECT
    proname function_name,
    pronamespace::regnamespace function_schema,
    proowner::regrole function_owner
FROM
    pg_proc
WHERE
    proname = 'postgres_get_av_diag';
function_name      | function_schema | function_owner
-----+-----+-----
postgres_get_av_diag | rds_tools      | rds_superuser
(1 row)

```

## Functions of `postgres_get_av_diag()` in Aurora PostgreSQL

The `postgres_get_av_diag()` function retrieves diagnostic information about autovacuum processes that are blocking or lagging behind in a Aurora PostgreSQL database. The query needs to be executed in the database with the oldest transaction ID for accurate results. For more information about using the database with the oldest transaction ID, see [Not connected to the database with the age of oldest transaction ID](#)

```

SELECT
    blocker,
    DATABASE,
    blocker_identifier,
    wait_event,
    TO_CHAR(autovacuum_lagging_by, 'FM9,999,999,999') AS autovacuum_lagging_by,
    suggestion,
    suggested_action
FROM (
    SELECT
        *
    FROM
        rds_tools.postgres_get_av_diag ()
    ORDER BY
        autovacuum_lagging_by DESC) q;

```

The `postgres_get_av_diag()` function returns a table with the following information:

### **blocker**

Specifies the category of database activity that is blocking the vacuum.

- [Active statement](#)
- [Idle in transaction](#)
- [Prepared transaction](#)
- [Logical replication slot](#)
- [Reader instances](#)
- [Temporary tables](#)

**database**

Specifies the name of the database where applicable and supported. This is the database in which the activity is ongoing and blocking or will block the autovacuum. This is the database you are required to connect to and take action.

**blocker\_identifier**

Specifies the identifier of the activity that is blocking or will block the autovacuum. The identifier can be a process ID along with a SQL statement, a prepared transaction, an IP address of a read replica, and the name of the replication slot, either logical or physical.

**wait\_event**

Specifies the [wait event](#) of the blocking session and is applicable for the following blockers:

- Active statement
- Idle in transaction

**autovacuum\_lagging\_by**

Specifies the number of transactions that autovacuum is lagging behind in its backlog work per category.

**suggestion**

Specifies suggestions to resolve the blocker. These instructions include the name of the database in which the activity exists where applicable, the Process ID (PID) of the session where applicable, and the action to be taken.

**suggested\_action**

Suggests the action that needs to be taken to resolve the blocker.

## Resolving identifiable vacuum blockers in Aurora PostgreSQL

Autovacuum performs aggressive vacuums and lowers the age of transaction IDs to below the threshold specified by the `autovacuum_freeze_max_age` parameter of your RDS instance. You can track this age using the Amazon CloudWatch metric `MaximumUsedTransactionIDs`.

To find the setting of `autovacuum_freeze_max_age` (which has a default of 200 million transaction IDs) for your Amazon RDS instance, you can use the following query:

```
SELECT
    TO_CHAR(setting::bigint, 'FM9,999,999,999') autovacuum_freeze_max_age
FROM
    pg_settings
WHERE
    name = 'autovacuum_freeze_max_age';
```

Note that `postgres_get_av_diag()` only checks for aggressive vacuum blockers when the age exceeds Amazon RDS' [adaptive autovacuum](#) threshold of 500 million transaction IDs. For `postgres_get_av_diag()` to detect blockers, the blocker must be at least 500 million transactions old.

The `postgres_get_av_diag()` function identifies the following types of blockers:

### Topics

- [Active statement](#)
- [Idle in transaction](#)
- [Prepared transaction](#)
- [Logical replication slot](#)
- [Reader instances](#)
- [Temporary tables](#)

### Active statement

In PostgreSQL, an active statement is an SQL statement that is currently being executed by the database. This includes queries, transactions, or any operations in progress. When monitoring via `pg_stat_activity`, the `state` column indicates that the process with the corresponding PID is active.

The `postgres_get_av_diag()` function displays output similar to the following when it identifies a statement that is an active statement.

```
blocker           | Active statement
database         | my_database
blocker_identifier | SELECT pg_sleep(20000);
wait_event       | Timeout:PgSleep
autovacuum_lagging_by | 568,600,871
suggestion       | Connect to database "my_database", review carefully and you
                 | may consider terminating the process using suggested_action. For more information, see
                 | Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action  | {"SELECT pg_terminate_backend (29621);"}
```

### Suggested action

Following the guidance in the `suggestion` column, the user can connect to the database where the active statement is present and, as specified in the `suggested_action` column, it's advisable to carefully review the option to terminate the session. If termination is safe, you may use the `pg_terminate_backend()` function to terminate the session. This action can be performed by an administrator (such as the RDS master account) or a user with the required `pg_terminate_backend()` privilege.

#### Warning

A terminated session will undo (ROLLBACK) changes it made. Depending on your requirements, you may want to rerun the statement. However, it is recommended to do so only after the autovacuum process has finished its aggressive vacuum operation.

### Idle in transaction

An idle in transaction statement refers to any session that has opened an explicit transaction (such as by issuing a `BEGIN` statement), performed some work, and is now waiting for the client to either pass more work or signal the end of the transaction by issuing a `COMMIT`, `ROLLBACK`, or `END` (which would result in an implicit `COMMIT`).

The `postgres_get_av_diag()` function displays output similar to the following when it identifies an `idle in transaction` statement as a blocker.

```
blocker           | idle in transaction
```

```
database          | my_database
blocker_identifier | INSERT INTO tt SELECT * FROM tt;
wait_event        | Client:ClientRead
autovacuum_lagging_by | 1,237,201,759
suggestion        | Connect to database "my_database", review carefully and you
                  | may consider terminating the process using suggested_action. For more information, see
                  | Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action   | {"SELECT pg_terminate_backend (28438);"}
```

## Suggested action

As indicated in the `suggestion` column, you can connect to the database where the idle in transaction session is present and terminate the session using the `pg_terminate_backend()` function. The user can be your admin (RDS master account) user or a user with the `pg_terminate_backend()` privilege.

### Warning

A terminated session will undo (ROLLBACK) changes it made. Depending on your requirements, you may want to rerun the statement. However, it is recommended to do so only after the autovacuum process has finished its aggressive vacuum operation.

## Prepared transaction

PostgreSQL allows transactions that are part of a two-phase commit strategy called [prepared transactions](#). These are enabled by setting the `max_prepared_transactions` parameter to a non-zero value. Prepared transactions are designed to ensure that a transaction is durable and remains available even after database crashes, restarts, or client disconnections. Like regular transactions, they are assigned a transaction ID and can affect the autovacuum. If left in a prepared state, autovacuum cannot perform freezing and it can lead to transaction ID wraparound.

When transactions are left prepared indefinitely without being resolved by a transaction manager, they become orphaned prepared transactions. The only way to fix this is to either commit or rollback the transaction using the `COMMIT PREPARED` or `ROLLBACK PREPARED` commands, respectively.

**Note**

Be aware that a backup taken during a prepared transaction will still contain that transaction after restoration. Refer to the following information about how to locate and close such transactions.

The `postgres_get_av_diag()` function displays the following output when it identifies a blocker that is a prepared transaction.

```
blocker          | Prepared transaction
database        | my_database
blocker_identifier | myptx
wait_event      | Not applicable
autovacuum_lagging_by | 1,805,802,632
suggestion      | Connect to database "my_database" and consider either COMMIT
or ROLLBACK the prepared transaction using suggested_action. For more information, see
Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action | {"COMMIT PREPARED 'myptx';",[OR],"ROLLBACK PREPARED 'myptx';"}
```

**Suggested action**

As mentioned in the suggestion column, connect to the database where the prepared transaction is located. Based on the `suggested_action` column, carefully review whether to perform either COMMIT or ROLLBACK, and then the appropriate the action.

To monitor prepared transactions in general, PostgreSQL offers a catalog view called `pg_prepared_xacts`. You can use the following query to find prepared transactions.

```
SELECT
  gid,
  prepared,
  owner,
  database,
  transaction AS oldest_xmin
FROM
  pg_prepared_xacts
ORDER BY
  age(transaction) DESC;
```

## Logical replication slot

The purpose of a replication slot is to hold unconsumed changes until they are replicated to a target server. For more information, see PostgreSQL's [Logical replication](#).

There are two types of logical replication slots.

### Inactive logical replication slots

When replication is terminated, unconsumed transaction logs can't be removed, and the replication slot becomes inactive. Although an inactive logical replication slot isn't currently used by a subscriber, it remains on the server, leading to the retention of WAL files and preventing the removal of old transaction logs. This can increase disk usage and specifically block autovacuum from cleaning up internal catalog tables, as the system must preserve LSN information from being overwritten. If not addressed, this can result in catalog bloat, performance degradation, and an increased risk of wraparound vacuum, potentially causing transaction downtime.

### Active but slow logical replication slots

Sometimes removal of dead tuples of catalog is delayed due to the performance degradation of logical replication. This delay in replication slows down updating the `catalog_xmin` and can lead to catalog bloat and wraparound vacuum.

The `postgres_get_av_diag()` function displays output similar to the following when it finds a logical replication slot as a blocker.

```
blocker          | Logical replication slot
database        | my_database
blocker_identifier | slot1
wait_event      | Not applicable
autovacuum_lagging_by | 1,940,103,068
suggestion      | Ensure replication is active and resolve any lag for the slot
                 | if active. If inactive, consider dropping it using the command in suggested_action.
                 | For more information, see Working with PostgreSQL autovacuum in the Amazon RDS User
                 | Guide.
suggested_action | {"SELECT pg_drop_replication_slot('slot1') FROM
pg_replication_slots WHERE active = 'f';"}
```

### Suggested action

To resolve this problem, check the replication configuration for issues with the target schema or data that might be terminating the apply process. The most common reasons are the following:

- Missing columns
- Incompatible data type
- Data mismatch
- Missing table

If the problem is related to infrastructure issues:

- Network issues - [How do I resolve issues with an Amazon RDS DB in an incompatible network state?](#)
- Database or DB instance is not available due to the following reasons:
  - Replica instance is out of storage - Review [Amazon RDS DB instances run out of storage](#) for information about adding storage.
  - Incompatible-parameters - Review [How can I fix an Amazon RDS DB instance that is stuck in the incompatible-parameters status?](#) for more information about how you can resolve the issue.

If your instance is outside the Amazon network or on Amazon EC2, consult your administrator on how to resolve the availability or infrastructure-related issues.

## Dropping the inactive slot

### Warning

Caution: Before dropping a replication slot, carefully ensure that it has no ongoing replication, is inactive, and is in an unrecoverable state. Dropping a slot prematurely could disrupt replication or cause data loss.

After confirming that the replication slot is no longer needed, drop it to allow autovacuum to continue. The condition `active = 'f'` ensures that only an inactive slot is dropped.

```
SELECT pg_drop_replication_slot('slot1') WHERE active = 'f'
```

## Reader instances

When the `hot_standby_feedback` setting is enabled, it prevents autovacuum on the writer instance from removing dead rows that might still be needed by queries running on the reader instance.

This behavior is necessary because queries running on the reader instance (also applicable to reader instances in Aurora Global Database) require those rows to remain available on the writer instance preventing query conflicts and cancellations.

 **Note**

`hot_standby_feedback` is enabled by default and unmodifiable in Aurora PostgreSQL.

The `postgres_get_av_diag()` function displays output similar to the following when it finds a read replica with physical replication slot as the blocker.

```
blocker           | Oldest query running on aurora reader
database         | Not applicable
blocker_identifier | my-aurora-reader-2
wait_event       | Not applicable
autovacuum_lagging_by | 540,122,859
suggestion       | Run the following query on the reader "my-aurora-reader-2" to
                  | find the long running query:
                  |
                  |         | SELECT * FROM pg_catalog.pg_stat_activity WHERE
backend_xmin::text::bigint = 523476310;
                  |
                  | Review carefully and you may consider terminating the query on
reader using suggested_action.
suggested_action  | {"SELECT pg_terminate_backend(pid) FROM
pg_catalog.pg_stat_activity WHERE backend_xmin::text::bigint = 523476310;","
                  |
                  | [OR]
                  |
                  | ", "Delete the reader if not needed"}
```

As recommended in the `suggested_action` column, carefully review these options to unblock autovacuum.

- **Terminate the query** – Following the guidance in the `suggestion` column, you can connect to the read replica, as specified in the `suggested_action` column, it's advisable to carefully review the option to terminate the session. If termination is deemed safe, you may use the `pg_terminate_backend()` function to terminate the session. This action can be

performed by an administrator (such as the RDS master account) or a user with the required `pg_terminate_backend()` privilege.

You may run the following SQL command on the read replica to terminate the query that is preventing the vacuum on the primary from cleaning up old rows. The value of `backend_xmin` is reported in the function's output:

```
SELECT
  pg_terminate_backend(pid)
FROM
  pg_catalog.pg_stat_activity
WHERE
  backend_xmin::text::bigint = backend_xmin;
```

- **Delete the reader instances if not needed** – If the reader instance is no longer necessary, you can delete it. This will remove the associated replication overhead and allow the primary to recycle transaction logs without being held back by the instance.

## Temporary tables

[Temporary tables](#), created using the `TEMPORARY` keyword, reside in the `temp` schema, for example `pg_temp_xxx`, and are only accessible to the session that created them. Temporary tables are dropped when the session ends. However, these tables are invisible to PostgreSQL's autovacuum process, and must be manually vacuumed by the session that created them. Trying to vacuum the temp table from another session has no effect.

In unusual circumstances, a temporary table exists without an active session owning it. If the owning session ends unexpectedly due to a fatal crash, network issue, or similar event, the temporary table might not be cleaned up, leaving it behind as an "orphaned" table. When the PostgreSQL autovacuum process detects an orphaned temporary table, it logs the following message:

```
LOG: autovacuum: found orphan temp table \"%s\".\"%s\" in database \"%s\"
```

The `postgres_get_av_diag()` function displays output similar to the following when it identifies a temporary table as a blocker. For the function to correctly show the output related to temporary tables, it needs to be executed within the same database where those tables exist.

```
blocker          | Temporary table
```

```

database          | my_database
blocker_identifier | pg_temp_14.ttemp
wait_event        | Not applicable
autovacuum_lagging_by | 1,805,802,632
suggestion        | Connect to database "my_database". Review carefully, you
                  | may consider dropping temporary table using command in suggested_action. For more
                  | information, see Working with PostgreSQL autovacuum in the Amazon RDS User Guide.
suggested_action  | {"DROP TABLE ttemp;"}

```

## Suggested action

Follow the instructions provided in the `suggestion` column of the output to identify and remove the temporary table that is preventing autovacuum from running. Use the following command to drop the temporary table reported by `postgres_get_av_diag()`. Replace the table name based on the output provided by the `postgres_get_av_diag()` function.

```
DROP TABLE my_temp_schema.my_temp_table;
```

The following query can be used to identify temporary tables:

```

SELECT
    oid,
    relname,
    relnamespace::regnamespace,
    age(relfrozenxid)
FROM
    pg_class
WHERE
    relpersistence = 't'
ORDER BY
    age(relfrozenxid) DESC;

```

## Resolving unidentifiable vacuum blockers in Aurora PostgreSQL

This section explores additional reasons that can prevent vacuuming from making progress. These issues are currently not directly identifiable by the `postgres_get_av_diag()` function.

### Topics

- [Index inconsistency](#)
- [Exceptionally high transaction rate](#)

## Index inconsistency

A logically inconsistent index can prevent autovacuum from making progress. The following errors or similar errors are logged during either the vacuum phase of the index or when the index is accessed by SQL statements.

```
ERROR: right sibling's left-link doesn't match:block 5 links to 10 instead of expected
2 in index ix_name
```

```
ERROR: failed to re-find parent key in index "XXXXXXXXXX" for deletion target page XXX
CONTEXT:  while vacuuming index index_name of relation schema.table
```

## Guidance

Rebuild the index or skip indexes using `INDEX_CLEANUP` on manual `VACUUM FREEZE`.

- **Using the `CONCURRENTLY` option** – Prior to PostgreSQL version 12, rebuilding an index required an exclusive table lock, restricting access to the table. With PostgreSQL version 12, and later versions, the `CONCURRENTLY` option allows for row-level locking, significantly improving the table's availability. Following is the command:

```
REINDEX INDEX ix_name CONCURRENTLY;
```

While `CONCURRENTLY` is less disruptive, it can be slower on busy tables. Consider building the index during low-traffic periods if possible. For more information, see [REINDEX](#) in *PostgreSQL* documentation.

- **Using the `INDEX_CLEANUP FALSE` option** – If the indexes are large and estimated to require a significant amount of time to finish, you can unblock autovacuum by executing a manual `VACUUM FREEZE` while excluding indexes. This functionality is available in PostgreSQL version 12 and later versions.

Bypassing indexes will allow you to skip the vacuum process of the inconsistent index and mitigate the wraparound issue. However, this will not resolve the underlying invalid page problem. To fully address and resolve the invalid page issue, you will still need to rebuild the index.

## Exceptionally high transaction rate

In PostgreSQL, high transaction rates can significantly impact autovacuum's performance, leading to slower cleanup of dead tuples and increased risk of transaction ID wraparound. You can monitor the transaction rate by measuring the difference in `max(age(datfrozenxid))` between two time periods, typically per second. Additionally, you can use the following counter metrics from RDS Performance Insights to measure the transaction rate (the sum of `xact_commit` and `xact_rollback`) which is the total number of transactions.

Counter	Type	Unit	Metric
<code>xact_commit</code>	Transactions	Commits per second	<code>db.Transactions.xact_commit</code>
<code>xact_rollback</code>	Transactions	Rollbacks per second	<code>db.Transactions.xact_rollback</code>

A rapid increase indicates a high transaction load, which can overwhelm autovacuum, causing bloat, lock contention, and potential performance issues. This can negatively impact the autovacuum process in a couple of ways:

- **Table Activity:** The specific table being vacuumed could be experiencing a high volume of transactions, causing delays.
- **System Resources** The overall system might be overloaded, making it difficult for autovacuum to access the necessary resources to function efficiently.

Consider the following strategies for allowing autovacuum to operate more effectively and keep up with its tasks:

1. Reduce the transaction rate if possible. Consider to batch or group similar transactions where feasible.
2. Target frequently updated tables with manual `VACUUM FREEZE` operation nightly, weekly, or biweekly during off-peak hours.
3. Consider scaling up your instance class to allocate more system resources to handle the high transaction volume and autovacuum.

## Resolving vacuum performance issues in Aurora PostgreSQL

This section discusses factors that often contribute to slower vacuum performance and how to address these issues.

### Topics

- [Vacuum large indexes](#)
- [Too many tables or databases to vacuum](#)
- [Aggressive vacuum \(to prevent wraparound\) is running](#)

### Vacuum large indexes

VACUUM operates through sequential phases: initialization, heap scanning, index and heap vacuuming, index cleanup, heap truncation, and final cleanup. During the heap scan, the process prunes pages, defragments and freezes them. After completing the heap scan, VACUUM cleans indexes, returns empty pages to the operating system, and performs final cleanup tasks like vacuuming the free space map and updating statistics.

Index vacuuming may require multiple passes when `maintenance_work_mem` (or `autovacuum_work_mem`) is insufficient to process the index. In PostgreSQL 16 and earlier, a 1 GB memory limit for storing dead tuple IDs often forced multiple passes on large indexes. PostgreSQL 17 introduces `TidStore`, which dynamically allocates memory instead of using a single-allocation array. This removes the 1 GB constraint, uses memory more efficiently, and reduces the need for multiple index scans per each index.

Large indexes may still require multiple passes in PostgreSQL 17 if available memory can't accommodate the entire index processing at once. Typically, larger indexes contain more dead tuples that require multiple passes.

### Detecting slow vacuum operations

The `postgres_get_av_diag()` function can detect when vacuum operations are running slowly due to insufficient memory. For more information on this function, see [Installing autovacuum monitoring and diagnostic tools in Aurora PostgreSQL](#).

The `postgres_get_av_diag()` function issues the following notices when the available memory is not enough to complete the index vacuuming in a single pass.

### **rds\_tools 1.9**

NOTICE: Your database is currently running aggressive vacuum to prevent wraparound and it might be slow.

NOTICE: The current setting of `autovacuum_work_mem` is XX might not be sufficient. Consider increasing the setting to XXX, and if necessary, scaling up the RDS instance class for more memory. The suggested value is an estimate based on the current number of dead tuples for the table being vacuumed, which might not fully reflect the latest state. Additionally, review the possibility of manual vacuum with exclusion of indexes using `(VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) table_name;)`. For more information, see

[Working with PostgreSQL autovacuum in the Amazon Aurora User Guide.](#)

### Note

The `postgres_get_av_diag()` function relies on `pg_stat_all_tables.n_dead_tup` for estimating the amount of memory required for index vacuuming.

When the `postgres_get_av_diag()` function identifies a slow vacuum operation that requires multiple index scans due to insufficient `autovacuum_work_mem`, it will generate the following message:

NOTICE: Your vacuum is performing multiple index scans due to insufficient `autovacuum_work_mem:XXX` for index vacuuming.

For more information, see [Working with PostgreSQL autovacuum in the Amazon Amazon RDS User Guide.](#)

## Guidance

You can apply the following workarounds using manual `VACUUM FREEZE` to speed up freezing the table.

### Increase the memory for vacuuming

As suggested by the `postgres_get_av_diag()` function, it's advisable to increase the `autovacuum_work_mem` parameter to address potential memory constraints at the instance level. While `autovacuum_work_mem` is a dynamic parameter, it's important to note that for the new

memory setting to take effect, the autovacuum daemon needs to restart its workers. To accomplish this:

1. Confirm that the new setting is in place.
2. Terminate the processes currently running autovacuum.

This approach ensures that the adjusted memory allocation is applied to new autovacuum operations.

For more immediate results, consider manually performing a VACUUM FREEZE operation with an increased `maintenance_work_mem` setting within your session:

```
SET maintenance_work_mem TO '1GB';  
VACUUM FREEZE VERBOSE table_name;
```

If you're using Amazon RDS and find that you need additional memory to support higher values for `maintenance_work_mem` or `autovacuum_work_mem`, consider upgrading to an instance class with more memory. This can provide the necessary resources to enhance both manual and automatic vacuum operations, leading to improved overall vacuum and database performance.

## Disable INDEX\_CLEANUP

Manual VACUUM in PostgreSQL version 12 and later allows skipping the index cleanup phase, while emergency autovacuum in PostgreSQL version 14 and later does this automatically based on the [vacuum\\_failsafe\\_age](#) parameter.

### Warning

Skipping index cleanup can lead to index bloat and negatively impact query performance. To mitigate this, consider reindexing or vacuuming affected indexes during a maintenance window.

For additional guidance on handling large indexes, refer to the documentation on [Managing autovacuum with large indexes](#).

## Parallel index vacuuming

Starting with PostgreSQL 13, indexes can be vacuumed and cleaned in parallel by default using manual VACUUM, with one vacuum worker process assigned to each index. However, for PostgreSQL to determine if a vacuum operation qualifies for parallel execution, specific criteria must be met:

- There must be at least two indexes.
- The `max_parallel_maintenance_workers` parameter should be set to at least 2.
- The index size must exceed the `min_parallel_index_scan_size` limit, which defaults to 512KB.

You can adjust the `max_parallel_maintenance_workers` setting based on the number of vCPUs available on your Amazon RDS instance and the number of indexes on the table to optimize vacuuming turnaround time.

For more information, see [Parallel vacuuming in Amazon RDS for PostgreSQL and Amazon Aurora PostgreSQL](#).

### Too many tables or databases to vacuum

As mentioned in PostgreSQL's [The Autovacuum Daemon](#) documentation, the autovacuum daemon operates through multiple processes. This includes a persistent autovacuum launcher responsible for starting autovacuum worker processes for each database within the system. The launcher schedules these workers to initiate approximately every `autovacuum_naptime` seconds per database.

With 'N' databases, a new worker begins roughly every `[autovacuum_naptime/N seconds]`. However, the total number of concurrent workers is limited by the `autovacuum_max_workers` setting. If the number of databases or tables requiring vacuuming exceeds this limit, the next database or table will be processed as soon as a worker becomes available.

When many large tables or databases require vacuuming concurrently, all available autovacuum workers can become occupied for an extended duration, delaying maintenance on other tables and databases. In environments with high transaction rates, this bottleneck can quickly escalate and potentially lead to wraparound vacuum issues within your Amazon RDS instance.

When `postgres_get_av_diag()` detects a high number of tables or databases, it provides the following recommendation:

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound and it might be slow.
```

```
NOTICE: The current setting of autovacuum_max_workers:3 might not be sufficient.
Consider increasing the setting and, if necessary, consider scaling up the Amazon RDS
instance class for more workers.
```

## Guidance

### Increase autovacuum\_max\_workers

To expedite the vacuuming, we recommend adjusting the `autovacuum_max_workers` parameter to allow more concurrent autovacuum workers. If performance bottlenecks persist, consider scaling up your Amazon RDS instance to a class with more vCPUs, which can further improve the parallel processing capabilities.

### Aggressive vacuum (to prevent wraparound) is running

The age of the database (`MaximumUsedTransactionIDs`) in PostgreSQL only decreases when an aggressive vacuum (to prevent wraparound) is successfully completed. Until this vacuum finishes, the age will continue to increase depending on the transaction rate.

The `postgres_get_av_diag()` function generates the following NOTICE when it detects an aggressive vacuum. However, it only triggers this output after the vacuum has been active for at least two minutes.

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound,
monitor autovacuum performance.
```

For more information about aggressive vacuum, see [When an aggressive vacuum is already running](#).

You can verify if an aggressive vacuum is in progress with the following query:

```
SELECT
  a.xact_start AS start_time,
  v.datname "database",
  a.query,
  a.wait_event,
  v.pid,
  v.phase,
  v.relid::regclass,
  pg_size_pretty(pg_relation_size(v.relid)) AS heap_size,
```

```

(
  SELECT
    string_agg(pg_size_pretty(pg_relation_size(i.indexrelid)) || ':' ||
i.indexrelid::regclass || chr(10), ', ')
  FROM
    pg_index i
  WHERE
    i.indrelid = v.relid
) AS index_sizes,
trunc(v.heap_blks_scanned * 100 / NULLIF(v.heap_blks_total, 0)) AS step1_scan_pct,
v.index_vacuum_count || '/' || (
  SELECT
    count(*)
  FROM
    pg_index i
  WHERE
    i.indrelid = v.relid
) AS step2_vacuum_indexes,
trunc(v.heap_blks_vacuumed * 100 / NULLIF(v.heap_blks_total, 0)) AS
step3_vacuum_pct,
age(CURRENT_TIMESTAMP, a.xact_start) AS total_time_spent_sofar
FROM
  pg_stat_activity a
  INNER JOIN pg_stat_progress_vacuum v ON v.pid = a.pid;

```

You can determine if it's an aggressive vacuum (to prevent wraparound) by checking the query column in the output. The phrase "to prevent wraparound" indicates that it is an aggressive vacuum.

```
query | autovacuum: VACUUM public.t3 (to prevent wraparound)
```

For example, suppose you have a blocker at transaction age 1 billion and a table requiring an aggressive vacuum to prevent wraparound at the same transaction age. Additionally, there's another blocker at transaction age 750 million. After clearing the blocker at transaction age 1 billion, the transaction age won't immediately drop to 750 million. It will remain high until the table needing the aggressive vacuum or any transaction with an age over 750 million is completed. During this period, the transaction age of your PostgreSQL cluster will continue to rise. Once the vacuum process is completed, the transaction age will drop to 750 million but will start increasing again until further vacuuming is finished. This cycle will continue as long as these conditions persist, until the transaction age eventually drops to the level configured for your Amazon RDS instance, specified by `autovacuum_freeze_max_age`.

## Explanation of the NOTICE messages in Aurora PostgreSQL

The `postgres_get_av_diag()` function provides the following NOTICE messages:

### When the age has not reached the monitoring threshold yet

The monitoring threshold for `postgres_get_av_diag()` to identify blockers is 500 million transactions by default. If `postgres_get_av_diag()` generates the following NOTICE, it indicates that the transaction age has not yet reached this threshold.

```
NOTICE: postgres_get_av_diag() checks for blockers that prevent aggressive vacuums only, it does so only after exceeding dvb_threshold which is 500,000,000 and age of this PostgreSQL cluster is currently at 2.
```

### Not connected to the database with the age of oldest transaction ID

The `postgres_get_av_diag()` function provides the most accurate output when connected to the database with the oldest transaction ID age. The database with the oldest transaction ID age reported by `postgres_get_av_diag()` will be different than “my\_database” in your case. If you are not connected to the correct database, the following NOTICE is generated:

```
NOTICE: You are not connected to the database with the age of oldest transaction ID. Connect to my_database database and run postgres_get_av_diag() for accurate reporting.
```

Connecting to the database with the oldest transaction age is important for the following reasons:

- **Identifying temporary table blockers:** Because the metadata for temporary tables is specific to each database, they are typically found in the database where they are created. However, if a temporary table happens to be the top blocker and resides in the database with the oldest transaction, this could be misleading. Connecting to the correct database ensures the accurate identification of the temporary table blocker.
- **Diagnosing slow vacuums:** The index metadata and table count information are database-specific and necessary for diagnosing slow vacuum issues.

### Database with oldest transaction by age is on an `rdsadmin` or `template0` database

In certain cases, the `rdsadmin` or `template0` databases may be identified as the database with the oldest transaction ID age. If this happens, `postgres_get_av_diag()` will issue the following NOTICE:

```
NOTICE: The database with the age of oldest transaction ID is rdsadmin or template0,
reach out to support if the reported blocker is in rdsadmin or template0.
```

Verify that the listed blocker is not originating from either of these two databases. If the blocker is reported to be present in either `rdsadmin` or `template0`, contact support as these databases are not user-accessible and require intervention.

It is highly unlikely for either the `rdsadmin` or `template0` database to contain a top blocker.

### When an aggressive vacuum is already running

The `postgres_get_av_diag()` function is designed to report when an aggressive vacuum process is running, but it only triggers this output after the vacuum has been active for at least 1 minute. This intentional delay helps reduce the chances of false positives. By waiting, the function ensures that only effective, significant vacuums are reported, leading to more accurate and reliable monitoring of vacuum activity.

The `postgres_get_av_diag()` function generates the following NOTICE when it detects one or more aggressive vacuums in progress.

```
NOTICE: Your database is currently running aggressive vacuum to prevent wraparound,
monitor autovacuum performance.
```

As indicated in the NOTICE, continue to monitor the performance of vacuum. For more information about aggressive vacuum see [Aggressive vacuum \(to prevent wraparound\) is running](#)

### When autovacuum is off

The `postgres_get_av_diag()` function generates the following NOTICE if autovacuum is disabled on your database instance:

```
NOTICE: Autovacuum is OFF, we strongly recommend to enable it, no restart is
necessary.
```

Autovacuum is a critical feature of your Aurora PostgreSQL DB instance that ensures smooth database operation. It automatically removes old row versions, reclaims storage space, and prevents table bloat, helping to keep tables and indexes efficient for optimal performance. Additionally, it protects against transaction ID wraparound, which can halt transactions on your Amazon RDS instance. Disabling autovacuum can lead to long-term declines in database

performance and stability. We suggest you to keep it on all the times. For more information, see [Understanding autovacuum in Aurora PostgreSQL environments](#).

**Note**

Turning off autovacuum doesn't stop aggressive vacuums. These will still occur once your tables hit the `autovacuum_freeze_max_age` threshold.

### The number of transactions remaining is critically low

The `postgres_get_av_diag()` function generates the following NOTICE when a wraparound vacuum is imminent. This NOTICE is issued when your Amazon RDS instance is 100 million transactions away from potentially rejecting new transactions.

```
WARNING: Number of transactions remaining is critically low, resolve issues with
autovacuum or perform manual VACUUM FREEZE before your instance stops accepting
transactions.
```

Your immediate action is required to avoid database downtime. You should closely monitor your vacuuming operations and consider manually initiating a `VACUUM FREEZE` on the affected database to prevent transaction failures.

## Managing TOAST OID contention in Amazon Aurora PostgreSQL

TOAST (The Oversized-Attribute Storage Technique) is a PostgreSQL feature designed to handle large data values that exceed the typical 8KB database block size. PostgreSQL doesn't allow physical rows to span multiple blocks. The block size acts as an upper limit on row size. TOAST overcomes this restriction by splitting large field values into smaller chunks. It stores them separately in a dedicated TOAST table linked to the main table. For more information, see the [PostgreSQL TOAST storage mechanism and implementation documentation](#).

### Topics

- [Understanding TOAST operations](#)
- [Identifying performance challenges](#)
- [Recommendations](#)

- [Monitoring](#)

## Understanding TOAST operations

TOAST performs compression and stores large field values out of line. TOAST assigns a unique OID (Object Identifier) to each chunk of oversized data stored in the TOAST table. The main table stores the TOAST value ID and relation ID on the page to reference the corresponding row in the TOAST table. This allows PostgreSQL to efficiently locate and manage these TOAST chunks. However, as the TOAST table grows, the system risks exhausting available OIDs, leading to both performance degradation and potential downtime due to OID depletion.

### Object identifiers in TOAST

An Object Identifier (OID) is a system-wide unique identifier used by PostgreSQL to reference database objects like tables, indexes, and functions. These identifiers play a vital role in PostgreSQL's internal operations, allowing the database to efficiently locate and manage objects.

For tables with eligible data sets for toasting, PostgreSQL assigns OIDs to uniquely identify each chunk of oversized data stored in the associated TOAST table. The system associates each chunk with a `chunk_id`, which helps PostgreSQL organize and locate these chunks efficiently within the TOAST table.

### Identifying performance challenges

PostgreSQL's OID management relies on a global 32-bit counter so that it wraps around after generating 4 billion unique values. While the database cluster shares this counter, OID allocation involves two steps during TOAST operations:

- **Global counter for allocation** – The global counter assigns a new OID across the cluster.
- **Local search for conflicts** – The TOAST table ensures the new OID does not conflict with existing OIDs already used in that specific table.

Performance degradation can occur when:

- The TOAST table has high fragmentation or dense OID usage, leading to delays in assigning the OID.
- The system frequently allocates and reuses OIDs in environments with high data churn or wide tables that use TOAST extensively.

For more information, see the [PostgreSQL TOAST table size limits and OID allocation documentation](#):

A global counter generates the OIDs and wraps around every 4 billion values, so that from time to time, the system generates an already-used value again. PostgreSQL detects that and tries again with the next OID. A slow INSERT could occur if there is a very long run of used OID values with no gaps in the TOAST table. These challenges become more pronounced as the OID space fills, leading to slower inserts and updates.

## Identifying the problem

- Simple INSERT statements take significantly longer than usual in an inconsistent and random manner.
- Delays occur only for INSERT and UPDATE statements involving TOAST operations.
- The following log entries appear in PostgreSQL logs when the system struggles to find available OIDs in TOAST tables:

```
LOG: still searching for an unused OID in relation "pg_toast_20815"  
DETAIL: OID candidates have been checked 1000000 times, but no unused OID has been  
found yet.
```

- Performance Insights indicates a high number of average active sessions (AAS) associated with LWLock:buffer\_io and LWLock:OidGenLock wait events.

You can run the following SQL query to identify long-running INSERT transactions with wait events:

```
SELECT  
    datname AS database_name,  
    username AS database_user,  
    pid,  
    now() - pg_stat_activity.xact_start AS transaction_duration,  
    concat(wait_event_type, ':', wait_event) AS wait_event,  
    substr(query, 1, 30) AS TRANSACTION,  
    state  
FROM  
    pg_stat_activity  
WHERE (now() - pg_stat_activity.xact_start) > INTERVAL '60 seconds'  
    AND state IN ('active', 'idle in transaction', 'idle in transaction (aborted)',  
    'fastpath function call', 'disabled')  
    AND pid <> pg_backend_pid()
```

```
AND lower(query) LIKE '%insert%'
ORDER BY
    transaction_duration DESC;
```

Example query results displaying INSERT operations with extended wait times:

```
database_name | database_user | pid | transaction_duration | wait_event
|             | transaction   | state
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
postgres     | db_admin_user| 70965 | 00:10:19.484061     | LWLock:buffer_io |
INSERT INTO "products" (..... | active
postgres     | db_admin_user| 69878 | 00:06:14.976037     | LWLock:buffer_io |
INSERT INTO "products" (..... | active
postgres     | db_admin_user| 68937 | 00:05:13.942847     | :                 |
INSERT INTO "products" (..... | active
```

## Isolating the problem

- **Test small insert** – Insert a record smaller than the `toast_tuple_target` threshold. Remember that compression is applied before TOAST storage. If this operates without performance issues, the problem is related to TOAST operations.
- **Test new table** – Create a new table with the same structure and insert a record larger than `toast_tuple_target`. If this works without issues, the problem is localized to the original table's OID allocation.

## Recommendations

The following approaches can help resolve TOAST OID contention issues.

- **Data cleanup and archive** – Review and delete any obsolete or unnecessary data to free up OIDs for future use, or archive the data. Consider the following limitations:
  - Limited scalability, as future cleanup might not always be possible.
  - Possible long-running VACUUM operation to remove the resulting dead tuples.
- **Write to a new table** – Create a new table for future inserts and use a UNION ALL view to combine old and new data for queries. This view presents the combined data from both old and new tables, allowing queries to access them as a single table. Consider the following limitations:

- Updates on the old table might still cause OID exhaustion.
- **Partition or Shard** – Partition the table or shard data for better scalability and performance. Consider the following limitations:
  - Increased complexity in query logic and maintenance, potential need for application changes to handle partitioned data correctly.

## Monitoring

### Using system tables

You can use PostgreSQL's system tables to monitor growth of OID usage.

#### Warning

Depending on the number of OIDs in the TOAST table, it may take time to complete. We recommend that you schedule monitoring during off-business hours to minimize impact.

The following anonymous block counts the number of distinct OIDs used in each TOAST table and displays the parent table information:

```
DO $$
DECLARE
    r record;
    o bigint;
    parent_table text;
    parent_schema text;
BEGIN
    SET LOCAL client_min_messages TO notice;
    FOR r IN
    SELECT
        c.oid,
        c.oid::regclass AS toast_table
    FROM
        pg_class c
    WHERE
        c.relkind = 't'
        AND c.relowner != 10 LOOP
        -- Fetch the number of distinct used OIDs (chunk IDs) from the TOAST table
```

```

EXECUTE 'SELECT COUNT(DISTINCT chunk_id) FROM ' || r.toast_table INTO o;
-- If there are used OIDs, find the associated parent table and its schema
IF o <> 0 THEN
    SELECT
        n.nspname,
        c.relname INTO parent_schema,
        parent_table
    FROM
        pg_class c
        JOIN pg_namespace n ON c.relnamespace = n.oid
    WHERE
        c.reltoastrelid = r.oid;
    -- Raise a concise NOTICE message
    RAISE NOTICE 'Parent schema: % | Parent table: % | Toast table: %
| Number of used OIDs: %', parent_schema, parent_table, r.toast_table, TO_CHAR(o,
'FM9,999,999,999,999');
    END IF;
END LOOP;
END
$$;
```

Example output displaying OID usage statistics by TOAST table:

```

NOTICE: Parent schema: public | Parent table: my_table | Toast table:
pg_toast.pg_toast_16559 | Number of used OIDs: 45,623,317
NOTICE: Parent schema: public | Parent table: my_table1 | Toast table:
pg_toast.pg_toast_45639925 | Number of used OIDs: 10,000
NOTICE: Parent schema: public | Parent table: my_table2 | Toast table:
pg_toast.pg_toast_45649931 | Number of used OIDs: 1,000,000
DO
```

The following anonymous block retrieves the maximum assigned OID for each non-empty TOAST table:

```

DO $$
DECLARE
    r record;
    o bigint;
    parent_table text;
    parent_schema text;
BEGIN
    SET LOCAL client_min_messages TO notice;
    FOR r IN
```

```

SELECT
    c.oid,
    c.oid::regclass AS toast_table
FROM
    pg_class c
WHERE
    c.relkind = 't'
    AND c.relowner != 10 LOOP
    -- Fetch the max(chunk_id) from the TOAST table
    EXECUTE 'SELECT max(chunk_id) FROM ' || r.toast_table INTO o;
    -- If there's at least one TOASTed chunk, find the associated parent table
and its schema
    IF o IS NOT NULL THEN
        SELECT
            n.nspname,
            c.relname INTO parent_schema,
            parent_table
        FROM
            pg_class c
            JOIN pg_namespace n ON c.relnamespace = n.oid
        WHERE
            c.reltoastrelid = r.oid;
        -- Raise a concise NOTICE message
        RAISE NOTICE 'Parent schema: % | Parent table: % | Toast table:
% | Max chunk_id: %', parent_schema, parent_table, r.toast_table, TO_CHAR(o,
'FM9,999,999,999,999');
        END IF;
    END LOOP;
END
$$;

```

Example output displaying maximum chunk IDs for TOAST tables:

```

NOTICE: Parent schema: public | Parent table: my_table | Toast table:
pg_toast.pg_toast_16559 | Max chunk_id: 45,639,907
NOTICE: Parent schema: public | Parent table: my_table1 | Toast table:
pg_toast.pg_toast_45639925 | Max chunk_id: 45,649,929
NOTICE: Parent schema: public | Parent table: my_table2 | Toast table:
pg_toast.pg_toast_45649931 | Max chunk_id: 46,649,935
DO

```

## Using Performance Insights

The wait events `LWLock:buffer_io` and `LWLock:OidGenLock` appear in Performance Insights during operations that require assigning new Object Identifiers (OIDs). High Average Active Sessions (AAS) for these events typically point to contention during OID assignment and resource management. This is particularly common in environments with high data churn, extensive large data usage, or frequent object creation.

### **LWLock:buffer\_io**

`LWLock:buffer_io` is a wait event that occurs when a PostgreSQL session is waiting for I/O operations on a shared buffer to complete. This typically happens when the database reads data from disk into memory or writes modified pages from memory to disk. The `BufferIO` wait event ensures consistency by preventing multiple processes from accessing or modifying the same buffer while I/O operations are in progress. High occurrences of this wait event may indicate disk bottlenecks or excessive I/O activity in the database workload.

During TOAST operations:

- PostgreSQL allocates OIDs for large objects and ensures their uniqueness by scanning the TOAST table's index.
- Large TOAST indexes may require accessing multiple pages to verify OID uniqueness. This results in increased disk I/O, especially when the buffer pool cannot cache all required pages.

The size of the index directly affects the number of buffer pages that need to be accessed during these operations. Even if the index is not bloated, its sheer size can increase buffer I/O, particularly in high-concurrency or high-churn environments. For more information, see [LWLock:BufferIO wait event troubleshooting guide](#).

### **LWLock:OidGenLock**

`OidGenLock` is a wait event that occurs when a PostgreSQL session is waiting to allocate a new object identifier (OID). This lock ensures that OIDs are generated sequentially and safely, allowing only one process to generate OIDs at a time.

During TOAST operations:

- **OID allocation for chunks in TOAST table** – PostgreSQL assigns OIDs to chunks in TOAST tables when managing large data records. Each OID must be unique to prevent conflicts in the system catalog.

- **High concurrency** – Since access to OID generator is sequential, when multiple sessions are concurrently creating objects that require OIDs, contention for `OidGenLock` can occur. This increases the likelihood of sessions waiting for OID allocation to complete.
- **Dependency on system catalog access** – Allocating OIDs requires updates to shared system catalog tables like `pg_class` and `pg_type`. If these tables experience heavy activity (due to frequent DDL operations), it can increase lock contention for `OidGenLock`.
- **High OID allocation demand** – TOAST heavy workloads with large data records require constant OID allocation, increasing contention.

Additional factors that increase OID contention:

- **Frequent object creation** – Workloads that frequently create and drop objects, such as temporary tables, amplify contention on the global OID counter.
- **Global counter locking** – The global OID counter is accessed serially to ensure uniqueness, creating a single point of contention in high-concurrency environments.

# Using Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL extends your Aurora PostgreSQL DB cluster with the ability to accept database connections from SQL Server clients. With Babelfish, applications that were originally built for SQL Server can work directly with Aurora PostgreSQL with few code changes compared to a traditional migration and without changing database drivers. For more information about migrating, see [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL](#).

Babelfish provides an additional endpoint for an Aurora PostgreSQL database cluster that allows it to understand the SQL Server wire-level protocol and commonly used SQL Server statements. Client applications that use the Tabular Data Stream (TDS) wire protocol can connect natively to the TDS listener port on Aurora PostgreSQL. To learn more about TDS, see [\[MS-TDS\]: Tabular Data Stream Protocol](#) on the Microsoft website.

## Note

Babelfish for Aurora PostgreSQL supports TDS versions 7.1 through 7.4.

Babelfish also provides access to data using the PostgreSQL connection. By default, both SQL dialects supported by Babelfish are available through their native wire protocols at the following ports:

- SQL Server dialect (T-SQL), clients connect to port 1433.
- PostgreSQL dialect (PL/pgSQL), clients connect to port 5432.

Babelfish runs the Transact-SQL (T-SQL) language with some differences. For more information, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server](#).

In the following sections, you can find information about setting up and using a Babelfish for Aurora PostgreSQL DB cluster.

## Topics

- [Babelfish limitations](#)
- [Understanding Babelfish architecture and configuration](#)
- [Creating a Babelfish for Aurora PostgreSQL DB cluster](#)
- [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL](#)

- [Database authentication with Babelfish for Aurora PostgreSQL](#)
- [Connecting to a Babelfish DB cluster](#)
- [Working with Babelfish](#)
- [Troubleshooting Babelfish](#)
- [Turning off Babelfish](#)
- [Managing Babelfish for Aurora PostgreSQL version updates](#)
- [Babelfish for Aurora PostgreSQL reference](#)

## Babelfish limitations

The following limitations currently apply to Babelfish for Aurora PostgreSQL:

- Babelfish doesn't support the following Aurora features:
  - Amazon Identity and Access Management
  - Database Activity Streams (DAS)
  - RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned
  - RDS Proxy with RDS for SQL Server
  - Salted challenge response authentication mechanism (SCRAM)
  - Query editor
  - Zero-ETL integrations
- Babelfish doesn't provide the following client driver API support:
  - API requests with the connection attributes related to Microsoft Distributed Transaction Coordinator (MSDTC) aren't supported. These include XA calls by the `SQLServerXAResource` class in the SQL server JDBC driver.
- Babelfish currently doesn't support the following Aurora PostgreSQL extensions:
  - `bloom`
  - `btree_gin`
  - `btree_gist`
  - `citext`
  - `cube`
  - `hstore`
  - `hypopg`
  - Logical replication using `pglogical`
  - `ltree`
  - `pgcrypto`
  - Query plan management using `apg_plan_mgmt`

To learn more about PostgreSQL extensions, see [Working with extensions and foreign data wrappers](#).

- The open source [jTDS driver](#) that is designed as an alternative to the Microsoft JDBC driver is not supported.

## Understanding Babelfish architecture and configuration

You manage the Aurora PostgreSQL-Compatible Edition DB cluster running Babelfish much as you would any Aurora DB cluster. That is, you benefit from the scalability, high-availability with failover support, and built-in replication provided by an Aurora DB cluster. To learn more about these capabilities, see [Managing performance and scaling for Aurora DB clusters](#), [High availability for Amazon Aurora](#), and [Replication with Amazon Aurora](#). You also have access to many other Amazon tools and utilities, including the following:

- Amazon CloudWatch is a monitoring and observability service that provides you with data and actionable insights. For more information, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#).
- Performance Insights is a database performance tuning and monitoring feature that helps you quickly assess the load on your database. To learn more, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).
- Aurora global databases span multiple Amazon Web Services Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire Amazon Web Services Region. For more information, see [Using Amazon Aurora Global Database](#).
- Automatic software patching keeps your database up-to-date with the latest security and feature patches when they become available.
- Amazon RDS events notify you by email or SMS message of important database events, such as an automated failover. For more information, see [Monitoring Amazon Aurora events](#).

Following, you can learn about Babelfish architecture and how the SQL Server databases that you migrate are handled by Babelfish. When you create your Babelfish DB cluster, you need to make some decisions up front about single database or multiple databases, collations, and other details.

### Topics

- [Babelfish architecture](#)
- [DB cluster parameter group settings for Babelfish](#)
- [Understanding Collations in Babelfish for Aurora PostgreSQL](#)
- [Managing Babelfish error handling with escape hatches](#)

## Babelfish architecture

When you create an Aurora PostgreSQL cluster with Babelfish turned on, Aurora provisions the cluster with a PostgreSQL database named `babelfish_db`. This database is where all migrated SQL Server objects and structures reside.

### Note

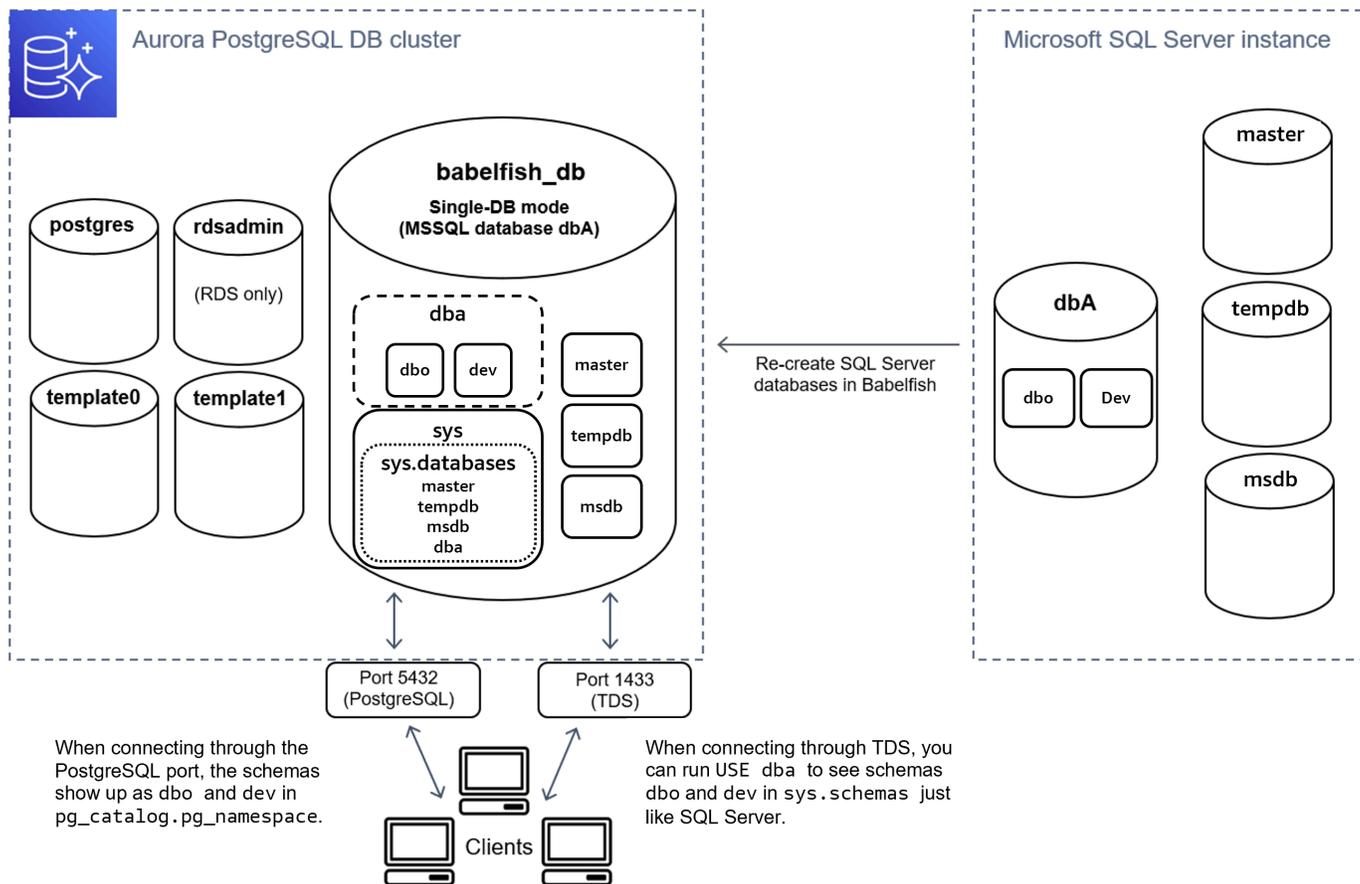

In an Aurora PostgreSQL cluster, the `babelfish_db` database name is reserved for Babelfish. Creating your own "babelfish\_db" database on a Babelfish DB cluster prevents Aurora from successfully provisioning Babelfish.

When you connect to the TDS port, the session is placed in the `babelfish_db` database. From T-SQL, the structure looks similar to being connected to a SQL Server instance. You can see the `master`, `msdb`, and `tempdb` databases, and the `sys.databases` catalog. You can create additional user databases and switch between databases with the `USE` statement. When you create a SQL Server user database, it's flattened into the `babelfish_db` PostgreSQL database. Your database retains cross-database syntax and semantics equal to or similar to those provided by SQL Server.

### Using Babelfish with a single database or multiple databases

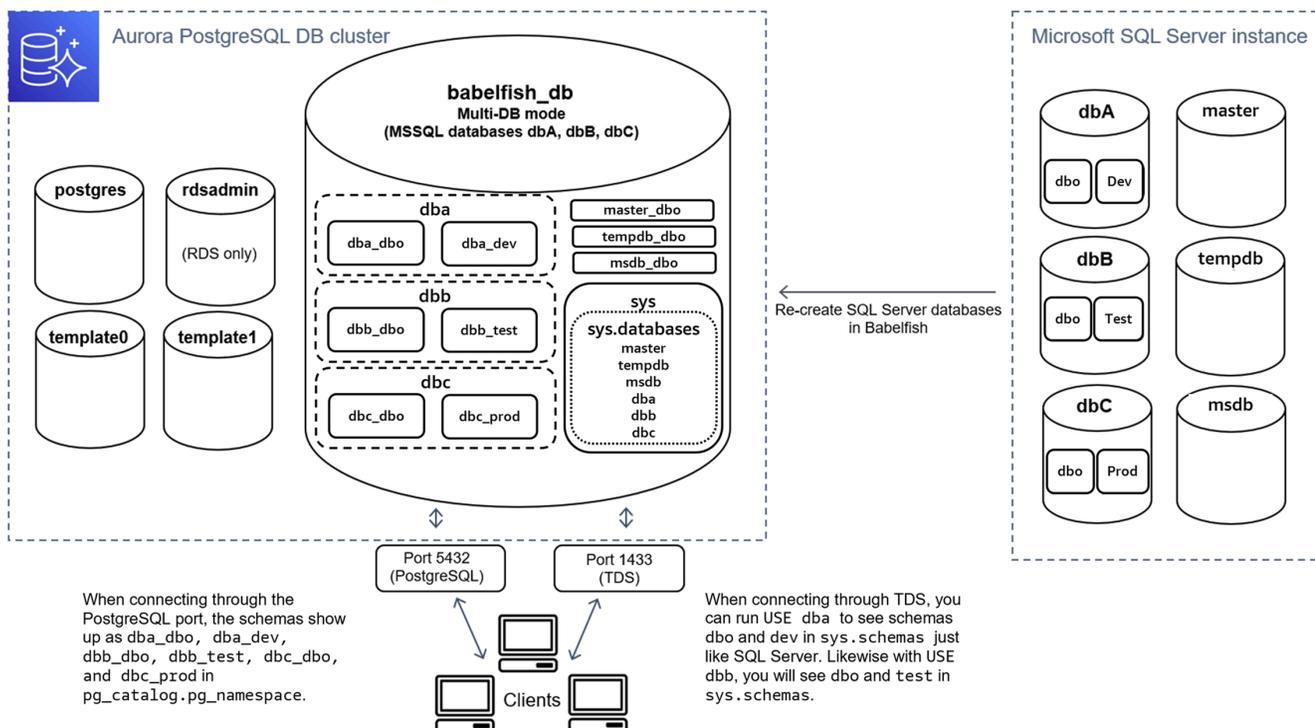

When you create an Aurora PostgreSQL cluster to use with Babelfish, you choose between using a single SQL Server database on its own or multiple SQL Server databases together. Your choice affects how the names of SQL Server schemas inside the `babelfish_db` database appear from Aurora PostgreSQL. The migration mode is stored in the `migration_mode` parameter. You must not change this parameter after creating your cluster as you could lose access to all your previously created SQL objects.

In single-db mode, the schema names of the SQL Server database remain the same in the `babelfish_db` database of the PostgreSQL. If you choose to migrate only a single database, the schema names of the migrated user database can be referenced in PostgreSQL with the same names used in SQL Server. For example, the `dbo` and `smith` schemas reside inside the `dbA` database.

When connecting through TDS, you can run `USE dba` to see schemas `dbo` and `dev` from T-SQL, as you would in SQL Server. The unchanged schema names are also visible from PostgreSQL.

In multiple-database mode, the schema names of user databases become `dbname_schemaname` when accessed from PostgreSQL. The schema names remain the same when accessed from T-SQL.

As shown in the image, multiple-database mode and single-database mode are the same as SQL Server when connecting through the TDS port and using T-SQL. For example, USE dbA lists schemas dbo and dev just as it does in SQL Server. The mapped schema names, such as dba\_dbo and dba\_dev, are visible from PostgreSQL.

Each database still contains your schemas. The name of each database is prepended to the name of the SQL Server schema, using an underscore as a delimiter, for example:

- dba contains dba\_dbo and dba\_dev.
- dbb contains dbb\_dbo and dbb\_test.
- dbc contains dbc\_dbo and dbc\_prod.

Inside the babelfish\_db database, the T-SQL user still needs to run USE dbname to change database context, so the look and feel remains similar to SQL Server.

## Choosing a migration mode

Each migration mode has advantages and disadvantages. Choose your migration mode based on the number of user databases you have, and your migration plans. After you create a cluster for use with Babelfish, you must not change the migration mode as you might lose access to all your

previously created SQL objects. When choosing a migration mode, consider the requirements of your user databases and clients.

When you create a cluster for use with Babelfish, Aurora PostgreSQL creates the system databases, `master` and `tempdb`. If you created or modified objects in the system databases (`master` or `tempdb`), make sure to recreate those objects in your new cluster. Unlike SQL Server, Babelfish doesn't reinitialize `tempdb` after a cluster reboot.

Use single database migration mode in the following cases:

- If you are migrating a single SQL Server database. In single database mode, migrated schema names when accessed from PostgreSQL are identical to those in original SQL Server schema names. This reduces code changes to existing SQL queries if you want to optimize them to run with a PostgreSQL connection.
- If your end goal is a complete migration to native Aurora PostgreSQL. Before migrating, consolidate your schemas into a single schema (`dbo`) and then migrate into a single cluster to lessen required changes.

Use multiple database migration mode in the following cases:

- If you want the default SQL Server experience with multiple user databases in the same instance.
- If multiple user databases need to be migrated together.

## DB cluster parameter group settings for Babelfish

When you create an Aurora PostgreSQL DB cluster and choose **Turn on Babelfish**, a DB cluster parameter group is created for you automatically if you choose **Create new**. This DB cluster parameter group is based on the Aurora PostgreSQL DB cluster parameter group for the Aurora PostgreSQL version chosen for the install, for example, Aurora PostgreSQL version 14. It's named using the following general pattern:

```
custom-aurora-postgresql14-babelfish-compat-3
```

You can change the following settings during the cluster creation process but some of these can't be changed once they're stored in the custom parameter group, so choose carefully:

- Single database or Multiple databases
- Default collation locale
- Collation name
- DB parameter group

To use an existing Aurora PostgreSQL DB cluster version 13 or higher parameter group, edit the group and set the `babelfish_status` parameter to on. Specify any Babelfish options before creating your Aurora PostgreSQL cluster. To learn more, see [Parameter groups for Amazon Aurora](#).

The following parameters control Babelfish preferences. Unless otherwise stated in the Description, parameters are modifiable. The default value is included in the description. To see the allowable values for any parameter, do as follows:

### Note

When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot.

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Parameter groups** from the navigation menu.

3. Choose the `default.aurora-postgresql14` DB cluster parameter group from the list.
4. Enter the name of a parameter in the search field. For example, enter `babelfishpg_tsql.default_locale` in the search field to display this parameter and its default value and allowable settings.

 **Note**

Babelfish for Aurora PostgreSQL global databases works in secondary regions only if the following parameters are turned on in those regions.

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tsql.pg_enable_correlated_scalar_transform</code>	Enables the planner to transform correlated scalar subquery in Babelfish. (Default: on) (Allowable: on, off)	dynamic	true
<code>babelfishpg_tsql.pg_enable_subquery_cache</code>	Enables the use of cache for correlated scalar subquery in Babelfish. (Default: on) (Allowable: on, off)	dynamic	true
<code>babelfishpg_tds.tds_default_numeric_scale</code>	Sets the default scale of numeric type to be sent in the TDS column metadata if the engine doesn't specify one. (Default: 8) (Allowable: 0–38)	dynamic	true

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tds.tds_default_numeric_precision</code>	An integer that sets the default precision of numeric type to be sent in the TDS column metadata if the engine doesn't specify one. (Default: 38) (Allowable: 1–38)	dynamic	true
<code>babelfishpg_tds.tds_default_packet_size</code>	An integer that sets the default packet size for connecting SQL Server clients. (Default: 4096) (Allowable: 512–32767)	dynamic	true
<code>babelfishpg_tds.tds_default_protocol_version</code>	An integer that sets a default TDS protocol version for connecting clients. (Default: DEFAULT) (Allowable: TDSv7.0, TDSv7.1, TDSv7.1.1, TDSv7.2, TDSv7.3A, TDSv7.3B, TDSv7.4, DEFAULT)	dynamic	true
<code>babelfishpg_tds.default_server_name</code>	A string that identifies the default name of the Babelfish server. (Default: Microsoft SQL Server) (Allowable: null)	dynamic	true

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tds.tds_debug_log_level</code>	An integer that sets the logging level in TDS; 0 turns off logging. (Default: 1) (Allowable: 0, 1, 2, 3)	dynamic	true
<code>babelfishpg_tds.listen_addresses</code>	A string that sets the host name or IP address or addresses to listen for TDS on. This parameter can't be modified after the Babelfish DB cluster is created. (Default: *) (Allowable: null)	–	false
<code>babelfishpg_tds.port</code>	An integer that specifies the TCP port used for requests in SQL Server syntax. (Default: 1433) (Allowable: 1–65535)	static	true
<code>babelfishpg_tds.tds_ssl_encrypt</code>	A boolean that turns encryption on (0) or off (1) for data traversing the TDS listener port. For detailed information about using SSL for client connections, see <a href="#">Babelfish SSL settings and client connections</a> . (Default: 0) (Allowable: 0, 1)	dynamic	true

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tds.tds_ssl_max_protocol_version</code>	A string that specifies the highest SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1.2') (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')	dynamic	true
<code>babelfishpg_tds.tds_ssl_min_protocol_version</code>	A string that specifies the minimum SSL/TLS protocol version to use for the TDS session. (Default: 'TLSv1.2' from Aurora PostgreSQL version 16, 'TLSv1' for versions older than Aurora PostgreSQL version 16) (Allowable: 'TLSv1', 'TLSv1.1', 'TLSv1.2')	dynamic	true
<code>babelfishpg_tds.unix_socket_directories</code>	A string that identifies the TDS server Unix socket directory. This parameter can't be modified after the Babelfish DB cluster is created. (Default: /tmp) (Allowable: null)	–	false

Parameter	Description	Apply Type	Is Modifiable
babelfishpg_tds.unix_socket_group	A string that identifies the TDS server Unix socket group. This parameter can't be modified after the Babelfish DB cluster is created. (Default: rdsdb) (Allowable: null)	–	false
babelfishpg_tsqldb.default_locale	A string that specifies the default locale used for Babelfish collations. The default locale is the locale only and doesn't include any qualifiers.  Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, changes to this parameter are ignored. (Default: en_US) (Allowable: See <a href="#">tables</a> )	static	true

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tsql.migration_mode</code>	A non-modifiable list that specifies support for single- or multiple user databases. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, you can't modify this parameter's value. (Default: multi-db from Aurora PostgreSQL version 16, single-db for versions older than Aurora PostgreSQL version 16) (Allowable: single-db, multi-db,null)	static	true

Parameter	Description	Apply Type	Is Modifiable
<code>babelfishpg_tsql.server_collation_name</code>	A string that specifies the name of the collation used for server-level actions. Set this parameter when you provision a Babelfish DB cluster. After the DB cluster is provisioned, don't modify the value of this parameter. (Default: <code>bbf_unicode_general_ci_as</code> ) (Allowable: See <a href="#">tables</a> )	static	true
<code>babelfishpg_tsql.version</code>	A string that sets the output of <code>@@VERSION</code> variable. Don't modify this value for Aurora PostgreSQL DB clusters. (Default: <code>null</code> ) (Allowable: <code>default</code> )	dynamic	true

Parameter	Description	Apply Type	Is Modifiable
rds.babelfish_status	A string that sets the state of Babelfish functionality. When this parameter is set to <code>datatypes only</code> , Babelfish is turned off but SQL Server data types are still available. (Default: <code>off</code> ) (Allowable: <code>on</code> , <code>off</code> , <code>datatypesonly</code> )	static	true
unix_socket_permissions	An integer that sets the TDS server Unix socket permissions. This parameter can't be modified after the Babelfish DB cluster is created. (Default: <code>0700</code> ) (Allowable: <code>0-511</code> )	–	false

## Babelfish SSL settings and client connections

To require SSL/TLS connections to your Babelfish for Aurora PostgreSQL DB cluster, use the `rds.force_ssl` parameter.

- To require SSL/TLS connections, set the `rds.force_ssl` parameter value to 1 (on).
- To turn off required SSL/TLS connections, set the `rds.force_ssl` parameter value to 0 (off).

The default value of this parameter depends on the Aurora PostgreSQL version:

- For Aurora PostgreSQL versions 17 and later: The default value is 1 (on).
- For Aurora PostgreSQL versions 16 and older: The default value is 0 (off).

### Note

When you perform a major version upgrade from Aurora PostgreSQL version 16 or earlier to version 17 or later, the default value of the parameter changes from 0 (off) to 1 (on). This change may cause connectivity failures for applications that are not configured for SSL. You can revert to the previous default behavior by setting this parameter to 0 (off).

For driver-specific details, see [Connecting to a Babelfish DB cluster](#).

When a client connects to the TDS port (default 1433), Babelfish compares the Secure Sockets Layer (SSL) setting sent during the client handshake to the Babelfish SSL parameter setting (`tds_ssl_encrypt`). Babelfish then determines if a connection is allowed. If a connection is allowed, encryption behavior is either enforced or not, depending on your parameter settings and the support for encryption offered by the client.

The table following shows how Babelfish behaves for each combination.

Client SSL setting	Babelfish SSL setting	<code>rds.force_ssl</code>	Connection allowed?	Value returned to client
ENCRYPT_ON	Any	Any	Allowed, the entire connection is encrypted	ENCRYPT_ON

Client SSL setting	Babelfish SSL setting	rds.force_ssl	Connection allowed?	Value returned to client
ENCRYPT_OFF	tds_ssl_encrypt=1	Any	Allowed, the entire connection is encrypted	ENCRYPT_REQ
ENCRYPT_OFF	tds_ssl_encrypt=0	rds.force_ssl=0	Allowed, the login packet is encrypted	ENCRYPT_OFF
ENCRYPT_OFF	tds_ssl_encrypt=0	rds.force_ssl=1	No, connection closed	ENCRYPT_OFF
ENCRYPT_N OT_SUP	tds_ssl_encrypt=0	rds.force_ssl=0	Yes	ENCRYPT_N OT_SUP
ENCRYPT_N OT_SUP	tds_ssl_encrypt=1	Any	No, connection closed	ENCRYPT_REQ
ENCRYPT_N OT_SUP	tds_ssl_encrypt=0	rds.force_ssl=1	No, connection closed	ENCRYPT_N OT_SUP
ENCRYPT_C LIENT_CERT	Any	Any	No, connection closed	Unsupported

## Understanding Collations in Babelfish for Aurora PostgreSQL

When you create an Aurora PostgreSQL DB cluster with Babelfish, you choose a collation for your data. A *collation* specifies the sort order and bit patterns that produce the text or characters in a given written human language. A collation includes rules comparing data for a given set of bit patterns. Collation is related to localization. Different locales affect character mapping, sort order, and the like. Collation attributes are reflected in the names of various collations. For information about attributes, see the [Babelfish collation attributes table](#).

Babelfish maps SQL Server collations to comparable collations provided by Babelfish. Babelfish predefines Unicode collations with culturally sensitive string comparisons and sort orders. Babelfish also provides a way to translate the collations in your SQL Server DB to the closest-matching Babelfish collation. Locale-specific collations are provided for different languages and regions.

Some collations specify a code page that corresponds to a client-side encoding. Babelfish automatically translates from the server encoding to the client encoding depending on the collation of each output column.

Babelfish supports the collations listed in the [Babelfish supported collations table](#). Babelfish maps SQL Server collations to comparable collations provided by Babelfish.

Babelfish uses version 153.80 of the International Components for Unicode (ICU) collation library. For more information about ICU collations, see [Collation](#) in the ICU documentation. To learn more about PostgreSQL and collation, see [Collation Support](#) in the the PostgreSQL documentation.

### DB cluster parameters that control collation and locale

The following parameters affect collation behavior.

## `babelfishpg_tsql.default_locale`

This parameter specifies the default locale used by the collation. This parameter is used in combination with attributes listed in the [Babelfish collation attributes table](#) to customize collations for a specific language and region. The default value for this parameter is en-US.

The default locale applies to all Babelfish collation names that start with "BBF" and to all SQL Server collations that are mapped to Babelfish collations. Changing the setting for this parameter on an existing Babelfish DB cluster doesn't affect the locale of existing collations. For the list of collations, see the [Babelfish supported collations table](#).

## `babelfishpg_tsql.server_collation_name`

This parameter specifies the default collation for the server (Aurora PostgreSQL DB cluster instance) and the database. The default value is `sql_latin1_general_cp1_ci_as`. The `server_collation_name` has to be a CI\_AS collation because in T-SQL, the server collation determines how identifiers are compared.

When you create your Babelfish DB cluster, you choose the **Collation name** from the selectable list. These include the collations listed in the [Babelfish supported collations table](#). Don't modify the `server_collation_name` after the Babelfish database is created.

The settings you choose when you create your Babelfish for Aurora PostgreSQL DB cluster are stored in the DB cluster parameter group associated with the cluster for these parameters and set its collation behavior.

## Deterministic and nondeterministic collations in Babelfish

Babelfish supports deterministic and nondeterministic collations:

- A *deterministic collation* evaluates characters that have identical byte sequences as equal. That means that `x` and `X` aren't equal in a deterministic collation. Deterministic collations can be case-sensitive (CS) and accent-sensitive (AS).
- A *nondeterministic collation* doesn't need an identical match. A nondeterministic collation evaluates `x` and `X` as equal. Nondeterministic collations are case-insensitive (CI) or accent-insensitive (AI), or both.

In the table following, you can find some behavior differences between Babelfish and PostgreSQL when using nondeterministic collations.

Babelfish	PostgreSQL
Supports the LIKE clause for CI_AS collations.	Doesn't support the LIKE clause on nondeterministic collations.
<p>Supports the LIKE clause only on the following AI collations from Babelfish version 4.2.0:</p> <ul style="list-style-type: none"> <li>• bbf_unicode_cp1250_ci_ai</li> <li>• bbf_unicode_cp1250_cs_ai</li> <li>• bbf_unicode_cp1257_ci_ai</li> <li>• bbf_unicode_cp1257_cs_ai</li> <li>• bbf_unicode_cp1_ci_ai</li> <li>• bbf_unicode_cp1_cs_ai</li> <li>• estonian_ci_ai</li> <li>• finnish_swedish_ci_ai</li> <li>• french_ci_ai</li> <li>• latin1_general_ci_ai</li> <li>• latin1_general_cs_ai</li> <li>• modern_spanish_ci_ai</li> <li>• polish_ci_ai</li> <li>• sql_latin1_general_cp1_ci_ai</li> <li>• sql_latin1_general_cp1_cs_ai</li> <li>• traditional_spanish_ci_ai</li> </ul>	Doesn't support the LIKE clause on nondeterministic collations.

For a list of other limitations and behavior differences for Babelfish compared to SQL Server and PostgreSQL, see [Collation limitations and behavior differences](#).

Babelfish and SQL Server follow a naming convention for collations that describe the collation attributes, as shown in the table following.

Attribute	Description
AI	Accent-insensitive.
AS	Accent-sensitive.
BIN2	BIN2 requests data to be sorted in code point order. Unicode code point order is the same character order for UTF-8, UTF-16, and UCS-2 encodings. Code point order is a fast deterministic collation.
CI	Case-insensitive.
CS	Case-sensitive.
PREF	To sort uppercase letters before lowercase letters, use a PREF collation . If comparison is case-insensitive, the uppercase version of a letter sorts before the lowercase version, if there is no other distinction. The ICU library supports uppercase preference with <code>collCaseFirst=upper</code> , but not for CI_AS collations.  PREF can be applied only to CS_AS deterministic collations.

## Collations supported at database level in Babelfish

The following collations are supported at database level in Babelfish:

- `bbf_unicode_bin2`
- `bbf_unicode_cp1_ci_ai`
- `bbf_unicode_cp1_ci_as`
- `bbf_unicode_cp1250_ci_ai`
- `bbf_unicode_cp1250_ci_as`
- `bbf_unicode_cp1257_ci_ai`
- `bbf_unicode_cp1257_ci_as`
- `estonian_ci_ai`
- `estonian_ci_as`
- `finnish_swedish_ci_ai`

- finnish\_swedish\_ci\_as
- french\_ci\_ai
- french\_ci\_as
- latin1\_general\_bin2
- latin1\_general\_ci\_ai
- latin1\_general\_ci\_as
- latin1\_general\_90\_bin2
- latin1\_general\_100\_bin2
- latin1\_general\_140\_bin2
- modern\_spanish\_ci\_ai
- modern\_spanish\_ci\_as
- polish\_ci\_ai
- polish\_ci\_as
- sql\_latin1\_general\_cp1\_ci\_ai
- sql\_latin1\_general\_cp1\_ci\_as
- sql\_latin1\_general\_cp1250\_ci\_as
- sql\_latin1\_general\_cp1251\_ci\_as
- sql\_latin1\_general\_cp1257\_ci\_as
- traditional\_spanish\_ci\_ai
- traditional\_spanish\_ci\_as

**Note**

To use a different collation at the database level, ensure it matches the server-level collation. For more information, see [Server and object Collations in Babelfish](#)

## Server and object Collations in Babelfish

Use the following collations as a server collation or an object collation.

Collation ID	Notes
--------------	-------

Collation ID	Notes
bbf_unicode_general_ci_as	Supports case-insensitive comparison and the LIKE operator.
bbf_unicode_cp1_ci_as	<a href="#">Nondeterministic collation</a> also known as CP1252.
bbf_unicode_CP1250_ci_as	<a href="#">Nondeterministic collation</a> used to represent texts in Central European and Eastern European languages that use Latin script.
bbf_unicode_CP1251_ci_as	<a href="#">Nondeterministic collation</a> for languages that use the Cyrillic script.
bbf_unicode_cp1253_ci_as	<a href="#">Nondeterministic collation</a> used to represent modern Greek.
bbf_unicode_cp1254_ci_as	<a href="#">Nondeterministic collation</a> that supports Turkish.
bbf_unicode_cp1255_ci_as	<a href="#">Nondeterministic collation</a> that supports Hebrew.
bbf_unicode_cp1256_ci_as	<a href="#">Nondeterministic collation</a> used to write languages that use Arabic script.
bbf_unicode_cp1257_ci_as	<a href="#">Nondeterministic collation</a> used to support Estonian, Latvian, and Lithuanian languages.
bbf_unicode_cp1258_ci_as	<a href="#">Nondeterministic collation</a> used to write Vietnamese characters.
bbf_unicode_cp874_ci_as	<a href="#">Nondeterministic collation</a> used to write Thai characters.
sql_latin1_general_cp1250_ci_as	<a href="#">Nondeterministic single-byte character encoding</a> used to represent Latin characters.

Collation ID	Notes
sql_latin1_general_cp1251_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1253_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1254_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1255_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1256_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1257_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
sql_latin1_general_cp1258_ci_as	<a href="#">Nondeterministic collation</a> that supports Latin characters.
chinese_prc_ci_as	Nondeterministic collation that supports Chinese (PRC).
cyrillic_general_ci_as	Nondeterministic collation that supports Cyrillic.
finnish_swedish_ci_as	Nondeterministic collation that supports Finnish.

Collation ID	Notes
french_ci_as	Nondeterministic collation that supports French.
japanese_ci_as	Nondeterministic collation that supports Japanese. Supported in Babelfish 2.1.0 and higher releases.
korean_wansung_ci_as	Nondeterministic collation that supports Korean (with dictionary sort).
latin1_general_ci_as	Nondeterministic collation that supports Latin characters.
modern_spanish_ci_as	Nondeterministic collation that supports Modern Spanish.
polish_ci_as	Nondeterministic collation that supports Polish.
thai_ci_as	Nondeterministic collation that supports Thai.
traditional_spanish_ci_as	Nondeterministic collation that supports Spanish (traditional sort).
turkish_ci_as	Nondeterministic collation that supports Turkish.
ukrainian_ci_as	Nondeterministic collation that supports Ukrainian.
vietnamese_ci_as	Nondeterministic collation that supports Vietnamese.

You can use the following collations as object collations.

Dialect	Deterministic options	Nondeterministic options
Arabic	Arabic_CS_AS	Arabic_CI_AS

Dialect	Deterministic options	Nondeterministic options
		Arabic_CI_AI
Arabic script	BBF_Unicode_CP1256_CS_AS BBF_Unicode_Pref_CP1256_CS_AS	BBF_Unicode_CP1256_CI_AI BBF_Unicode_CP1256_CS_AI
Binary	latin1_general_bin2 BBF_Unicode_BIN2	–
Central European and Eastern European languages that use Latin script	BBF_Unicode_CP1250_CS_AS BBF_Unicode_Pref_CP1250_CS_AS	BBF_Unicode_CP1250_CI_AI BBF_Unicode_CP1250_CS_AI
Chinese	Chinese_PRC_CS_AS	Chinese_PRC_CI_AS Chinese_PRC_CI_AI
Cyrillic_General	Cyrillic_General_CS_AS	Cyrillic_General_CI_AS Cyrillic_General_CI_AI
Cyrillic script	BBF_Unicode_CP1251_CS_AS BBF_Unicode_Pref_CP1251_CS_AS	BBF_Unicode_CP1251_CI_AI BBF_Unicode_CP1251_CS_AI
Estonian	Estonian_CS_AS	Estonian_CI_AS Estonian_CI_AI

Dialect	Deterministic options	Nondeterministic options
Estonian, Latvian, and Lithuanian	BBF_Unicode_CP1257_CS_AS BBF_Unicode_Pref_CP1257_CS_AS	BBF_Unicode_CP1257_CI_AI BBF_Unicode_CP1257_CS_AI
Finnish_Swedish	Finnish_Swedish_CS_AS	Finnish_Swedish_CI_AS Finnish_Swedish_CI_AI
French	French_CS_AS	French_CI_AS French_CI_AI
Greek	Greek_CS_AS	Greek_CI_AS Greek_CI_AI
Hebrew	BBF_Unicode_CP1255_CS_AS BBF_Unicode_Pref_CP1255_CS_AS Hebrew_CS_AS	BBF_Unicode_CP1255_CI_AI BBF_Unicode_CP1255_CS_AI Hebrew_CI_AS Hebrew_CI_AI
Japanese (Babelfish 2.1.0 and higher)	Japanese_CS_AS	Japanese_CI_AI Japanese_CI_AS
Korean_Wa msung	Korean_Wamsung_CS_AS	Korean_Wamsung_CI_AS Korean_Wamsung_CI_AI

Dialect	Deterministic options	Nondeterministic options
Latin characters for code page CP1252	latin1_general_cs_as BBF_Unicode_General_CS_AS BBF_Unicode_General_Pref_CS_AS BBF_Unicode_Pref_CP1_CS_AS BBF_Unicode_CP1_CS_AS	latin1_general_ci_as latin1_general_ci_ai latin1_general_cs_ai BBF_Unicode_General_CI_AI BBF_Unicode_General_CS_AI BBF_Unicode_CP1_CI_AI BBF_Unicode_CP1_CS_AI
Modern Greek	BBF_Unicode_CP1253_CS_AS BBF_Unicode_Pref_CP1253_CS_AS	BBF_Unicode_CP1253_CI_AI BBF_Unicode_CP1253_CS_AI
Modern_Spanish	Modern_Spanish_CS_AS	Modern_Spanish_CI_AS Modern_Spanish_CI_AI
Mongolian	Mongolian_CS_AS	Mongolian_CI_AS Mongolian_CI_AI
Polish	Polish_CS_AS	Polish_CI_AS Polish_CI_AI
Thai	BBF_Unicode_CP874_CS_AS BBF_Unicode_Pref_CP874_CS_AS Thai_CS_AS	BBF_Unicode_CP874_CI_AI BBF_Unicode_CP874_CS_AI Thai_CI_AS, Thai_CI_AI

Dialect	Deterministic options	Nondeterministic options
Traditional_Spanish	Traditional_Spanish_CS_AS	Traditional_Spanish_CI_AS Traditional_Spanish_CI_AI

Ukrainian	Ukrainian_CS_AS	Ukrainian_CI_AS Ukrainian_CI_AI
Vietnamese	BBF_Unicode_CP1258_CS_AS BBF_Unicode_Pref_CP1258_CS_AS Vietnamese_CS_AS	BBF_Unicode_CP1258_CI_AI BBF_Unicode_CP1258_CS_AI Vietnamese_CI_AS Vietnamese_CI_AI

## Default Collation behavior in Babelfish

Earlier, the default collation of the collatable datatypes was `pg_catalog.default`. The datatypes and the objects that depends on these datatypes follows cases-sensitive collation. This condition potentially impacts the T-SQL objects of the data set with case-insensitive collation. Starting with Babelfish 2.3.0, the default collation for the collatable data types (except TEXT and NTEXT) is the same as the collation in the `babelfishpg_tsql.server_collation_name` parameter. When you upgrade to Babelfish 2.3.0, the default collation is picked automatically at the time of DB cluster creation, which doesn't create any visible impact.

## Managing collations

The ICU library provides collation version tracking to ensure that indexes that depend on collations can be reindexed when a new version of ICU becomes available. To see if your current database has

collations that need refreshing, you can use the following query after connecting using `psql` or `pgAdmin`:

```
SELECT pg_describe_object(refclassid, refobjid,
    refobjsubid) AS "Collation",
    pg_describe_object(classid, objid, objsubid) AS "Object"
FROM pg_depend d JOIN pg_collation c ON refclassid = 'pg_collation'::regclass
AND refobjid = c.oid WHERE c.collversion <> pg_collation_actual_version(c.oid)
ORDER BY 1, 2;
```

This query returns output such as the following:

```
Collation | Object
-----+-----
(0 rows)
```

In this example, no collations need to be updated.

To get a listing of the predefined collations in your Babelfish database, you can use `psql` or `pgAdmin` with the following query:

```
SELECT * FROM pg_collation;
```

Predefined collations are stored in the `sys.fn_helpcollations` table. You can use the following command to display information about a collation (such as its `lcid`, `style`, and `collate` flags). To get a listing of all collations by using `sqlcmd`, connect to the T-SQL port (1433, by default) and run the following query:

```
1> :setvar SQLCMDMAXVARTYPEWIDTH 40
2> :setvar SQLCMDMAXFIXEDTYPEWIDTH 40
3> SELECT * FROM fn_helpcollations()
4> GO
name                description
-----
arabic_cs_as        Arabic, case-sensitive, accent-sensitive
arabic_ci_ai        Arabic, case-insensitive, accent-insensi
arabic_ci_as        Arabic, case-insensitive, accent-sensiti
bbf_unicode_bin2    Unicode-General, case-sensitive, accent-
bbf_unicode_cp1250_ci_ai    Default locale, code page 1250, case-ins
bbf_unicode_cp1250_ci_as    Default locale, code page 1250, case-ins
bbf_unicode_cp1250_cs_ai    Default locale, code page 1250, case-sen
```

```
bbf_unicode_cp1250_cs_as      Default locale, code page 1250, case-sen
bbf_unicode_pref_cp1250_cs_as Default locale, code page 1250, case-sen
bbf_unicode_cp1251_ci_ai     Default locale, code page 1251, case-ins
bbf_unicode_cp1251_ci_as     Default locale, code page 1251, case-ins
bbf_unicode_cp1254_ci_ai     Default locale, code page 1254, case-ins
...
(124 rows affected)
```

Lines 1 and 2 shown in the example narrow the output for documentation readability purposes only.

```
1> SELECT SERVERPROPERTY('COLLATION')
2> GO
serverproperty
-----
sql_latin1_general_cp1_ci_as

(1 rows affected)
1>
```

## Collation limitations and behavior differences

Babelfish uses the ICU library for collation support. PostgreSQL is built with a specific version of ICU and can match at most one version of a collation. Variations across versions are unavoidable, as are minor variations across time as languages evolve. In the following list you can find known limitations and behavior variations of Babelfish collations:

- **Indexes and collation type dependency** – An index on a user-defined type that depends on the International Components for Unicode (ICU) collation library (the library used by Babelfish) isn't invalidated when the library version changes.
- **COLLATIONPROPERTY function** – Collation properties are implemented only for the supported Babelfish BBF collations. For more information, see the [Babelfish supported collations table](#).
- **Unicode sorting rule differences** – SQL collations for SQL Server sort Unicode-encoded data (`nchar` and `nvarchar`) differently than data that's not Unicode-encoded (`char` and `varchar`). Babelfish databases are always UTF-8 encoded and always apply Unicode sorting rules consistently, regardless of data type, so the sort order for `char` or `varchar` is the same as it is for `nchar` or `nvarchar`.
- **Secondary-equal collations and sorting behavior** – The default ICU Unicode secondary-equal (`CI_AS`) collation sorts punctuation marks and other nonalphanumeric characters before

numeric characters, and numeric characters before alphabetic characters. However, the order of punctuation and other special characters is different.

- **Tertiary collations, workaround for ORDER BY** – SQL collations, such as `SQL_Latin1_General_Pref_CP1_CI_AS`, support the `TERTIARY_WEIGHTS` function and the ability to sort strings that compare equally in a `CI_AS` collation to be sorted uppercase first: `ABC`, `ABc`, `AbC`, `Abc`, `aBC`, `aBc`, `abC`, and finally `abc`. Thus, the `DENSE_RANK OVER (ORDER BY column)` analytic function assesses these strings as having the same rank but orders them uppercase first within a partition.

You can get a similar result with Babelfish by adding a `COLLATE` clause to the `ORDER BY` clause that specifies a tertiary `CS_AS` collation that specifies `@colCaseFirst=upper`. However, the `colCaseFirst` modifier applies only to strings that are tertiary-equal (rather than secondary-equal such as with `CI_AS` collation). Thus, you can't emulate tertiary SQL collations using a single ICU collation.

As a workaround, we recommend that you modify applications that use the `SQL_Latin1_General_Pref_CP1_CI_AS` collation to use the `BBF_SQL_Latin1_General_CP1_CI_AS` collation first. Then add `COLLATE BBF_SQL_Latin1_General_Pref_CP1_CS_AS` to any `ORDER BY` clause for this column.

- **Character expansion** – A character expansion treats a single character as equal to a sequence of characters at the primary level. SQL Server's default `CI_AS` collation supports character expansion. ICU collations support character expansion for accent-insensitive collations only.

When character expansion is required, then use a `AI` collation for comparisons. However, such collations aren't currently supported by the `LIKE` operator.

- **char and varchar encoding** – When SQL collations are used for `char` or `varchar` data types, the sort order for characters preceding ASCII 127 is determined by the specific code page for that SQL collation. For SQL collations, strings declared as `char` or `varchar` might sort differently than strings declared as `nchar` or `nvarchar`.

PostgreSQL encodes all strings with the database encoding, so all characters are converted to UTF-8 and sorted using Unicode rules.

Because SQL collations sort `nchar` and `nvarchar` data types using Unicode rules, Babelfish encodes all strings on the server using UTF-8. Babelfish sorts `nchar` and `nvarchar` strings the same way it sorts `char` and `varchar` strings, using Unicode rules.

- **Supplementary character** – The SQL Server functions NCHAR, UNICODE, and LEN support characters for code-points outside the Unicode Basic Multilingual Plane (BMP). In contrast, non-SC collations use surrogate pair characters to handle supplementary characters. For Unicode data types, SQL Server can represent up to 65,535 characters using UCS-2, or the full Unicode range (1,114,114 characters) if supplementary characters are used.
- **Kana-sensitive (KS) collations** – A Kana-sensitive (KS) collation is one that treats Hiragana and Katakana Japanese Kana characters differently. ICU supports the Japanese collation standard JIS X 4061. The now deprecated `colhiraganaQ [on | off]` locale modifier might provide the same functionality as KS collations. However, KS collations of the same name as SQL Server aren't currently supported by Babelfish.
- **Width-sensitive (WS) collations** – When a single-byte character (half-width) and the same character represented as a double-byte character (full-width) are treated differently, the collation is called *width-sensitive (WS)*. WS collations with the same name as SQL Server aren't currently supported by Babelfish.
- **Variation-selector sensitive (VSS) collations** – Variation-selector sensitive (VSS) collations distinguish between ideographic variation selectors in Japanese collations `Japanese_Bushu_Kakusu_140` and `Japanese_XJIS_140`. A variation sequence is made up of a base character plus an additional variation selector. If you don't select the `_VSS` option, the variation selector isn't considered in the comparison.

VSS collations aren't currently supported by Babelfish.

- **BIN and BIN2 collations** – A BIN2 collation sorts characters according to code point order. The byte-by-byte binary order of UTF-8 preserves Unicode code point order, so this is also likely to be the best-performing collation. If Unicode code point order works for an application, consider using a BIN2 collation. However, using a BIN2 collation can result in data being displayed on the client in an order that is culturally unexpected. New mappings to lowercase characters are added to Unicode as time progresses, so the LOWER function might perform differently on different versions of ICU. This is a special case of the more general collation versioning problem rather than as something specific to the BIN2 collation.

Babelfish provides the `BBF_Latin1_General_BIN2` collation with the Babelfish distribution to collate in Unicode code point order. In a BIN collation only the first character is sorted as a `wchar`. Remaining characters are sorted byte-by-byte, effectively in code point order according to its encoding. This approach doesn't follow Unicode collation rules and isn't supported by Babelfish.

- **Non-deterministic collations and CHARINDEX limitation** – For Babelfish releases older than version 2.1.0, you can't use CHARINDEX with non-deterministic collations. By default, Babelfish

uses a case-insensitive (non-deterministic) collation. Using CHARINDEX for older versions of Babelfish raises the following runtime error:

```
nondeterministic collations are not supported for substring searches
```

### Note

This limitation and workaround apply to Babelfish version 1.x only (Aurora PostgreSQL 13.x versions). Babelfish 2.1.0 and higher releases don't have this issue.

You can work around this issue in one of the following ways:

- Explicitly convert the expression to a case-sensitive collation and case-fold both arguments by applying LOWER or UPPER. For example, `SELECT charindex('x', a) FROM t1` would become the following:

```
SELECT charindex(LOWER('x'), LOWER(a COLLATE sql_latin1_general_cp1_cs_as)) FROM t1
```

- Create a SQL function `f_charindex`, and replace CHARINDEX calls with calls to the following function:

```
CREATE function f_charindex(@s1 varchar(max), @s2 varchar(max)) RETURNS int
AS
BEGIN
declare @i int = 1
WHILE len(@s2) >= len(@s1)
BEGIN
    if LOWER(@s1) = LOWER(substring(@s2,1,len(@s1))) return @i
    set @i += 1
    set @s2 = substring(@s2,2,999999999)
END
return 0
END
go
```

## Managing Babelfish error handling with escape hatches

Babelfish mimics SQL behavior for control flow and transaction state whenever possible. When Babelfish encounters an error, it returns an error code similar to the SQL Server error code. If Babelfish can't map the error to a SQL Server code, it returns a fixed error code (33557097) and takes specific actions based on the type of error, as follows:

- For compile time errors, Babelfish rolls back the transaction.
- For runtime errors, Babelfish ends the batch and rolls back the transaction.
- For protocol error between client and server, the transaction isn't rolled back.

If an error code can't be mapped to an equivalent code and the code for a similar error is available, the error code is mapped to the alternative code. For example, the behaviors that cause SQL Server codes 8143 and 8144 are both mapped to 8143.

Errors that can't be mapped don't respect a TRY . . . CATCH construct.

You can use @@ERROR to return a SQL Server error code, or the @@PGERROR function to return a PostgreSQL error code. You can also use the `fn_mapped_system_error_list` function to return a list of mapped error codes. For information about PostgreSQL error codes, see [the PostgreSQL website](#).

### Modifying Babelfish escape hatch settings

To handle statements that might fail, Babelfish defines certain options called escape hatches. An *escape hatch* is an option that specifies Babelfish behavior when it encounters an unsupported feature or syntax.

You can use the `sp_babelfish_configure` stored procedure to control the settings of an escape hatch. Use the script to set the escape hatch to `ignore` or `strict`. If it's set to `strict`, Babelfish returns an error that you need to correct before continuing.

To apply changes to the current session and on the cluster level, include the `server` keyword.

The usage is as follows:

- To list all escape hatches and their status, plus usage information, run `sp_babelfish_configure`.

- To list the named escape hatches and their values, for the current session or cluster-wide, run the command `sp_babelfish_configure 'hatch_name'` where *hatch\_name* is the identifier of one or more escape hatches. *hatch\_name* can use SQL wildcards, such as '%'.
- To set one or more escape hatches to the value specified, run `sp_babelfish_configure ['hatch_name' [, 'strict'|'ignore' [, 'server']]]`. To make the settings permanent on a cluster-wide level, include the `server` keyword, such as shown in the following:

```
EXECUTE sp_babelfish_configure 'escape_hatch_unique_constraint', 'ignore', 'server'
```

To set them for the current session only, don't use `server`.

- To reset all escape hatches to their default values, run `sp_babelfish_configure 'default'` (Babelfish 1.2.0 and higher).

The string identifying the hatch (or hatches) can include SQL wildcards. For example, the following sets all syntax escape hatches to `ignore` for the Aurora PostgreSQL cluster.

```
EXECUTE sp_babelfish_configure '%', 'ignore', 'server'
```

In the following table you can find descriptions and default values for the Babelfish predefined escape hatches.

Escape hatch	Description	Default
<code>escape_hatch_checkpoint</code>	Allows the use of CHECKPOINT statement in the procedural code, but the CHECKPOINT statement is currently not implemented.	ignore
<code>escape_hatch_constraint_name_for_default</code>	Controls Babelfish behavior related to default constraint names.	ignore
<code>escape_hatch_database_misc_options</code>	Controls Babelfish behavior related to the following options on CREATE DATABASE:	ignore

Escape hatch	Description	Default
	CONTAINMENT, DB_CHAINING, TRUSTWORTHY, PERSISTENT_LOG_BUFFER.	
escape_hatch_for_replication	Controls Babelfish behavior related to the [NOT] FOR REPLICATION clause when creating or altering a table.	strict
escape_hatch_fulltext	Controls Babelfish behavior related to FULLTEXT features, such a DEFAULT_FULLTEXT_LANGUAGE in CREATE/ALTER DATABASE, CREATE FULLTEXT INDEX, or sp_fulltext_database.	ignore
escape_hatch_ignore_dup_key	Controls Babelfish behavior related to CREATE/ALTER TABLE and CREATE INDEX. When IGNORE_DUP_KEY=ON, raises an error when set to strict (the default) or ignores the error when set to ignore (Babelfish version 1.2.0 and higher).	strict
escape_hatch_index_clustering	Controls Babelfish behavior related to the CLUSTERED or NONCLUSTERED keywords for indexes and PRIMARY KEY or UNIQUE constraints. When CLUSTERED is ignored, the index or constraint is still created as if NONCLUSTERED was specified.	ignore

Escape hatch	Description	Default
<code>escape_hatch_index_columnstore</code>	Controls Babelfish behavior related to the COLUMNSTORE clause. If you specify <code>ignore</code> , Babelfish creates a regular B-tree index.	<code>strict</code>
<code>escape_hatch_join_hints</code>	Controls the behavior of keywords in a JOIN operator: LOOP, HASH, MERGE, REMOTE, REDUCE, REDISTRIBUTE, REPLICATE.	<code>ignore</code>
<code>escape_hatch_language_non_english</code>	Controls Babelfish behavior related to languages other than English for onscreen messages. Babelfish currently supports only <code>us_english</code> for onscreen messages. SET LANGUAGE might use a variable containing the language name, so the actual language being set can only be detected at run time.	<code>strict</code>
<code>escape_hatch_login_hashed_password</code>	When ignored, suppresses the error for the HASHED keyword for CREATE LOGIN and ALTER LOGIN.	<code>strict</code>

Escape hatch	Description	Default
escape_hatch_login_misc_options	When ignored, suppresses the error for other keywords besides HASHED, MUST_CHANGE , OLD_PASSWORD , and UNLOCK for CREATE LOGIN and ALTER LOGIN.	strict
escape_hatch_login_old_password	When ignored, suppresses the error for the OLD_PASSWORD keyword for CREATE LOGIN and ALTER LOGIN.	strict
escape_hatch_login_password_must_change	When ignored, suppresses the error for the MUST_CHANGE keyword for CREATE LOGIN and ALTER LOGIN.	strict
escape_hatch_login_password_unlock	When ignored, suppresses the error for the UNLOCK keyword for CREATE LOGIN and ALTER LOGIN.	strict
escape_hatch_nocheck_add_constraint	Controls Babelfish behavior related to the WITH CHECK or NOCHECK clause for constraints.	strict
escape_hatch_nocheck_existing_constraint	Controls Babelfish behavior related to FOREIGN KEY or CHECK constraints.	strict

Escape hatch	Description	Default
escape_hatch_query_hints	Controls Babelfish behavior related to query hints. When this option is set to <code>ignore</code> , the server ignores hints that use the <code>OPTION (...)</code> clause to specify query processing aspects. Examples include <code>SELECT FROM ... OPTION(MERGE JOIN HASH, MAXRECURSION 10))</code> .	ignore
escape_hatch_rowversion	Controls the behavior of the <code>ROWVERSION</code> and <code>TIMESTAMP</code> datatypes. For usage information, see <a href="#">Using Babelfish features with limited implementation</a> .	strict
escape_hatch_schemabinding_function	Controls Babelfish behavior related to the <code>WITH SCHEMABINDING</code> clause. By default, the <code>WITH SCHEMABINDING</code> clause is ignored when specified with the <code>CREATE</code> or <code>ALTER FUNCTION</code> command.	ignore
escape_hatch_schemabinding_procedure	Controls Babelfish behavior related to the <code>WITH SCHEMABINDING</code> clause. By default, the <code>WITH SCHEMABINDING</code> clause is ignored when specified with the <code>CREATE</code> or <code>ALTER PROCEDURE</code> command.	ignore

Escape hatch	Description	Default
<code>escape_hatch_rowguidcol_column</code>	Controls Babelfish behavior related to the ROWGUIDCOL clause when creating or altering a table.	strict
<code>escape_hatch_schemabinding_trigger</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER TRIGGER command.	ignore
<code>escape_hatch_schemabinding_view</code>	Controls Babelfish behavior related to the WITH SCHEMABINDING clause. By default, the WITH SCHEMABINDING clause is ignored when specified with the CREATE or ALTER VIEW command.	ignore
<code>escape_hatch_session_settings</code>	Controls Babelfish behavior toward unsupported session-level SET statements.	ignore
<code>escape_hatch_showplan_all</code>	Controls Babelfish behavior related to SET SHOWPLAN_ALL and SET STATISTICS PROFILE. When set to ignore, they behave like SET BABELFISH_SHOWPLAN_ALL and SET BABELFISH_STATISTICS PROFILE; when set to strict, they are silently ignored.	strict

Escape hatch	Description	Default
escape_hatch_storage_on_partition	Controls Babelfish behavior related to the ON partition_scheme column clause when defining partitioning. Babelfish currently doesn't implement partitioning.	strict
escape_hatch_storage_options	Escape hatch on any storage option used in CREATE, ALTER DATABASE, TABLE, INDEX. This includes clauses (LOG) ON, TEXTIMAGE_ON, FILESTREAM_ON that define storage locations (partitions, file groups) for tables, indexes, and constraints, and also for a database. This escape hatch setting applies to all of these clauses (including ON [PRIMARY] and ON "DEFAULT"). The exception is when a partition is specified for a table or index with ON partition_scheme (column).	ignore
escape_hatch_table_hints	Controls the behavior of table hints specified using the WITH (...) clause.	ignore

Escape hatch	Description	Default
escape_hatch_unique_constraint	<p>When set to strict, an obscure semantic difference between SQL Server and PostgreSQL in handling NULL values on indexed columns can raise errors. The semantic difference only emerges in unrealistic use cases, so you can set this escape hatch to 'ignore' to avoid seeing the error.</p> <p>Deprecated from the following versions: 3.6.0 and higher versions, 4.2.0 and higher versions</p>	strict

## Creating a Babelfish for Aurora PostgreSQL DB cluster

Babelfish for Aurora PostgreSQL is supported on Aurora PostgreSQL version 13.4 and higher.

You can use the Amazon Web Services Management Console or the Amazon CLI to create an Aurora PostgreSQL cluster with Babelfish.

### Note

In an Aurora PostgreSQL cluster, the `babelfish_db` database name is reserved for Babelfish. Creating your own "babelfish\_db" database on a Babelfish for Aurora PostgreSQL prevents Aurora from successfully provisioning Babelfish.

## Console

### To create a cluster with Babelfish running with the Amazon Web Services Management Console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>, and choose **Create database**.

The screenshot displays the Amazon RDS console interface for creating a database. The main content area is titled 'Resources' and shows a summary of resources used in the US West (Oregon) region. It lists various resource types and their current usage/limits, such as DB instances (0/40), DB clusters (0/40), snapshots (0), and parameter groups (0). A 'Refresh' button is located in the top right of this section. Below the resource summary, there is a 'Create database' section with a brief description of Amazon RDS and two buttons: 'Restore from S3' and 'Create database' (highlighted in orange). The right sidebar, titled 'Recommended for you', contains several links to helpful guides and documentation, including 'Build RDS Operational Tasks', 'Amazon RDS Backup and Restore using Backup', 'Time-Series Tables in PostgreSQL', and 'Implementing Cross-Region DR'.

2. For **Choose a database creation method**, do one of the following:
  - To specify detailed engine options, choose **Standard create**.
  - To use preconfigured options that support best practices for an Aurora cluster, choose **Easy create**.
3. For **Engine type**, choose **Aurora (PostgreSQL Compatible)**.

4. Choose **Show filters**, and then choose **Show versions that support the Babelfish for PostgreSQL feature** to list the engine types that support Babelfish. Babelfish is currently supported on Aurora PostgreSQL 13.4 and higher versions.
5. For **Available versions**, choose an Aurora PostgreSQL version. To get the latest Babelfish features, choose the highest Aurora PostgreSQL major version.

**Engine version** [Info](#)  
View the engine versions that support the following database features.

▼ **Hide filters**

---

**Show versions that support the global database feature**  
Allows a single Amazon Aurora database to span multiple  Regions.

**Show versions that support the Babelfish for PostgreSQL feature**  
Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

Available versions (2/20) [Info](#)

Aurora PostgreSQL (Compatible with PostgreSQL 13.4) ▼

6. For **Templates**, choose the template that matches your use case.
7. For **DB cluster identifier**, enter a name that you can easily find later in the DB cluster list.
8. For **Master username**, enter an administrator user name. The default value for Aurora PostgreSQL is `postgres`. You can accept the default or choose a different name. For example, to follow the naming convention used on your SQL Server databases, you can enter `sa` (system administrator) for the Master username.

If you don't create a user named `sa` at this time, you can create one later with your choice of client. After creating the user, use the `ALTER SERVER ROLE` command to add it to the `sysadmin` group (role) for the cluster.

### **Warning**

Master username must always use lowercase characters failing which the DB cluster can't connect to Babelfish via the TDS port.

9. For **Master password**, create a strong password and confirm the password.
10. For the options that follow, until the **Babelfish settings** section, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters](#).

11. To make Babelfish functionality available, select the **Turn on Babelfish** box.

### Database authentication

Database authentication options [Info](#)

- Password authentication**  
Authenticates using database passwords.
- Password and IAM database authentication**  
Authenticates using the database password and user credentials through  IAM users and roles.
- Password and Kerberos authentication**  
Choose a directory in which you want to allow authorized users to authenticate with this DB instance using Kerberos Authentication.

---

### Babelfish settings - new [Info](#)

Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

- Turn on Babelfish**  
Babelfish uses default values for database mode, strict mode, time zone, collation, and Tabular Data Stream (TDS) port if you don't modify these settings in the "Additional configuration" section below. RDS creates a DB cluster parameter group for you to store the settings.

12. For **DB cluster parameter group**, do one of the following:

- Choose **Create new** to create a new parameter group with Babelfish turned on.
- Choose **Choose existing** to use an existing parameter group. If you use an existing group, make sure to modify the group before creating the cluster and add values for Babelfish parameters. For information about Babelfish parameters, see [DB cluster parameter group settings for Babelfish](#).

If you use an existing group, provide the group name in the box that follows.

13. For **Database migration mode**, choose one of the following:

- **Single database** to migrate a single SQL Server database.

In some cases, you might migrate multiple user databases together, with your end goal a complete migration to native Aurora PostgreSQL without Babelfish. If the final applications require consolidated schemas (a single dbo schema), make sure to first consolidate your SQL

Server databases into a single SQL server database. Then migrate to Babelfish using **Single database** mode.

- **Multiple databases** to migrate multiple SQL Server databases (originating from a single SQL Server installation). Multiple database mode doesn't consolidate multiple databases that don't originate from a single SQL Server installation. For information about migrating multiple databases, see [Using Babelfish with a single database or multiple databases](#).

### Note

From Aurora PostgreSQL 16 version, **Multiple databases** is chosen by default as the Database migration mode.

## ▼ Additional configuration

Database options, encryption enabled, failover, backup enabled, backtrack disabled, Performance Insights enabled, Enhanced Monitoring enabled, maintenance, CloudWatch Logs, delete protection disabled.

### Database options

#### DB cluster parameter group [Info](#)

Choose a compatible DB Cluster parameter group to turn on Babelfish feature for your database.

**Create new**

Creates a custom DB cluster parameter group with Babelfish parameters turned on.

**Choose existing**

Choose an existing DB cluster parameter group with Babelfish parameters turned on.

#### New custom DB cluster parameter group name

custom-aurora-postgresql13-babelfish-compat-1

### Babelfish configuration

#### Database migration mode [Info](#)

**Single database**

Use for migrating a single SQL Server database. Migrated schema names are identical between TDS connections and PostgreSQL connections.

**Multiple databases**

Use for migrating multiple SQL Server databases together. Migrated database and schema names are mapped to similar schema names in PostgreSQL.

14. For **Default collation locale**, enter your server locale. The default is en-US. For detailed information about collations, see [Understanding Collations in Babelfish for Aurora PostgreSQL](#).
15. For **Collation name** field, enter your default collation. The default is sql\_latin1\_general\_cp1\_ci\_as. For detailed information, see [Understanding Collations in Babelfish for Aurora PostgreSQL](#).
16. For **Babelfish TDS port**, enter the default port 1433. Currently, Babelfish only supports port 1433 for your DB cluster.
17. For **DB parameter group**, choose a parameter group or have Aurora create a new group for you with default settings.
18. For **Failover priority**, choose a failover priority for the instance. If you don't choose a value, the default is tier-1. This priority determines the order in which replicas are promoted when recovering from a primary instance failure. For more information, see [Fault tolerance for an Aurora DB cluster](#).
19. For **Backup retention period**, choose the length of time (1–35 days) that Aurora retains backup copies of the database. You can use backup copies for point-in-time restores (PITR) of your database down to the second. The default retention period is seven days.

**Default collation locale** [Info](#)

en-US ▼

**Collation name** [Info](#)

sql\_latin1\_general\_cp1\_ci\_as ▼

**Babelfish TDS port** [Info](#)

TDS port that the database will use for application connections.

1433 ▼

**DB parameter group** [Info](#)

default.aurora-postgresql13 ▼

**Option group** [Info](#)

default:aurora-postgresql-13 ▼

**Failover priority**

No preference ▼

## Backup

**Backup retention period** [Info](#)

Choose the number of days that RDS should retain automatic backups for this instance.

7 days ▼

20. Choose **Copy tags to snapshots** to copy any DB instance tags to a DB snapshot when you create a snapshot.

**Note**

When restoring a DB cluster from a snapshot, it does not restore as a Babelfish for Aurora PostgreSQL DB cluster. You need to turn on the parameters that control Babelfish preferences in the DB cluster parameter group to enable Babelfish again. For more information on the Babelfish parameters, see [DB cluster parameter group settings for Babelfish](#).

21. Choose **Enable encryption** to turn on encryption at rest (Aurora storage encryption) for this DB cluster.
22. Choose **Enable Performance Insights** to turn on Amazon RDS Performance Insights.
23. Choose **Enable Enhanced monitoring** to start gathering metrics in real time for the operating system that your DB cluster runs on.
24. Choose **PostgreSQL log** to publish the log files to Amazon CloudWatch Logs.
25. Choose **Enable auto minor version upgrade** to automatically update your Aurora DB cluster when a minor version upgrade is available.
26. For **Maintenance window**, do the following:
  - To choose a time for Amazon RDS to make modifications or perform maintenance, choose **Select window**.
  - To perform Amazon RDS maintenance at an unscheduled time, choose **No preference**.
27. Select the **Enable deletion protection** box to protect your database from being deleted by accident.

If you turn on this feature, you can't directly delete the database. Instead, you need to modify the database cluster and turn off this feature before deleting the database.

## Maintenance

Auto minor version upgrade [Info](#)

**Enable auto minor version upgrade**

Enabling auto minor version upgrade will automatically upgrade to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database.

### Maintenance window [Info](#)

Select the period you want pending modifications or maintenance applied to the database by Amazon RDS.

**Select window**

**No preference**

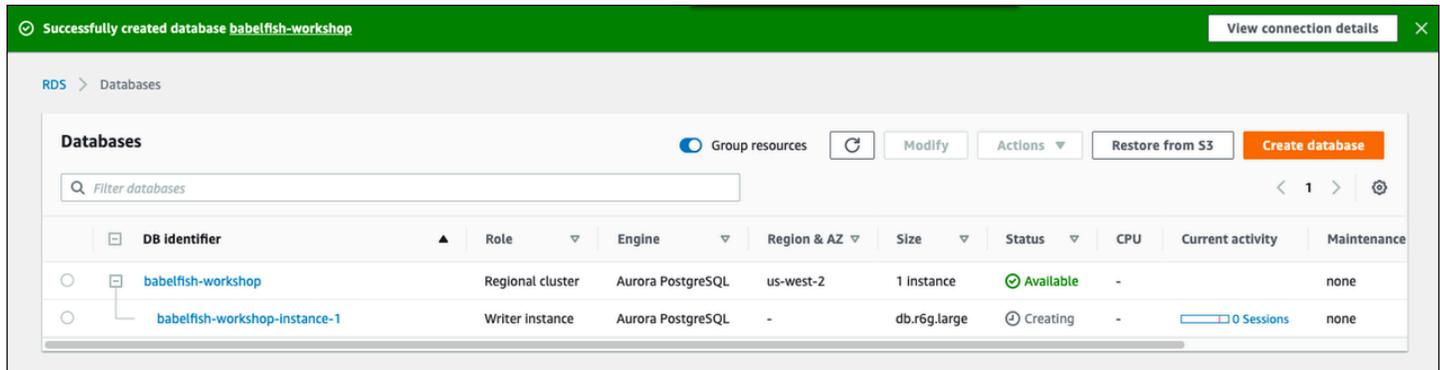

## Deletion protection

**Enable deletion protection**

Protects the database from being deleted accidentally. While this option is enabled, you can't delete the database.

28. Choose **Create database**.

You can find your new database set up for Babelfish in the **Databases** listing. The **Status** column displays **Available** when the deployment is complete.

## Amazon CLI

When you create an Babelfish for Aurora PostgreSQL; using the Amazon CLI, you need to pass the command the name of the DB cluster parameter group to use for the cluster. For more information, see [DB cluster prerequisites](#).

Before you can use the Amazon CLI to create an Aurora PostgreSQL cluster with Babelfish, do the following:

- Choose your endpoint URL from the list of services at [Amazon Aurora endpoints and quotas](#).
- Create a parameter group for the cluster. For more information about parameter groups, see [Parameter groups for Amazon Aurora](#).
- Modify the parameter group, adding the parameter that turns on Babelfish.

## To create an Aurora PostgreSQL DB cluster with Babelfish using the Amazon CLI

The examples that follow use the default Master username, postgres. Replace as needed with the username that you created for your DB cluster, such as sa or whatever username you chose if you didn't accept the default.

1. Create a parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
--endpoint-url endpoint-url \
--db-cluster-parameter-group-name parameter-group \
```

```
--db-parameter-group-family aurora-postgresql14 \  
--description "description"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^  
--endpoint-url endpoint-URL ^  
--db-cluster-parameter-group-name parameter-group ^  
--db-parameter-group-family aurora-postgresql14 ^  
--description "description"
```

## 2. Modify your parameter group to turn on Babelfish.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
--endpoint-url endpoint-url \  
--db-cluster-parameter-group-name parameter-group \  
--parameters  
"ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
--endpoint-url endpoint-url ^  
--db-cluster-parameter-group-name parameter-group ^  
--parameters  
"ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

## 3. Identify your DB subnet group and the virtual private cloud (VPC) security group ID for your new DB cluster, and then call the [create-db-cluster](#) command.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
--db-cluster-identifier cluster-name \  
--master-username postgres \  
--manage-master-user-password \  
--engine aurora-postgresql \  
--engine-version 14.3 \  
--vpc-security-group-ids security-group \  
--db-subnet-group-name subnet-group-name \  
--db-subnet-ids subnet-ids \  
--availability-zone availability-zone \  
--region region
```

```
--db-cluster-parameter-group-name parameter-group
```

For Windows:

```
aws rds create-db-cluster ^  
--db-cluster-identifier cluster-name ^  
--master-username postgres ^  
--manage-master-user-password ^  
--engine aurora-postgresql ^  
--engine-version 14.3 ^  
--vpc-security-group-ids security-group ^  
--db-subnet-group-name subnet-group ^  
--db-cluster-parameter-group-name parameter-group
```

This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

4. Explicitly create the primary instance for your DB cluster. Use the name of the cluster that you created in step 3 for the `--db-cluster-identifier` argument when you call the [create-db-instance](#) command, as shown following.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
--db-instance-identifier instance-name \  
--db-instance-class db.r6g \  
--db-subnet-group-name subnet-group \  
--db-cluster-identifier cluster-name \  
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^  
--db-instance-identifier instance-name ^  
--db-instance-class db.r6g ^  
--db-subnet-group-name subnet-group ^  
--db-cluster-identifier cluster-name ^  
--engine aurora-postgresql
```

# Migrating a SQL Server database to Babelfish for Aurora PostgreSQL

You can use Babelfish for Aurora PostgreSQL to migrate an SQL Server database to an Amazon Aurora PostgreSQL DB cluster. Before migrating, review [Using Babelfish with a single database or multiple databases](#).

## Topics

- [Overview of the migration process](#)
- [Evaluating and handling differences between SQL Server and Babelfish](#)
- [Import/export tools for migrating from SQL Server to Babelfish](#)

## Overview of the migration process

The following summary lists the steps required to successfully migrate your SQL Server application and make it work with Babelfish. For information about the tools you can use for the export and import processes and for more detail, see [Import/export tools for migrating from SQL Server to Babelfish](#). To load the data, we recommend using Amazon DMS with an Aurora PostgreSQL DB cluster as the target endpoint.

1. Create a new Aurora PostgreSQL DB cluster with Babelfish turned on. To learn how, see [Creating a Babelfish for Aurora PostgreSQL DB cluster](#).

To import the various SQL artifacts exported from your SQL Server database, connect to the Babelfish cluster using a SQL Server tool such as [sqlcmd](#). For more information, see [Using a SQL Server client to connect to your DB cluster](#).

2. On the SQL Server database that you want to migrate, export the data definition language (DDL). The DDL is SQL code that describes database objects that contain user data (such as tables, indexes, and views) and user-written database code (such as stored procedures, user-defined functions, and triggers).

For more information, see [Using SQL Server Management Studio \(SSMS\) to migrate to Babelfish](#).

3. Run an assessment tool to evaluate the scope of any changes that you might need to make so that Babelfish can effectively support the application running on SQL Server. For more information, see [Evaluating and handling differences between SQL Server and Babelfish](#).
4. Review the Amazon DMS target endpoint limitations and update the DDL script as necessary. For more information, see Limitations to using a PostgreSQL target endpoint with Babelfish tables in [Using Babelfish for Aurora PostgreSQL as a target](#).

5. On your new Babelfish DB cluster, run the DDL within your specified T-SQL database to create only the schemas, user-defined data types, and tables with their primary key constraints.
6. Use Amazon DMS to migrate your data from SQL Server to Babelfish tables. For continuous replication using SQL Server Change Data Capture or SQL Replication, use Aurora PostgreSQL instead of Babelfish as the endpoint. To do so, see the [Using Babelfish for Aurora PostgreSQL as a target for Amazon Database Migration Service](#).
7. When the data load completes, create all the remaining T-SQL objects that support the application on your Babelfish cluster.
8. Reconfigure your client application to connect to the Babelfish endpoint instead of your SQL Server database. For more information, see [Connecting to a Babelfish DB cluster](#).
9. Modify your application as needed and retest. For more information, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server](#).

You still need to assess your client-side SQL queries. The schemas generated from your SQL Server instance convert only the server-side SQL code. We recommend that you take the following steps:

- Capture client-side queries by using the SQL Server Profiler with the TSQL\_Replay predefined template. This template captures T-SQL statement information that you can then replay for iterative tuning and testing. You can start the profiler within SQL Server Management Studio from the **Tools** menu. Choose **SQL Server Profiler** to open the profiler and choose the TSQL\_Replay template.

To use for your Babelfish migration, start a trace and then run your application using your functional tests. The profiler captures the T-SQL statements. When you finish testing, stop the trace. Save the result to an XML file with your client-side queries (File > Save as > Trace XML File for Replay).

For more information, see [SQL Server Profiler](#) in the Microsoft documentation. For more information about the TSQL\_Replay template, see [SQL Server Profiler Templates](#).

- For applications with complex client-side SQL queries, we recommend that you use Babelfish Compass to analyze these queries for Babelfish compatibility. If the analysis indicates that the client-side SQL statements contain unsupported SQL features, review the SQL aspects in the client application and modify as needed.
- You can also capture the SQL queries as extended events (.xel format). To do so, use the SSMS XEvent Profiler. After generating the .xel file, extract the SQL statements into .xml files that

Compass can then process. For more information, see [Use the SSMS XEvent Profiler](#) in the Microsoft documentation.

When you're satisfied with all testing, analysis, and any modifications needed for your migrated application, you can start using your Babelfish database for production. To do so, stop the original database and redirect live client applications to use the Babelfish TDS port.

#### Note

Amazon DMS now supports replicating data from Babelfish. For more information, see [Amazon DMS now supports Babelfish for Aurora PostgreSQL as a source](#).

## Evaluating and handling differences between SQL Server and Babelfish

For best results, we recommend that you evaluate the generated DDL/DML and the client query code before actually migrating your SQL Server database application to Babelfish. Depending on the version of Babelfish and the specific features of SQL Server that your application implements, you might need to refactor your application or use alternatives for functionality that aren't fully supported yet in Babelfish.

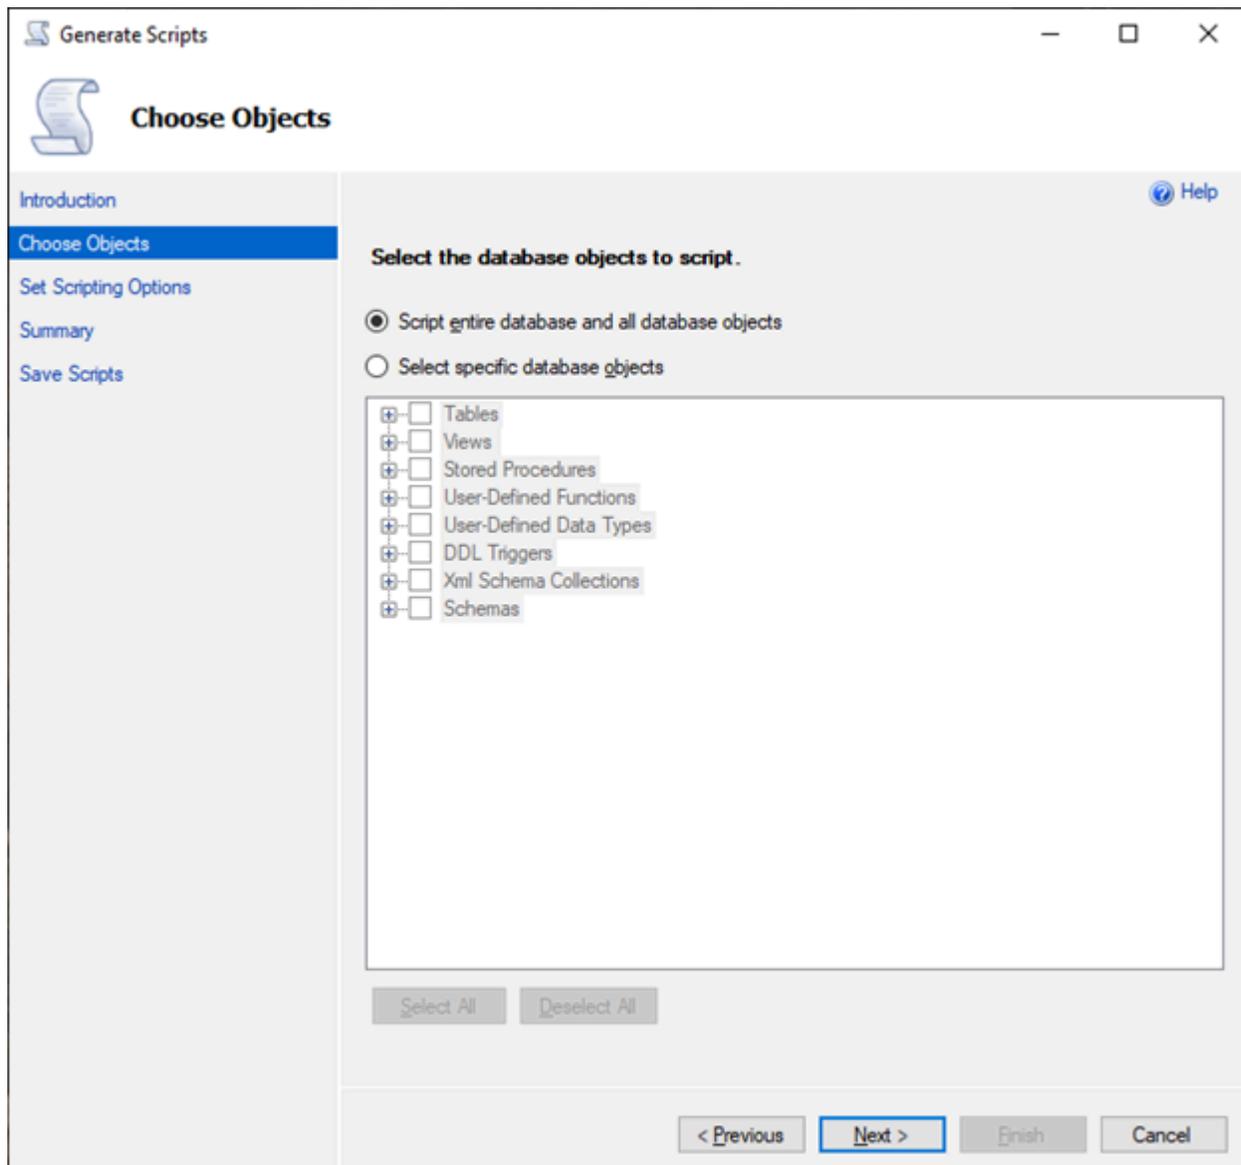

- To assess your SQL Server application code, use Babelfish Compass on the generated DDL to determine how much T-SQL code is supported by Babelfish. Identify T-SQL code that might need modifications before running on Babelfish. For more information about this tool, see [Babelfish Compass tool](#) on GitHub.

#### Note

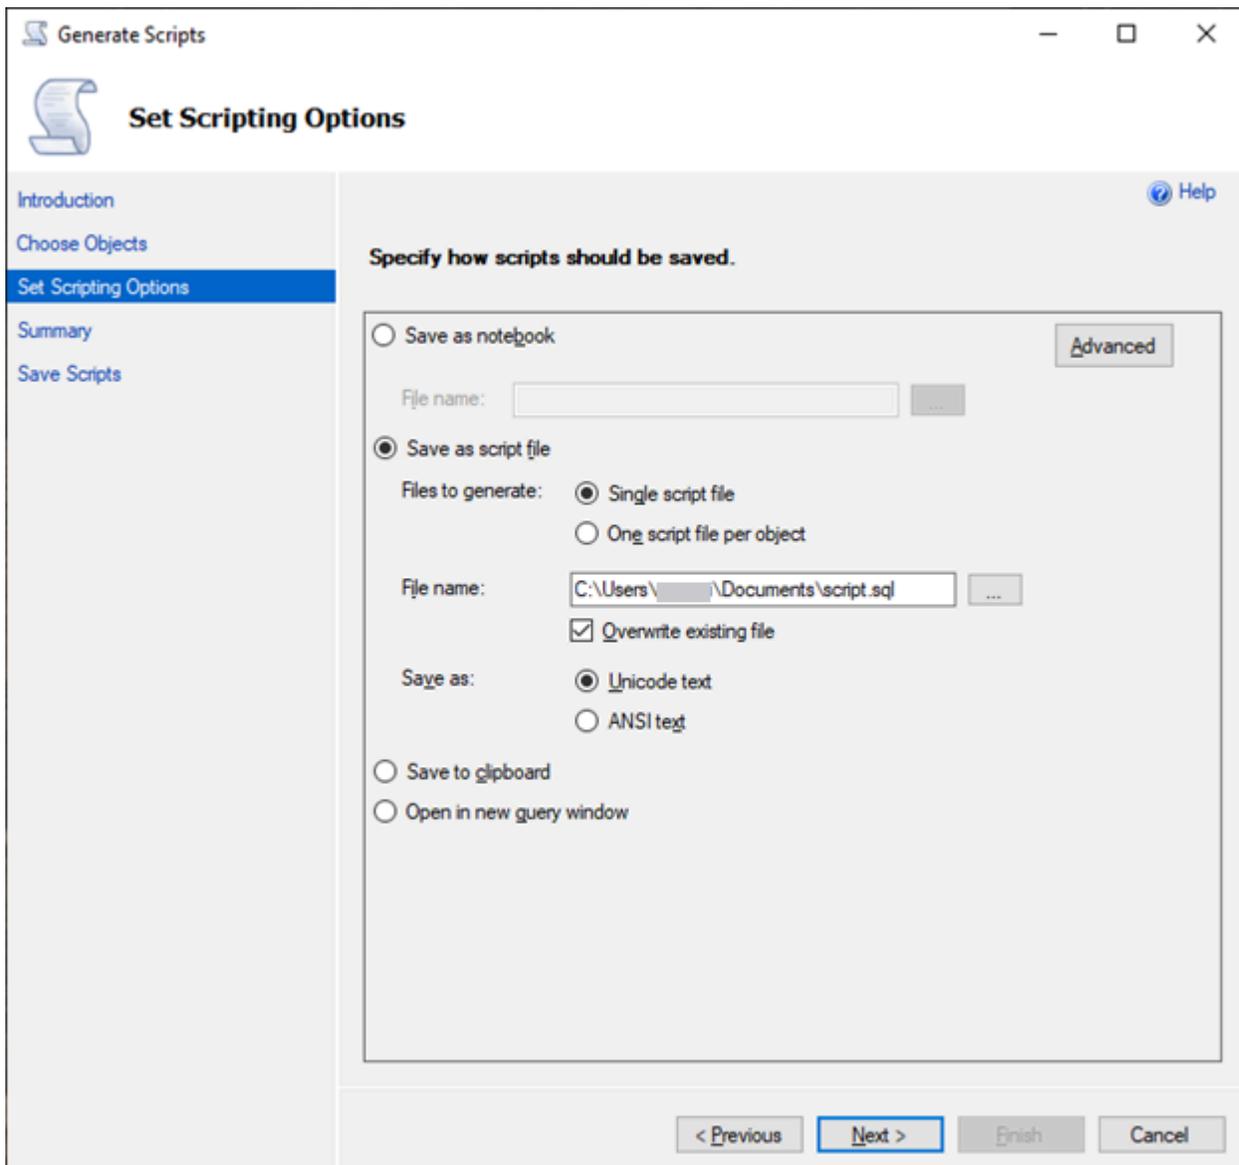

Babelfish Compass is an open-source tool. Report any issues with Babelfish Compass through GitHub instead of through Amazon Support.

You can use Generate Script Wizard with SQL Server Management Studio (SSMS) to generate the SQL file that is assessed by Babelfish Compass or Amazon Schema Conversion Tool CLI. We recommend the following steps to streamline the assessment.

1. On the **Choose Objects** page, choose **Script entire database and all database objects**.

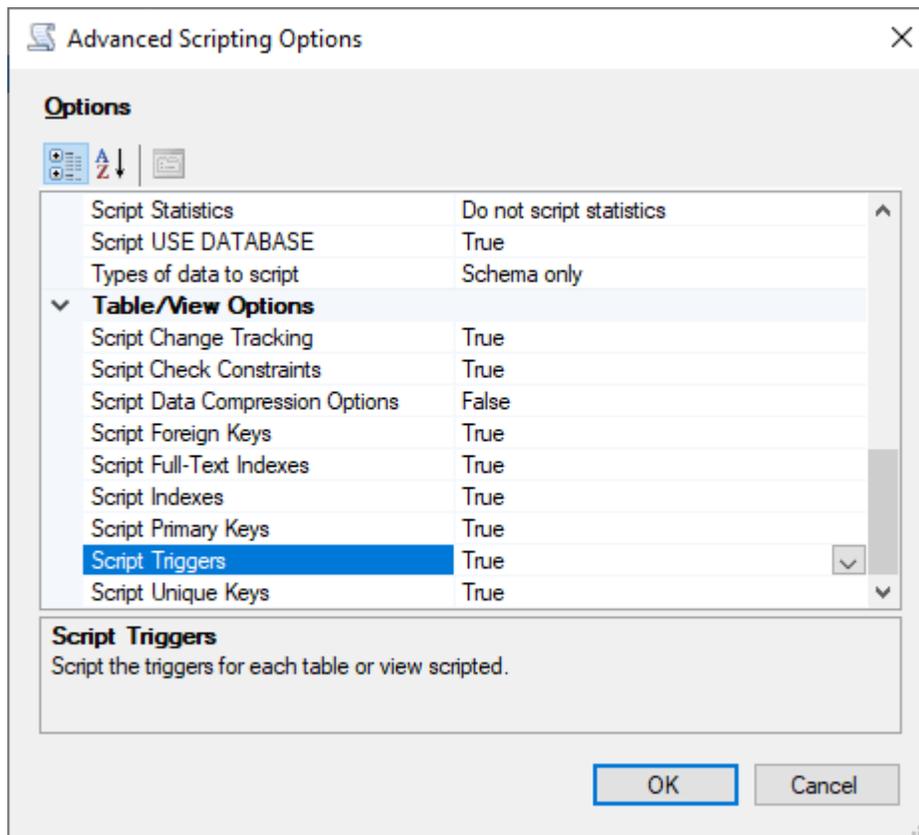

2. For the **Set Scripting Options**, choose **Save as script file** as a **Single script file**.

3. Choose **Advanced** to change the default scripting options to identify features that normally are set to false for a full assessment:

- Script Change Tracking to True
- Script Full-Text Indexes to True
- Script Triggers to True
- Script Logins to True
- Script Owner to True
- Script Object-Level Permissions to True
- Script Collations to True

4. Perform the remaining steps in the wizard to generate the file.

## Import/export tools for migrating from SQL Server to Babelfish

We recommend that you use Amazon DMS as the primary tool for migrating from SQL Server to Babelfish. However, Babelfish supports several other ways to migrate data using SQL Server tools that includes the following.

- SQL Server Integration Services (SSIS) for all versions of Babelfish. For more information, see [Migrate from SQL Server to Aurora PostgreSQL using SSIS and Babelfish](#).
- Use the SSMS Import/Export Wizard for Babelfish versions 2.1.0 and later. This tool is available through the SSMS, but it's also available as a standalone tool. For more information, see [Welcome to SQL Server Import and Export Wizard](#) in the Microsoft documentation.
- The Microsoft bulk data copy program (bcp) utility lets you copy data from a Microsoft SQL Server instance to a data file in the format you specify. For more information, see [bcp Utility](#) in the Microsoft documentation. Babelfish now supports the data migration using the BCP client and the bcp utility now supports -E flag (for identity columns) and -b flag (for batching inserts). Certain bcp options aren't supported, including -C, -T, -G, -K, -R, -V, and -h.

## Using SQL Server Management Studio (SSMS) to migrate to Babelfish

We recommend generating separate files for each of the specific object types. You can use the Generate Scripts wizard in SSMS for each set of DDL statements first, and then modify the objects as a group to fix any issues found during the assessment.

Perform these steps to migrate the data using Amazon DMS or other data migration methods. Run these create script types first for a better and faster approach to load the data on the Babelfish tables in Aurora PostgreSQL.

1. Run `CREATE SCHEMA` statements.
2. Run `CREATE TYPE` statements to create user-defined data types.
3. Run basic `CREATE TABLE` statements with the primary keys or unique constraints.

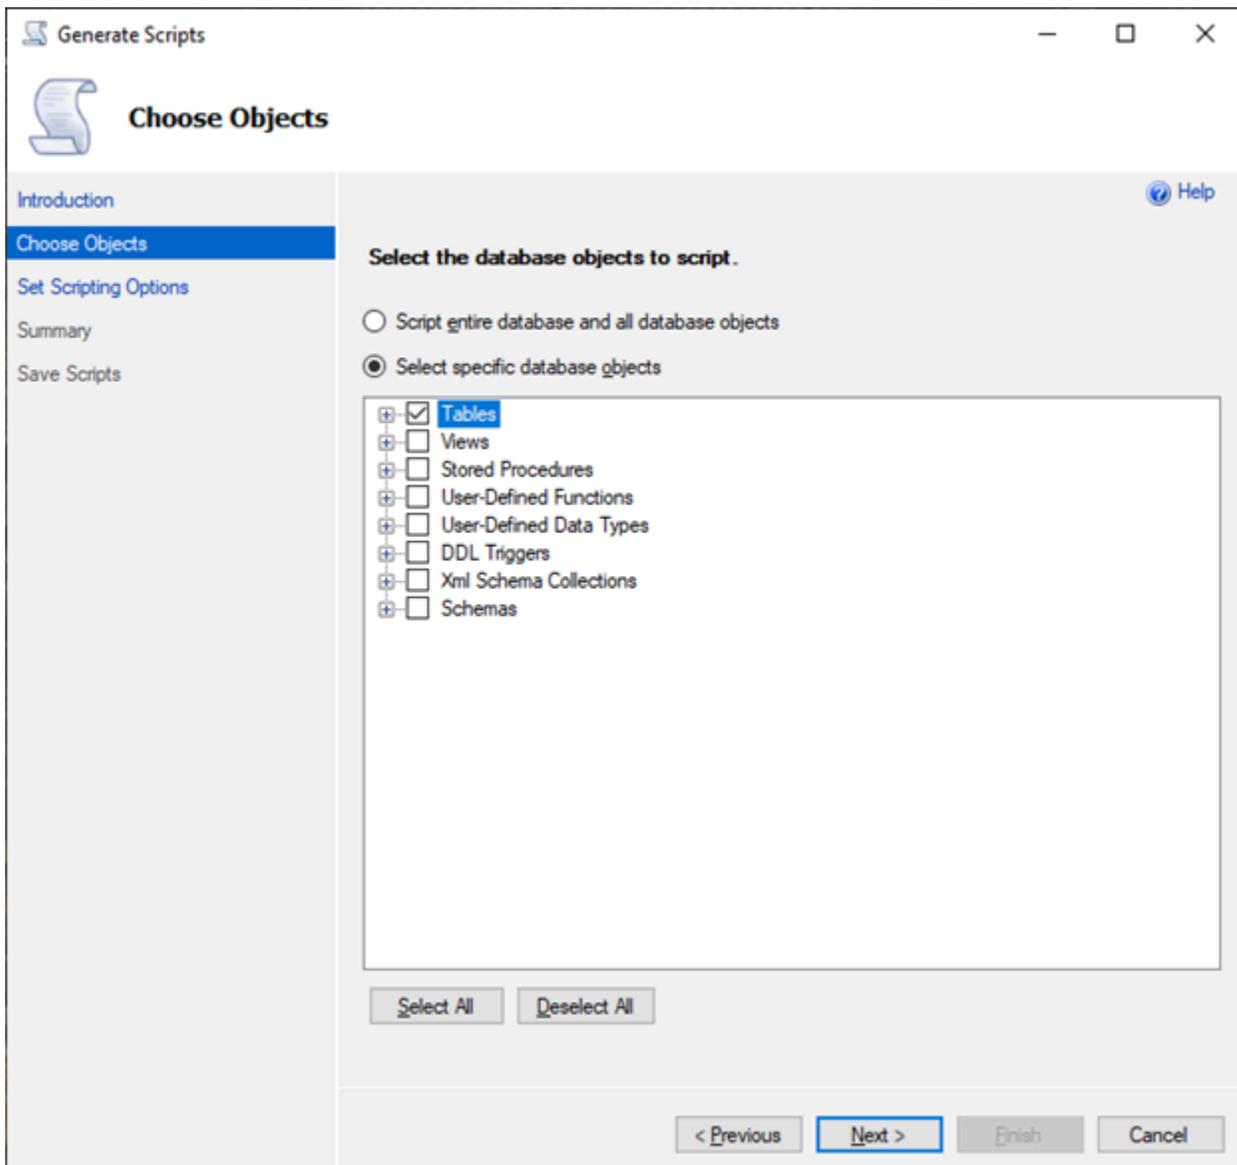

Perform the data load using the recommended import/export tool. Run the modified scripts for the following steps to add the remaining database objects. You need the create table statements to run these scripts for the constraints, triggers, and indexes. After the scripts generate, delete the create table statements.

1. Run `ALTER TABLE` statements for the check constraints, foreign key constraints, default constraints.
2. Run `CREATE TRIGGER` statements.
3. Run `CREATE INDEX` statements.
4. Run `CREATE VIEW` statements.
5. Run `CREATE STORED PROCEDURE` statements.

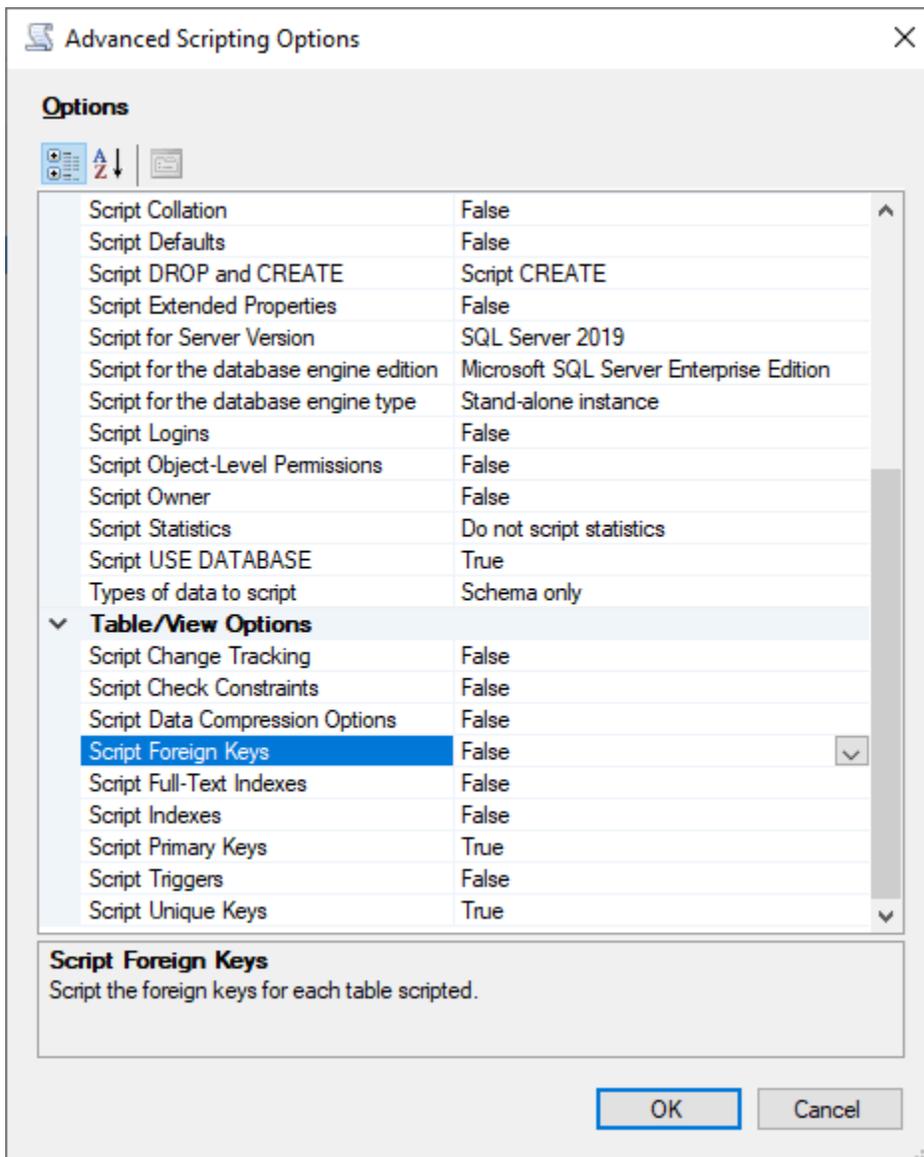

### To generate scripts for each object type

Use the following steps to create the basic create table statements using the Generate Scripts wizard in SSMS. Follow the same steps to generate scripts for the different object types.

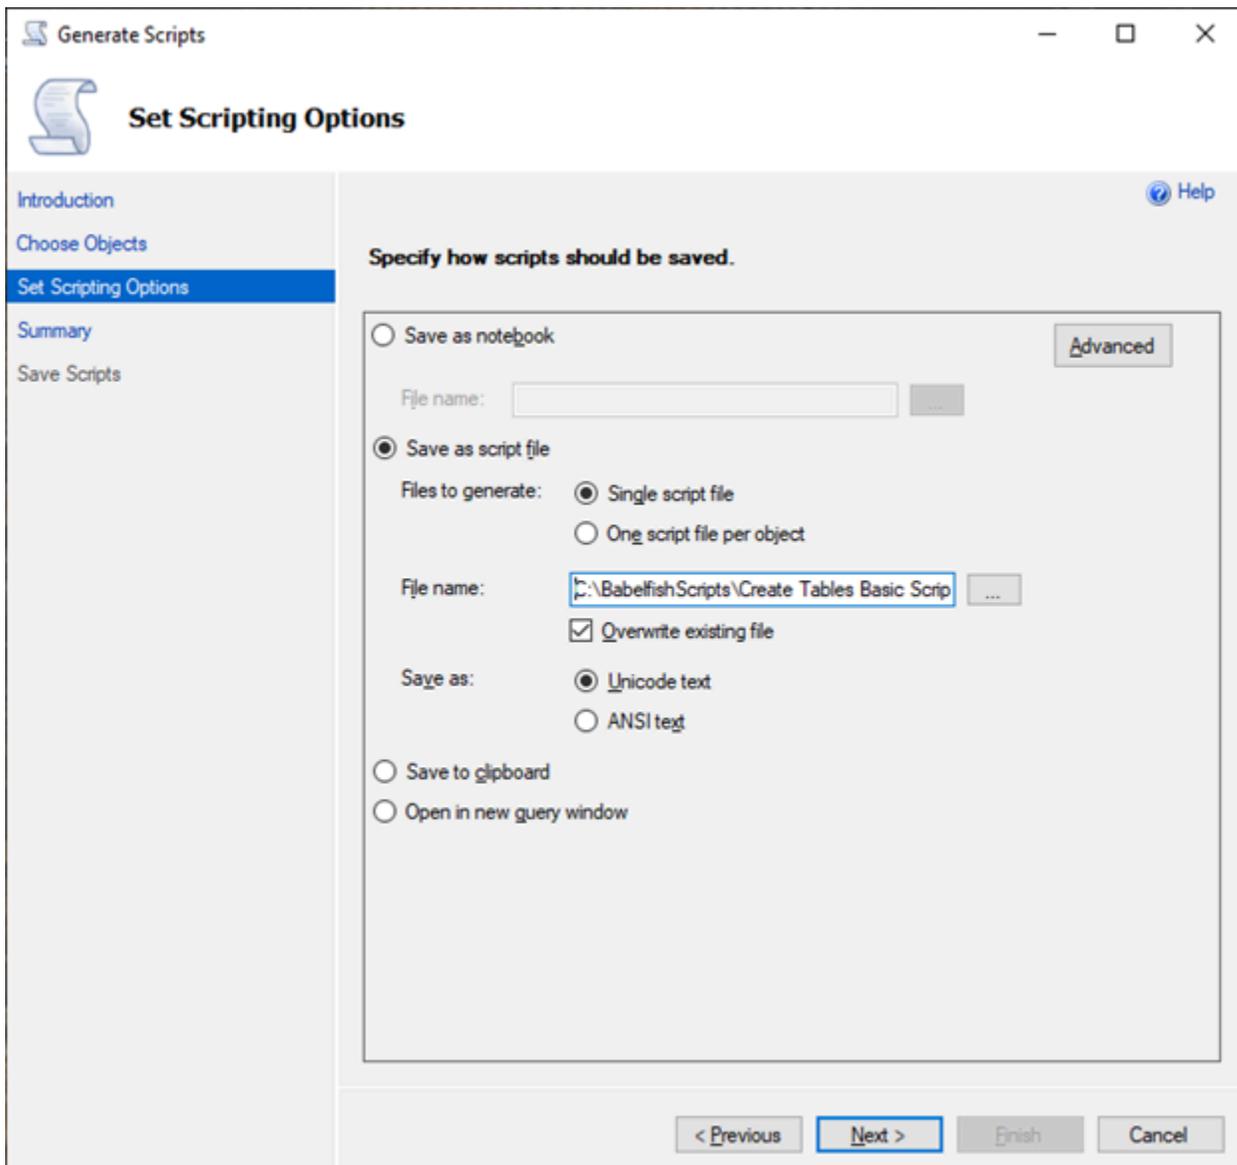

1. Connect to your existing SQL Server instance.
2. Open the context (right-click) menu for a database name.
3. Choose **Tasks**, and then choose **Generate Scripts....**
4. On the **Choose Objects** pane, choose **Select specific database objects**. Choose **Tables**, select all tables. Choose **Next** to continue.

5. On the **Set Scripting Options** page, choose **Advanced** to open the **Options** settings. To generate the basic create table statements, change the following default values:
  - Script Defaults to False.
  - Script Extended Properties to False. Babelfish does not support extended properties.
  - Script Check Constraints to False. Script Foreign Keys to False.

6. Choose **OK**.
7. On the **Set Scripting Options** page, choose **Save as script file** and then choose the **Single script file** option. Enter your **File name**.

8. Choose **Next** to view the **Summary wizard** page.
9. Choose **Next** to start the script generation.

You can continue to generate scripts for the other object types in the wizard. Instead of choosing **Finish** after the file is saved, choose the **Previous** button three times to go back to the **Choose Objects** page. Then repeat the steps in the wizard to generate scripts for the other object types.

## Database authentication with Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL supports two ways to authenticate database users. Password authentication is available by default for all Babelfish DB clusters. You can also add Kerberos authentication for the same DB cluster.

### Topics

- [Password authentication with Babelfish](#)
- [Kerberos authentication with Babelfish](#)
- [Setting up Kerberos authentication using Active Directory security groups for Babelfish](#)

### Password authentication with Babelfish

Babelfish for Aurora PostgreSQL supports password authentication. Passwords are stored in encrypted form on disk. For more information about authentication on an Aurora PostgreSQL cluster, see [Security with Amazon Aurora PostgreSQL](#).

You might be prompted for credentials each time you connect to Babelfish. Any user migrated to or created on Aurora PostgreSQL can use the same credentials on both the SQL Server port and the PostgreSQL port. Babelfish doesn't enforce password policies, but we recommend that you do the following:

- Require a complex password that's at least eight (8) characters long.
- Enforce a password expiration policy.

To review a complete list of database users, use the command `SELECT * FROM pg_user;`

## Kerberos authentication with Babelfish

Babelfish for Aurora PostgreSQL 15.2 version supports authentication to your DB cluster using Kerberos. This method allows you to use Microsoft Windows Authentication to authenticate users when they connect to your Babelfish database. To do so, you must first configure your DB cluster to use Amazon Directory Service for Microsoft Active Directory for Kerberos authentication. For more information, see [What is Amazon Directory Service?](#) in the *Amazon Directory Service Administration Guide*.

### Setting up Kerberos Authentication

Babelfish for Aurora PostgreSQL DB cluster can connect using two different ports, but Kerberos authentication setup is a one-time process. Therefore, you must first set up Kerberos authentication for your DB cluster. For more information, see [Setting up Kerberos authentication](#). After completing the setup, ensure that you can connect with a PostgreSQL client using Kerberos. For more information, see [Connecting with Kerberos Authentication](#).

### Login and user provisioning in Babelfish

Windows logins created from the Tabular Data Stream (TDS) port can be used either with the TDS port or the PostgreSQL port. First, the login that can use Kerberos for authentication must be provisioned from the TDS port before it is used by the T-SQL users and applications to connect to a Babelfish database. When creating Windows logins, administrators can provide the login using either the DNS domain name or the NetBIOS domain name. Typically, NetBIOS domain is the subdomain of the DNS domain name. For example, if the DNS domain name is CORP.EXAMPLE.COM, then the NetBIOS domain can be CORP. If the NetBIOS domain name format is provided for a login, a mapping must exist to the DNS domain name.

### Managing NetBIOS domain name to DNS domain name mapping

To manage mappings between the NetBIOS domain name and DNS domain name, Babelfish provides system stored procedures to add, remove, and truncate mappings. Only a user with a sysadmin role can run these procedures.

To create mapping between NetBIOS and DNS domain name, use the Babelfish provided system stored procedure `babelfish_add_domain_mapping_entry`. Both arguments must have a valid value and are not NULL.

## Example

```
EXEC babelfish_add_domain_mapping_entry 'netbios_domain_name',  
    'fully_qualified_domain_name'
```

The following example shows how to create the mapping between the NetBIOS name CORP and DNS domain name CORP.EXAMPLE.COM.

## Example

```
EXEC babelfish_add_domain_mapping_entry 'corp', 'corp.example.com'
```

To delete an existing mapping entry, use the system stored procedure `babelfish_remove_domain_mapping_entry`.

## Example

```
EXEC babelfish_remove_domain_mapping_entry 'netbios_domain_name'
```

The following example shows how to remove the mapping for the NetBIOS name CORP.

## Example

```
EXEC babelfish_remove_domain_mapping_entry 'corp'
```

To remove all existing mapping entries, use the system stored procedure `babelfish_truncate_domain_mapping_table`:

## Example

```
EXEC babelfish_truncate_domain_mapping_table
```

To view all mappings between NetBIOS and DNS domain name, use the following query.

## Example

```
SELECT netbios_domain_name, fq_domain_name FROM babelfish_domain_mapping;
```

## Managing Logins

### Create logins

Connect to the DB through the TDS endpoint using a login that has the correct permissions. If there is no database user created for the login, then the login is mapped to guest user. If the guest user is not enabled, then the login attempt fails.

Create a Windows login using the following query. The FROM WINDOWS option allows authentication using Active Directory.

```
CREATE LOGIN login_name FROM WINDOWS [WITH DEFAULT_DATABASE=database]
```

### Example

The following example shows creating a login for the Active Directory user [corp\test1] with a default database of db1.

```
CREATE LOGIN [corp\test1] FROM WINDOWS WITH DEFAULT_DATABASE=db1
```

This example assumes that there is a mapping between the NetBIOS domain CORP and the DNS domain name CORP.EXAMPLE.COM. If there is no mapping, then you must provide the DNS domain name [CORP.EXAMPLE.COM\test1].

#### Note

Logins based on Active Directory users, are limited to names of fewer than 21 characters.

### Drop login

To drop a login, use the same syntax as for any login, as shown in the following example:

```
DROP LOGIN [DNS domain name\login]
```

### Alter login

To alter a login, use the same syntax as for any login, as in the following example:

```
ALTER LOGIN [DNS domain name\login] { ENABLE|DISABLE|WITH DEFAULT_DATABASE=[master] }
```

The ALTER LOGIN command supports limited options for Windows logins, including the following:

- DISABLE – To disable a login. You can't use a disabled login for authentication.
- ENABLE – To enable a disabled login.
- DEFAULT\_DATABASE – To change the default database of a login.

 **Note**

All password management is performed through Amazon Directory Service, so the ALTER LOGIN command doesn't allow database administrators to change or set passwords for Windows logins.

### Connecting to Babelfish for Aurora PostgreSQL with Kerberos authentication

Typically, the database users who authenticate using Kerberos are doing so from their client machines. These machines are members of the Active Directory domain. They use Windows Authentication from their client applications to access the Babelfish for Aurora PostgreSQL server on the TDS port.

### Connecting to Babelfish for Aurora PostgreSQL on the PostgreSQL port with Kerberos authentication

You can use logins created from the TDS port with either the TDS port or the PostgreSQL port. However, PostgreSQL uses case-sensitive comparisons by default for usernames. For Aurora PostgreSQL to interpret Kerberos usernames as case-insensitive, you must set the `krb_caseins_users` parameter as `true` in the custom Babelfish cluster parameter group. This parameter is set to `false` by default. For more information, see [Configuring for case-insensitive user names](#). In addition, you must specify the login username in the format `<login@DNS domain name>` from the PostgreSQL client applications. You can't use `<DNS domain name\login>` format.

### Frequently occurring errors

You can configure forest trust relationships between your on-premises Microsoft Active Directory and the Amazon Managed Microsoft AD. For more information, see [Create a trust relationship](#). Then, you must connect using a specialized domain specific endpoint instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint. If you don't use the correct domain specific endpoint, you might encounter the following error:

```
Error: "Authentication method "NTLMSSP" not supported (Microsoft SQL Server, Error: 514)"
```

This error occurs when the TDS client can't cache the service ticket for the supplied endpoint URL. For more information, see [Connecting with Kerberos](#).

## Setting up Kerberos authentication using Active Directory security groups for Babelfish

Starting from Babelfish version 4.2.0, you can setup Kerberos authentication for Babelfish with Active Directory security groups. The following are prerequisites to complete for setting up Kerberos authentication using Active Directory:

- You must follow all the steps mentioned at [Kerberos authentication with Babelfish](#).
- Ensure that DB instance is associated with Active Directory. To verify this, you can view the status of the domain membership in the console or by running the [describe-db-instances](#) Amazon CLI command.

The status of the DB instance should be kerberos-enabled. For more information on understanding domain membership, see [Understanding Domain membership](#).

- Verify mappings between NetBIOS domain name and DNS domain name using the following query:

```
SELECT netbios_domain_name, fq_domain_name FROM babelfish_domain_mapping;
```

- Before proceeding further, verify Kerberos authentication using individual login works as expected. The connection using Kerberos authentication as an Active Directory user should be successful. If you face any issues, see [Frequently occurring errors](#).

## Setting up the pg\_ad\_mapping extension

You must follow all the steps mentioned at [Setting up the pg\\_ad\\_mapping extension](#) . To verify that the extension is installed, run the following query from TDS endpoint:

```
1> SELECT extname, extversion FROM pg_extension where extname like 'pg_ad_mapping';
2> GO
extname          extversion
```

```
-----  
pg_ad_mapping 0.1  
  
(1 rows affected)
```

## Managing Group Logins

Create group logins by following the steps mentioned at [Managing Logins](#). We recommend that the login name be the same as the Active Directory (AD) security group name for easier maintenance, although it's not mandatory. For example:

```
CREATE LOGIN [corp\accounts-group] FROM WINDOWS [WITH DEFAULT_DATABASE=database]
```

## Mapping T-SQL group logins with AD security group

You need to explicitly provision T-SQL Windows Group Login for each AD security group that requires access to the database server. An AD user, who is part of at least one provisioned AD security group, will get access to the database server.

### Note

This T-SQL login can no longer authenticate using a password based authentication.

For example, accounts-group is a security group in AD and if you would like to provision this security group in Babelfish, you must use the format [corp\accounts-group].

- AD Security Group : accounts-group
- TSQL Login : [corp\accounts-group]
- Equivalent PG role for given TSQL Login : accounts-group@CORP.EXAMPLE.COM

Admin can now proceed to create the mapping between AD security group and T-SQL login from PostgreSQL endpoint via following psql command. For more information on the function usage, see [Using functions from the pg\\_ad\\_mapping extension](#).

### Note

T-SQL login should be specified in login\_name@FQDN format while adding the mapping. Weights are ignored when connecting through TDS endpoint. For more information about

usage of weights, see [Connecting to Babelfish via PostgreSQL endpoint on the PostgreSQL port.](#)

```
postgres=>select pgadmap_set_mapping('accounts-group', 'accounts-
group@CORP.EXAMPLE.COM', <SID>, <Weight>);
```

For information on retrieving SID of AD security group, see [Retrieving Active Directory Group SID in PowerShell.](#)

The following table shows a sample mapping from AD security groups to T-SQL logins:

AD Security Groups	TSQL Logins	Equivalent PG role for given TSQL Login	Weight
accounts-group	[corp\accounts-group]	accounts-group@CORP.EXAMPLE.COM	7
sales-group	[corp\sales-group]	sales-group@CORP.EXAMPLE.COM	10
dev-group	[corp\dev-group]	dev-group@CORP.EXAMPLE.COM	7

```
postgres=> select admap.ad_sid, admap.ad_grp, lgn.orig_loginname, lgn.rolname,
admap.weight from pgadmap_read_mapping() as admap, sys.babelfish_authid_login_ext as
lgn where admap.pg_role = lgn.rolname;
 ad_sid | ad_grp | orig_loginname | rolname
| weight
-----+-----+-----+-----
+-----
S-1-5-67-890 | accounts-group | corp\accounts-group | accounts-group@CORP.EXAMPLE.COM
| 7
S-1-2-34-560 | sales-group | corp\sales-group | sales-group@CORP.EXAMPLE.COM
| 10
```

```
S-1-8-43-612 | dev-group      | corp\dev-group      | dev-group@CORP.EXAMPLE.COM
|      7
(7 rows)
```

## Connecting to Babelfish via TDS endpoint

In the following example, user1 is member of accounts-group and sales-group, user2 is member of accounts-group and dev-group.

Username	AD Security Groups membership
user1	accounts-group, sales-group
user2	accounts-group, dev-group

Connect to Babelfish database server using sqlcmd utility. You can verify if an user (user1 in this example) was authenticated using Kerberos by following the example below:

```
1> select principal, gss_authenticated from pg_stat_gssapi where pid =
  pg_backend_pid();
2> GO
principal          gss_authenticated
-----
user1@CORP.EXAMPLE.COM  1

((1 rows affected))
1> select suser_name();
2> GO
suser_name
-----
corp\user1

(1 rows affected)
```

In this example, user1 will inherit the privileges of accounts-group and sales-group. You can verify the group membership using `sys.login_token` system view.

```
1> SELECT name, type FROM sys.login_token;
2> GO
name          type
```

```
-----  
corp\accounts-group WINDOWS GROUP  
corp\sales-group     WINDOWS GROUP  
  
(2 rows affected)
```

## Auditing and Logging

To determine the AD security principal identity, use the following commands:

```
1> select suser_name();  
2> GO  
suser_name  
-----  
corp\user1  
  
(1 rows affected)
```

Currently, AD user identity isn't visible in the logs. You can turn on the `log_connections` parameter to log DB session establishment. For more information, see [log\\_connections](#). The output includes the AD user identity as principal as shown in the following example. The backend PID associated with this output can then help attribute actions back to the actual AD user.

```
bbf_group_ad_login@babelfish_db:[615]:LOG: connection authorized:  
user=bbf_group_ad_login database=babelfish_db application_name=sqlcmd GSS  
(authenticated=yes, encrypted=yes, principal=user1@CORP.EXAMPLE.COM)
```

## Utilizing privileges of AD security group membership

### Inheriting server-level privileges

AD users that are members of given AD security group will inherit server-level privileges granted to the mapped Windows group login. For example, consider the `accounts-group` AD security group, that is granted membership to the `sysadmin` server role on the Babelfish. You can inherit the server-level privileges using the following command:

```
1> ALTER SERVER ROLE sysadmin ADD MEMBER [corp\accounts-group];
```

Consequently, any Active Directory user who is a member of the accounts-group AD security group will inherit the server-level privileges associated with the sysadmin role. This means that a user like corp\user1, being a member of accounts-group, will now have the ability to perform server-level operations within Babelfish.

### Note

To perform server-level DDLs, Windows login for individual AD user must exist. For more information, see [Limitations](#).

## Inheriting database-level privileges

To grant the database level privileges, a database user has to be created and mapped with Windows group login. AD users which are members of given AD security group will inherit database-level privileges granted to that database user. In the following example, you can see how database level privileges for Windows group [corp\accounts-group] are assigned.

```
1> CREATE DATABASE db1;
2> GO
1> USE db1;
2> GO
Changed database context to 'db1'.
1> CREATE TABLE dbo.t1(a int);
2> GO
```

Create a database user [corp\sales-group] for Windows group login [corp\accounts-group]. To perform this step, connect through TDS endpoint using login who is a member of sysadmin.

```
1> CREATE USER [corp\accounts-group] FOR LOGIN [corp\accounts-group];
2> GO
```

Now, connect as AD user user1 to check access of table t1. Since we have not yet granted the database level privileges, it will result in permission denied error.

```
1> SELECT * FROM dbo.t1;
2> GO
Msg 33557097, Level 16, State 1, Server db-inst, Line 1
permission denied for table t1
```

Grant SELECT on table t1 to database user [corp\accounts-group]. To perform this step, connect through TDS endpoint using login who is member of sysadmin.

```
1> GRANT SELECT ON dbo.t1 TO [corp\accounts-group];
2> GO
```

Connect as AD user user1 to validate the access.

```
1> SELECT * FROM dbo.t1;
2> GO
a
-----
(0 rows affected)
```

## Handling DDL Statement behavior based on default or explicit schema

When using an AD authenticated session, the default schema for the current session is determined by the following conditions:

- If an individual database user exists, the user's default schema is considered as current session's default schema.
- If the default schema for a group database user exists, the group database user's default schema is considered as current session's default schema with the smallest principal id.

## Understanding CREATE DDL statement behavior

If there is no explicit schema specified in the CREATE DDL statement then object creation will take place in the default schema of current session. If the schema can't be determined whether default or explicit, then the DDL statement will throw following error:

```
"Babelfish Unsupported Command : Schema required for CREATE DDLs when connecting with Active Directory Group authentication. Assign default schema to group user or specify schema in command."
```

### Example : Default schema doesn't exist for Windows group user

Windows group user [corp\accounts-group] have NULL default schema and AD user user1 is trying to perform the DDL without specifying the schema explicitly. Since individual windows login and user doesn't exist for user1, it will get the database level privileges of Windows group user [corp \accounts-group] only.

```
1> create TABLE t2(a int);
2> GO
```

```
Msg 33557097, Level 16, State 1, Server db-inst, Line 1
Babelfish Unsupported Command : Schema required for CREATE DDLs when connecting with Active Directory Group authentication. Assign default schema to group user or specify schema in command.
```

#### Note

Individual windows login and user doesn't exist for AD user user1

### Example : Default schema exists for Windows group users

Create Windows group user for [corp\accounts-group] login with default schema using sysadmin.

```
1> CREATE USER [corp\accounts-group] FOR LOGIN [corp\accounts-group] WITH
  DEFAULT_SCHEMA = sch_acc;
2> GO
1> CREATE SCHEMA sch_acc AUTHORIZATION [gad\accounts-group];
2> GO
```

```

1> SELECT name, principal_id, default_schema_name FROM sys.database_principals WHERE
   name = 'corp\accounts-group';
2> GO

name                principal_id default_schema_name
-----
corp\accounts-group 24162          sch_acc

(1 rows affected)

```

Try creating object without specifying schema explicitly using AD user user1. Table t2 will be created in default schema of [corp\accounts-group] Windows group user Owner of this object will be same as owner of schema sch\_acc.

```

1> CREATE TABLE t_group(a int);
2> GO
1> SELECT name, schema_name(schema_id) FROM sys.objects WHERE name like 't_group';
2> GO

name    schema_name
-----
t_group sch_acc

(1 rows affected)

```

### Note

Individual windows login and user doesn't exist for AD user user1

### Example : Individual database user also exists for an AD user

If an individual database user also exists for an AD user then the objects will always be created in the schema associated with individual database user. If the schema doesn't exist for the database user then dbo schema will be used. Create individual windows login and database user for AD user user1. Connect through TDS endpoint using a sysadmin login

```

1> CREATE LOGIN [corp\user1] FROM WINDOWS;
2> GO
1> CREATE USER [corp\user1] FOR LOGIN [corp\user1] WITH DEFAULT_SCHEMA = sch1;
2> GO
1> CREATE SCHEMA sch1 AUTHORIZATION [corp\user1];
2> GO
1> SELECT name, default_schema_name FROM sys.database_principals WHERE name = 'corp
\user1';
2> GO

name          default_schema_name
-----
corp\user1    sch1

(1 rows affected)

```

Connect using AD user user1 and try creating object without specifying schema explicitly. Table t2 will be created in schema sch1. Also note that owner of this object will be same as owner of schema sch1.

```

1> CREATE TABLE t2(a int);
2> GO
1> SELECT name, schema_name(schema_id) FROM sys.objects WHERE name like 't2';
2> GO

name schema_name
----
t2   sch1

(1 rows affected)

```

## Limitations

- Dump/Restore utility doesn't support dumping the pg\_ad\_mapping extension mappings. You will need to recreate those mappings after restore.

- Blue-Green deployment isn't supported for Babelfish and Aurora PostgreSQL instances with `pg_ad_mapping`.
- Implicit schema creation is not supported. DDL statements that requires implicit schema creation isn't supported.
- Server-level DDLs ALTER AUTHORIZATION ON DATABASE , CREATE DATABASE, CREATE LOGIN, ALTER LOGIN, ALTER SERVER ROLE, ALTER DATABASE are not supported in a Group AD authenticated session when individual Windows login doesn't exist, only group Windows login exists. To workaround this limitation, It is recommended to perform these operations in a password authenticated session or create individual Windows login.
- Implicit user creation isn't supported. Ideal T-SQL behavior [not yet supported in Babelfish]; In some cases like DDL and access-control statements like GRANT/REVOKE where AD user's name is specified in the command but it doesn't exist in database then database user named as AD user get implicitly created.
- For DDLs in PL/pgSQL Procedures or Functions which are created from PSQL endpoint and gets executed from TDS endpoint in Group AD authenticated session:
  - ALTER/DROP statements will be supported.
  - CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE FUNCTION/PROC, CREATE TYPE, CREATE SEQUENCE, CREATE TRIGGER, SELECT INTO, CREATE FULLTEXT INDEX , CREATE UNIQUE INDEX will throw an error if schema is not provided explicitly and default schema is null for current session.
  - CREATE DATABASE , CREATE EXTENSION and all other CREATE statements for PG(not in T-SQL) specific objects CREATE subscription, CREATE tablespace, CREATE policy, CREATE conversion will not be supported.
- DDLs from PostgreSQL endpoint is not supported in Group AD authenticated session. As a workaround, you can always connect using master user or any other user using password based authentication mechanism.
- System objects like SUSER\_SID(), IS\_SRVROLEMEMBER(), IS\_MEMBER(), sys.dm\_exec\_sessions has following limitations.
  - SUSER\_SID() won't return the SID when AD User or AD Security Group is supplied.
  - IS\_SRVROLEMEMBER() won't consider the role membership if current AD user is inheriting the server role membership from any Windows group login's server role membership.
  - IS\_MEMBER() will return false for any Windows Group related query.
  - sys.dm\_exec\_sessions won't show expected values login\_name, nt\_user\_name columns.

## Connecting to Babelfish via PostgreSQL endpoint on the PostgreSQL port

You can utilize group logins created from the TDS port to connect through PostgreSQL port as well. To connect through PostgreSQL port, you need to specify the AD user's name in the format <ad\_username@FQDN> from the PostgreSQL client applications. You can't use the <DNS domain name\ad\_username> format.

PostgreSQL uses case-sensitive comparisons by default for usernames. For Aurora PostgreSQL to interpret Kerberos usernames as case-insensitive, you must set the `krb_caseins_users` parameter as `true` in the custom Babelfish cluster parameter group. This parameter is set to `false` by default. For more information, see [Configuring your Aurora PostgreSQL DB cluster for case-insensitive usernames](#).

### Behavior differences between T-SQL and PostgreSQL endpoints when an AD user is part of multiple groups

Consider that AD user `user1` is part of two AD security groups [`corp\accounts-group`] and [`corp\sales-group`] and DB admin has set the user mapping in following way.

```
postgres=> select * from pgadmap_read_mapping();
```

ad_sid	pg_role	weight	ad_grp
S-1-5-67-980	accounts-group@CORP.EXAMPLE.COM	7	accounts-group
S-1-2-34-560	sales-group@CORP.EXAMPLE.COM	10	sales-group

(2 rows)

If the user is connecting from the T-SQL endpoint then during the authorization, it will inherit the privileges from all the associated T-SQL logins. In this example `user1` will inherit the union of privileges from both the T-SQL group login and weights will be ignored. This is inline with the standard T-SQL behavior.

However if same user connects from the PostgreSQL endpoint then it can inherit privileges from only one associated T-SQL login with the highest weight. If the two T-SQL group login were assigned same weight then AD user will inherit the privileges of the T-SQL login corresponding to the mapping that was added most recently. For the PostgreSQL, the recommendation is to specify weights that reflect the relative permissions/privileges of individual DB roles to avoid the

ambiguity. In below example, user1 connected through PSQL endpoint and inherited only sales-groups privileges.

```
babelfish_db=> select session_user, current_user;
```

session_user	current_user
sales-group@CORP.EXAMPLE.COM	sales-group@CORP.EXAMPLE.COM

(1 row)

```
babelfish_db=> select principal, gss_authenticated from pg_stat_gssapi where pid =  
pg_backend_pid();
```

principal	gss_authenticated
user1@CORP.EXAMPLE.COM	t

(1 row)

## Connecting to a Babelfish DB cluster

To connect to Babelfish, you connect to the endpoint of the Aurora PostgreSQL cluster running Babelfish. Your client can use one of the following client drivers compliant with TDS version 7.1 through 7.4:

- Open Database Connectivity (ODBC)
- OLE DB Driver/MSOLEDBSQL
- Java Database Connectivity (JDBC) version 8.2.2 (mssql-jdbc-8.2.2) and higher
- Microsoft SqlClient Data Provider for SQL Server
- .NET Data Provider for SQL Server
- SQL Server Native Client 11.0 (deprecated)
- OLE DB Provider/SQLOLEDB (deprecated)

With Babelfish, you run the following:

- SQL Server tools, applications, and syntax on the TDS port, by default port 1433.
- PostgreSQL tools, applications, and syntax on the PostgreSQL port, by default port 5432.

To learn more about connecting to Aurora PostgreSQL in general, see [Connecting to an Amazon Aurora PostgreSQL DB cluster](#).

### Note

Third-party developer tools using the SQL Server OLEDB provider to access metadata aren't supported. We recommend you to use SQL Server JDBC, ODBC, or SQL Native client connections for these tools.

Starting with Babelfish version 5.1.0, end-to-end connection encryption is enforced by default. To ensure continued connectivity:

- Configure SSL/TLS encryption for your connections. For more information, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).
- Import the required certificates on your client computers. For more information, see [Using SSL with a Microsoft SQL Server DB instance](#).

If you want to continue using the encryption settings from a previous version of Babelfish (prior to version 5.1.0), you can set the `rds.force_ssl` parameter to `0` in your DB cluster parameter group.

## Topics

- [Finding the writer endpoint and port number](#)
- [Creating C# or JDBC client connections to Babelfish](#)
- [Using a SQL Server client to connect to your DB cluster](#)
- [Using a PostgreSQL client to connect to your DB cluster](#)

## Finding the writer endpoint and port number

To connect to your Babelfish DB cluster, you use the endpoint associated with the DB cluster's writer (primary) instance. The instance must have a status of **Available**. It can take up to 20 minutes for the instances to be available after creating the Babelfish for Aurora PostgreSQL DB cluster.

### To find your database endpoint

1. Open the console for Babelfish.
2. Choose **Databases** from the navigation pane.
3. Choose your Babelfish for Aurora PostgreSQL DB cluster from those listed to see its details.
4. On the **Connectivity & security** tab, note the available cluster **Endpoints** values. Use the cluster endpoint for the writer instance in your connection strings for any applications that perform database write or read operations.

RDS > Databases > babelfish-workshop

Connect babelfish database Actions Create custom endpoint

Filter by endpoint

Endpoint name	Status	Type	Port
babelfish-workshop.cluster-ro-...rds.amazonaws.com	Available	Reader instance	5432, 1433 (Babelfish)
<b>babelfish-workshop.cluster-...rds.amazonaws.com</b>	Available	<b>Writer instance</b>	5432, 1433 (Babelfish)

For more information about Aurora DB cluster details, see [Creating an Amazon Aurora DB cluster](#).

## Creating C# or JDBC client connections to Babelfish

In the following you can find some examples of using C# and JDBC classes to connect to an Babelfish for Aurora PostgreSQL.

### Example : Using C# code to connect to a DB cluster

```
string dataSource = 'babelfishServer_11_24';

//Create connection
connectionString = @"Data Source=" + dataSource
    +";Initial Catalog=your-DB-name"
    +";User ID=user-id;Password=password";

// [optional] To validate server certificate during TLS/SSL connection
connectionString = connectionString + ";ServerCertificate=/path/to/certificate.pem";

SqlConnection cnn = new SqlConnection(connectionString);
cnn.Open();
```

### Example : Using generic JDBC API classes and interfaces to connect to a DB cluster

```
String dbServer =
    "database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
String connectionUrl = "jdbc:sqlserver://" + dbServer + ":1433;" +
    "databaseName=your-DB-name;user=user-id;password=password";

// [optional] To validate server certificate during TLS/SSL connection
connectionUrl = connectionUrl + ";serverCertificate=/path/to/certificate.pem";

// Load the SQL Server JDBC driver and establish the connection.
System.out.print("Connecting Babelfish Server ... ");
Connection cnn = DriverManager.getConnection(connectionUrl);
```

### Example : Using SQL Server-specific JDBC classes and interfaces to connect to a DB cluster

```
// Create datasource.
SQLServerDataSource ds = new SQLServerDataSource();
ds.setUser("user-id");
ds.setPassword("password");
String babelfishServer =
```

```
"database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";

ds.setServerName(babelfishServer);
ds.setPortNumber(1433);
ds.setDatabaseName("your-DB-name");

// [optional] To validate server certificate during TLS/SSL connection
ds.setServerCertificate("/path/to/certificate.pem");

Connection con = ds.getConnection();
```

** Important**

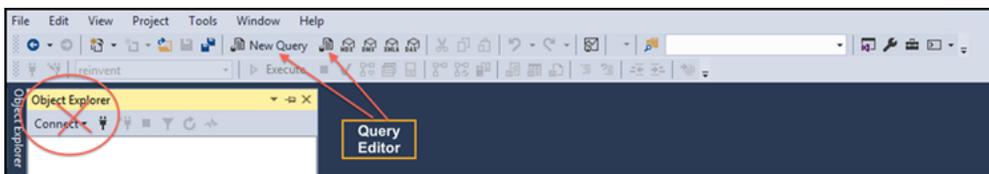

Ensure the certificate matches the Certificate Authority shown in your DB cluster configuration on the Amazon Web Services Management Console.

## Using a SQL Server client to connect to your DB cluster

You can use a SQL Server client to connect with Babelfish on the TDS port. As of Babelfish 2.1.0 and higher releases, you can use the SSMS Object Explorer or the SSMS Query Editor to connect to your Babelfish cluster.

### Limitations

- In Babelfish 2.1.0 and older versions, using PARSE to check SQL syntax doesn't work as it should. Rather than checking the syntax without running the query, the PARSE command runs the query but doesn't display any results. Using the SMSS <Ctrl><F5> key combination to check syntax has the same anomalous behavior, that is, Babelfish unexpectedly runs the query without providing any output.
- Babelfish doesn't support MARS (Multiple Active Result Sets). Be sure that any client applications that you use to connect to Babelfish aren't set to use MARS.
- For Babelfish 1.3.0 and older versions, only the Query Editor is supported for SSMS. To use SSMS with Babelfish, be sure to open the Query Editor connection dialog in SSMS, and not the Object Explorer. If the Object Explorer dialog does open, cancel the dialog and re-open the Query Editor. In the following image, you can find the menu options to choose when connecting to Babelfish 1.3.0 or older versions.

For more information about interoperability and behavioral differences between SQL Server and Babelfish, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server](#).

### Using sqlcmd to connect to the DB cluster

You can connect to and interact with an Aurora PostgreSQL DB cluster that supports Babelfish by only using version 19.1 and earlier SQL Server `sqlcmd` command line client. SSMS version 19.2 isn't supported to connect to a Babelfish cluster. Use the following command to connect.

```
sqlcmd -S endpoint,port -U login-id -P password -d your-DB-name
```

The options are as follows:

- -S is the endpoint and (optional) TDS port of the DB cluster.
- -U is the login name of the user.
- -P is the password associated with the user.
- -d is the name of your Babelfish database.

After connecting, you can use many of the same commands that you use with SQL Server. For some examples, see [Getting information from the Babelfish system catalog](#).

## Using SSMS to connect to the DB cluster

You can connect to an Aurora PostgreSQL DB cluster running Babelfish by using Microsoft SQL Server Management Studio (SSMS). SSMS includes a variety of tools, including the SQL Server Import and Export Wizard discussed in [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL](#). For more information about SSMS, see [Download SQL Server Management Studio \(SSMS\)](#) in the Microsoft documentation. To configure SSL/TLS, see [Using SSL with a Microsoft SQL Server DB instance](#).

### To connect to your Babelfish database with SSMS

1. Start SSMS.
2. Open the **Connect to Server** dialog box. To continue with the connection, do one of the following:
  - Choose **New Query**.
  - If the Query Editor is open, choose **Query, Connection, Connect**.
3. Provide the following information for your database:
  - a. For **Server type**, choose **Database Engine**.
  - b. For **Server name**, enter the DNS name. For example, your server name should look similar to the following.

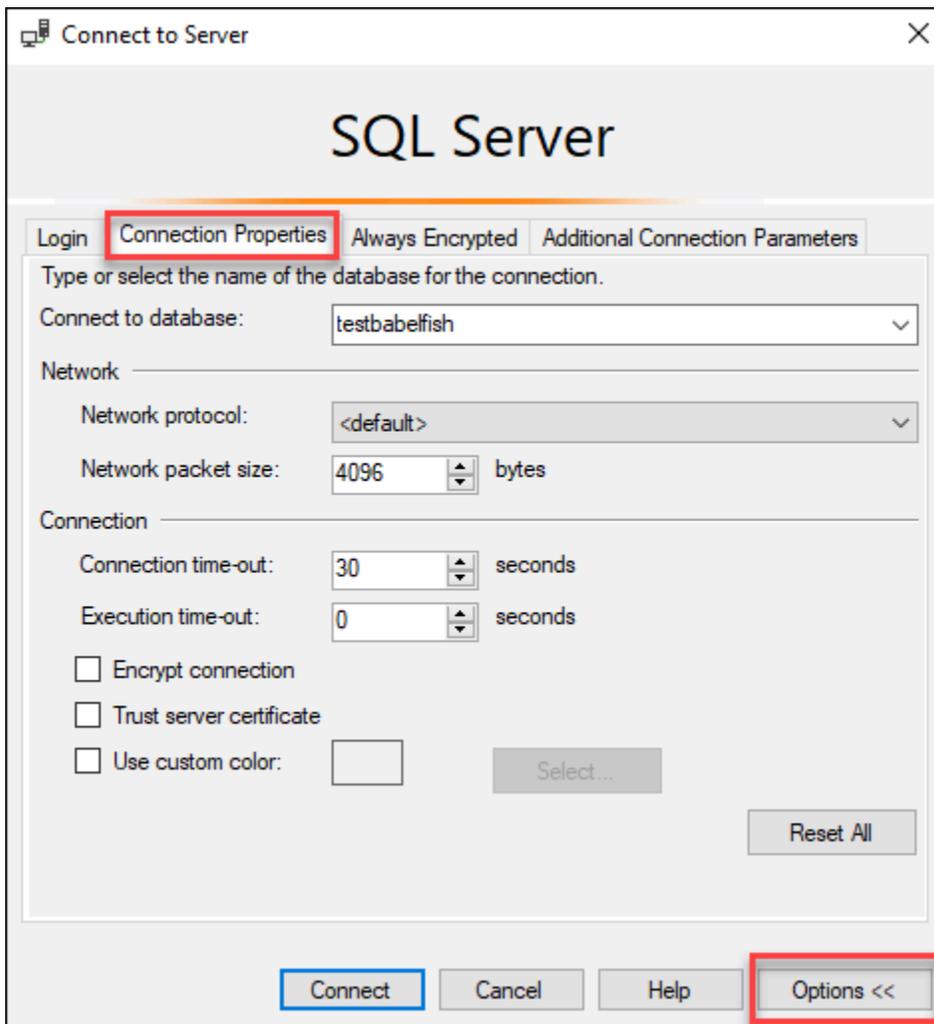

```
cluster-name.cluster-555555555555.aws-region.rds.amazonaws.com,1433
```
  - c. For **Authentication**, choose **SQL Server Authentication**.
  - d. For **Login**, enter the user name that you chose when you created your database.
  - e. For **Password**, enter the password that you chose when you created your database.

The screenshot shows a 'Connect to Server' dialog box with the following fields and options:

- Server type:** Database Engine
- Server name:** babelfish-workshop.cluster, us-east-1.rds.amr
- Authentication:** SQL Server Authentication
- Login:** postgres
- Password:** [masked]
- Remember password

Buttons at the bottom: Connect, Cancel, Help, Options >>

4. (Optional) Choose **Options**, and then choose the **Connection Properties** tab.

5. (Optional) For **Connect to database**, specify the name of the migrated SQL Server database to connect to, and choose **Connect**.

If a message appears indicating that SSMS can't apply connection strings, choose **OK**.

If you are having trouble connecting to Babelfish, see [Connection failure](#).

For more information about SQL Server connection issues, see [Troubleshooting connections to your SQL Server DB instance](#) in the *Amazon RDS User Guide*.

## Using a PostgreSQL client to connect to your DB cluster

You can use a PostgreSQL client to connect to Babelfish on the PostgreSQL port. Starting with version 5.1.0, the Babelfish server enforces end-to-end connection encryption by default. Update your application to work with SSL/TLS certificates. For more information about configuring SSL/TLS certificates, see [the section called "Securing Aurora PostgreSQL data with SSL/TLS"](#).

### Using psql to connect to the DB cluster

You can download the PostgreSQL client from the [PostgreSQL](#) website. Follow the instructions specific to your operating system version to install psql.

You can query an Aurora PostgreSQL DB cluster that supports Babelfish with the psql command line client. When connecting, use the PostgreSQL port (by default, port 5432). Typically, you don't need to specify the port number unless you changed it from the default. Use the following command to connect to Babelfish from the psql client:

```
psql -h bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com  
-p 5432 -U postgres -d babelfish_db
```

The parameters are as follows:

- -h – The host name of the DB cluster (cluster endpoint) that you want to access.
- -p – The PostgreSQL port number used to connect to your DB instance.
- -d – The database that you want to connect to. The default is babelfish\_db.
- -U – The database user account that you want to access. (The example shows the default master username.)

When you run a SQL command on the psql client, you end the command with a semicolon. For example, the following SQL command queries the [pg\\_tables system view](#) to return information about each table in the database.

```
SELECT * FROM pg_tables;
```

The psql client also has a set of built-in metacommands. A *metacommand* is a shortcut that adjusts formatting or provides a shortcut that returns meta-data in an easy-to-use format. For example, the following metacommand returns similar information to the previous SQL command:

\d

Metacommands don't need to be terminated with a semicolon (;).

To exit the psql client, enter \q.

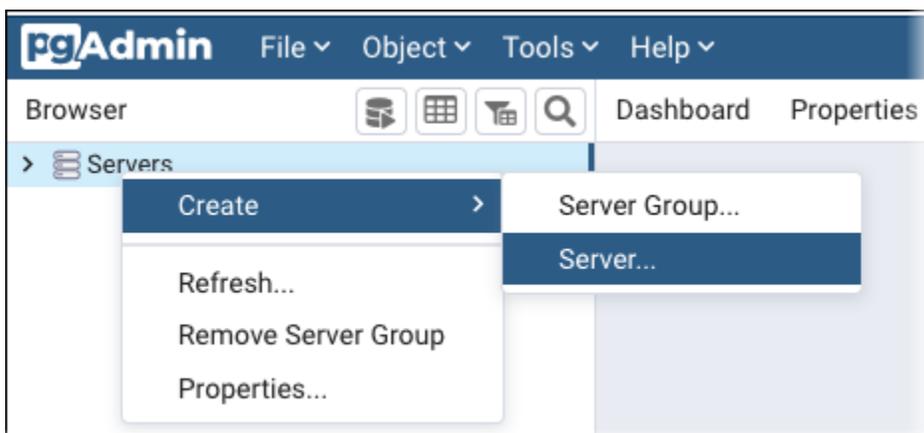

For more information about using the psql client to query an Aurora PostgreSQL cluster, see [the PostgreSQL documentation](#).

## Using pgAdmin to connect to the DB cluster

You can use the pgAdmin client to access your data in native PostgreSQL dialect.

### To connect to the cluster with the pgAdmin client

1. Download and install the pgAdmin client from the [pgAdmin website](#).
2. Open the client and authenticate with pgAdmin.
3. Open the context (right-click) menu for **Servers**, and then choose **Create, Server**.

4. Enter information in the **Create - Server** dialog box.

On the **Connection** tab, add the Aurora PostgreSQL cluster address for **Host** and the PostgreSQL port number (by default, 5432) for **Port**. Provide authentication details, and choose **Save**.

**Create - Server**

General **Connection** SSL SSH Tunnel Advanced

Host name/address: babelfish\_db.cluster-...us-east-1.rds.ama

Port: 5432

Maintenance database: babelfish\_db

Username: postgres

Kerberos authentication?

Password: .....

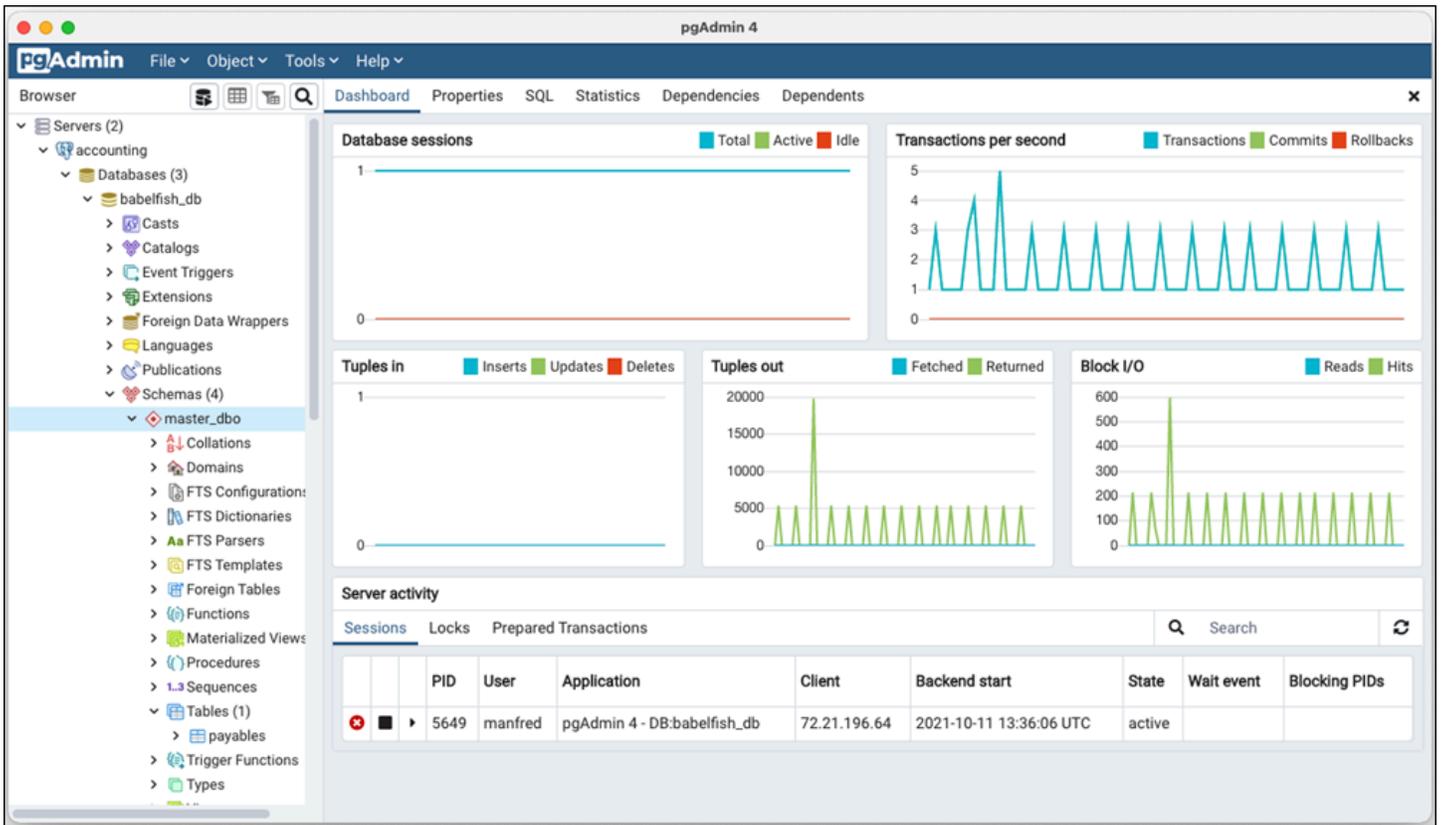

Save password?

Role:

Service:

*i* *?*

After connecting, you can use pgAdmin functionality to monitor and manage your Aurora PostgreSQL cluster on the PostgreSQL port.

To learn more, see the [pgAdmin](#) web page.

## Working with Babelfish

Following, you can find usage information for Babelfish, including some of the differences between working with Babelfish and SQL Server, and between Babelfish and PostgreSQL databases.

### Topics

- [Getting information from the Babelfish system catalog](#)
- [Managing permissions and access control in Babelfish for Aurora PostgreSQL](#)
- [Differences between Babelfish for Aurora PostgreSQL and SQL Server](#)
- [Using Babelfish features with limited implementation](#)
- [Improving Babelfish query performance](#)
- [Using Aurora PostgreSQL extensions with Babelfish](#)
- [Babelfish supports linked servers](#)
- [Using Full Text Search in Babelfish](#)
- [Babelfish supports Geospatial data types](#)
- [Understanding partitioning in Babelfish](#)

### Getting information from the Babelfish system catalog

You can obtain information about the database objects that are stored in your Babelfish cluster by querying many of the same system views as used in SQL Server. Each new release of Babelfish adds support for more system views. For a list of available views currently available, see the [SQL Server system catalog views](#) table.

These system views provide information from the system catalog (`sys . schemas`). In the case of Babelfish, these views contain both SQL Server and PostgreSQL system schemas. To query Babelfish for system catalog information, you can use the TDS port or the PostgreSQL port, as shown in the following examples.

- **Query the T-SQL port using `sqlcmd` or another SQL Server client.**

```
1> SELECT * FROM sys . schemas
2> GO
```

This query returns SQL Server and Aurora PostgreSQL system schemas, as shown in the following.

```

name
-----
demographic_dbo
public
sys
master_dbo
tempdb_dbo
...

```

- **Query the PostgreSQL port using psql or pgAdmin.** This example uses the psql list schemas metacommand (\dn):

```

babelfish_db=> \dn

```

The query returns the same result set as that returned by sqlcmd on the T-SQL port.

```

          List of schemas
          Name
-----
demographic_dbo

public
sys
master_dbo
tempdb_dbo
...

```

## SQL Server system catalogs available in Babelfish

In the following table you can find the SQL Server views currently implemented in Babelfish. For more information about the system catalogs in SQL Server, see [System Catalog Views \(Transact-SQL\)](#) in Microsoft documentation.

View name	Description or Babelfish limitation (if any)
sys.all_columns	All columns in all tables and views
sys.all_objects	All objects in all schemas

View name	Description or Babelfish limitation (if any)
<code>sys.all_sql_modules</code>	The union of <code>sys.sql_modules</code> and <code>sys.system_sql_modules</code>
<code>sys.all_views</code>	All views in all schemas
<code>sys.columns</code>	All columns in user-defined tables and views
<code>sys.configurations</code>	Babelfish support limited to a single read-only configuration.
<code>sys.data_spaces</code>	Contains a row for each data space. This can be a filegroup, partition scheme, or FILESTREAM data filegroup.
<code>sys.database_files</code>	A per-database view that contains one row for each file of a database as stored in the database itself.
<code>sys.database_mirroring</code>	For information, see <a href="#">sys.database_mirroring</a> in Microsoft Transact-SQL documentation.
<code>sys.database_principals</code>	For information, see <a href="#">sys.database_principals</a> in Microsoft Transact-SQL documentation.
<code>sys.database_role_members</code>	For information, see <a href="#">sys.database_role_members</a> in Microsoft Transact-SQL documentation.
<code>sys.databases</code>	All databases in all schemas
<code>sys.dm_exec_connections</code>	For information, see <a href="#">sys.dm_exec_connections</a> in Microsoft Transact-SQL documentation.
<code>sys.dm_exec_sessions</code>	For information, see <a href="#">sys.dm_exec_sessions</a> in Microsoft Transact-SQL documentation.

View name	Description or Babelfish limitation (if any)
sys.dm_hadr_database_replica_states	For information, see <a href="#">sys.dm_hadr_database_replica_states</a> in Microsoft Transact-SQL documentation.
sys.dm_os_host_info	For information, see <a href="#">sys.dm_os_host_info</a> in Microsoft Transact-SQL documentation.
sys.endpoints	For information, see <a href="#">sys.endpoints</a> in Microsoft Transact-SQL documentation.
sys.indexes	For information, see <a href="#">sys.indexes</a> in Microsoft Transact-SQL documentation.
sys.languages	For information, see <a href="#">sys.languages</a> in Microsoft Transact-SQL documentation.
sys.schemas	All schemas
sys.server_principals	All logins and roles
sys.sql_modules	For information, see <a href="#">sys.sql_modules</a> in Microsoft Transact-SQL documentation.
sys.sysconfigures	Babelfish support limited to a single read-only configuration.
sys.syscurconfigs	Babelfish support limited to a single read-only configuration.
sys.sysprocesses	For information, see <a href="#">sys.sysprocesses</a> in Microsoft Transact-SQL documentation.
sys.system_sql_modules	For information, see <a href="#">sys.system_sql_modules</a> in Microsoft Transact-SQL documentation.
sys.table_types	For information, see <a href="#">sys.table_types</a> in Microsoft Transact-SQL documentation.

View name	Description or Babelfish limitation (if any)
<code>sys.tables</code>	All tables in a schema
<code>sys.xml_schema_collections</code>	For information, see <a href="#">sys.xml_schema_collections</a> in Microsoft Transact-SQL documentation.

PostgreSQL implements system catalogs that are similar to the SQL Server object catalog views. For a complete list of system catalogs, see [System Catalogs](#) in the PostgreSQL documentation.

### DDL exports supported by Babelfish

From Babelfish 2.4.0 and 3.1.0 versions, Babelfish supports DDL exports using various tools. For example, you can use this functionality from SQL Server Management Studio (SSMS) to generate the data definition scripts for various objects in a Babelfish for Aurora PostgreSQL database. You can then use the generated DDL commands in this script to create the same objects in another Babelfish for Aurora PostgreSQL or SQL Server database.

Babelfish supports DDL exports for the following objects in the specified versions.

List of objects	2.4.0	3.1.0
User tables	Yes	Yes
Primary keys	Yes	Yes
Foreign keys	Yes	Yes
Unique constraints	Yes	Yes
Indexes	Yes	Yes
Check constraints	Yes	Yes
Views	Yes	Yes
Stored procedures	Yes	Yes
User-defined functions	Yes	Yes

List of objects	2.4.0	3.1.0
Table-valued functions	Yes	Yes
Triggers	Yes	Yes
User Defined Datatypes	No	No
User Defined Table Types	No	No
Users	No	No
Logins	No	No
Sequences	No	No
Roles	No	No

### Limitations with the exported DDLs

- **Use escape hatches before recreating the objects with the exported DDLs** – Babelfish doesn't support all the commands in the exported DDL script. Use escape hatches to avoid errors caused when recreating the objects from the DDL commands in Babelfish. For more information on escape hatches, see [Managing Babelfish error handling with escape hatches](#)
- **Objects containing CHECK constraints with explicit COLLATE clauses** – The scripts with these objects generated from a SQL Server database have different but equivalent collations as in the Babelfish database. For example, a few collations, such as `sql_latin1_general_cp1_cs_as`, `sql_latin1_general_cp1251_cs_as`, and `latin1_general_cs_as` are generated as `latin1_general_cs_as`, which is the closest Windows collation.

### Managing permissions and access control in Babelfish for Aurora PostgreSQL

In Babelfish for Aurora PostgreSQL, you can manage permissions and access control for databases, schemas, and objects. The following tables will outline the specific SQL commands for granting permissions in Babelfish to achieve various access control scenarios. It will cover supported use cases that can be implemented as well as workarounds for currently unsupported cases. This will allow you to configure appropriate permissions to meet your security and compliance requirements when working with Babelfish databases.

## Supported use cases

The following table explains the use cases that are supported in Babelfish. For each use case, the table shows the action needed to achieve it and sample SQL commands.

Use case	Action	SQL commands	Comments	Babelfish version compatibility
Allow login to do SELECTs/DMLs/DDIs in any database	Add login to sysadmin server role	ALTER SERVER ROLE sysadmin ADD MEMBER login	None	All versions
Allow login to do SELECTs/DMLs/DDIs in a database	Make login the owner of the database	ALTER AUTHORIZATION ON DATABASE: :database TO login	A database can have only one owner.	Version 3.4 and higher
Allow database user to do SELECTs/DMLs on a schema	Grant permission to database user on schema	GRANT SELECT/EXECUTE/INSERT/UPDATE/DELETE ON SCHEMA::schema TO user	None	Version 3.6 and higher, 4.2 and higher
Allow database user to do SELECTs/DMLs on a schema	Make database user owner of schema at schema creation time	CREATE SCHEMA schema AUTHORIZATION user	Changing schema ownership after creation isn't currently supported.	Version 1.2 and higher
Allow database user to do	Grant permission to database user on object	GRANT SELECT/EXECUTE/INSERT/UPDATE	None	All versions

Use case	Action	SQL commands	Comments	Babelfish version compatibility
SELECTs/DMLs on an object		E/DELETE ON OBJECT::object TO user		
Allow database user to do SELECTs/DMLs/DDIs in a database including dropping database	Add user to db_owner fixed database role	ALTER ROLE db_owner ADD MEMBER user	Only users can be added db_owner fixed database role. Adding roles to db_owner role is not yet supported.	Version 4.5 and higher, 5.1 and higher
Allow user or members of a custom database role to do only SELECTs in a database	Add user or role to db_datareader fixed database role	ALTER ROLE db_datareader ADD MEMBER user / role	None	Version 4.5 and higher, 5.1 and higher
Allow user or members of a custom database role to do only DMLs in a database	Add user or role to db_datawriter fixed database role	ALTER ROLE db_datawriter ADD MEMBER user / role	None	Version 4.5 and higher, 5.1 and higher
Allow user or members of a custom database role to do only DDLs in a database	Add user or role to db_accessadmin fixed database role	ALTER ROLE db_accessadmin ADD MEMBER user / role	None	Version 4.5 and higher, 5.1 and higher

Use case	Action	SQL commands	Comments	Babelfish version compatibility
Allow user or members of a custom database role to only CREATE/ALTER/DROP custom roles, GRANT/REVOKE permissions on objects in a database and/or CREATE SCHEMA in a database	Add user or role to db_securityadmin fixed database role	ALTER ROLE db_securityadmin ADD MEMBER user / role	None	Version 4.5 and higher, 5.1 and higher
Allow user or members of a custom database role to only CREATE/ALTER/DROP any user, grant and revoke database access and map user accounts to logins and/or CREATE SCHEMA in a database	Add user or role to db_accessadmin fixed database role	ALTER ROLE db_accessadmin ADD MEMBER user / role	None	Version 4.5 and higher, 5.1 and higher
Allow login to only CREATE/DROP/ALTER any database	Add login to dbcreator fixed server role	ALTER SERVER ROLE dbcreator ADD MEMBER login	Only those databases can be altered on which dbcreator login has access.	Version 4.5 and higher, 5.1 and higher

Use case	Action	SQL commands	Comments	Babelfish version compatibility
Allow login to only CREATE/ALTER/DROP any login	Add login to securityadmin fixed server role	ALTER SERVER ROLE securityadmin ADD MEMBER login	None	Version 4.5 and higher, 5.1 and higher

### Unsupported use cases with the workarounds

The following table explains the use cases that aren't supported in Babelfish, but which can be achieved using a workaround.

Use case	Action	SQL commands	Comments	Babelfish version compatibility for workarounds
Allow user to do SELECTs/DMLs on an object/schema along with option to GRANT these permissions to other users	GRANT the permissions to all the other users directly	GRANT SELECT/EXECUTE/INSERT/UPDATE/DELETE ON OBJECT/SCHEMA::object/schema TO user	GRANT ... WITH GRANT OPTION isn't currently supported.	Version 3.6 and higher, 4.2 and higher
Allow database user to do SELECTs/DMLs/DDIs in a database including	Add members of role to db_owner fixed database role	ALTER ROLE db_owner ADD MEMBER user	Adding roles to db_owner role isn't currently supported.	Version 4.5 and higher, 5.1 and higher

Use case	Action	SQL commands	Comments	Babelfish version compatibility for workarounds
dropping database				

## Unsupported use cases

The following table explains the use cases that aren't supported in Babelfish.

Use case	Comments
Deny user or members of a custom database role to do SELECTs in a database	db_denydatareader fixed database role is not yet supported
Deny user or members of a custom database role to do DMLs in a database	db_denydatawriter fixed database role isn't currently supported.
Allow login to only KILL any database connection	processadmin fixed server role isn't currently supported.
Allow login to only add or remove linked servers	setupadmin fixed server role isn't currently supported.

## Addressing object ownership differences after upgrade

Babelfish versions 4.6 and later, and 5.2 and later include a change to object ownership handling through the TDS endpoint. When you create new objects through the TDS endpoint, these objects are now owned by the schema owner instead of the current user. This ownership change might affect permissions behavior for new objects compared to existing objects when you upgrade from versions earlier than 4.6 or 5.2.

To resolve these ownership differences, Babelfish provides the `sys.generate_alter_ownership_statements()` function. This function generates SQL statements that align object ownership with schema ownership.

Be aware of the following limitations when addressing object ownership:

- Users with CREATE permissions granted through the PostgreSQL endpoint can't create objects through the TDS endpoint in those schemas.
- Modifying permissions on T-SQL objects through the PostgreSQL endpoint is not recommended and might cause incorrect T-SQL behavior.
- Access permissions might differ between old and new objects because of their ownership mismatch. For example, consider a schema owned by `sch_own` that includes objects owned by `dbo`. In this case, objects owned by `dbo` that were created before the upgrade might have different access permissions compared to objects owned by `sch_own` that were created after the upgrade. This may affect operations like SELECT and INSERT.

If your DB cluster includes objects created in Babelfish versions earlier than 4.6 or 5.2, consider aligning their ownership.

### To address object ownership differences

1. Connect to the `babelfish_db` database in your DB cluster using the PostgreSQL endpoint.
2. Run the following command:

```
SELECT * from sys.generate_alter_ownership_statements();
```

This generates a list of SQL statements intended to standardize ownership among the objects.

3. Execute the generated statements on a test environment first to validate their effect before applying on your production environment.

We recommend that you execute these statements to achieve a consistent object ownership model across your database.

## Differences between Babelfish for Aurora PostgreSQL and SQL Server

Babelfish is an evolving Aurora PostgreSQL feature, with new functionality added in each release since the initial offering in Aurora PostgreSQL 13.4. It's designed to provide T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. Each new version of Babelfish adds features and functions that better align with T-SQL functionality and behavior, as shown in the [Supported functionalities in Babelfish by version](#) table. For best results when working with Babelfish, we recommend that you understand the differences that currently exist between the

T-SQL supported by SQL Server and Babelfish for the latest version. To learn more, see [T-SQL differences in Babelfish](#).

In addition to the differences between T-SQL supported by Babelfish and SQL Server, you might also need to consider interoperability issues between Babelfish and PostgreSQL in the context of the Aurora PostgreSQL DB cluster. As mentioned previously, Babelfish supports T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. At the same time, the Babelfish database can also be accessed through the standard PostgreSQL port with PostgreSQL SQL statements. If you're considering using both PostgreSQL and Babelfish functionality in a production deployment, you need to be aware of the potential interoperability issues between schema names, identifiers, permissions, transactional semantics, multiple result sets, default collations, and so on. In simple terms, when PostgreSQL statements or PostgreSQL access occur in the context of Babelfish, interference between PostgreSQL and Babelfish can occur and can potentially affecting syntax, semantics, and compatibility when new versions of Babelfish are released. For complete information and guidance about all the considerations, see the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation.

#### Note

Before using both PostgreSQL native functionality and Babelfish functionality in the same application context, we strongly recommend that you consider the issues discussed in the [Guidance on Babelfish Interoperability](#) in the Babelfish for PostgreSQL documentation. These interoperability issues (Aurora PostgreSQL and Babelfish) are relevant only if you plan to use the PostgreSQL database instance in the same application context as Babelfish.

## Topics

- [Babelfish dump and restore](#)
- [T-SQL differences in Babelfish](#)
- [Transaction isolation levels in Babelfish](#)

## Babelfish dump and restore

Starting with version 4.0.0 and 3.4.0, Babelfish users can now utilize the dump and restore utilities to backup and restore their databases. For more information, see [Babelfish dump and restore](#). This feature is built on top of PostgreSQL dump and restore utilities. For more information, see [pg\\_dump](#) and see [pg\\_restore](#). In order to effectively use this feature in Babelfish, you need to

use PostgreSQL-based tools that are specifically adapted for Babelfish. The backup and restore feature for Babelfish differs significantly from that of SQL Server. For more information on these differences, see [Dump and restore functionality differences : Babelfish and SQL Server](#). Babelfish for Aurora PostgreSQL provides additional capabilities for backing up and restoring Amazon Aurora PostgreSQL DB clusters. For more information, see [Backing up and restoring an Amazon Aurora DB cluster](#).

## T-SQL differences in Babelfish

Following, you can find a table of T-SQL functionality as supported in the current release of Babelfish with some notes about differences in the behavior from that of SQL Server.

For more information about support in various versions, see [Supported functionalities in Babelfish by version](#). For information about features that currently aren't supported, see [Unsupported functionalities in Babelfish](#).

Babelfish is available with Aurora PostgreSQL-Compatible Edition. For more information about Babelfish releases, see the [Release Notes for Aurora PostgreSQL](#).

Functionality or syntax	Description of behavior or difference
<code>\</code> (line continuation character)	The line continuation character (a backslash prior to a newline) for character and hexadecimal strings isn't currently supported. For character strings, the backslash-newline is interpreted as characters in the string. For hexadecimal strings, backslash-newline results in a syntax error.
<code>@@version</code>	The format of the value returned by <code>@@version</code> is slightly different from the value returned by SQL Server. Your code might not work correctly if it depends on the formatting of <code>@@version</code> .
Aggregate functions	Aggregate functions are partially supported (AVG, COUNT, COUNT_BIG, GROUPING, MAX, MIN, STRING_AGG, and SUM are supported). For a list of unsupported aggregate functions, see <a href="#">Functions that aren't supported</a> .
ALTER TABLE	Supports adding or dropping a single column or constraint only.

Functionality or syntax	Description of behavior or difference
ALTER TABLE..ALTER COLUMN	NULL and NOT NULL can't currently be specified. To change the nullability of a column, use the PostgreSQL statement ALTER TABLE..{SET DROP} NOT NULL.
AT TIME ZONE	<p>During the transition from Daylight Saving Time (DST) to Standard Time, the overlapping period is displayed using the Standard Time offset. To clarify, consider the following example:</p> <pre data-bbox="597 619 1507 856">SELECT CONVERT(DATETIME2(0), '2022-10-30T02:00:00', 126) AT TIME ZONE 'Central European Standard Time'; GO; Result: 2022-10-30 02:00:00 +01:00</pre>
Blank column names with no column alias	<p>The sqlcmd and psql utilities handle columns with blank names differently:</p> <ul data-bbox="597 1033 1393 1180" style="list-style-type: none"> <li>• SQL Server sqlcmd returns a blank column name.</li> <li>• PostgreSQL psql returns a generated column name.</li> </ul>
CHECKSUM function	Babelfish and SQL Server use different hashing algorithms for the CHECKSUM function. As a result, the hash values generated by CHECKSUM function in Babelfish might be different from those generated by CHECKSUM function in SQL Server.
Column default	When creating a column default, the constraint name is ignored. To drop a column default, use the following syntax: ALTER TABLE...ALTER COLUMN..DROP DEFAULT...
Constraint_name	In SQL Server, constraint names must be unique within the schema to which the table belongs. However, in Babelfish, this applies only to PRIMARY KEY and UNIQUE constraints. Other types of constraints are not subject to this restriction.

Functionality or syntax	Description of behavior or difference
Constraints	PostgreSQL doesn't support turning on and turning off individual constraints. The statement is ignored and a warning is raised.
Constraints with IGNORE_DUP_KEY	Constraints are created without this property.
CREATE, ALTER, DROP SERVER ROLE	<p>ALTER SERVER ROLE is supported only for sysadmin. All other syntax is unsupported.</p> <p>The T-SQL user in Babelfish has an experience that is similar to SQL Server for the concepts of a login (server principal), a database, and a database user (database principal).</p>
CREATE, ALTER LOGIN clauses are supported with limited syntax	The CREATE LOGIN... PASSWORD clause, ...DEFAULT_DATABASE clause, and ...DEFAULT_LANGUAGE clause are supported. The ALTER LOGIN... PASSWORD clause is supported, but ALTER LOGIN... OLD_PASSWORD clause isn't supported. Only a login that is a sysadmin member can modify a password.
CREATE DATABASE case-sensitive collation	Case-sensitive collations aren't supported with the CREATE DATABASE statement.
CREATE DATABASE keywords and clauses	Options except COLLATE and CONTAINMENT=NONE aren't supported. The COLLATE clause is accepted and is always set to the value of <code>babelfishpg_tsql.server_collation_name</code> .
CREATE SCHEMA... supporting clauses	You can use the CREATE SCHEMA command to create an empty schema. Use additional commands to create schema objects.
Database ID values are different on Babelfish	The master and tempdb databases won't be database IDs 1 and 2.

Functionality or syntax	Description of behavior or difference
Index clauses	The following clauses are ignored: FILLFACTOR, ALLOW_PAGE_LOCKS, ALLOW_ROW_LOCKS, PAD_INDEX, STATISTICS_NORECOMPUTE, OPTIMIZE_FOR_SEQUENTIAL_KEY, SORT_IN_TEMPDB, DROP_EXISTING, ONLINE, COMPRESSION_DELAY, MAXDOP, and DATA_COMPRESSION
JSON support	Order of the name-value pairs isn't guaranteed. But the array type remains unaffected.
LOGIN objects	All options for LOGIN objects are not supported except for PASSWORD, DEFAULT_DATABASE, DEFAULT_LANGUAGE, ENABLE, DISABLE.
NEWSEQUENTIALID function	Implemented as NEWID; sequential behavior isn't guaranteed. When calling NEWSEQUENTIALID , PostgreSQL generates a new GUID value.
OUTPUT clause is supported with the following limitations	OUTPUT and OUTPUT INTO aren't supported in the same DML query. References to non-target table of UPDATE or DELETE operations in an OUTPUT clause aren't supported. OUTPUT... DELETED *, INSERTED * aren't supported in the same query.
Procedure or function parameter limit	Babelfish supports a maximum of 100 parameters for a procedure or function.
ROWGUIDCOL	This clause is currently ignored. Queries referencing \$GUIDCOL cause a syntax error.
SEQUENCE object support	<p>SEQUENCE objects are supported for the data types tinyint, smallint, int, bigint, numeric, and decimal.</p> <p>Aurora PostgreSQL supports precision to 19 places for data types numeric and decimal in a SEQUENCE.</p>
Server-level roles	The sysadmin server-level role is supported. Other server-level roles (other than sysadmin) aren't supported.

Functionality or syntax	Description of behavior or difference
Database-level roles other than <code>db_owner</code>	The <code>db_owner</code> database-level roles and user-defined database-level roles are supported. Other database-level roles (other than <code>db_owner</code> ) aren't supported.
SQL keyword <code>SPARSE</code>	The keyword <code>SPARSE</code> is accepted and ignored.
SQL keyword clause <code>ON filegroup</code>	This clause is currently ignored.
SQL keywords <code>CLUSTERED</code> and <code>NONCLUSTERED</code> for indexes and constraints	Babelfish accepts and ignores the <code>CLUSTERED</code> and <code>NONCLUSTERED</code> keywords.
<code>sysdatabases.cmptlevel</code>	<code>sysdatabases.cmptlevel</code> is always set to 120.
<code>tempdb</code> isn't reinitialized at restart	Permanent objects (like tables and procedures) created in <code>tempdb</code> aren't removed when the database is restarted.
<code>TEXTIMAGE_ON</code> filegroup	Babelfish ignores the <code>TEXTIMAGE_ON</code> <i>filegroup</i> clause.
Time precision	Babelfish supports 6-digit precision for fractional seconds. No adverse effects are anticipated with this behavior.
Transaction isolation levels	<code>READUNCOMMITTED</code> is treated the same as <code>READCOMMITTED</code> .
Virtual computed columns (non-persistent)	Virtual computed columns are created as persistent.
Without <code>SCHEMABINDING</code> clause	This clause isn't supported in functions, procedures, triggers, or views. The object is created, but as if <code>WITH SCHEMABINDING</code> was specified.

## Transaction isolation levels in Babelfish

Babelfish supports transaction isolation levels `READ UNCOMMITTED`, `READ COMMITTED` and `SNAPSHOT`. Starting from Babelfish 3.4 version additional isolation levels `REPEATABLE READ` and `SERIALIZABLE` are supported. All the isolation levels in Babelfish are supported with the behavior of corresponding isolation levels in PostgreSQL. SQL Server and Babelfish use different underlying mechanisms for implementing transaction isolation levels (blocking for concurrent access, locks held by transactions, error handling etc). And, there are some subtle differences in how concurrent access may work out for different workloads. For more information on this PostgreSQL behavior, see [Transaction Isolation](#).

### Topics

- [Overview of the transaction isolation levels](#)

- [Enabling or disabling transaction isolation levels](#)
- [Comparing Babelfish and SQL Server isolation levels](#)

### Overview of the transaction isolation levels

The original SQL Server transaction isolation levels are based on pessimistic locking where only one copy of data exists and queries must lock resources such as rows before accessing them. Later, a variation of the `READ COMMITTED` isolation level was introduced. This enables the use of row versions to provide better concurrency between readers and writers using non-blocking access. In addition, a new isolation level called `SNAPSHOT` is available. It also uses row versions to provide better concurrency than `REPEATABLE READ` isolation level by avoiding shared locks on read data that are held till the end of the transaction.

Unlike SQL Server, all transaction isolation levels in Babelfish are based on optimistic Locking (MVCC). Each transaction sees a snapshot of the data either at the beginning of the statement (`READ COMMITTED`) or at the beginning of the transaction (`REPEATABLE READ`, `SERIALIZABLE`), regardless of the current state of the underlying data. Therefore, the execution behavior of concurrent transactions in Babelfish might differ from SQL Server.

For example, consider a transaction with isolation level `SERIALIZABLE` that is initially blocked in SQL Server but succeeds later. It may end up failing in Babelfish due to a serialization conflict with a concurrent transaction that reads or updates the same rows. There could also be cases where executing multiple concurrent transactions yields a different final result in Babelfish as compared

to SQL Server. Applications that use isolation levels, should be thoroughly tested for concurrency scenarios.

Isolation levels in SQL Server	Babelfish isolation level	PostgreSQL isolation level	Comments
READ UNCOMMITTED	READ UNCOMMITTED	READ UNCOMMITTED	READ UNCOMMITTED is same as READ COMMITTED in Babelfish or PostgreSQL
READ COMMITTED	READ COMMITTED	READ COMMITTED	SQL Server READ COMMITTED is pessimistic locking based, Babelfish READ COMMITTED is snapshot (MVCC) based.
READ COMMITTED SNAPSHOT	READ COMMITTED	READ COMMITTED	Both are snapshot (MVCC) based but not exactly same.
SNAPSHOT	SNAPSHOT	REPEATABLE READ	Exactly same.
REPEATABLE READ	REPEATABLE READ	REPEATABLE READ	SQL Server REPEATABLE READ is pessimistic locking based, Babelfish REPEATABLE READ is snapshot (MVCC) based.
SERIALIZABLE	SERIALIZABLE	SERIALIZABLE	SQL Server SERIALIZABLE is pessimistic isolation, Babelfish SERIALIZA

Isolation levels in SQL Server	Babelfish isolation level	PostgreSQL isolation level	Comments
			BLE is snapshot (MVCC) based.

### Note

The table hints are not currently supported and their behavior is controlled by using the Babelfish predefined escape hatch `escape_hatch_table_hints`.

## Setting up the transaction isolation levels

Use the following command to set transaction isolation level:

### Example

```
SET TRANSACTION ISOLATION LEVEL { READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ |
  SNAPSHOT | SERIALIZABLE }
```

## Enabling or disabling transaction isolation levels

Transaction isolation levels `REPEATABLE READ` and `SERIALIZABLE` are disabled by default in Babelfish and you have to explicitly enable them by setting the `babelfishpg_tsql.isolation_level_serializable` or `babelfishpg_tsql.isolation_level_repeatable_read` escape hatch to `pg_isolation` using `sp_babelfish_configure`. For more information, see [Managing Babelfish error handling with escape hatches](#).

Below are examples for enabling or disabling the use of `REPEATABLE READ` and `SERIALIZABLE` in the current session by setting their respective escape hatches. Optionally include `server` parameter to set the escape hatch for the current session as well as for all subsequent new sessions.

To enable the use of `SET TRANSACTION ISOLATION LEVEL REPEATABLE READ` in current session only.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'pg_isolation'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL REPEATABLE READ in current session and all consequent new sessions.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'pg_isolation',  
'server'
```

To disable the use of SET TRANSACTION ISOLATION LEVEL REPEATABLE READ in current session and consequent new sessions.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'off', 'server'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session only.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'pg_isolation'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session and all consequent new sessions.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'pg_isolation', 'server'
```

To disable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session and consequent new sessions.

## Example

```
EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'off', 'server'
```

## Comparing Babelfish and SQL Server isolation levels

Below are a few examples on the nuances in how SQL Server and Babelfish implement the ANSI isolation levels.

### Note

- Isolation level REPEATABLE READ and SNAPSHOT are the same in Babelfish.
- Isolation level READ UNCOMMITTED and READ COMMITTED are the same in Babelfish.

The following example shows how to create the base table for all the examples mentioned below:

```
CREATE TABLE employee (  
    id sys.INT NOT NULL PRIMARY KEY,  
    name sys.VARCHAR(255)NOT NULL,  
    age sys.INT NOT NULL  
);  
INSERT INTO employee (id, name, age) VALUES (1, 'A', 10);  
INSERT INTO employee (id, name, age) VALUES (2, 'B', 20);  
INSERT INTO employee (id, name, age) VALUES (3, 'C', 30);
```

## Babelfish READ UNCOMMITTED compared with SQL Server READ UNCOMMITTED isolation level

The following table provides details on the dirty reads when concurrent transactions are executed. It shows observed results when using the READ UNCOMMITTED isolation level in SQL Server compared to the Babelfish implementation.

Transaction 1	Transaction 2	SQL Server READ UNCOMMITTED	Babelfish READ UNCOMMITTED
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;	SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;	None	None
Idle in transaction	UPDATE employee SET age=0;	Update successful.	Update successful.
Idle in transaction	INSERT INTO employee VALUES (4, 'D', 40);	Insert successful.	Insert successful.
SELECT * FROM employee;	Idle in transaction	Transaction 1 can see uncommitted changes from transaction 2.	Same as READ COMMITTED in Babelfish. Uncommitted changes from transaction 2 are not visible to transaction 1.
Idle in transaction	COMMIT	None	None
SELECT * FROM employee;	Idle in transaction	Sees the changes committed by transaction 2.	Sees the changes committed by transaction 2.

## Babelfish READ COMMITTED compared with SQL Server READ COMMITTED isolation level

The following table provides details on the read-write blocking behavior when concurrent transactions are executed. It shows observed results when using the READ COMMITTED isolation level in SQL Server compared to the Babelfish implementation.

Transaction 1	Transaction 2	SQL Server READ COMMITTED	Babelfish READ COMMITTED
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL READ COMMITTED;	SET TRANSACTION ISOLATION LEVEL READ COMMITTED;	None	None
SELECT * FROM employee;	Idle in transaction	None	None
Idle in transaction	UPDATE employee SET age=100 WHERE id = 1;	Update successful.	Update successful.
UPDATE employee SET age = 0 WHERE age IN (SELECT MAX(age) FROM employee);	Idle in transaction	Step blocked until transaction 2 commits.	Transaction 2 changes is not visible yet. Updates row with id=3.
Idle in transaction	COMMIT	Transaction 2 commits successfully. Transaction 1 is now unblocked and sees the update from transaction 2.	Transaction 2 commits successfully.

Transaction 1	Transaction 2	SQL Server READ COMMITTED	Babelfish READ COMMITTED
SELECT * FROM employee;	Idle in transaction	Transaction 1 updates row with id = 1.	Transaction 1 updates row with id = 3.

### Babelfish READ COMMITTED compared with SQL Server READ COMMITTED SNAPSHOT isolation level

The following table provides details on the blocking behavior of the newly inserted rows when concurrent transactions are executed. It shows observed results when using the READ COMMITTED SNAPSHOT isolation level in SQL Server compared to the READ COMMITTED Babelfish implementation.

Transaction 1	Transaction 2	SQL Server READ COMMITTED SNAPSHOT	Babelfish READ COMMITTED
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL READ COMMITTED;	SET TRANSACTION ISOLATION LEVEL READ COMMITTED;	None	None
INSERT INTO employee VALUES (4, 'D', 40);	Idle in transaction	None	None
Idle in transaction	UPDATE employee SET age = 99;	Step is blocked until transaction 1 commits. Inserted row is locked by transaction 1.	Updated three rows. The newly inserted row is not visible yet.

Transaction 1	Transaction 2	SQL Server READ COMMITTED SNAPSHOT	Babelfish READ COMMITTED
COMMIT	Idle in transaction	Commit successful. Transaction 2 is now unblocked.	Commit successful.
Idle in transaction	SELECT * FROM employee;	All 4 rows have age=99.	Row with id = 4 has age value 40 since it was not visible to transaction 2 during update query. Other rows are updated to age=99.

### Babelfish REPEATABLE READ compared with SQL Server REPEATABLE READ isolation level

The following table provides details on the read-write blocking behavior when concurrent transactions are executed. It shows observed results when using the REPEATABLE READ isolation level in SQL Server compared to the REPEATABLE READ Babelfish implementation.

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	None	None
SELECT * FROM employee;	Idle in transaction	None	None

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
UPDATE employee SET name='A_TXN1' WHERE id=1;	Idle in transaction	None	None
Idle in transaction	SELECT * FROM employee WHERE id != 1;	None	None
Idle in transaction	SELECT * FROM employee;	Transaction 2 is blocked until transaction 1 commits.	Transaction 2 proceeds normally.
COMMIT	Idle in transaction	None	None
Idle in transaction	SELECT * FROM employee;	Update from transaction 1 is visible.	Update from transaction 1 is not visible.
COMMIT	Idle in transaction	None	None
Idle in transaction	SELECT * FROM employee;	sees the update from transaction 1.	sees the update from transaction 1.

The following table provides details on the write-write blocking behavior when concurrent transactions are executed. It shows observed results when using the REPEATABLE READ isolation level in SQL Server compared to the REPEATABLE READ Babelfish implementation.

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	None	None
UPDATE employee SET name='A_TXN1' WHERE id=1;	Idle in transaction	None	None
Idle in transaction	UPDATE employee SET name='A_TXN2' WHERE id=1;	Transaction 2 blocked.	Transaction 2 blocked.
COMMIT	Idle in transaction	Commit successful and transaction 2 has been unblocked.	Commit successful and transaction 2 fails with error could not serialize access due to concurrent update.
Idle in transaction	COMMIT	Commit successful.	Transaction 2 has already been aborted.
Idle in transaction	SELECT * FROM employee;	Row with id=1 has name='A_TX2'.	Row with id=1 has name='A_TX1'.

The following table provides details on the phantom reads behavior when concurrent transactions are executed. It shows observed results when using the REPEATABLE READ isolation level in SQL Server compared to the REPEATABLE READ Babelfish implementation.

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	None	None
SELECT * FROM employee;	Idle in transaction	None	None
Idle in transaction	INSERT INTO employee VALUES (4, 'NewRowName', 20);	Transaction 2 proceeds without any blocking.	Transaction 2 proceeds without any blocking.
Idle in transaction	SELECT * FROM employee;	Newly inserted row is visible.	Newly inserted row is visible.
Idle in transaction	COMMIT	None	None
SELECT * FROM employee;	Idle in transaction	New row inserted by transaction 2 is visible.	New row inserted by transaction 2 is not visible.
COMMIT	Idle in transaction	None	None
SELECT * FROM employee;	Idle in transaction	Newly inserted row is visible.	Newly inserted row is visible.

The following table provides details when concurrent transactions are executed and the different final results when using the REPEATABLE READ isolation level in SQL Server compared to the REPEATABLE READ Babelfish implementation.

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	None	None
UPDATE employee SET age = 100 WHERE age IN (SELECT MIN(age) FROM employee);	Idle in transaction	Transaction 1 updates row with id 1.	Transaction 1 updates row with id 1.
Idle in transaction	UPDATE employee SET age = 0 WHERE age IN (SELECT MAX(age) FROM employee);	Transaction 2 is blocked since the SELECT statement tries to read rows locked by UPDATE query in transaction 1.	Transaction 2 proceeds without any blocking since read is never blocked, SELECT statement executes and finally row with id = 3 is updated since transaction 1 changes are not visible yet.
Idle in transaction	SELECT * FROM employee;	This step is executed after transaction 1 has committed. Row with id = 1 is updated by transaction 2 in previous step and is visible here.	Row with id = 3 is updated by Transaction 2.

Transaction 1	Transaction 2	SQL Server REPEATABLE READ	Babelfish REPEATABLE READ
COMMIT	Idle in transaction	Transaction 2 is now unblocked.	Commit successful.
Idle in transaction	COMMIT	None	None
SELECT * FROM employee;	Idle in transaction	Both transaction execute update on row with id = 1.	Different rows are updated by transaction 1 and 2.

### Babelfish SERIALIZABLE compared with SQL Server SERIALIZABLE isolation level

The following table provides details on the range locks when concurrent transactions are executed. It shows observed results when using the SERIALIZABLE isolation level in SQL Server compared to the SERIALIZABLE Babelfish implementation.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	None	None
SELECT * FROM employee;	Idle in transaction	None	None
Idle in transaction	INSERT INTO employee VALUES (4, 'D', 35);	Transaction 2 is blocked until transaction 1 commits.	Transaction 2 proceeds without any blocking.
Idle in transaction	SELECT * FROM employee;	None	None

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
COMMIT	Idle in transaction	Transaction 1 commits successfully. Transaction 2 is now unblocked.	Transaction 1 commits successfully.
Idle in transaction	COMMIT	None	None
SELECT * FROM employee;	Idle in transaction	Newly inserted row is visible.	Newly inserted row is visible.

The following table provides details when concurrent transactions are executed and the different final results when using the SERIALIZABLE isolation level in SQL Server compared to the SERIALIZABLE Babelfish implementation.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	None	None
Idle in transaction	INSERT INTO employee VALUES (4, 'D', 40);	None	None
UPDATE employee SET age =99 WHERE id = 4;	Idle in transaction	Transaction 1 is blocked until transaction 2 commits.	Transaction 1 proceeds without any blocking.
Idle in transaction	COMMIT	Transaction 2 commits successfully.	Transaction 2 commits successfully.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
		Transaction 1 is now unblocked.	
COMMIT	Idle in transaction	None	None
SELECT * FROM employee;	Idle in transaction	Newly inserted row is visible with age value = 99.	Newly inserted row is visible with age value = 40.

The following table provides details when you INSERT into a table with unique constraint. It shows observed results when using the SERIALIZABLE isolation level in SQL Server compared to the SERIALIZABLE Babelfish implementation.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	None	None
Idle in transaction	INSERT INTO employee VALUES (4, 'D', 40);	None	None
INSERT INTO employee VALUES ((SELECT MAX(id)+1 FROM employee), 'E', 50);	Idle in transaction	Transaction 1 is blocked until transaction 2 commits.	Transaction 1 is blocked until transaction 2 commits.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
Idle in transaction	COMMIT	Transaction 2 commits successfully. Transaction 1 is now unblocked.	Transaction 2 commits successfully. Transaction 1 aborted with error duplicate key value violates unique constraint.
COMMIT	Idle in transaction	Transaction 1 commits successfully.	Transaction 1 commits fails with could not serialize access due to read or write dependencies among transactions.
SELECT * FROM employee;	Idle in transaction	row (5, 'E', 50) is inserted.	Only 4 rows exists.

In Babelfish, concurrent transactions running with Isolation Level serializable will fail with serialization anomaly error if the execution of these transaction is inconsistent with all possible serial (one at a time) executions of those transactions.

The following tables provides details on serialization anomaly when concurrent transactions are executed. It shows observed results when using the SERIALIZABLE isolation level in SQL Server compared to the SERIALIZABLE Babelfish implementation.

Transaction 1	Transaction 2	SQL Server SERIALIZABLE	Babelfish SERIALIZABLE
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	None	None

<b>Transaction 1</b>	<b>Transaction 2</b>	<b>SQL Server SERIALIZABLE</b>	<b>Babelfish SERIALIZABLE</b>
SELECT * FROM employee;	Idle in transaction	None	None
UPDATE employee SET age=5 WHERE age=10;	Idle in transaction	None	None
Idle in transaction	SELECT * FROM employee;	Transaction 2 is blocked until transaction 1 commits.	Transaction 2 proceeds without any blocking.
Idle in transaction	UPDATE employee SET age=35 WHERE age=30;	None	None
COMMIT	Idle in transaction	Transaction 1 commits successfully.	Transaction 1 is committed first and is able to commit successfully.
Idle in transaction	COMMIT	Transaction 2 commits successfully.	Transaction 2 commit fails with serialization error, the whole transaction has been rolled back. Retry transaction 2.
SELECT * FROM employee;	Idle in transaction	Changes from both transactions are visible.	Transaction 2 was rolled back. Only transaction 1 changes are seen.

In Babelfish, serialization anomaly is only possible if all the concurrent transactions are executing at isolation level SERIALIZABLE. In the following table, let's take the above example but set transaction 2 to isolation level REPEATABLE READ instead.

Transaction 1	Transaction 2	SQL Server isolation levels	Babelfish isolation levels
BEGIN TRANSACTION	BEGIN TRANSACTION	None	None
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;	SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;	None	None
SELECT * FROM employee;	Idle in transaction	None	None
UPDATE employee SET age=5 WHERE age=10;	Idle in transaction	None	None
Idle in transaction	SELECT * FROM employee;	Transaction 2 is blocked until transaction 1 commits.	Transaction 2 proceeds without any blocking.
Idle in transaction	UPDATE employee SET age=35 WHERE age=30;	None	None
COMMIT	Idle in transaction	Transaction 1 commits successfully.	Transaction 1 commits successfully.
Idle in transaction	COMMIT	Transaction 2 commits successfully.	Transaction 2 commits successfully.

Transaction 1	Transaction 2	SQL Server isolation levels	Babelfish isolation levels
SELECT * FROM employee;	Idle in transaction	Changes from both transactions are visible.	Changes from both transactions are visible.

## Using Babelfish features with limited implementation

Each new version of Babelfish adds support for features that better align with T-SQL functionality and behavior. Still, there are some unsupported features and differences in the current implementation. In the following, you can find information about functional differences between Babelfish and T-SQL, with some workarounds or usage notes.

As of version 1.2.0 of Babelfish, the following features currently have limited implementations:

- **SQL Server catalogs (system views)** – The catalogs `sys.sysconfigures`, `sys.syscurconfigs`, and `sys.configurations` support a single read-only configuration only. The `sp_configure` isn't currently supported. For more information about the other SQL Server views implemented by Babelfish, see [Getting information from the Babelfish system catalog](#).
- **GRANT permissions** – `GRANT...TO PUBLIC` is supported, but `GRANT..TO PUBLIC WITH GRANT OPTION` is not currently supported.
- **SQL Server ownership chain and permission mechanism limitation** – In Babelfish, the SQL Server ownership chain works for views but not for stored procedures. This means that procedures must be granted explicit access to other objects owned by the same owner as the calling procedures. In SQL Server, granting the caller `EXECUTE` permissions on the procedure is sufficient to call other objects owned by same owner. In Babelfish, caller must also be granted permissions on the objects accessed by the procedure.
- **Resolution of unqualified (without schema name) object references** – When a SQL object (procedure, view, function or trigger) references an object without qualifying it with a schema name, SQL Server resolves the object's schema name by using the schema name of the SQL object in which the reference occurs. Currently, Babelfish resolves this differently, by using the default schema of the database user executing the procedure.
- **Default schema changes, sessions, and connections** – If users change their default schema with `ALTER USER...WITH DEFAULT SCHEMA`, the change takes effect immediately in that session.

However, for other currently connected sessions belonging to the same user, the timing differs, as follows:

- For SQL Server: – The change takes effect across all other connections for this user immediately.
- For Babelfish: – The change takes effect for this user for new connections only.
- **ROWVERSION and TIMESTAMP datatypes implementation and escape hatch setting**  
– The ROWVERSION and TIMESTAMP datatypes are now supported in Babelfish. To use ROWVERSION or TIMESTAMP in Babelfish, you must change the setting for the escape hatch `babelfishpg_tsql.escape_hatch_rowversion` from its default (strict) to ignore. The Babelfish implementation of the ROWVERSION and TIMESTAMP datatypes is mostly semantically identical to SQL Server, with the following exceptions:

- The built-in `@@DBTS` function behaves similarly to SQL Server, but with small differences. Rather than returning the last-used value for `SELECT @@DBTS`, Babelfish generates a new timestamp, due to the underlying PostgreSQL database engine and its multi-version concurrency control (MVCC) implementation.
- In SQL Server, every inserted or updated row gets a unique ROWVERSION/TIMESTAMP value. In Babelfish, every inserted row updated by the same statement is assigned the same ROWVERSION/TIMESTAMP value.

For example, when an UPDATE statement or INSERT-SELECT statement affects multiple rows, in SQL Server, the affected rows all have different values in their ROWVERSION/TIMESTAMP column. In Babelfish (PostgreSQL), the rows have the same value.

- In SQL Server, when you create a new table with SELECT-INTO, you can cast an explicit value (such as NULL) to a to-be-created ROWVERSION/TIMESTAMP column. When you do the same thing in Babelfish, an actual ROWVERSION/TIMESTAMP value is assigned to each row in the new table for you, by Babelfish.

These minor differences in ROWVERSION/TIMESTAMP datatypes shouldn't have an adverse impact on applications running on Babelfish.

- **TOP N PERCENT clause** – Babelfish provides support for the TOP N PERCENT clause with some limitations. SELECT operations are supported while UPDATE, DELETE and INSERT operations with TOP N PERCENT are not supported. The WITH TIES option and subqueries within the TOP clause are also not supported. When the expression value exceeds 100, behavior differs:
  - For SQL Server – Throws an error.
  - For Babelfish – Treats the value as valid and returns results.

- **Schema creation, ownership, and permissions** – Permissions to create and access objects in a schema owned by a non-DBO user (using `CREATE SCHEMA schema name AUTHORIZATION user name`) differ for SQL Server and Babelfish non-DBO users, as shown in the following table:

Database user (non-DBO) who owns the schema can do the following:	SQL Server	Babelfish
Create objects in the schema without additional grants by the DBO?	No	Yes
Access objects created by DBO in the schema without additional grants?	Yes	No

- **CREATE OR ALTER VIEW / ALTER VIEW syntax** – The support for these syntax in Babelfish has the following limitations:
  - These statements cannot be used on views that have an INSTEAD-OF trigger attached.
  - These statements cannot be used on views that have another view based on this view.

## Improving Babelfish query performance

You can achieve faster query processing in Babelfish using query hints and the PostgreSQL optimizer.

### Topics

- [Using explain plan to improve Babelfish query performance](#)
- [Using T-SQL query hints to improve Babelfish query performance](#)

You can also improve the query performance using `sp_babelfish_volatility` procedure. For more information, see [sp\\_babelfish\\_volatility](#).

You can also improve the query performance using subquery transformation and subquery cache. For more information, see [Optimizing correlated subqueries in Aurora PostgreSQL](#).

## Using explain plan to improve Babelfish query performance

Starting with version 2.1.0, Babelfish includes two functions that transparently use the PostgreSQL optimizer to generate estimated and actual query plans for T-SQL queries on the TDS port. These functions are similar to using SET STATISTICS PROFILE or SET SHOWPLAN\_ALL with SQL Server databases to identify and improve slow running queries.

### Note

Getting query plans from functions, control flows, and cursors isn't currently supported.

In the table you can find a comparison of query plan explain functions across SQL Server, Babelfish, and PostgreSQL.

SQL Server	Babelfish	PostgreSQL
SHOWPLAN_ALL	BABELFISH_SHOWPLAN_ALL	EXPLAIN
STATISTICS PROFILE	BABELFISH_STATISTICS PROFILE	EXPLAIN ANALYZE
Uses the SQL Server optimizer	Uses the PostgreSQL optimizer	Uses the PostgreSQL optimizer
SQL Server input and output format	SQL Server input and PostgreSQL output format	PostgreSQL input and output format
Set for the session	Set for the session	Apply to a specific statement
Supports the following: <ul style="list-style-type: none"> <li>• SELECT</li> <li>• INSERT</li> <li>• UPDATE</li> <li>• DELETE</li> <li>• CURSOR</li> <li>• CREATE</li> </ul>	Supports the following: <ul style="list-style-type: none"> <li>• SELECT</li> <li>• INSERT</li> <li>• UPDATE</li> <li>• DELETE</li> <li>• CREATE</li> <li>• EXECUTE</li> </ul>	Supports the following: <ul style="list-style-type: none"> <li>• SELECT</li> <li>• INSERT</li> <li>• UPDATE</li> <li>• DELETE</li> <li>• CURSOR</li> <li>• CREATE</li> </ul>

SQL Server	Babelfish	PostgreSQL
<ul style="list-style-type: none"> <li>EXECUTE</li> <li>EXEC and functions, including control flow (CASE, WHILE-BREAK-CONTINUE, WAITFOR, BEGIN-END, IF-ELSE, and so on)</li> </ul>	<ul style="list-style-type: none"> <li>EXEC</li> <li>RAISEERROR</li> <li>THROW</li> <li>PRINT</li> <li>USE</li> </ul>	<ul style="list-style-type: none"> <li>EXECUTE</li> </ul>

Use the Babelfish functions as follows:

- SET BABELFISH\_SHOWPLAN\_ALL [ON|OFF] – Set to ON to generate an estimated query execution plan. This function implements the behavior of the PostgreSQL EXPLAIN command. Use this command to obtain the explain plan for given query.
- SET BABELFISH\_STATISTICS PROFILE [ON|OFF] – Set to ON for actual query execution plans. This function implements the behavior of PostgreSQL's EXPLAIN ANALYZE command.

For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE see [EXPLAIN](#) in the PostgreSQL documentation.

### Note

Starting with version 2.2.0, you can set the `escape_hatch_showplan_all` parameter to *ignore* in order to avoid the use of `BABELFISH_` prefix in the SQL Server syntax for `SHOWPLAN_ALL` and `STATISTICS PROFILE SET` commands.

For example, the following command sequence turns on query planning and then returns an estimated query execution plan for the SELECT statement without running the query. This example uses the SQL Server sample northwind database using the `sqlcmd` command-line tool to query the TDS port:

```
1> SET BABELFISH_SHOWPLAN_ALL ON
2> GO
1> SELECT t.territoryid, e.employeeid FROM
```

```

2> dbo.employeeterritories e, dbo.territories t
3> WHERE e.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO

```

QUERY PLAN

```

-----

Query Text: SELECT t.territoryid, e.employeeid FROM
dbo.employeeterritories e, dbo.territories t
WHERE e.territoryid=e.territoryid ORDER BY t.territoryid
Sort (cost=6231.74..6399.22 rows=66992 width=10)
  Sort Key: t.territoryid NULLS FIRST
  -> Nested Loop (cost=0.00..861.76 rows=66992 width=10)
    -> Seq Scan on employeeterritories e (cost=0.00..22.70 rows=1264 width=4)
        Filter: ((territoryid)::"varchar" IS NOT NULL)
    -> Materialize (cost=0.00..1.79 rows=53 width=6)
        -> Seq Scan on territories t (cost=0.00..1.53 rows=53 width=6)

```

When you finish reviewing and adjusting your query, you turn off the function as shown following:

```

1> SET BABELFISH_SHOWPLAN_ALL OFF

```

With BABELFISH\_STATISTICS PROFILE set to ON, each executed query returns its regular result set followed by an additional result set that shows actual query execution plans. Babelfish generates the query plan that provides the fastest result set when it invokes the SELECT statement.

```

1> SET BABELFISH_STATISTICS PROFILE ON
1>
2> GO
1> SELECT e.employeeid, t.territoryid FROM
2> dbo.employeeterritories e, dbo.territories t
3> WHERE t.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO

```

The result set and the query plan are returned (this example shows only the query plan).

QUERY PLAN

```

-----
Query Text: SELECT e.employeeid, t.territoryid FROM
dbo.employeeterritories e, dbo.territories t
WHERE t.territoryid=e.territoryid ORDER BY t.territoryid
Sort (cost=42.44..43.28 rows=337 width=10)
  Sort Key: t.territoryid NULLS FIRST

-> Hash Join (cost=2.19..28.29 rows=337 width=10)
  Hash Cond: ((e.territoryid)::"varchar" = (t.territoryid)::"varchar")
    -> Seq Scan on employeeterritories e (cost=0.00..22.70 rows=1270 width=36)
    -> Hash (cost=1.53..1.53 rows=53 width=6)
      -> Seq Scan on territories t (cost=0.00..1.53 rows=53 width=6)

```

To learn more about how to analyze your queries and the results returned by the PostgreSQL optimizer, see [explain.depesz.com](http://explain.depesz.com). For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE, see [EXPLAIN](#) in the PostgreSQL documentation.

### Parameters that control Babelfish explain options

You can use the parameters shown in the following table to control the type of information that's displayed by your query plan.

Parameter	Description
<code>babelfishpg_tsql.explain_buffers</code>	A boolean that turns on (and off) buffer usage information for the optimizer. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_costs</code>	A boolean that turns on (and off) estimated startup and total cost information for the optimizer. (Default: on) (Allowable: off, on)
<code>babelfishpg_tsql.explain_format</code>	Specifies the output format for the EXPLAIN plan. (Default: text) (Allowable: text, xml, json, yaml)
<code>babelfishpg_tsql.explain_settings</code>	A boolean that turns on (or off) the inclusion of information about configuration parameter

Parameter	Description
	s in the EXPLAIN plan output. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_summary</code>	A boolean that turns on (or off) summary information such as total time after the query plan. (Default: on) (Allowable: off, on)
<code>babelfishpg_tsql.explain_timing</code>	A boolean that turns on (or off) actual startup time and time spent in each node in the output. (Default: on) (Allowable: off, on)
<code>babelfishpg_tsql.explain_verbose</code>	A boolean that turns on (or off) the most detailed version of an explain plan. (Default: off) (Allowable: off, on)
<code>babelfishpg_tsql.explain_wal</code>	A boolean that turns on (or off) generation of WAL record information as part of an explain plan. (Default: off) (Allowable: off, on)

You can check the values of any Babelfish-related parameters on your system by using either PostgreSQL client or SQL Server client. Run the following command to get your current parameter values:

```
1> execute sp_babelfish_configure '%explain%';
2> GO
```

In the following output, you can see that all settings on this particular Babelfish DB cluster are at their default values. Not all output is shown in this example.

```

          name                setting          short_desc
-----
babelfishpg_tsql.explain_buffers  off          Include information on buffer usage
babelfishpg_tsql.explain_costs   on           Include information on estimated startup
and total cost

```

<code>babelfishpg_tsql.explain_format</code>	<code>text</code>	Specify the output format, which can be TEXT, XML, JSON, or YAML
<code>babelfishpg_tsql.explain_settings</code>	<code>off</code>	Include information on configuration parameters
<code>babelfishpg_tsql.explain_summary</code>	<code>on</code>	Include summary information (e.g., totaled timing information) after the query plan
<code>babelfishpg_tsql.explain_timing</code>	<code>on</code>	Include actual startup time and time spent in each node in the output
<code>babelfishpg_tsql.explain_verbose</code>	<code>off</code>	Display additional information regarding the plan
<code>babelfishpg_tsql.explain_wal</code>	<code>off</code>	Include information on WAL record generation

(8 rows affected)

You can change the setting for these parameters using `sp_babelfish_configure`, as shown in the following example.

```
1> execute sp_babelfish_configure 'explain_verbose', 'on';
2> GO
```

If you want make the setting permanent on a cluster-wide level, include the keyword `server`, as shown in the following example.

```
1> execute sp_babelfish_configure 'explain_verbose', 'on', 'server';
2> GO
```

## Using T-SQL query hints to improve Babelfish query performance

Starting with version 2.3.0, Babelfish supports the use of query hints using `pg_hint_plan`. In Aurora PostgreSQL, `pg_hint_plan` is installed by default. For more information about the PostgreSQL extension `pg_hint_plan`, see [https://github.com/oss-db/pg\\_hint\\_plan](https://github.com/oss-db/pg_hint_plan). For details about the version of this extension supported by Aurora PostgreSQL, see [Extension versions for Amazon Aurora PostgreSQL](#) in *Release Notes for Aurora PostgreSQL*.

The query optimizer is well-designed to find the optimal execution plan for a SQL statement. When selecting a plan, the query optimizer considers both the engine's cost model, and column and table statistics. However, the suggested plan might not meet the needs of your datasets. Thus, query hints addresses the performance issues to improve execution plans. A query hint is syntax added to the SQL standard that instructs the database engine about how to execute the query. For

example, a hint may instruct the engine to follow a sequential scan and override any plan that the query optimizer had selected.

### Turning on T-SQL query hints in Babelfish

Currently, Babelfish ignores all T-SQL hints by default. To apply T-SQL hints, run the command `sp_babelfish_configure` with the `enable_pg_hint` value as ON.

```
EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on' [, 'server']
```

You can make the settings permanent on a cluster-wide level by including the `server` keyword. To configure the setting for the current session only, don't use `server`.

After `enable_pg_hint` is ON, Babelfish applies the following T-SQL hints.

- INDEX hints
- JOIN hints
- FORCE ORDER hint
- MAXDOP hint

For example, the following command sequence turns on `pg_hint_plan`.

```
1> CREATE TABLE t1 (a1 INT PRIMARY KEY, b1 INT);
2> CREATE TABLE t2 (a2 INT PRIMARY KEY, b2 INT);
3> GO
1> EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on';
2> GO
1> SET BABELFISH_SHOWPLAN_ALL ON;
2> GO
1> SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2; --NO HINTS (HASH JOIN)
2> GO
```

No hint is applied to the `SELECT` statement. The query plan with no hint is returned.

```
QUERY PLAN
```

```
-----
Query Text: SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2
```

```

Hash Join (cost=60.85..99.39 rows=2260 width=16)
  Hash Cond: (t1.a1 = t2.a2)
    -> Seq Scan on t1 (cost=0.00..32.60 rows=2260 width=8)
    -> Hash (cost=32.60..32.60 rows=2260 width=8)
    -> Seq Scan on t2 (cost=0.00..32.60 rows=2260 width=8)

```

```

1> SELECT * FROM t1 INNER MERGE JOIN t2 ON t1.a1 = t2.a2;
2> GO

```

The query hint is applied to the SELECT statement. The following output shows that the query plan with merge join is returned.

#### QUERY PLAN

```

-----
Query Text: SELECT/*+ MergeJoin(t1 t2) Leading(t1 t2)*/ * FROM t1 INNER JOIN t2 ON
  t1.a1 = t2.a2
Merge Join (cost=0.31..190.01 rows=2260 width=16)
  Merge Cond: (t1.a1 = t2.a2)
    -> Index Scan using t1_pkey on t1 (cost=0.15..78.06 rows=2260 width=8)
    -> Index Scan using t2_pkey on t2 (cost=0.15..78.06 rows=2260 width=8)

```

```

1> SET BABELFISH_SHOWPLAN_ALL OFF;
2> GO

```

## Limitations

While using the query hints, consider the following limitations:

- If a query plan is cached before `enable_pg_hint` is turned on, hints won't be applied in the same session. It will be applied in the new session .
- If schema names are explicitly given, then hints can't be applied. You can use table aliases as a workaround.
- A query hint can't be applied to views and sub-queries.
- Hints don't work for UPDATE/DELETE statements with JOINS.
- An index hint for a non-existing index or table is ignored.

- The FORCE ORDER hint doesn't work for HASH JOINS and non-ANSI JOINS.

## Using Aurora PostgreSQL extensions with Babelfish

Aurora PostgreSQL provides extensions for working with other Amazon services. These are optional extensions that support various use cases, such as using Amazon S3 with your DB cluster for importing or exporting data.

- To import data from an Amazon S3 bucket to your Babelfish DB cluster, you set up the `aws_s3` Aurora PostgreSQL extension. This extension also lets you export data from your Aurora PostgreSQL DB cluster to an Amazon S3 bucket.
- Amazon Lambda is a compute service that lets you run code without provisioning or managing servers. You can use Lambda functions to do things like process event notifications from your DB instance. To learn more about Lambda, see [What is Amazon Lambda?](#) in the *Amazon Lambda Developer Guide*. To invoke Lambda functions from your Babelfish DB cluster, you set up the `aws_lambda` Aurora PostgreSQL extension.

To set up these extensions for your Babelfish cluster, you first need to grant permission to the internal Babelfish user to load the extensions. After granting permission, you can then load Aurora PostgreSQL extensions.

### Enabling Aurora PostgreSQL extensions in your Babelfish DB cluster

Before you can load the `aws_s3` or the `aws_lambda` extensions, you grant the needed privileges to your Babelfish DB cluster.

The procedure following uses the `psql` PostgreSQL command line tool to connect to the DB cluster. For more information, see [Using psql to connect to the DB cluster](#). You can also use `pgAdmin`. For details, see [Using pgAdmin to connect to the DB cluster](#).

This procedure loads both `aws_s3` and `aws_lambda`, one after the other. You don't need to load both if you want to use only one of these extensions. The `aws_commons` extension is required by each, and it's loaded by default as shown in the output.

### To set up your Babelfish DB cluster with privileges for the Aurora PostgreSQL extensions

1. Connect to your Babelfish DB cluster. Use the name for the "master" user (-U) that you specified when you created the Babelfish DB cluster. The default (`postgres`) is shown in the examples.

For Linux, macOS, or Unix:

```
psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com \  
-U postgres \  
-d babelfish_db \  
-p 5432
```

For Windows:

```
psql -h your-Babelfish.cluster.444455556666-us-east-1.rds.amazonaws.com ^  
-U postgres ^  
-d babelfish_db ^  
-p 5432
```

The command responds with a prompt to enter the password for the user name (-U).

```
Password:
```

Enter the password for the user name (-U) for the DB cluster. When you successfully connect, you see output similar to the following.

```
psql (13.4)  
SSL connection (protocol: TLSv1.3, cipher: TLS_AES_256_GCM_SHA384, bits: 256,  
compression: off)  
Type "help" for help.  
  
postgres=>
```

2. Grant privileges to the internal Babelfish user to create and load extensions.

```
babelfish_db=> GRANT rds_superuser TO master_dbo;  
GRANT ROLE
```

3. Create and load the `aws_s3` extension. The `aws_commons` extension is required, and it's installed automatically when the `aws_s3` is installed.

```
babelfish_db=> create extension aws_s3 cascade;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

#### 4. Create and load the `aws_lambda` extension.

```
babelfish_db=> create extension aws_lambda cascade;  
CREATE EXTENSION  
babelfish_db=>
```

### Using Babelfish with Amazon S3

If you don't already have an Amazon S3 bucket to use with your Babelfish DB cluster, you can create one. For any Amazon S3 bucket that you want to use, you provide access.

Before trying to import or export data using an Amazon S3 bucket, complete the following one-time steps.

#### To set up access for your Babelfish DB instance to your Amazon S3 bucket

1. Create an Amazon S3 bucket for your Babelfish instance, if needed. To do so, follow the instructions in [Create a bucket](#) in the *Amazon Simple Storage Service User Guideguide-s3-user*.
2. Upload files to your Amazon S3 bucket. To do so, follow the steps in [Add an object to a bucket](#) in the *Amazon Simple Storage Service User Guideguide-s3-user*.
3. Set up permissions as needed:
  - To import data from Amazon S3, the Babelfish DB cluster needs permission to access the bucket. We recommend using an Amazon Identity and Access Management (IAM) role and attaching an IAM policy to that role for your cluster. To do so, follow the steps in [Using an IAM role to access an Amazon S3 bucket](#).
  - To export data from your Babelfish DB cluster, your cluster must be granted access to the Amazon S3 bucket. As with importing, we recommend using an IAM role and policy. To do so, follow the steps in [Setting up access to an Amazon S3 bucket](#).

You can now use Amazon S3 with the `aws_s3` extension with your Babelfish DB cluster.

#### To import data from Amazon S3 to Babelfish and to export Babelfish data to Amazon S3

1. Use the `aws_s3` extension with your Babelfish DB cluster.

When you do, make sure to reference the tables as they exist in the context of PostgreSQL. That is, if you want to import into a Babelfish table named `[database].[schema].[tableA]`, refer to that table as `database_schema_tableA` in the `aws_s3` function:

- For an example of using an `aws_s3` function to import data, see [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster](#).
  - For examples of using `aws_s3` functions to export data, see [Exporting query data using the `aws\_s3.query\_export\_to\_s3` function](#).
2. Make sure to reference Babelfish tables using PostgreSQL naming when using the `aws_s3` extension and Amazon S3, as shown in the following table.

Babelfish table	Aurora PostgreSQL table
<code>database.schema.table</code>	<code>database_schema_table</code>

To learn more about using Amazon S3 with Aurora PostgreSQL, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster](#) and [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).

## Using Babelfish with Amazon Lambda

After the `aws_lambda` extension is loaded in your Babelfish DB cluster but before you can invoke Lambda functions, you give Lambda access to your DB cluster by following this procedure.

### To set up access for your Babelfish DB cluster to work with Lambda

This procedure uses the Amazon CLI to create the IAM policy and role, and associate these with the Babelfish DB cluster.

1. Create an IAM policy that allows access to Lambda from your Babelfish DB cluster.

```
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToExampleFunction",
      "Effect": "Allow",
```

```
        "Action": "lambda:InvokeFunction",
        "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"
    }
]
}'
```

2. Create an IAM role that the policy can assume at runtime.

```
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}'
```

3. Attach the policy to the role.

```
aws iam attach-role-policy \
    --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
    --role-name rds-lambda-role --region aws-region
```

4. Attach the role to your Babelfish DB cluster

```
aws rds add-role-to-db-cluster \
    --db-cluster-identifier my-cluster-name \
    --feature-name Lambda \
    --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \
    --region aws-region
```

After you complete these tasks, you can invoke your Lambda functions. For more information and examples of setting up Amazon Lambda for Aurora PostgreSQL DB cluster with Amazon Lambda, see [Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and Amazon Lambda](#).

## To invoke a Lambda function from your Babelfish DB cluster

Amazon Lambda supports functions written in Java, Node.js, Python, Ruby, and other languages. If the function returns text when invoked, you can invoke it from your Babelfish DB cluster. The following example is a placeholder python function that returns a greeting.

```
lambda_function.py
import json
def lambda_handler(event, context):
    #TODO implement
    return {
        'statusCode': 200,
        'body': json.dumps('Hello from Lambda!')
```

Currently, Babelfish doesn't support JSON. If your function returns JSON, you use a wrapper to handle the JSON. For example, say that the `lambda_function.py` shown preceding is stored in Lambda as `my-function`.

1. Connect to your Babelfish DB cluster using the `psql` client (or the `pgAdmin` client). For more information, see [Using psql to connect to the DB cluster](#).
2. Create the wrapper. This example uses PostgreSQL's procedural language for SQL, PL/pgSQL. To learn more, see [PL/pgSQL–SQL Procedural Language](#).

```
create or replace function master_dbo.lambda_wrapper()
returns text
language plpgsql
as
$$
declare
    r_status_code integer;
    r_payload text;
begin
    SELECT payload INTO r_payload
    FROM aws_lambda.invoke( aws_commons.create_lambda_function_arn('my-function',
    'us-east-1')
    , '{"body": "Hello from Postgres!"} '::json );
    return r_payload ;
end;
$$;
```

The function can now be run from the Babelfish TDS port (1433) or from the PostgreSQL port (5433).

- a. To invoke (call) this function from your PostgreSQL port:

```
SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-
function', 'us-east-1'), '{"body": "Hello from Postgres!"}':::json );
```

The output is similar to the following:

```
status_code |          payload          |
executed_version | log_result
-----+-----
+-----+-----
          200 | {"statusCode": 200, "body": "\"Hello from Lambda!\""} | $LATEST
          |
(1 row)
```

- b. To invoke (call) this function from the TDS port, connect to the port using the SQL Server `sqlcmd` command line client. For details, see [Using a SQL Server client to connect to your DB cluster](#). When connected, run the following:

```
1> select lambda_wrapper();
2> go
```

The command returns output similar to the following:

```
{"statusCode": 200, "body": "\"Hello from Lambda!\""}
```

To learn more about using Lambda with Aurora PostgreSQL, see [Invoking an Amazon Lambda function from an Aurora PostgreSQL DB cluster](#). For more information about working with Lambda functions, see [Getting started with Lambda](#) in the *Amazon Lambda Developer Guide*.

## Using `pg_stat_statements` in Babelfish

Babelfish for Aurora PostgreSQL supports `pg_stat_statements` extension from 3.3.0. To learn more, see [pg\\_stat\\_statements](#).

For details about the version of this extension supported by Aurora PostgreSQL, see [Extension versions](#).

## Creating pg\_stat\_statements extension

To turn on `pg_stat_statements`, you must turn on the Query identifier calculation. This is done automatically if `compute_query_id` is set to on or auto in the parameter group. The default value of `compute_query_id` parameter is auto. You also need to create this extension to turn on this feature. Use the following command to install the extension from T-SQL endpoint:

```
1>EXEC sp_execute_postgresql 'CREATE EXTENSION pg_stat_statements WITH SCHEMA sys';
```

You can access the query statistics using the following query:

```
postgres=>select * from pg_stat_statements;
```

### Note

During installation, if you don't provide the schema name for the extension then by default it will create it in public schema. To access it, you must use square brackets with schema qualifier as shown below:

```
postgres=>select * from [public].pg_stat_statements;
```

You can also create the extension from PSQL endpoint.

## Authorizing the extension

By default, you can see the statistics for queries performed within your T-SQL database without the need of any authorization.

To access query statistics created by others, you need to have `pg_read_all_stats` PostgreSQL role. Follow the steps mentioned below to construct `GRANT pg_read_all_stats` command.

1. In T-SQL, use the following query that returns the internal PG role name.

```
SELECT rolname FROM pg_roles WHERE oid = USER_ID();
```

2. Connect to Babelfish for Aurora PostgreSQL database with `rds_superuser` privilege and use the following command:

```
GRANT pg_read_all_stats TO <rolname_from_above_query>
```

## Example

From T-SQL endpoint:

```
1>SELECT rolname FROM pg_roles WHERE oid = USER_ID();  
2>go
```

```
rolname  
-----  
master_dbo  
(1 rows affected)
```

From PSQL endpoint:

```
babelfish_db=# grant pg_read_all_stats to master_dbo;
```

```
GRANT ROLE
```

You can access the query statistics using the `pg_stat_statements` view:

```
1>create table t1(cola int);  
2>go  
1>insert into t1 values (1),(2),(3);  
2>go
```

```
(3 rows affected)
```

```
1>select userid, dbid, queryid, query from pg_stat_statements;
```

```
2>go
```

```
userid dbid queryid          query
----- ---- -
37503 34582 6487973085327558478 select * from t1
37503 34582 6284378402749466286 SET QUOTED_IDENTIFIER OFF
37503 34582 2864302298511657420 insert into t1 values ($1),($2),($3)
10     34582 NULL                <insufficient privilege>
37503 34582 5615368793313871642 SET TEXTSIZE 4096
37503 34582 639400815330803392 create table t1(col1 int)
(6 rows affected)
```

## Resetting query statistics

You can use `pg_stat_statements_reset()` to reset the statistics gathered so far by `pg_stat_statements`. To learn more, see [pg\\_stat\\_statements](#). It is currently supported through PSQL endpoint only. Connect to BabelFish for Aurora PostgreSQL with `rds_superuser` privilege, use the following command:

```
SELECT pg_stat_statements_reset();
```

## Limitations

- Currently, `pg_stat_statements()` is not supported through T-SQL endpoint. `pg_stat_statements` view is the recommended way to gather the statistics.
- Some of the queries might be re-written by the T-SQL parser implemented by Aurora PostgreSQL engine, `pg_stat_statements` view will show the re-written query and not the original query.

### Example

```
select next value for [dbo].[newCounter];
```

The above query is re-written as the following in the `pg_stat_statements` view.

```
select nextval($1);
```

- Based on the execution flow of the statements, some of the queries might not be tracked by `pg_stat_statements` and will not be visible in the view. This includes the following statements: `use dbname`, `goto`, `print`, `raise error`, `set`, `throw`, `declare cursor`.
- For `CREATE LOGIN` and `ALTER LOGIN` statements, `query` and `queryid` will not be shown. It will show insufficient privileges.
- `pg_stat_statements` view always contains the below two entries, as these are executed internally by `sqlcmd` client.
  - `SET QUOTED_IDENTIFIER OFF`
  - `SET TEXTSIZE 4096`

## Using pgvector in Babelfish

`pgvector`, an open-source extension, lets you search for similar data directly within your Postgres database. Babelfish now supports this extension starting with versions 15.6 and 16.2. For more information, [pgvector Open source Documentation](#).

### Prerequisites

To enable `pgvector` functionality, install the extension in `sys` schema using one of the following methods:

- Run the following command in `sqlcmd` client:

```
exec sys.sp_execute_postgresql 'CREATE EXTENSION vector WITH SCHEMA sys';
```

- Connect to `babelfish_db` and run the following command in `psql` client:

```
CREATE EXTENSION vector WITH SCHEMA sys;
```

#### Note

After installing the `pgvector` extension, the vector data type will only be available in new database connections you establish. Existing connections won't recognize the new data type.

## Supported Functionality

Babelfish extends the T-SQL functionality to support the following:

- **Storing**

Babelfish now supports vector datatype compatible syntax, enhancing its T-SQL compatibility. To learn more about storing data with pgvector, see [Storing](#).

- **Querying**

Babelfish expands T-SQL expression support to include vector similarity operators. However, for all other queries, standard T-SQL syntax is still required.

**Note**

T-SQL doesn't support Array type, and the database drivers do not have any interface to handle them. As a workaround, Babelfish uses text strings (varchar/nvarchar) to store vector data. For example, when you request a vector value [1,2,3], Babelfish will return a string '[1,2,3]' as the response. You can parse and split this string at application level as per your needs.

To learn more about querying data with pgvector, see [Querying](#).

- **Indexing**

T-SQL Create Index now supports USING INDEX\_METHOD syntax. You can now define similarity search operator to be used on a specific column when creating an index.

The grammar is also extended to support Vector similarity operations on the required column (Check column\_name\_list\_with\_order\_for\_vector grammar).

```
CREATE [UNIQUE] [clustered] [COLUMNSTORE] INDEX <index_name> ON <table_name> [USING
vector_index_method] (<column_name_list_with_order_for_vector>)
Where column_name_list_with_order_for_vector is:
    <column_name> [ASC | DESC] [VECTOR_COSINE_OPS | VECTOR_IP_OPS | VECTOR_L2_OPS]
    (COMMA simple_column_name [ASC | DESC] [VECTOR_COSINE_OPS | VECTOR_IP_OPS |
VECTOR_L2_OPS])
```

To learn more about indexing data with pgvector, see [Indexing](#).

## • Performance

- Use `SET BABELFISH_STATISTICS PROFILE ON` to debug Query Plans from T-SQL endpoint.
- Increase `max_parallel_workers_get_gather` using the `set_config` function supported in T-SQL.
- Use `IVFFlat` for approximate searches. For more information, see [IVFFlat](#).

To improve performance with `pgvector`, see [Performance](#).

## Limitations

- Babelfish doesn't support Full Text Search for Hybrid Search. For more information, see [Hybrid Search](#).
- Babelfish doesn't currently support re-indexing functionality. However, you can still use PostgreSQL endpoint to re-index. For more information, see [Vacuuming](#).

## Using Amazon Aurora machine learning with Babelfish

You can extend the capabilities of your Babelfish for Aurora PostgreSQL DB cluster by integrating it with Amazon Aurora machine learning. This seamless integration grants you access to a range of powerful services like Amazon Comprehend or Amazon SageMaker AI or Amazon Bedrock, each tailored to address distinct machine learning needs.

As a Babelfish user, you can use existing knowledge of T-SQL syntax and semantics when working with Aurora machine learning. Follow the instructions provided in the Amazon documentation for Aurora PostgreSQL. For more information, see [Using Amazon Aurora machine learning with Aurora PostgreSQL](#).

## Prerequisites

- Before trying to set up your Babelfish for Aurora PostgreSQL DB cluster to use Aurora machine learning, you must understand the related requirements and prerequisites. For more information, see [Requirements for using Aurora machine learning with Aurora PostgreSQL](#).
- Make sure you install the `aws_ml` extension either using Postgres endpoint or the `sp_execute_postgresql` store procedure.

```
exec sys.sp_execute_postgresql 'Create Extension aws_ml'
```

**Note**

Currently BabelFish doesn't support cascade operations with `sp_execute_postgresql` in BabelFish. Since `aws_ml` relies on `aws_commons`, you'll need to install it separately using Postgres endpoint.

```
create extension aws_common;
```

**Handling T-SQL syntax and semantics with `aws_ml` functions**

The following examples explain how T-SQL syntax and semantics are applied to the Amazon ML services:

**Example : `aws_bedrock.invoke_model` – A simple query using Amazon Bedrock functions**

```
aws_bedrock.invoke_model(
  model_id      varchar,
  content_type  text,
  accept_type   text,
  model_input   text)
Returns Varchar(MAX)
```

The following example shows how to invoke an Anthropic Claude 2 model for Bedrock using `invoke_model`.

```
SELECT aws_bedrock.invoke_model (
  'anthropic.claude-v2', -- model_id
  'application/json', -- content_type
  'application/json', -- accept_type
  '{"prompt": "\n\nHuman:
You are a helpful assistant that answers questions directly
and only using the information provided in the context below.
\nDescribe the answer in detail.\n\nContext: %s \n\nQuestion:
%s \n\nAssistant:", "max_tokens_to_sample":4096, "temperature"
:0.5, "top_k":250, "top_p":0.5, "stop_sequences":[]}' -- model_input
);
```

## Example : `aws_comprehend.detect_sentiment` – A simple query using Amazon Comprehend functions

```
aws_comprehend.detect_sentiment(  
  input_text varchar,  
  language_code varchar,  
  max_rows_per_batch int)  
Returns table (sentiment varchar, confidence real)
```

The following example shows how to invoke the Amazon Comprehend service.

```
select sentiment from aws_comprehend.detect_sentiment('This is great', 'en');
```

## Example : `aws_sagemaker.invoke_endpoint` – A simple query using Amazon SageMaker functions

```
aws_sagemaker.invoke_endpoint(  
  endpoint_name varchar,  
  max_rows_per_batch int,  
  VARIADIC model_input "any") -- Babelfish inherits PG's variadic parameter type  
Returns Varchar(MAX)
```

Since `model_input` is marked as `VARIADIC` and of type “any”, users can pass a list of any length and any datatype to the function which will act as the input the input to the model. The following example shows how to invoke the Amazon SageMaker service.

```
SELECT CAST (aws_sagemaker.invoke_endpoint(  
  'sagemaker_model_endpoint_name',  
  NULL,  
  arg1, arg2 -- model inputs are separate arguments )  
AS INT) -- cast the output to INT
```

For more detailed information on using Aurora machine learning with Aurora PostgreSQL, see [Using Amazon Aurora machine learning with Aurora PostgreSQL](#).

## Limitations

- While Babelfish doesn't allow creating arrays, it can still handle data that represents arrays. When you use functions like `aws_bedrock.invoke_model_get_embeddings` that return arrays, the results is delivered as a string containing the array elements.

## Babelfish supports linked servers

Babelfish for Aurora PostgreSQL supports linked servers by using the PostgreSQL `tds_fdw` extension in version 3.1.0. To work with linked servers, you must install the `tds_fdw` extension. For more information about the `tds_fdw` extension, see [Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL](#).

### Installing the `tds_fdw` extension

You can install `tds_fdw` extension using the following methods.

#### Using `CREATE EXTENSION` from PostgreSQL endpoint

1. Connect to your PostgreSQL DB instance on the Babelfish database in the PostgreSQL port. Use an account that has the `rds_superuser` role.

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --  
username=test --dbname=babelfish_db --password
```

2. Install the `tds_fdw` extension. This is a one-time installation process. You don't need to reinstall when the DB cluster restarts.

```
babelfish_db=> CREATE EXTENSION tds_fdw;  
CREATE EXTENSION
```

#### Calling `sp_execute_postgresql` stored procedure from TDS endpoint

Babelfish supports installing `tds_fdw` extension by calling `sp_execute_postgresql` procedure from version 3.3.0. You can execute PostgreSQL statements from T-SQL endpoint without exiting the T-SQL port. For more information, see [Working with Babelfish for Aurora PostgreSQL procedures](#)

1. Connect to your PostgreSQL DB instance on the Babelfish database in the T-SQL port.

```
sqlcmd -S your-DB-instance.aws-region.rds.amazonaws.com -U test -P password
```

2. Install the `tds_fdw` extension.

```
1>EXEC sp_execute_postgresql N'CREATE EXTENSION tds_fdw';  
2>go
```

## Supported functionality

Babelfish supports adding remote RDS for SQL Server or Babelfish for Aurora PostgreSQL endpoints as the linked server. You can also add other remote SQL Server instances as linked servers. Then, use `OPENQUERY()` to retrieve data from these linked servers. Starting from Babelfish version 3.2.0, four-part names are also supported.

The following stored procedures and catalog views are supported in order to use the linked servers.

### Stored procedures

- **sp\_addlinkedserver** – Babelfish doesn't support the `@provstr` parameter.
- **sp\_addlinkedsrvlogin**
  - You must provide an explicit remote username and password to connect to the remote data source. You can't connect with the user's self credentials. Babelfish supports only `@useself = false`.
  - Babelfish doesn't support the `@locallogin` parameter since configuring remote server access specific to local login isn't supported.
- **sp\_linkedservers**
- **sp\_helplinkedsrvlogin**
- **sp\_dropserver**
- **sp\_droplinkedsrvlogin** – Babelfish doesn't support the `@locallogin` parameter since configuring remote server access specific to local login isn't supported.
- **sp\_serveroption** – Babelfish supports the following server options:
  - query timeout (from Babelfish version 3.2.0)
  - connect timeout (from Babelfish version 3.3.0)
- **sp\_testlinkedserver** (from Babelfish version 3.3.0)

- `sp_enum_oledb_providers` (from Babelfish version 3.3.0)

## Catalog views

- `sys.servers`
- `sys.linked_logins`

## Using encryption in transit for the connection

The connection from the source Babelfish for Aurora PostgreSQL server to the target remote server uses encryption in transit (TLS/SSL), depending on the remote server database configuration. If the remote server isn't configured for encryption, the Babelfish server making the request to the remote database falls back to unencrypted.

## To enforce connection encryption

- If the target linked server is an RDS for SQL Server instance, set `rds.force_ssl = on` for the target SQL Server instance. For more information about SSL/TLS configuration for RDS for SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#)
- If the target linked server is a Babelfish for Aurora PostgreSQL cluster, set `babelfishpg_tds.tds_ssl_encrypt = on` and `ssl = on` for the target server. For more information about SSL/TLS, see [Babelfish SSL settings and client connections](#).

## Adding Babelfish as a linked server from SQL Server

Babelfish for Aurora PostgreSQL can be added as a linked server from a SQL Server. On a SQL Server database, you can add Babelfish as a linked server using Microsoft OLE DB provider for ODBC : MSDASQL.

There are two ways to configure Babelfish as a linked server from SQL Server using MSDASQL provider:

- Providing ODBC connection string as the provider string.
- Provide the System DSN of ODBC data source while adding the linked server.

## Limitations

- `OPENQUERY()` works only for `SELECT` and doesn't work for `DML`.

- Four-part object names work only for reading and doesn't work for modifying the remote table. An UPDATE can reference a remote table in the FROM clause without modifying it.
- Executing stored procedures against Babelfish linked servers isn't supported.
- Babelfish major version upgrade might not work if there are objects dependent on OPENQUERY() or objects referenced through four-part names. You must ensure that any objects referencing OPENQUERY() or four-part names are dropped before a major version upgrade.
- The following datatypes don't work as expected against remote Babelfish server: nvarchar(max), varchar(max), varbinary(max), binary(max) and time. We recommend using the CAST function to convert these to the supported datatypes.

## Example

In the following example, a Babelfish for Aurora PostgreSQL instance is connecting to an instance of RDS for SQL Server in the cloud.

```
EXEC master.dbo.sp_addlinkedserver @server=N'rds_sqlserver', @srvproduct=N'',
  @provider=N'SQLNCLI', @datasrc=N'myserver.CB2XKFSFFMY7.US-WEST-2.RDS.AMAZONAWS.COM';
EXEC master.dbo.sp_addlinkedsrvlogin
  @rmtsrvname=N'rds_sqlserver',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassw
```

When the linked server is in place, you can then use T-SQL OPENQUERY() or standard four-part naming to reference a table, view, or other supported objects, on the remote server:

```
SELECT * FROM OPENQUERY(rds_sqlserver, 'SELECT * FROM TestDB.dbo.t1');
SELECT * FROM rds_sqlserver.TestDB.dbo.t1;
```

To drop the linked server and all associated logins:

```
EXEC master.dbo.sp_dropserver @server=N'rds_sqlserver', @droplogins=N'droplogins';
```

## Troubleshooting

You can use the same security group for both source and remote servers to allow them to communicate with each other. Security group should allow only inbound traffic on TDS port (1433 by default) and source IP in security group can be set as the security group ID itself. For more information on how to set the rules for connecting to an instance from another instance with the same security group, see [Rules to connect to instances from an instance with the same security group](#).

If access isn't configured correctly, an error message similar to the following example appears when you try to query the remote server.

```
TDS client library error: DB #: 20009, DB Msg: Unable to connect: server is unavailable
or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 110, OS Msg:
Connection timed out, Level: 9
```

## Using Full Text Search in Babelfish

Starting with version 4.0.0, Babelfish provides limited support for Full Text Search (FTS). FTS is a powerful feature in relational databases that enables efficient searching and indexing of text-heavy data. It allows you to perform complex text searches and retrieve relevant results quickly. FTS is particularly valuable for applications that deal with large volumes of textual data, such as content management systems, e-commerce platforms, and document archives.

### Understanding Babelfish Full Text Search supported features

Babelfish supports the following Full Text Search features:

- CONTAINS Clause:
  - Basic support for the CONTAINS clause.

```
CONTAINS (
    {
        column_name
    }
    , '<contains_search_condition>'
)
```

**Note**

Currently, only English language is supported.

- Comprehensive handling and translation of `simple_term` search strings.
- FULLTEXT INDEX Clause:
  - Supports only `CREATE FULLTEXT INDEX ON table_name(column_name [...n]) KEY INDEX index_name` statement.
  - Supports full `DROP FULLTEXT INDEX` statement.

**Note**

In order to re-index the Full Text Index, you need to drop the Full Text Index and create a new one on the same column.

- Special characters in search condition:
  - Babelfish ensures that single occurrences of special characters in search strings are handled effectively.

**Note**

While Babelfish now identifies special characters in search string, it's essential to recognize that the results obtained may vary compared to those obtained with T-SQL.

- Table alias in `column_name`:
  - With table alias support, users can create more concise and readable SQL queries for Full-Text Search.

## Limitations in Babelfish Full Text Search

- Currently, the following options aren't supported in Babelfish for CONTAINS Clause.
  - Special characters and Languages other than English aren't supported. You will receive the generic error message for unsupported characters and language

Full-text search conditions with special characters or languages other than English are not currently supported in Babelfish

- Multiple columns like `column_list`
- `PROPERTY` attribute
- `prefix_term`, `generation_term`, `generic_proximity_term`, `custom_proximity_term`, and `weighted_term`
- Boolean operators aren't supported and you will receive the following error message when used:

```
boolean operators not supported
```

- Identifier names with dots aren't supported.
- Currently, the following options aren't supported in Babelfish for `CREATE FULLTEXT INDEX` Clause.
  - `[ TYPE COLUMN type_column_name ]`
  - `[ LANGUAGE language_term ]`
  - `[ STATISTICAL_SEMANTICS ]`
  - catalog filegroup options
  - `with options`
- Creating a full text catalog isn't supported. Creating a full text index doesn't require a full text catalog.
- `CREATE FULLTEXT INDEX` doesn't support identifier names with dots.
- Babelfish doesn't currently support consecutive special characters in search strings. You will receive the following error message when used:

```
Consecutive special characters in the full-text search condition are not currently supported in Babelfish
```

## Babelfish supports Geospatial data types

Starting with versions 3.5.0 and 4.1.0, Babelfish includes support for the following two spatial data types:

- **Geometry data type** – This data type is intended for storing planar or Euclidean (flat-earth) data.

- **Geography data type** – This data type is intended for storing ellipsoidal or round-earth data, such as GPS latitude and longitude coordinates.

These data types allow for the storage and manipulation of spatial data, but with limitations.

## Understanding the Geospatial data types in Babelfish

- Geospatial data types are supported in various database objects such as views, procedures, and tables.
- Supports point data type to store location data as points defined by latitude, longitude, and a valid Spatial Reference System Identifier (SRID). A point may contain Z (elevation), M (measure) values and can be empty.
- Supports linestring data type (from version 5.4.0) defined by a sequence of points and the line segments connecting them and a valid Spatial Reference System Identifier (SRID). A linestring may contain points with Z (elevation), M (measure) values and can be empty.
- Applications connecting to Babelfish through drivers like JDBC, ODBC, DOTNET, and PYTHON can utilize this Geospatial feature.

## Geometry data type functions supported in Babelfish

- **STGeomFromText (*geometry\_tagged\_text*, SRID )** – Creates a geometry instance using Well-Known Text (WKT) representation.
- **STPointFromText (*point\_tagged\_text*, SRID )** – Creates a point instance using WKT representation.
- **Point ( X, Y, SRID )** – Creates a point instance using float values of x and y coordinates.
- **<geometry\_instance>.STAsText ( )** – Extracts WKT representation from geometry instance.
- **<geometry\_instance>.STAsBinary ( )** – Extracts WKB representation from geometry instance.
- **<geometry\_instance>.STArea ( )** – Calculates the total surface area of geometry instance.
- **<geometry\_instance>.STSrid ( )** – Extracts the spatial reference identifier (SRID) of the geometry instance.
- **<geometry\_instance>.STDimension ( )** – Retrieves spatial dimension of geometry instance.
- **<geometry\_instance>.STIsEmpty ( )** – Checks if the geometry instance is empty.
- **<geometry\_instance>.STIsClosed ( )** – Checks if the geometry instance is closed.
- **<geometry\_instance>.STIsValid ( )** – Checks if the geometry instance is valid.

- **<geometry\_instance>.STDistance (other\_geometry)** – Calculates the distance between two geometry instances.
- **<geometry\_instance>.STEquals (other\_geometry)** – Checks if the geometry instance represents the same point set as another geometry instance.
- **<geometry\_instance>.STContains (other\_geometry)** – Checks if the geometry instance contains the other\_geometry instance.
- **<geometry\_instance>.STDisjoint (other\_geometry)** – Checks if two geometry instances have no points in common.
- **<geometry\_instance>.STIntersects (other\_geometry)** – Checks if two geometry instances spatially intersect.
- **<geometry\_instance>.STX** – Extracts the X coordinate (longitude) for geometry instance.
- **<geometry\_instance>.STY** – Extracts the Y coordinate (latitude) for geometry instance.

Starting with versions 4.7.0 and 5.3.0, Babelfish includes support for the following spatial data functions:

- **<geometry\_instance>.M** – Extracts the M coordinate of the geometry instance.
- **<geometry\_instance>.Z** – Extracts the Z coordinate of the geometry instance.
- **<geometry\_instance>.HasM** – Checks if the geometry instance has atleast one M value.
- **<geometry\_instance>.HasZ** – Checks if the geometry instance has atleast one Z value.

Starting with versions 5.4.0, Babelfish includes support for the following spatial data function:

- **STLineFromText (*linestring\_tagged\_text*, SRID )** – Creates a linestring instance using WKT representation.

### Geography data type functions supported in Babelfish

- **STGeomFromText (*geography\_tagged\_text*, SRID )** – Creates a geography instance using WKT representation.
- **STPointFromText (*point\_tagged\_text*, SRID )** – Creates a point instance using WKT representation.
- **Point (Lat, Long, SRID)** – Creates a point instance using float values of Latitude and Longitude.
- **<geography\_instance>.STAsText ( )** – Extracts WKT representation from geography instance.

- **<geography\_instance>.STAsBinary ( )** – Extracts WKB representation from geography instance.
- **<geography\_instance>.STArea ( )** – Calculates the total surface area of geography instance.
- **<geography\_instance>.STSrid ( )** – Extracts the spatial reference identifier (SRID) of the geography instance.
- **<geography\_instance>.STDimension ( )** – Retrieves spatial dimension of geography instance.
- **<geography\_instance>.STIsEmpty ( )** – Checks if the geography instance is empty.
- **<geography\_instance>.STIsClosed ( )** – Checks if the geography instance is closed.
- **<geography\_instance>.STIsValid( )** – Checks if the geography instance is valid.
- **<geography\_instance>.STDistance (other\_geography)** – Calculates the distance between two geography instances.
- **<geography\_instance>.STEquals (other\_geography)** – Checks if the geography instance represents the same point set as another geography instance.
- **<geography\_instance>.STContains (other\_geography)** – Checks if the geography instance contains the other\_geography instance.
- **<geography\_instance>.STDisjoint (other\_geography)** – Checks if two geography instances have no points in common.
- **<geography\_instance>.STIntersects (other\_geography)** – Checks if two geography instances spatially intersect.
- **<geography\_instance>.Lat** – Extracts the Latitude value for geography instance.
- **<geography\_instance>.Long** – Extracts the Longitude value for geography instance.

Starting with versions 4.7.0 and 5.3.0, Babelfish includes support for the following spatial data functions:

- **<geography\_instance>.M** – Extracts the M coordinate of the geography instance.
- **<geography\_instance>.Z** – Extracts the Z coordinate of the geography instance.
- **<geography\_instance>.HasM** – Checks if the geography instance has atleast one M value.
- **<geography\_instance>.HasZ** – Checks if the geography instance has atleast one Z value.

Starting with versions 5.4.0, Babelfish includes support for the following spatial data function:

- **STLineFromText (*linestring\_tagged\_text*, SRID )** – Creates a linestring instance using WKT representation.

## Limitations in Babelfish for Geospatial data types

- Geometry and Geography types other than point and linestring instances aren't currently supported:
  - CircularString
  - CompoundCurve
  - Polygon
  - CurvePolygon
  - MultiPoint
  - MultiLineString
  - MultiPolygon
  - GeometryCollection
- Currently, spatial indexing isn't supported for Geospatial data types.
- Only the listed functions are currently supported for these data types. For more information, see [Geometry data type functions supported in Babelfish](#) and [Geography data type functions supported in Babelfish](#).
- STDistance function output for Geography data might have minor precision variations compared to T-SQL. This is due to the underlying PostGIS implementation. For more information, see [ST\\_Distance](#)
- STIsValid function output for both Geometry and Geography data might have some deviations compared to T-SQL. Due to this, the functions - STDistance, STContains, STIntersects, STDisjoint, STDimension, STArea, STEquals may also deviate from T-SQL for some cases ( returns output instead of throwing error ). This is due to the underlying PostGIS implementation. For more information, see [ST\\_IsValid](#).
- For optimal performance, use built-in Geospatial data types, without creating additional layers of abstraction in Babelfish.
- In Babelfish, Geospatial function names are used as keywords and will perform spatial operations only if used in the intended way.

## Understanding partitioning in Babelfish

Starting with version 4.3.0, Babelfish introduces table and index partitioning with limited support. The following sections provide details on creating partition functions, defining partition schemes, and implementing partitioned tables and indexes in Babelfish.

## Topics

- [Introducing to partitioning in Babelfish](#)
- [Limitations and workarounds](#)

## Introducing to partitioning in Babelfish

### • Partition functions:

- `CREATE PARTITION FUNCTION`: Defines how a table or index is partitioned by specifying the partitioning column type and the range of values for each partition.
- `DROP PARTITION FUNCTION`: Removes an existing partition function.

### • Partition schemes:

- `CREATE PARTITION SCHEME`: Defines the mapping between partitions and filegroups.

#### Note

In Babelfish, filegroups are treated as dummy objects and do not represent physical storage locations.

- `DROP PARTITION SCHEME`: Removes an existing partition scheme.

### • System function:

- `$PARTITION`: This system function returns the partition number to which a specified value in a partitioning column would belong in a specified partitioned table.

### • Partitioned tables and indexes:

- `CREATE TABLE ... ON partition_scheme_name (partition_column_name)`: Creates a partitioned table based on a specified partition scheme and partitioning column.
- `CREATE INDEX ... ON partition_scheme_name (partition_column_name)`: Creates a partitioned index based on a specified partition scheme and partitioning column.

### • System views for partitioning metadata:

The following system views are added to provide metadata related to partitioning:

- `sys.destination_data_spaces`
- `sys.partitions`
- `sys.partition_functions`
- `sys.partition_parameters`

- `sys.partition_range_values`
- `sys.partition_schemes`

## Limitations and workarounds

The following SQL Server partitioning capabilities aren't yet supported by Babelfish:

- `ALTER PARTITION FUNCTION` and `ALTER PARTITION SCHEME`.

### Note

Babelfish doesn't support split and merge operations. Define all partitions in the partition functions during creation because you can't add or remove partitions later.

- Computed columns as partitioning columns.
- `INSERT BULK` and `BCP` utility for partitioned tables.
- `LEFT` boundary option for partition functions.
- `SQL_VARIANT` data type for partition functions.
- `TRUNCATE TABLE ... WITH PARTITION`.
- `ALTER TABLE ... SWITCH PARTITION`.
- Un-aligned partitioned indexes such as partition scheme and partition column that differs from the partitioned table.
- DMS migration from Babelfish source is supported only for Full Load tasks on partitioned tables.
- Babelfish doesn't support these syntax options but provides workarounds:
  - Usage of partition scheme with constraints or indexes in the `CREATE TABLE` statement.
  - `ALTER TABLE ... ADD CONSTRAINT ... ON partition_scheme_name (partition_column_name)`.

### Note

You can set the `babelfishpg_tsql.escape_hatch_storage_on_partition` escape hatch to ignore. This will allow the parser to ignore the partition scheme option used with constraints or indexes, and the backend will create individual constraints or indexes for each partition.

# Troubleshooting Babelfish

Following, you can find troubleshooting ideas and workarounds for some Babelfish DB cluster issues.

## Topics

- [Connection failure](#)

## Connection failure

Common causes of connection failures to a new Aurora DB cluster with Babelfish include the following:

- **Security group doesn't allow access** – If you're having trouble connecting to a Babelfish, make sure that you added your IP address to the default Amazon EC2 security group. You can use <https://checkip.amazonaws.com/> to determine your IP address and then add it to your in-bound rule for the TDS port and the PostgreSQL port. For more information, see [Add rules to a security group](#) in the *Amazon EC2 User Guide*.
- **Mismatching SSL configurations** – If the `rds.force_ssl` parameter is turned on (set to 1) on Aurora PostgreSQL, then clients must connect to Babelfish over SSL. If your client isn't set up correctly, you see an error message such as the following:

```
Cannot connect to your-Babelfish-DB-cluster, 1433
-----
ADDITIONAL INFORMATION:
no pg_hba_conf entry for host "256.256.256.256", user "your-user-name",
"database babelfish_db", SSL off (Microsoft SQL Server, Error: 33557097)
...
```

This error indicates a possible SSL configuration issue between your local client and the Babelfish DB cluster, and that the cluster requires clients to use SSL (its `rds.force_ssl` parameter is set to 1). For more information about configuring SSL, see [Using SSL with a PostgreSQL DB instance](#) in the *Amazon RDS User Guide*.

If you are using SQL Server Management Studio (SSMS) to connect to Babelfish and you see this error, you can choose **Encrypt connection** and **Trust server certificate** connection options on the Connection Properties pane and try again. These settings handle the SSL connection requirement for SSMS.

---

For more information about troubleshooting Aurora connection issues, see [Can't connect to Amazon RDS DB instance](#).

## Turning off Babelfish

When you no longer need Babelfish, you can turn off Babelfish functionality.

Be aware of some considerations:

- In some cases, you might turn off Babelfish before completing a migration to Aurora PostgreSQL. If you do and your DDL depends on SQL Server data types or you use any T-SQL functionality in your code, your code fails.
- If after provisioning a Babelfish instance you turn off the Babelfish extension, you can't provision that same database again on the same cluster.

To turn off Babelfish, modify your parameter group, setting `rds.babelfish_status` to OFF. You can continue to use your SQL Server data types with Babelfish off, by setting `rds.babelfish_status` to `datatypesonly`.

If you turn off Babelfish in parameter group, all clusters that use that parameter group lose Babelfish functionality.

For more information about modifying parameter groups, see [Parameter groups for Amazon Aurora](#). For information about Babelfish-specific parameters, see [DB cluster parameter group settings for Babelfish](#).

## Managing Babelfish for Aurora PostgreSQL version updates

Babelfish is an option available with Aurora PostgreSQL version 13.4 and higher releases. Updates to Babelfish become available with certain new releases of the Aurora PostgreSQL database engine. For more information, see the [Release Notes for Aurora PostgreSQL](#).

### Note

Babelfish DB clusters running on any version of Aurora PostgreSQL 13 can't be upgraded to Aurora PostgreSQL 14.3, 14.4, and 14.5. Also, Babelfish doesn't support a direct upgrade from 13.x to 15.x. You must first upgrade your 13.x DB cluster to 14.6 and higher version and then upgrade to 15.x version.

For a list of supported functionality across different Babelfish releases, see [Supported functionalities in Babelfish by version](#).

For a list of currently unsupported functionality, see [Unsupported functionalities in Babelfish](#).

You can get a list of Aurora PostgreSQL versions that support Babelfish by querying your Amazon Web Services Region using the [describe-db-engine-versions](#) Amazon CLI command, as follows.

For Linux, macOS, or Unix:

```
$ aws rds describe-db-engine-versions --region us-east-1 \  
  --engine aurora-postgresql \  
  --query '*[?SupportsBabelfish==`true`].[EngineVersion]' \  
  --output text
```

For more information, see [describe-db-engine-versions](#) in the *Amazon CLI Command Reference*.

In the following topics, you can learn how to identify the version of Babelfish running on your Aurora PostgreSQL DB cluster, and how to upgrade to a new version.

### Contents

- [Identifying your version of Babelfish](#)
- [Upgrading your Babelfish cluster to a new version](#)
  - [Upgrading Babelfish to a new minor version](#)

- [Upgrading Babelfish to a new major version](#)
  - [Before upgrading Babelfish to a new major version](#)
  - [Performing major version upgrade](#)
  - [After upgrading to a new major version](#)
  - [Example: Upgrading the Babelfish DB cluster to a major release](#)
- [Using Babelfish product version parameter](#)
  - [Configuring Babelfish product version parameter](#)
  - [Affected queries and parameter](#)
  - [Interface with babelfishpg\\_tsql.version parameter](#)

## Identifying your version of Babelfish

You can query Babelfish to find details about the Babelfish version, the Aurora PostgreSQL version, and the compatible Microsoft SQL Server version. You can use the TDS port or the PostgreSQL port.

- [To use the TDS port to query for version information](#)
- [To use the PostgreSQL port to query for version information](#)

### To use the TDS port to query for version information

1. Use `sqlcmd` or `ssms` to connect to the endpoint for your Babelfish DB cluster.

```
sqlcmd -S bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com,1433 -U  
login-id -P password -d db_name
```

2. To identify the Babelfish version, run the following query:

```
1> SELECT CAST(serverproperty('babelfishversion') AS VARCHAR)  
2> GO
```

The query returns results similar to the following:

```
serverproperty  
-----  
3.4.0
```

```
(1 rows affected)
```

- To identify the version of the Aurora PostgreSQL DB cluster, run the following query:

```
1> SELECT aurora_version() AS aurora_version
2> GO
```

The query returns results similar to the following:

```
aurora_version
```

```
-----
```

```
15.5.0
```

```
(1 rows affected)
```

- To identify the compatible Microsoft SQL Server version, run the following query:

```
1> SELECT @@VERSION AS version
2> GO
```

The query returns results similar to the following:

```
Babelfish for Aurora PostgreSQL with SQL Server Compatibility - 12.0.2000.8
```

```
Dec 7 2023 09:43:06
```

```
Copyright (c) Amazon Web Services
```

```
PostgreSQL 15.5 on x86_64-pc-linux-gnu (Babelfish 3.4.0)
```

```
(1 rows affected)
```

As an example that shows one minor difference between Babelfish and Microsoft SQL Server, you can run the following query. On Babelfish, the query returns 1, while on Microsoft SQL Server, the query returns NULL.

```
SELECT CAST(serverproperty('babelfish') AS VARCHAR) AS runs_on_babelfish
```

You can also use the PostgreSQL port to obtain version information, as shown in the following procedure.

### To use the PostgreSQL port to query for version information

1. Use `psql` or `pgAdmin` to connect to the endpoint for your Babelfish DB cluster.

```
psql host=bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com
      port=5432 dbname=babelfish_db user=sa
```

2. Turn on the extended feature (`\x`) of `psql` for more readable output.

```
babelfish_db=> \x
babelfish_db=> SELECT
babelfish_db=> aurora_version() AS aurora_version,
babelfish_db=> version() AS postgresql_version,
babelfish_db=> sys.version() AS Babelfish_compatibility,
babelfish_db=> sys.SERVERPROPERTY('BabelfishVersion') AS Babelfish_Version;
```

The query returns output similar to the following:

```
-[ RECORD 1 ]-----
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
aurora_version          | 15.5.0
postgresql_version     | PostgreSQL 15.5 on x86_64-pc-linux-gnu, compiled by
x86_64-pc-linux-gnu-gcc (GCC) 9.5.0, 64-bit
babelfish_compatibility | Babelfish for Aurora Postgres with SQL Server
Compatibility - 12.0.2000.8
                        | Dec 7 2023 09:43:06
                        +
                        | Copyright (c) Amazon Web Services
                        +
                        | PostgreSQL 15.5 on x86_64-pc-linux-gnu (Babelfish 3.4.0)
babelfish_version      | 3.4.0
```

## Upgrading your Babelfish cluster to a new version

New versions of Babelfish become available with some new releases of the Aurora PostgreSQL database engine after version 13.4. Each new release of Babelfish has its own version number. As

with Aurora PostgreSQL, Babelfish uses the *major.minor.patch* naming scheme for versions. For example, the first Babelfish release, Babelfish version 1.0.0, became available as part of Aurora PostgreSQL 13.4.0.

Babelfish doesn't require a separate installation process. As discussed in [Creating a Babelfish for Aurora PostgreSQL DB cluster](#), **Turn on Babelfish** is an option that you choose when you create an Aurora PostgreSQL DB cluster.

Likewise, you can't upgrade Babelfish independently from the supporting Aurora DB cluster. To upgrade an existing Babelfish for Aurora PostgreSQL DB cluster to a new version of Babelfish, you upgrade the Aurora PostgreSQL DB cluster to a new version that supports the version of Babelfish that you want to use. The procedure that you follow for the upgrade depends on the version of Aurora PostgreSQL that's supporting your Babelfish deployment, as follows.

### Major version upgrades

You must upgrade the following Aurora PostgreSQL versions to Aurora PostgreSQL 14.6 and higher version before upgrading to Aurora PostgreSQL 15.2 version.

- Aurora PostgreSQL 13.8 and all higher versions
- Aurora PostgreSQL 13.7.1 and all higher minor versions
- Aurora PostgreSQL 13.6.4 and all higher minor versions

You can upgrade Aurora PostgreSQL 14.6 and higher versions to Aurora PostgreSQL 15.2 and higher versions.

Upgrading an Aurora PostgreSQL DB cluster to a new major version involves several preliminary tasks. For more information, see [Performing a major version upgrade](#). To successfully upgrade your Babelfish for Aurora PostgreSQL DB cluster, you need to create a custom DB cluster parameter group for the new Aurora PostgreSQL version. This new parameter group must contain the same Babelfish parameter settings as that of the cluster that you're upgrading. For more information and for a table of major version upgrade sources and targets, see [Upgrading Babelfish to a new major version](#).

### Minor version upgrades and patches

Minor versions and patches don't require the creation of a new DB cluster parameter group for the upgrade. Minor versions and patches can use the minor version upgrade process, whether that's applied automatically or manually. For more information and a table of version sources and targets, see [Upgrading Babelfish to a new minor version](#).

**Note**

Before performing a major or a minor upgrade, apply all pending maintenance tasks to your Babelfish for Aurora PostgreSQL cluster.

**Topics**

- [Upgrading Babelfish to a new minor version](#)
- [Upgrading Babelfish to a new major version](#)

**Upgrading Babelfish to a new minor version**

A minor version update aims to maintain backward compatibility. However, in some cases, critical security fixes or important bug fixes may not be fully backward compatible. A *patch* version includes important fixes for a minor version after its release. For example, the version label for the first release of Aurora PostgreSQL 13.4 was Aurora PostgreSQL 13.4.0. Several patches for that minor version have been released to date, including Aurora PostgreSQL 13.4.1, 13.4.2, and 13.4.4. You can find the patches available for each Aurora PostgreSQL version in the **Patch releases** list at the top of the Aurora PostgreSQL release notes for that version. For an example, see [PostgreSQL 14.3](#) in the *Release Notes for Aurora PostgreSQL*.

If your Aurora PostgreSQL DB cluster is configured with the **Auto minor version upgrade** option, your Babelfish for Aurora PostgreSQL DB cluster is upgraded automatically during the cluster's maintenance window. To learn more about auto minor version upgrade (AmVU) and how to use it, see [Automatic minor version upgrades for Aurora DB clusters](#). If your cluster isn't using AmVU, you can manually upgrade your Babelfish for Aurora PostgreSQL DB cluster to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

When you choose an Aurora PostgreSQL version to install and when you view an existing Aurora PostgreSQL DB cluster in the Amazon Web Services Management Console, the version displays the *major.minor* digits only. For example, the following image from the Console for an existing Babelfish for Aurora PostgreSQL DB cluster with Aurora PostgreSQL 13.4 recommends upgrading the cluster to version 13.7, a new minor release of Aurora PostgreSQL.

<input type="checkbox"/>	Resource	Recommendation
<input type="checkbox"/>	docs-lab-bfish-main	Your DB cluster is running aurora-postgresql version 13.4. Upgrade to version 13.7.
<input type="checkbox"/>	docs-lab-rpg-gis	Your DB instance is running postgres version 10.17. Upgrade to version 10.21.
<input type="checkbox"/>	docs-lab-rpg-sub	Your DB instance is running postgres version 13.4. Upgrade to version 13.7.

To get complete version details, including the *patch* level, you can query the Aurora PostgreSQL DB cluster using the `aurora_version` Aurora PostgreSQL function. For more information, see [aurora\\_version](#) in the [Aurora PostgreSQL functions reference](#). You can find an example of using the function in the [To use the PostgreSQL port to query for version information](#) procedure in [Identifying your version of Babelfish](#).

The following table shows Aurora PostgreSQL and Babelfish version and the available target versions that can support the minor version upgrade process.

Current source versions	Newest upgrade targets
Aurora PostgreSQL (Babelfish)	Aurora PostgreSQL (Babelfish)
17.4 (5.1)	17.5 (5.2)
16.8 (4.5)	16.9 (4.6)
16.6 (4.4.0)	16.9 (4.6), 16.8 (4.5.0)

Current source versions	Newest upgrade targets
16.4 (4.3.0)	16.9 (4.6), 16.8 (4.5.0), 16.6 (4.4.0)
16.3 (4.2.0)	16.9 (4.6), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0)
16.2 (4.1.0)	16.9 (4.6), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0)
16.1 (4.0.0)	16.9 (4.6), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0)
15.12 (3.9.0)	15.13 (3.10)

13.7 (1.3.0)	13.9 (1.5.0), 13.8 (1.4.0)

## Upgrading Babelfish to a new major version

For a major version upgrade, you need to first upgrade your Babelfish for Aurora PostgreSQL DB cluster to a version that supports the major version upgrade. To achieve this, apply patch updates or minor version upgrades to your DB cluster. For more information, see [Upgrading Babelfish to a new minor version](#).

The following table shows Aurora PostgreSQL version and Babelfish version that can support a major version upgrade.

Current source versions	Newest upgrade targets
Aurora PostgreSQL (Babelfish)	Aurora PostgreSQL (Babelfish)
16.9 (4.6.0)	17.5 (5.2.0)
16.8 (4.5.0)	17.5 (5.2.0), 17.4 (5.1.0)
16.6 (4.4.0)	17.5 (5.2.0), 17.4 (5.1.0)
16.4 (4.3.0)	17.5 (5.2.0), 17.4 (5.1.0)
16.3 (4.2.0)	17.5 (5.2.0), 17.4 (5.1.0)
16.2 (4.1.0)	17.5 (5.2.0), 17.4 (5.1.0)
16.1 (4.0.0)	17.5 (5.2.0), 17.4 (5.1.0)
15.13 (3.10)	17.5 (5.2.0) 16.9 (4.6.0)
15.12 (3.9.0)	17.5 (5.2.0), 17.4 (5.1.0)

Current source versions	Newest upgrade targets
	16.9 (4.6.0), 16.8 (4.5.0)
15.10 (3.8.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0)
15.8 (3.7.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0)
15.7 (3.6.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0)
15.6 (3.5.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0)
15.5 (3.4.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0), 16.1 (4.0.0)
15.4 (3.3.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0), 16.1 (4.0.0)
15.3 (3.2.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0), 16.1 (4.0.0)
15.2 (3.1.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0), 16.4 (4.3.0), 16.3 (4.2.0), 16.2 (4.1.0), 16.1 (4.0.0)

Current source versions	Newest upgrade targets
14.18 (2.13.0)	17.5 (5.2.0) 16.9 (4.6.0) 15.13 (3.10.0)
14.17 (2.12.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0) 15.13 (3.10.0), 15.12 (3.9.0)
14.15 (2.11.0)	17.5 (5.2.0), 17.4 (5.1.0) 16.9 (4.6.0), 16.8 (4.5.0), 16.6 (4.4.0) 15.13 (3.10.0), 15.12 (3.9.0), 15.10 (3.8.0)

13.8 (1.4.0)	14.6 (2.3.0)
13.7 (1.3.0)	14.6 (2.3.0)

## Before upgrading Babelfish to a new major version

An upgrade might involve brief outages. For that reason, we recommend that you perform or schedule upgrades during your maintenance window or during other periods of low usage.

## Before you perform a major version upgrade

1. Identify the Babelfish version of your existing Aurora PostgreSQL DB cluster by using the commands outlined in [Identifying your version of Babelfish](#). The Aurora PostgreSQL version and Babelfish version information is handled by PostgreSQL, so follow the steps detailed in the [To use the PostgreSQL port to query for version information](#) procedure to get the details.

2. Verify if your version supports the major version upgrade. For the list of versions that support the major version upgrade feature, see [Upgrading Babelfish to a new minor version](#) and perform the necessary pre-upgrade tasks.

For example, if your Babelfish version is running on an Aurora PostgreSQL 13.5 DB cluster and you want to upgrade to Aurora PostgreSQL 15.2, then first apply all the minor releases and patches to upgrade your cluster to Aurora PostgreSQL 14.6 or higher version. When your cluster is at version 14.6 or higher, continue with the major version upgrade process.

3. Create a manual snapshot of your current Babelfish DB cluster as a backup. The backup lets you restore the cluster to its Aurora PostgreSQL version, Babelfish version, and restore all data to the state before the upgrade. For more information, see [Creating a DB cluster snapshot](#). Be sure to keep your existing custom DB cluster parameter group to use again if you decide to restore this cluster to its pre-upgraded state. For more information, see [Restoring from a DB cluster snapshot](#) and [Parameter group considerations](#).
4. Prepare a custom DB cluster parameter group for the target Aurora PostgreSQL DB version. Duplicate the settings for the Babelfish parameters from your current Babelfish for Aurora PostgreSQL DB cluster. To find a list of all Babelfish parameters, see [DB cluster parameter group settings for Babelfish](#). For a major version upgrade, the following parameters require the same settings as the source DB cluster. For the upgrade to succeed, all the settings must be the same.
  - `rds.babelfish_status`
  - `babelfishpg_tds.tds_default_numeric_precision`
  - `babelfishpg_tds.tds_default_numeric_scale`
  - `babelfishpg_tsqldb.database_name`
  - `babelfishpg_tsqldb.default_locale`
  - `babelfishpg_tsqldb.migration_mode`
  - `babelfishpg_tsqldb.server_collation_name`

### **Warning**

If the settings for the Babelfish parameters in the custom DB cluster parameter group for the new Aurora PostgreSQL version don't match the parameter values of the cluster that you're upgrading, the `ModifyDBCluster` operation fails. An `InvalidParameterCombination` error message appears in the Amazon Web

Services Management Console or in the output from the `modify-db-cluster` Amazon CLI command.

5. Use the Amazon Web Services Management Console or the Amazon CLI to create the custom DB cluster parameter group. Choose the applicable Aurora PostgreSQL family for the version of Aurora PostgreSQL that you want for the upgrade.

**Tip**

Parameter groups are managed at the Amazon Web Services Region level. When you work with Amazon CLI, you can configure with a default Region instead of specifying the `--region` in the command. To learn more about using the Amazon CLI, see [Quick setup](#) in the *Amazon Command Line Interface User Guide*.

## Performing major version upgrade

1. Upgrade Aurora PostgreSQL DB cluster to a new major version. For more information, see [Upgrading the Aurora PostgreSQL engine to a new major version](#).
2. Reboot the writer instance of the cluster, so that the parameter settings can take effect.

## After upgrading to a new major version

After a major version upgrade to a new Aurora PostgreSQL version, the IDENTITY value in tables with an IDENTITY column might be larger (+32) than the value was before the upgrade. The result is that when the next row is inserted into such tables, the generated identity column value jumps to the +32 number and starts the sequence from there. This condition won't negatively affect the functions of your Babelfish DB cluster. However, if you want, you can reset the sequence object based on the maximum value of the column. To do so, connect to the T-SQL port on your Babelfish writer instance using `sqlcmd` or another SQL Server client. For more information, see [Using a SQL Server client to connect to your DB cluster](#).

```
sqlcmd -S bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com,1433 -U  
sa -P ***** -d dbname
```

When connected, use the following SQL command to generate statements that you can use to seed the associated sequence object. This SQL command works for both single database and multiple

database Babelfish configurations. For more information about these two deployment models, see [Using Babelfish with a single database or multiple databases](#).

```

DECLARE @schema_prefix NVARCHAR(200) = ''
IF current_setting('babelfishpg_tsql.migration_mode') = 'multi-db'
    SET @schema_prefix = db_name() + '_'
SELECT 'SELECT setval(pg_get_serial_sequence('' + @schema_prefix +
schema_name(tables.schema_id)
+ '.' + tables.name + ''', '' + columns.name + '''),(select max(' + columns.name +
'))
FROM ' + schema_name(tables.schema_id) + '.' + tables.name + ');
'FROM sys.tables tables JOIN sys.columns
columns ON tables.object_id = columns.object_id
WHERE columns.is_identity = 1
GO

```

The query generates a series of SELECT statements that you can then run to reset the maximum IDENTITY value and close any gap. The following shows the output when using the sample SQL Server database, Northwind, running on a Babelfish cluster.

```

-----
SELECT setval(pg_get_serial_sequence('northwind_dbo.categories', 'categoryid'),(select
max(categoryid)
FROM dbo.categories));

SELECT setval(pg_get_serial_sequence('northwind_dbo.orders', 'orderid'),(select
max(orderid)
FROM dbo.orders));

SELECT setval(pg_get_serial_sequence('northwind_dbo.products', 'productid'),(select
max(productid)
FROM dbo.products));

SELECT setval(pg_get_serial_sequence('northwind_dbo.shippers', 'shipperid'),(select
max(shipperid)
FROM dbo.shippers));

SELECT setval(pg_get_serial_sequence('northwind_dbo.suppliers', 'supplierid'),(select
max(supplierid)
FROM dbo.suppliers));

```

```
(5 rows affected)
```

Run the statements one by one to reset the sequence values.

### Example: Upgrading the Babelfish DB cluster to a major release

In this example, you can find the series of Amazon CLI commands that explains how to upgrade an Aurora PostgreSQL 13.6.4 DB cluster running Babelfish version 1.2.2 to Aurora PostgreSQL 14.6. First, you create a custom DB cluster parameter group for Aurora PostgreSQL 14. Next, you modify the parameter values to match those of your Aurora PostgreSQL version 13 source. Finally, you perform the upgrade by modifying the source cluster. For more information, see [DB cluster parameter group settings for Babelfish](#). In that topic, you can also find information about using the Amazon Web Services Management Console to perform the upgrade.

Use the [create-db-cluster-parameter-group](#) CLI command to create the DB cluster parameter group for the new version.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \  
  --db-parameter-group-family aurora-postgresql14 \  
  --description 'New custom parameter group for upgrade to new major version' \  
  --region us-west-1
```

When you issue this command, the custom DB cluster parameter group is created in the Amazon Web Services Region. You see output similar to the following.

```
{  
  "DBClusterParameterGroup": {  
    "DBClusterParameterGroupName": "docs-lab-babelfish-apg-14",  
    "DBParameterGroupFamily": "aurora-postgresql14",  
    "Description": "New custom parameter group for upgrade to new major version",  
    "DBClusterParameterGroupArn": "arn:aws:rds:us-west-1:111122223333:cluster-pg:docs-lab-babelfish-apg-14"  
  }  
}
```

For more information, see [Creating a DB cluster parameter group in Amazon Aurora](#).

Use the [modify-db-cluster-parameter-group](#) CLI command to modify the settings so that they match the source cluster.

For Windows:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 ^
  --parameters
  "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tds.tds_default_numeric_precision,ParameterValue=38,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tds.tds_default_numeric_scale,ParameterValue=8,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tsql.database_name,ParameterValue=babelfish_db,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tsql.default_locale,ParameterValue=en-US,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tsql.migration_mode,ParameterValue=single-db,ApplyMethod=pending-reboot" ^
  "ParameterName=babelfishpg_tsql.server_collation_name,ParameterValue=sql_latin1_general_cp1_ci_ks_uca1400,ApplyMethod=pending-reboot"
```

The response looks similar to the following.

```
{
  "DBClusterParameterGroupName": "docs-lab-babelfish-apg-14"
}
```

Use the [modify-db-cluster](#) CLI command to modify the cluster to use the new version and the new custom DB cluster parameter group. You also specify the `--allow-major-version-upgrade` argument, as shown in the following sample.

```
aws rds modify-db-cluster \
  --db-cluster-identifier docs-lab-bfish-apg-14 \
  --engine-version 14.6 \
  --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \
  --allow-major-version-upgrade \
  --region us-west-1 \
  --apply-immediately
```

Use the [reboot-db-instance](#) CLI command to reboot the writer instance of the cluster, so that the parameter settings can take effect.

```
aws rds reboot-db-instance \  
--db-instance-identifier docs-lab-bfish-apg-14-instance-1\  
--region us-west-1
```

## Using Babelfish product version parameter

A new Grand Unified Configuration (GUC) parameter called `babelfishpg_tds.product_version` is introduced from Babelfish 2.4.0 and 3.1.0 versions. This parameter allows you to set the SQL Server product version number as the output of Babelfish.

The parameter is a 4-part version ID string, and each part should be separated by ".".

### Syntax

```
Major.Minor.Build.Revision
```

- Major Version: A number between 11 and 16.
- Minor Version: A number between 0 and 255.
- Build Version: A number between 0 and 65535.
- Revision: 0 and any positive number.

## Configuring Babelfish product version parameter

You must use the cluster parameter group to set the `babelfishpg_tds.product_version` parameter in the console. For more information on how to modify the DB cluster parameter, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

When you set the product version parameter to an invalid value, the change will not take effect. Although the console might show you the new value, the parameter retains the previous value. Check the engine log file for details about the error messages.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbparametergroup \
--parameters
"ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediat
```

### For Windows:

```
aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbparametergroup ^
--parameters
"ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediat
```

### Affected queries and parameter

Query/Parameter	Result	Effective time
SELECT @@VERSION	Returns user defined SQL Server version (babelfishpg_tsql.version value = Default)	Immediately
SELECT SERVERPROPERTY('ProductVersion')	Returns user defined SQL Server version	Immediately
SELECT SERVERPROPERTY('ProductMajorVersion')	Returns Major Version of the user defined SQL Server version	Immediately
VERSION tokens in PRELOGIN Response Message	Server returns PRELOGIN messages with user defined SQL Server version	Takes effect when a user creates a new session
SQLServerVersion in LoginAck when using JDBC	DatabaseMetaData.getDatabaseProductVersion() returns user defined SQL Server version	Takes effect when a user creates a new session

## Interface with `babelfishpg_tsql.version` parameter

You can set the output of the `@@VERSION` using the parameters `babelfishpg_tsql.version` and `babelfishpg_tds.product_version`. The following examples show how these two parameters interface.

- When `babelfishpg_tsql.version` parameter is "default" and `babelfishpg_tds.product_version` is 15.0.2000.8.
  - Output of `@@version` – 15.0.2000.8.
- When `babelfishpg_tsql.version` parameter is set to 13.0.2000.8 and `babelfishpg_tds.product_version` parameter is 15.0.2000.8.
  - Output of `@@version` – 13.0.2000.8.

Functionality or syntax	Description
Column attributes	ROWGUIDCOL, SPARSE, FILESTREAM, and MASKED aren't supported.
Contained databases	Contained databases with logins authenticated at the database level rather than at the server level aren't supported.
Cross-database DDL	Performing DDL statements that reference or operate on objects across multiple databases isn't yet supported.
Cursors (updatable)	Updatable cursors aren't supported.
Cursors (global)	GLOBAL cursors aren't supported.
Cursor (fetch behaviors)	The following cursor fetch behaviors aren't supported: FETCH PRIOR, FIRST, LAST, ABSOLUTE, and RELATIVE
Cursor-typed output parameters	Cursor-typed variables and parameters aren't supported for output parameters (an error is raised).
Cursor options	SCROLL, KEYSET, DYNAMIC, FAST_FORWARD, SCROLL_LOCKS, OPTIMISTIC, TYPE_WARNING, and FOR UPDATE
Data encryption	Data encryption isn't supported.
Data-tier applications (DAC)	Data-tier applications (DAC) import or export operations with DAC package (.dacpac) or DAC backup (.bacpac) files aren't supported.
DBCC commands	Microsoft SQL Server Database Console Commands (DBCC) aren't supported. DBCC CHECKIDENT is supported in Babelfish 3.4.0 and higher releases.
DROP IF EXISTS	This syntax isn't supported for USER and SCHEMA objects. It's supported for the objects TABLE, VIEW, PROCEDURE, FUNCTION, and DATABASE.
Encryption	Built-in functions and statements don't support encryption.

Functionality or syntax	Description
ENCRYPT_CLIENT_CERT connections	Client certificate connections aren't supported.
EXECUTE AS statement	This statement isn't supported.
EXECUTE AS SELF clause	This clause isn't supported in functions, procedures, or triggers.
EXECUTE AS USER clause	This clause isn't supported in functions, procedures, or triggers.
Foreign key constraints referencing database name	Foreign key constraints that reference the database name aren't supported.
FORMAT	User-defined types aren't supported.
Function declarations with greater than 100 parameters	Function declarations that contain more than 100 parameters aren't supported.
Function calls that include DEFAULT as a parameter value	DEFAULT isn't a supported parameter value for a function call. DEFAULT as a parameter value for a function call is supported from Babelfish 3.4.0 and higher releases.
Functions, externally defined	External functions, including SQL CLR functions, aren't supported.
Global temporary tables (tables with names that start with ##)	Global temporary tables aren't supported.
Graph functionality	All SQL graph functionality isn't supported.
General Extended stored procedures	System stored procedures that provide an interface from an instance of SQL Server to external programs, for various maintenance activities aren't supported. This includes xp_cmdshell and other system stored procedures. For more information, see <a href="#">General Extended stored procedures</a> .

Functionality or syntax	Description
Identifiers (variables or parameters) with multiple leading @ characters	Identifiers that start with more than one leading @ aren't supported.
Identifiers, table or column names that contain @ or ]] characters	Table or column names that contain an @ sign or square brackets aren't supported.
Inline indexes	Inline indexes aren't supported.
Invoking a procedure whose name is in a variable	Using a variable as a procedure name isn't supported.
Materialized views	Materialized views aren't supported.
NOT FOR REPLICATION clause	This syntax is accepted and ignored.
ODBC escape functions	ODBC escape functions aren't supported.
Procedure calls that includes DEFAULT as a parameter value	DEFAULT isn't a supported parameter value. DEFAULT as a parameter value for a function call is supported from Babel fish 3.4.0 and higher releases.
Procedure declarations with more than 100 parameters	Declarations with more than 100 parameters aren't supported.
Procedures, externally defined	Externally defined procedures, including SQL CLR procedures, aren't supported.
Procedure versioning	Procedure versioning isn't supported.
Procedures WITH RECOMPILE	WITH RECOMPILE (when used in conjunction with the DECLARE and EXECUTE statements) isn't supported.

Functionality or syntax	Description
Remote object references	Executing stored procedures against Babelfish linked servers isn't supported. Four-part object names work only for reading and doesn't work for modifying the remote table. An UPDATE can reference a remote table in the FROM clause without modifying it. For more information, see <a href="#">Babelfish supports linked servers</a> .
Row-level security	Row-level security with CREATE SECURITY POLICY and inline table-valued functions isn't supported.
Service broker functionality	Service broker functionality isn't supported.
SESSIONPROPERTY	Unsupported properties: ANSI_NULLS, ANSI_PADDING, ANSI_WARNINGS, ARITHABORT, CONCAT_NULL_YIELDS_NULL, and NUMERIC_ROUNDABORT
SET LANGUAGE	This syntax isn't supported with any value other than english or us_english .
SP_CONFIGURE	This system stored procedure isn't supported.
SQL keyword SPARSE	The keyword SPARSE is accepted and ignored.
Table value constructor syntax (FROM clause)	The unsupported syntax is for a derived table constructed with the FROM clause.
Temporal tables	Temporal tables aren't supported.
Temporary procedures aren't dropped automatically	This functionality isn't supported.
Triggers, externally defined	These triggers aren't supported, including SQL Common Language Runtime (CLR).

## Settings that aren't supported

The following settings aren't supported:

- SET ANSI\_NULL\_DFLT\_OFF ON
- SET ANSI\_NULL\_DFLT\_ON OFF
- SET ANSI\_PADDING OFF
- SET ANSI\_WARNINGS OFF
- SET ARITHABORT OFF
- SET ARITHIGNORE ON
- SET CURSOR\_CLOSE\_ON\_COMMIT ON
- SET NUMERIC\_ROUNDABORT ON
- SET PARSEONLY ON (command doesn't work as expected)
- SET FMTONLY ON (command doesn't work as expected. It suppresses only the execution of SELECT statements but not others.)

### Commands that aren't supported

Certain functionality for the following commands isn't supported:

- ADD SIGNATURE
- ALTER DATABASE, ALTER DATABASE SET
- BACKUP/RESTORE DATABASE/LOG
- BACPAC and DACPAC FILES RESTORE
- CREATE, ALTER, DROP AUTHORIZATION. ALTER AUTHORIZATION is supported for database objects.
- CREATE, ALTER, DROP AVAILABILITY GROUP
- CREATE, ALTER, DROP BROKER PRIORITY
- CREATE, ALTER, DROP COLUMN ENCRYPTION KEY
- CREATE, ALTER, DROP DATABASE ENCRYPTION KEY
- CREATE, ALTER, DROP, BACKUP CERTIFICATE
- CREATE AGGREGATE
- CREATE CONTRACT
- CHECKPOINT

## Column names or attributes that aren't supported

The following column names aren't supported:

- \$IDENTITY
- \$ROWGUID
- IDENTITYCOL

## Data types that aren't supported

The following data types aren't supported:

- HIERARCHYID

## Object types that aren't supported

The following object types aren't supported:

- COLUMN MASTER KEY
- CREATE, ALTER EXTERNAL DATA SOURCE
- CREATE, ALTER, DROP DATABASE AUDIT SPECIFICATION
- CREATE, ALTER, DROP EXTERNAL LIBRARY
- CREATE, ALTER, DROP SERVER AUDIT
- CREATE, ALTER, DROP SERVER AUDIT SPECIFICATION
- CREATE, ALTER, DROP, OPEN/CLOSE SYMMETRIC KEY
- CREATE, DROP DEFAULT
- CREDENTIAL
- CRYPTOGRAPHIC PROVIDER
- DIAGNOSTIC SESSION
- Indexed views
- SERVICE MASTER KEY
- SYNONYM

## Functions that aren't supported

The following built-in functions aren't supported:

### Aggregate functions

- APPROX\_COUNT\_DISTINCT
- CHECKSUM\_AGG
- GROUPING\_ID
- STRING\_AGG using the WITHIN GROUP clause

### Cryptographic functions

- CERTENCODED function
- CERTID function
- CERTPROPERTY function

### Metadata functions

- COLUMNPROPERTY
- TYPEPROPERTY
- SERVERPROPERTY function – The following properties aren't supported:
  - BuildClrVersion
  - ComparisonStyle
  - ComputerNamePhysicalNetBIOS
  - HadrManagerStatus
  - InstanceDefaultDataPath
  - InstanceDefaultLogPath
  - IsClustered
  - IsHadrEnabled
  - LCID
  - NumLicenses
  - ProcessID
  - ProductBuild

- ProductBuildType
- ProductUpdateReference
- ResourceLastUpdateDateTime
- ResourceVersion
- ServerName
- SqlCharSet
- SqlCharSetName
- SqlSortOrder
- SqlSortOrderName
- FilestreamShareName
- FilestreamConfiguredLevel
- FilestreamEffectiveLevel

### **Security functions**

- CERTPRIVATEKEY
- LOGINPROPERTY

### **Statements, operators, other functions**

- EVENTDATA function
- GET\_TRANSMISSION\_STATUS
- OPENXML

### **Syntax that isn't supported**

The following syntax isn't supported:

- ALTER DATABASE
- ALTER DATABASE SCOPED CONFIGURATION
- ALTER DATABASE SCOPED CREDENTIAL
- ALTER DATABASE SET HADR
- ALTER INDEX

- ALTER PARTITION FUNCTION
- ALTER PARTITION SCHEME
- ALTER SCHEMA
- ALTER SERVER CONFIGURATION
- ALTER SERVICE, BACKUP/RESTORE SERVICE MASTER KEY clause
- BEGIN CONVERSATION TIMER
- BEGIN DISTRIBUTED TRANSACTION
- BEGIN DIALOG CONVERSATION
- BULK INSERT
- CREATE COLUMNSTORE INDEX
- CREATE EXTERNAL FILE FORMAT
- CREATE EXTERNAL TABLE
- CREATE, ALTER, DROP APPLICATION ROLE
- CREATE, ALTER, DROP ASSEMBLY
- CREATE, ALTER, DROP ASYMMETRIC KEY
- CREATE, ALTER, DROP CREDENTIAL
- CREATE, ALTER, DROP CRYPTOGRAPHIC PROVIDER
- CREATE, ALTER, DROP ENDPOINT
- CREATE, ALTER, DROP EVENT SESSION
- CREATE, ALTER, DROP EXTERNAL LANGUAGE
- CREATE, ALTER, DROP EXTERNAL RESOURCE POOL
- CREATE, ALTER, DROP FULLTEXT CATALOG
- CREATE, ALTER, DROP FULLTEXT INDEX
- CREATE, ALTER, DROP FULLTEXT STOPLIST
- CREATE, ALTER, DROP MESSAGE TYPE
- CREATE, ALTER, DROP, OPEN/CLOSE, BACKUP/RESTORE MASTER KEY
- CREATE, ALTER, DROP QUEUE
- CREATE, ALTER, DROP RESOURCE GOVERNOR
- CREATE, ALTER, DROP RESOURCE POOL
- CREATE, ALTER, DROP ROUTE

- CREATE, ALTER, DROP SEARCH PROPERTY LIST
- CREATE, ALTER, DROP SECURITY POLICY
- CREATE, ALTER, DROP SELECTIVE XML INDEX clause
- CREATE, ALTER, DROP SERVICE
- CREATE, ALTER, DROP SPATIAL INDEX
- CREATE, ALTER, DROP TYPE
- CREATE, ALTER, DROP XML INDEX
- CREATE, ALTER, DROP XML SCHEMA COLLECTION
- CREATE/DROP RULE
- CREATE, DROP WORKLOAD CLASSIFIER
- CREATE, ALTER, DROP WORKLOAD GROUP
- ALTER TRIGGER
- CREATE TABLE... GRANT clause
- CREATE TABLE... IDENTITY clause
- CREATE USER – This syntax isn't supported. The PostgreSQL statement CREATE USER doesn't create a user that is equivalent to the SQL Server CREATE USER syntax. For more information, see [T-SQL differences in Babelfish](#).
- DENY
- END, MOVE CONVERSATION
- EXECUTE with AS LOGIN or AT option

## Working with Babelfish for Aurora PostgreSQL procedures

### Overview

You can use the following procedure for Amazon RDS DB instances running Babelfish for Aurora PostgreSQL for a better query performance:

- [sp\\_babelfish\\_volatility](#)
- [sp\\_execute\\_postgresql](#)

### sp\_babelfish\_volatility

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.

### Syntax

```
sp_babelfish_volatility 'function_name', 'volatility'
```

### Arguments

*function\_name (optional)*

You can either specify the value of this argument with a two-part name as `schema_name.function_name` or only the `function_name`. If you specify only the `function_name`, the schema name is the default schema for the current user.

*volatility (optional)*

The valid PostgreSQL values of volatility are `stable`, `volatile`, or `immutable`. For more information, see <https://www.postgresql.org/docs/current/xfunc-volatility.html>

#### Note

When `sp_babelfish_volatility` is called with `function_name` which has multiple definitions, it will throw an error.

## Result set

If the parameters are not mentioned then the result set is displayed under the following columns: schemaname, functionname, volatility.

## Usage notes

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.

## Examples

The following examples shows how to create simple functions and later explains how to use `sp_babelfish_volatility` on these functions using different methods.

```
1> create function f1() returns int as begin return 0 end
2> go
```

```
1> create schema test_schema
2> go
```

```
1> create function test_schema.f1() returns int as begin return 0 end
2> go
```

The following example displays volatility of the functions:

```
1> exec sp_babelfish_volatility
2> go

schemaname  functionname  volatility
-----
dbo         f1            volatile
test_schema f1            volatile
```

The following example shows how to change the volatility of the functions:

```
1> exec sp_babelfish_volatility 'f1','stable'
2> go
1> exec sp_babelfish_volatility 'test_schema.f1','immutable'
2> go
```

When you specify only the `function_name`, it displays the schema name, function name and volatility of that function. The following example displays volatility of functions after changing the values:

```
1> exec sp_babelfish_volatility 'test_schema.f1'
2> go
```

schemaname	functionname	volatility
-----	-----	-----
test_schema	f1	immutable

```
1> exec sp_babelfish_volatility 'f1'
2> go
```

schemaname	functionname	volatility
-----	-----	-----
dbo	f1	stable

When you don't specify any argument, it displays a list of functions (schema name, function name, volatility of the functions) present in the current database:

```
1> exec sp_babelfish_volatility
2> go
```

schemaname	functionname	volatility
-----	-----	-----
dbo	f1	stable
test_schema	f1	immutable

## sp\_execute\_postgresql

You can execute PostgreSQL statements from T-SQL endpoint. This simplifies your applications as you don't need to exit T-SQL port to execute these statements.

### Syntax

```
sp_execute_postgresql [ @stmt = ] statement
```

## Arguments

[ @stmt ] statement

The argument is of datatype varchar. This argument accept PG dialect statements.

### Note

You can only pass one PG dialect statement as an argument otherwise it will raise the following error.

```
1>exec sp_execute_postgresql 'create extension pg_stat_statements; drop extension
pg_stat_statements'
2>go
```

```
Msg 33557097, Level 16, State 1, Server BABELFISH, Line 1
expected 1 statement but got 2 statements after parsing
```

## Usage notes

### CREATE EXTENSION

Creates and loads a new extension into the current database.

```
1>EXEC sp_execute_postgresql 'create extension [ IF NOT EXISTS ] <extension name>
[ WITH ] [SCHEMA schema_name] [VERSION version]';
2>go
```

The following example shows how to create an extension:

```
1>EXEC sp_execute_postgresql 'create extension pg_stat_statements with schema sys
version "1.10"';
2>go
```

Use the following command to access extension objects:

```
1>select * from pg_stat_statements;  
2>go
```

### Note

If schema name is not provided explicitly during extension creation, by default the extensions are installed in the public schema. You must provide the schema qualifier to access the extension objects as mentioned below:

```
1>select * from [public].pg_stat_statements;  
2>go
```

## Supported extensions

The following extensions available with Aurora PostgreSQL works with Babelfish.

- pg\_stat\_statements
- tds\_fdw
- fuzzystmatch

## Limitations

- Users need to have sysadmin role on T-SQL and rds\_superuser on postgres to install the extensions.
- Extensions cannot be installed in user created schemas and also in dbo and guest schemas for master, tempdb and msdb database.
- CASCADE option is not supported.

## ALTER EXTENSION

You can upgrade to a new extension version using ALTER extension.

```
1>EXEC sp_execute_postgresql 'alter extension <extension name> UPDATE TO
<new_version>';
2>go
```

## Limitations

- You can upgrade the version of your extension only using the ALTER Extension statement. Other operations aren't supported.

## DROP EXTENSION

Drops the specified extension. You can also use `if exists` or `restrict` options to drop the extension.

```
1>EXEC sp_execute_postgresql 'drop extension <extension name>';
2>go
```

## Limitations

- CASCADE option is not supported.

## Babelfish supports XML datatype methods

Starting with version 5.4.0, Babelfish now supports stored procedures `sp_xml_preparedocument` and `sp_xml_removedocument`, rowset function `OPENXML()` and xml datatype method `.VALUE()`. With these functions and procedures querying on XML data becomes much easier.

### Understanding XML procedures and methods

- **sp\_xml\_preparedocument** – The procedure `sp_xml_preparedocument` parses an XML text given as input and returns a handle to this document. This handle is valid during the session or until it is removed by `sp_xml_removedocument`.
- **sp\_xml\_removedocument** – The procedure `sp_xml_removedocument` invalidates the handle which was created by procedure `sp_xml_preparedocument`.
- **OPENXML()** – `OPENXML` provides a rowset view over an XML document. Since `OPENXML` is a rowset provider and it returns a set of rows, we can use `OPENXML` in the `FROM` clause just as we can use any other table, view, or table-valued function.
- **VALUE()** – XML Datatype method `VALUE()` is used to extract a value from an XML instance stored in an xml type column, parameter, or variable.

### Limitations in Babelfish XML procedures and methods

- Babelfish only supports XPATH 1.0 syntax for second argument (i.e. `ROWPATTERN`) of `OPENXML()`.
- The meta-properties and flag 8 are not currently not supported in `OPENXML()`.
- Babelfish only supports XPATH 1.0 syntax for first argument (i.e. `XQuery`) of `VALUE()` datatype method.

## Performance and scaling for Amazon Aurora PostgreSQL

The following section discusses managing performance and scaling for an Amazon Aurora PostgreSQL DB cluster. It also includes information about other maintenance tasks.

### Topics

- [Scaling Aurora PostgreSQL DB instances](#)
- [Maximum connections to an Aurora PostgreSQL DB instance](#)

- [Temporary storage limits for Aurora PostgreSQL](#)
- [Huge pages for Aurora PostgreSQL](#)
- [Testing Amazon Aurora PostgreSQL by using fault injection queries](#)
- [Displaying volume status for an Aurora PostgreSQL DB cluster](#)
- [Specifying the RAM disk for the stats\\_temp\\_directory](#)
- [Managing temporary files with PostgreSQL](#)

## Scaling Aurora PostgreSQL DB instances

You can scale Aurora PostgreSQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see [Read scaling](#).

You can scale your Aurora PostgreSQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora PostgreSQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 terabytes (TB).

### Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see [DB instance class types](#).

Scaling isn't instantaneous. It can take 15 minutes or more to complete the change to a different DB instance class. If you use this approach to modify the DB instance class, you apply the change during the next scheduled maintenance window (rather than immediately) to avoid affecting users.

As an alternative to modifying the DB instance class directly, you can minimize downtime by using the high availability features of Amazon Aurora. First, add an Aurora Replica to your cluster. When creating the replica, choose the DB instance class size that you want to use for your cluster. When the Aurora Replica is synchronized with the cluster, you then failover to the newly added Replica. To learn more, see [Aurora Replicas](#) and [Fast failover with Amazon Aurora PostgreSQL](#).

For detailed specifications of the DB instance classes supported by Aurora PostgreSQL, see [Supported DB engines for DB instance classes](#).

## Maximum connections to an Aurora PostgreSQL DB instance

An Aurora PostgreSQL DB cluster allocates resources based on the DB instance class and its available memory. Each connection to the DB cluster consumes incremental amounts of these resources, such as memory and CPU. Memory consumed per connection varies based on query type, count, and whether temporary tables are used. Even an idle connection consumes memory and CPU. That's because when queries run on a connection, more memory is allocated for each query and it's not released completely, even when processing stops. Thus, we recommend that you make sure your applications aren't holding on to idle connections: each one of these wastes resources and affects performance negatively. For more information, see [Resources consumed by idle PostgreSQL connections](#).

The maximum number of connections allowed by an Aurora PostgreSQL DB instance is determined by the `max_connections` parameter value specified in the parameter group for that DB instance. The ideal setting for the `max_connections` parameter is one that supports all the client connections your application needs, without an excess of unused connections, plus at least 3 more connections to support Amazon automation. Before modifying the `max_connections` parameter setting, we recommend that you consider the following:

- If the `max_connections` value is too low, the Aurora PostgreSQL DB instance might not have sufficient connections available when clients attempt to connect. If this happens, attempts to connect using `psql` raise error messages such as the following:

```
psql: FATAL: remaining connection slots are reserved for non-replication superuser connections
```

- If the `max_connections` value exceeds the number of connections that are actually needed, the unused connections can cause performance to degrade.

The default value of `max_connections` is derived from the following Aurora PostgreSQL LEAST function:

```
LEAST({DBInstanceClassMemory/9531392}, 5000).
```

If you want to change the value for `max_connections`, you need to create a custom DB cluster parameter group and change its value there. After applying your custom DB parameter group to your cluster, be sure to reboot the primary instance so the new value takes effect. For more information, see [Amazon Aurora PostgreSQL parameters](#) and [Creating a DB cluster parameter group in Amazon Aurora](#).

**Tip**

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see [Amazon RDS Proxy for Aurora](#).

For details about how Aurora Serverless v2 instances handle this parameter, see [Maximum connections for Aurora Serverless v2](#).

## Temporary storage limits for Aurora PostgreSQL

Aurora PostgreSQL stores tables and indexes in the Aurora storage subsystem. Aurora PostgreSQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large data sets during query processing or for index build operations. For more information, see the article [How can I troubleshoot local storage issues in Aurora PostgreSQL-Compatible instances?](#)

These local storage volumes are backed by Amazon Elastic Block Store and can be extended by using a larger DB instance class. For more information about storage, see [Amazon Aurora storage](#). You can also increase your local storage for temporary objects by using an NVMe enabled instance type and Aurora Optimized Reads-enabled temporary objects. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

**Note**

You might see storage-optimization events when scaling DB instances, for example, from db.r5.2xlarge to db.r5.4xlarge.

The following table shows the maximum amount of temporary storage available for each Aurora PostgreSQL DB instance class. For more information on DB instance class support for Aurora, see [Amazon Aurora DB instance classes](#).

DB instance class	Maximum temporary storage available (GiB)
db.x2g.16xlarge	1829
db.x2g.12xlarge	1606
db.x2g.8xlarge	1071
db.x2g.4xlarge	535
db.x2g.2xlarge	268

db.r5.xlarge	62
db.r5.large	31
db.r4.16xlarge	960
db.r4.8xlarge	480
db.r4.4xlarge	240
db.r4.2xlarge	120

DB instance class	Maximum temporary storage available (GiB)
db.r4.xlarge	60
db.r4.large	30
db.t4g.large	16.5
db.t4g.medium	8.13
db.t3.large	16
db.t3.medium	7.5

### Note

NVMe enabled instance types can increase the temporary space available by up to the total NVMe size. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

You can monitor the temporary storage available for a DB instance with the `FreeLocalStorage` CloudWatch metric, --> described in [Amazon CloudWatch metrics for Amazon Aurora](#). (This doesn't apply to Aurora Serverless v2.)

For some workloads, you can reduce the amount of temporary storage by allocating more memory to the processes that are performing the operation. To increase the memory available to an operation, increasing the values of the [work\\_mem](#) or [maintenance\\_work\\_mem](#) PostgreSQL parameters.

## Huge pages for Aurora PostgreSQL

*Huge pages* are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available Aurora PostgreSQL versions.

`Huge_pages` parameter is turned on by default for all DB instance classes other than `t3.medium`, `db.t3.large`, `db.t4g.medium`, `db.t4g.large` instance classes. You can't change the

huge\_pages parameter value or turn off this feature in the supported instance classes of Aurora PostgreSQL.

On Aurora PostgreSQL DB instances that don't support the huge pages memory feature, specific process memory usage might increase without corresponding workload changes.

The system allocates shared memory segments like the buffer cache during server startup. When huge memory pages aren't available, the system doesn't charge these allocations to the postmaster process. Instead, it includes the memory in the process that first accessed each 4KB page in the shared memory segment.

### Note

Active connections share allocated memory as needed, regardless of how shared memory usage is tracked across processes.

## Testing Amazon Aurora PostgreSQL by using fault injection queries

You can test the fault tolerance of your Aurora PostgreSQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. Fault injection queries let you crash the instance so that you can test failover and recovery. You can also simulate Aurora Replica failure, disk failure, and disk congestion. Fault injection queries are supported by all available Aurora PostgreSQL versions, as follows.

- Aurora PostgreSQL versions 12, 13, 14, and higher
- Aurora PostgreSQL version 11.7 and higher
- Aurora PostgreSQL version 10.11 and higher

### Topics

- [Testing an instance crash](#)
- [Testing an Aurora Replica failure](#)
- [Testing a disk failure](#)
- [Testing disk congestion](#)

When a fault injection query specifies a crash, it forces a crash of the Aurora PostgreSQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause

the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see [Amazon Aurora endpoint connections](#).

## Testing an instance crash

You can force a crash of an Aurora PostgreSQL instance by using the fault injection query function `aurora_inject_crash()`.

For this fault injection query, a failover does not occur. If you want to test a failover, then you can choose the **Failover** instance action for your DB cluster in the RDS console, or use the [failover-db-cluster](#) Amazon CLI command or the [FailoverDBCluster](#) RDS API operation.

### Syntax

```
SELECT aurora_inject_crash ('instance' | 'dispatcher' | 'node');
```

### Options

This fault injection query takes one of the following crash types. The crash type is not case sensitive:

*'instance'*

A crash of the PostgreSQL-compatible database for the Amazon Aurora instance is simulated.

*'dispatcher'*

A crash of the dispatcher on the primary instance for the Aurora DB cluster is simulated. The *dispatcher* writes updates to the cluster volume for an Amazon Aurora DB cluster.

*'node'*

A crash of both the PostgreSQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated.

## Testing an Aurora Replica failure

You can simulate the failure of an Aurora Replica by using the fault injection query function `aurora_inject_replica_failure()`.

An Aurora Replica failure blocks replication to the Aurora Replica or all Aurora Replicas in the DB cluster by the specified percentage for the specified time interval. When the time interval completes, the affected Aurora Replicas are automatically synchronized with the primary instance.

## Syntax

```
SELECT aurora_inject_replica_failure(  
    percentage_of_failure,  
    time_interval,  
    'replica_name'  
);
```

## Options

This fault injection query takes the following parameters:

### *percentage\_of\_failure*

The percentage of replication to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no replication is blocked. If you specify 100, then all replication is blocked.

### *time\_interval*

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

#### **Note**

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long an interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

### *replica\_name*

The Aurora Replica in which to inject the failure simulation. Specify the name of an Aurora Replica to simulate a failure of the single Aurora Replica. Specify an empty string to simulate failures for all Aurora Replicas in the DB cluster.

To identify replica names, see the `server_id` column from the `aurora_replica_status()` function. For example:

```
postgres=> SELECT server_id FROM aurora_replica_status();
```

## Testing a disk failure

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_failure()`.

During a disk failure simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as faulting. Requests to those segments are blocked for the duration of the simulation.

### Syntax

```
SELECT aurora_inject_disk_failure(  
    percentage_of_failure,  
    index,  
    is_disk,  
    time_interval  
);
```

### Options

This fault injection query takes the following parameters:

#### *percentage\_of\_failure*

The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

#### *index*

A specific logical block of data in which to simulate the failure event. If you exceed the range of available logical blocks or storage nodes data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster](#).

### *is\_disk*

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

### *time\_interval*

The amount of time to simulate the disk failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

## Testing disk congestion

You can simulate a disk congestion for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_congestion()`.

During a disk congestion simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as congested. Requests to those segments are delayed between the specified minimum and maximum delay time for the duration of the simulation.

### Syntax

```
SELECT aurora_inject_disk_congestion(  
    percentage_of_failure,  
    index,  
    is_disk,  
    time_interval,  
    minimum,  
    maximum  
);
```

### Options

This fault injection query takes the following parameters:

#### *percentage\_of\_failure*

The percentage of the disk to mark as congested during the failure event. This is a double value between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

## *index*

A specific logical block of data or storage node to use to simulate the failure event.

If you exceed the range of available logical blocks or storage nodes of data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster](#).

## *is\_disk*

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

## *time\_interval*

The amount of time to simulate the disk congestion. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

## *minimum, maximum*

The minimum and maximum amount of congestion delay, in milliseconds. Valid values range from 0.0 to 100.0 milliseconds. Disk segments marked as congested are delayed for a random amount of time within the minimum and maximum range for the duration of the simulation. The maximum value must be greater than the minimum value.

## Displaying volume status for an Aurora PostgreSQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](#) on the Amazon Database Blog. To learn more about Aurora cluster volumes in general, see [Amazon Aurora storage](#).

Use the `aurora_show_volume_status()` function to return the following server status variables:

- **Disks** — The total number of logical blocks of data for the DB cluster volume.

- **Nodes** — The total number of storage nodes for the DB cluster volume.

You can use the `aurora_show_volume_status()` function to help avoid an error when using the `aurora_inject_disk_failure()` fault injection function. The `aurora_inject_disk_failure()` fault injection function simulates the failure of an entire storage node, or a single logical block of data within a storage node. In the function, you specify the index value of a specific logical block of data or storage node. However, the statement returns an error if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume. For more information about fault injection queries, see [Testing Amazon Aurora PostgreSQL by using fault injection queries](#).

### Note

The `aurora_show_volume_status()` function is available for Aurora PostgreSQL version 10.11. For more information about Aurora PostgreSQL versions, see [Amazon Aurora PostgreSQL releases and engine versions](#).

## Syntax

```
SELECT * FROM aurora_show_volume_status();
```

## Example

```
customer_database=> SELECT * FROM aurora_show_volume_status();
 disks | nodes
-----+-----
      96 |      45
```

## Specifying the RAM disk for the stats\_temp\_directory

You can use the Aurora PostgreSQL parameter, `rds.pg_stat_ramdisk_size`, to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is only available in Aurora PostgreSQL 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease IO requirements. For more information about the `stats_temp_directory`, see [Run-time Statistics](#)

in the PostgreSQL documentation. From PostgreSQL version 15, the PostgreSQL community switched to use dynamic shared memory. So, there is no need to set `stats_temp_directory`.

To enable a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to a non-zero value in the DB cluster parameter group used by your DB cluster. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the `rds.pg_stat_ramdisk_size` parameter. Be sure to restart the DB cluster so that the change takes effect. For information about setting parameters, see [Parameter groups for Amazon Aurora](#). For more information about restarting the DB cluster, see [Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance](#).

As an example, the following Amazon CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name db-cl-pg-ramdisk-testing \  
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, \  
  ApplyMethod=pending-reboot"
```

After you restart the DB cluster, run the following command to see the status of the `stats_temp_directory`:

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following:

```
stats_temp_directory  
-----  
/rdsdbramdisk/pg_stat_tmp  
(1 row)
```

## Managing temporary files with PostgreSQL

In PostgreSQL, a complex query might perform several sort or hash operations at the same time, with each operation using instance memory to store results up to the value specified in the [work\\_mem](#) parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In Aurora PostgreSQL, these files share local storage with other log files. You can monitor your Aurora PostgreSQL DB cluster's local storage

space by watching the Amazon CloudWatch metric for `FreeLocalStorage`. For more information, see [Troubleshoot local storage issues](#).

We recommend using Aurora Optimized Read clusters for workloads involving multiple concurrent queries that increase the usage of temporary files. These clusters use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

You can use the following parameters and functions to manage the temporary files in your instance.

- [temp\\_file\\_limit](#) – This parameter cancels any query exceeding the size of temp\_files in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```
postgres=>select * from pgbench_accounts, pg_class, big_table;
```

```
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- [log\\_temp\\_files](#) – This parameter sends messages to the `postgresql.log` when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

The following example shows that when the query successfully completes, the entries are logged in the `postgresql.log` file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
temporary file: path "base/pgsql_tmp/pgsql_tmp31236.5", size 140353536
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
temporary file: path "base/pgsql_tmp/pgsql_tmp31236.4", size 180428800
```

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
  select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
  a.bid limit 10;
```

- [\*\*pg\\_ls\\_tmpdir\*\*](#) – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```
postgres=>select * from pg_ls_tmpdir();
```

name	size	modification
pgsql_tmp8355.1	1072250880	2023-02-06 22:54:56+00
pgsql_tmp8351.0	1072250880	2023-02-06 22:54:43+00
pgsql_tmp8327.0	1072250880	2023-02-06 22:54:56+00
pgsql_tmp8351.1	703168512	2023-02-06 22:54:56+00
pgsql_tmp8355.0	1072250880	2023-02-06 22:54:00+00
pgsql_tmp8328.1	835031040	2023-02-06 22:54:56+00
pgsql_tmp8328.0	1072250880	2023-02-06 22:54:40+00

(7 rows)

```
postgres=>select query from pg_stat_activity where pid = 8355;
```

```
query
```

```
-----
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
  a.bid
(1 row)
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.

```
postgres=>select replace(left(name, strpos(name, '.')-1), 'pgsql_tmp', '') as pid,
  count(*), sum(size) from pg_ls_tmpdir() group by pid;
```

```

pid | count | sum
-----+-----
8355 |      2 | 2144501760
8351 |      2 | 2090770432
8327 |      1 | 1072250880
8328 |      2 | 2144501760
(4 rows)

```

- [pg\\_stat\\_statements](#) – If you activate the `pg_stat_statements` parameter, then you can view the average temporary file usage per call. You can identify the `query_id` of the query and use it to examine the temporary file usage as shown in the following example.

```

postgres=>select queryid from pg_stat_statements where query like 'select a.aid from
pgbench%';

```

```

      queryid
-----
-7170349228837045701
(1 row)

```

```

postgres=>select queryid, substr(query,1,25), calls, temp_blks_read/calls
temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from
pg_stat_statements where queryid = -7170349228837045701;

```

```

      queryid      |      substr      | calls | temp_blks_read_per_call |
temp_blks_written_per_call
-----+-----+-----+-----
+-----+
-7170349228837045701 | select a.aid from pgbench |    50 |                239226 |
388678
(1 row)

```

- [Performance Insights](#) – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics **temp\_bytes** and **temp\_files**. Then, you can see the

average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see [Analyzing metrics with the Performance Insights dashboard](#).

For an example of viewing temporary file usage with Performance Insights, see [Viewing temporary file usage with Performance Insights](#)

## Viewing temporary file usage with Performance Insights

You can use Performance Insights to view temporary file usage by turning on the metrics **temp\_bytes** and **temp\_files**. The view in Performance Insights doesn't show the specific queries that generate temporary files, however, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

1. In the Performance Insights dashboard, choose **Manage Metrics**.
2. Choose **Database metrics**, and select the **temp\_bytes** and **temp\_files** metrics as shown in the following image.

**Select metrics shown on the graph**

Check the metrics that you want to see on the Performance Insights dashboard.

Find metrics

OS metrics (0) | **Database metrics (3)**

- ▶ Cache
- ▶ Checkpoint
- ▶ Concurrency
- ▶ IO
- ▶ SQL
- ▼ Temp
  - temp\_bytes
  - temp\_files
  - ▶ Transactions
  - ▶ User
  - ▶ WAL
  - ▶ state

3. In the **Top SQL** tab, choose the **Preferences** icon.
4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL** tab and choose **Continue**.
  - Temp writes/sec
  - Temp reads/sec
  - Tmp blk write/call
  - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.

SQL statements	Calls/sec	Rows/sec	Temp wri...	Temp rea...	Tmp blk ...	Tmp blk r...
11.77 <code>select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order...</code>	0.04	0.43	16589.14	10307.89	381550.15	237081.46

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on `IO:BufFileRead` and `IO:BufFileWrite` by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see [Overview of the Top SQL tab](#). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see [IO:BufFileRead and IO:BufFileWrite](#).

### Note

The `work_mem` parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.

## Tuning with wait events for Aurora PostgreSQL

Wait events are an important tuning tool for Aurora PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. Before delving into this section, we strongly recommend that you understand basic Aurora concepts, especially the following topics:

- [Amazon Aurora storage](#)
- [Managing performance and scaling for Aurora DB clusters](#)

### Important

The wait events in this section are specific to Aurora PostgreSQL. Use the information in this section to tune Amazon Aurora only, not RDS for PostgreSQL.

Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works differently from open source storage, so storage-related wait events indicate different resource conditions.

## Essential concepts for Aurora PostgreSQL tuning

Before you tune your Aurora PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of Aurora PostgreSQL. For a helpful architecture diagram, see the [PostgreSQL](#) wikibook.

### Topics

- [Aurora PostgreSQL wait events](#)
- [Aurora PostgreSQL memory](#)
- [Aurora PostgreSQL processes](#)

## Aurora PostgreSQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `Client:ClientRead` occurs when Aurora PostgreSQL is waiting to receive data from the client. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

## Aurora PostgreSQL memory

Aurora PostgreSQL memory is divided into shared and local.

### Topics

- [Shared memory in Aurora PostgreSQL](#)
- [Local memory in Aurora PostgreSQL](#)

## Shared memory in Aurora PostgreSQL

Aurora PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

### Topics

- [Shared buffers](#)
- [Write ahead log \(WAL\) buffers](#)

## Shared buffers

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, Aurora PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

## Write ahead log (WAL) buffers

A *write-ahead log (WAL) buffer* holds transaction data that Aurora PostgreSQL later writes to persistent storage. Using the WAL mechanism, Aurora PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, Aurora PostgreSQL writes the changes to the WAL buffer. When the client issues a COMMIT, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

## Local memory in Aurora PostgreSQL

Every backend process allocates local memory for query processing.

## Topics

- [Work memory area](#)
- [Maintenance work memory area](#)

- [Temporary buffer area](#)

## Work memory area

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an `ORDER BY` clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

## Maintenance work memory area

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

## Temporary buffer area

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

## Aurora PostgreSQL processes

Aurora PostgreSQL uses multiple processes.

### Topics

- [Postmaster process](#)
- [Backend processes](#)

- [Background processes](#)

## Postmaster process

The *postmaster process* is the first process started when you start Aurora PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

## Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

## Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer

Aurora PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows Aurora PostgreSQL to use the logs to recover the database after a failure.

- Background writer

This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- Autovacuum daemon

The daemon consists of the following:

- The autovacuum launcher

- The autovacuum worker processes

When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

- Recover or reuse disk space occupied by updated or deleted rows
- Update statistics used by the planner
- Protect against loss of old data because of transaction ID wraparound

The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

## Aurora PostgreSQL wait events

The following table lists the wait events for Aurora PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions. The following wait events are a subset of the list in [Amazon Aurora PostgreSQL wait events](#).

Wait event	Definition
<a href="#">Client:ClientRead</a>	This event occurs when Aurora PostgreSQL is waiting to receive data from the client.
<a href="#">Client:ClientWrite</a>	This event occurs when Aurora PostgreSQL is waiting to write data to the client.
<a href="#">CPU</a>	This event occurs when a thread is active in CPU or is waiting for CPU.
<a href="#">IO:BufFileRead and IO:BufFileWrite</a>	These events occur when Aurora PostgreSQL creates temporary files.
<a href="#">IO:DataFileRead</a>	This event occurs when a connection waits on a backend process to read a required page from

Wait event	Definition
	storage because the page isn't available in shared memory.
<a href="#">IO:XactSync</a>	This event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction.
<a href="#">IPC:DamRecordTxAck</a>	This event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.
<a href="#">Lock:advisory</a>	This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.
<a href="#">Lock:extend</a>	This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.
<a href="#">Lock:Relation</a>	This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.
<a href="#">Lock:transactionid</a>	This event occurs when a transaction is waiting for a row-level lock.
<a href="#">Lock:tuple</a>	This event occurs when a backend process is waiting to acquire a lock on a tuple.
<a href="#">LWLock:buffer_content (BufferContent)</a>	This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.

Wait event	Definition
<a href="#">LWLock:buffer_mapping</a>	This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.
<a href="#">LWLock:BufferIO (IPC:BufferIO)</a>	This event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.
<a href="#">LWLock:lock_manager</a>	This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.
<a href="#">LWLock:MultiXact</a>	This type of event occurs when Aurora PostgreSQL is keeping a session open to complete multiple transactions that involve the same row in a table. The wait event denotes which aspect of multiple transaction processing is generating the wait event, that is, LWLock:MultiXactOffsetSLRU, LWLock:MultiXactOffsetBuffer, LWLock:MultiXactMemberSLRU, or LWLock:MultiXactMemberBuffer.
<a href="#">Timeout:PgSleep</a>	This event occurs when a server process has called the <code>pg_sleep</code> function and is waiting for the sleep timeout to expire.

## Client:ClientRead

The `Client:ClientRead` event occurs when Aurora PostgreSQL is waiting to receive data from the client.

### Topics

- [Supported engine versions](#)

- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

### Context

An Aurora PostgreSQL DB cluster is waiting to receive data from the client. The Aurora PostgreSQL DB cluster must receive the data from the client before it can send more data to the client. The time that the cluster waits before receiving data from the client is a `Client:ClientRead` event.

### Likely causes of increased waits

Common causes for the `Client:ClientRead` event to appear in top waits include the following:

#### Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for DB cluster to receive data from the client.

#### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

#### Excessive network round trips

A large number of network round trips between the Aurora PostgreSQL DB cluster and the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

#### Large copy operation

During a copy operation, the data is transferred from the client's file system to the Aurora PostgreSQL DB cluster. Sending a large amount of data to the DB cluster can delay transmission of data from the client to the DB cluster.

## Idle client connection

A connection to an Aurora PostgreSQL DB instance is in idle in transaction state and is waiting for a client to send more data or issue a command. This state can lead to an increase in `Client:ClientRead` events.

## PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called `pkt_buf`, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the `pkt_buf` setting to 8,192. If the new setting doesn't decrease the number of `Client:ClientRead` events, we recommend increasing the `pkt_buf` setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the cluster](#)
- [Scale your client](#)
- [Use current generation instances](#)
- [Increase network bandwidth](#)
- [Monitor maximums for network performance](#)
- [Monitor for transactions in the "idle in transaction" state](#)

## Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster. Make sure that the clients are as geographically close to the DB cluster as possible.

## Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

## Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see [Amazon Aurora DB instance classes](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

## Increase network bandwidth

Use `NetworkReceiveThroughput` and `NetworkTransmitThroughput` Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the Amazon client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora](#).

## Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide* and [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

## Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

## Client:ClientWrite

The `Client:ClientWrite` event occurs when Aurora PostgreSQL is waiting to write data to the client.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

## Context

A client process must read all of the data received from an Aurora PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a `Client:ClientWrite` event.

Reduced network throughput between the Aurora PostgreSQL DB cluster and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. *CPU pressure* is when the CPU is fully utilized and there are tasks waiting for CPU time. *Network saturation* is when the network between the database and client is carrying more data than it can handle.

## Likely causes of increased waits

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

### Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora PostgreSQL DB cluster.

### Large volume of data sent to the client

The Aurora PostgreSQL DB cluster might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the cluster](#)
- [Use current generation instances](#)
- [Reduce the amount of data sent to the client](#)
- [Scale your client](#)

### Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster.

### Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This

technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see [Amazon Aurora DB instance classes](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

## Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the Aurora PostgreSQL DB cluster sends to the client. Making such adjustments relieves CPU and network contention on the client.

## Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

## CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

### Topics

- [Supported engine versions](#)
- [Context](#)

- [Actions](#)

## Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

## Context

The *central processing unit (CPU)* is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. *CPU scheduling* is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

## Topics

- [How to tell when this wait occurs](#)
- [DBLoadCPU metric](#)
- [os.cpuUtilization metrics](#)
- [Likely cause of CPU scheduling](#)

## How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

## DBLoadCPU metric

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the Amazon CloudWatch metric `CPUUtilization`. The latter metric is collected from the Hypervisor for a database instance.

## os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

### Likely cause of CPU scheduling

From an operating system perspective, the CPU is active when it isn't running the idle thread. The CPU is active while it performs a computation, but it's also active when it waits on memory I/O. This type of I/O dominates a typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch `CPUUtilization` metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `loadAverageMinute` metric in the OS metrics section in Performance Insights.

### Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

#### Topics

- [Likely causes of sudden spikes](#)
- [Likely causes of long-term high frequency](#)
- [Corner cases](#)

### Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators

- An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

### Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

### Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- CPU context switching has increased.
- Aurora PostgreSQL code is missing wait events.

### Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

### Topics

- [Investigate whether the database is causing the CPU increase](#)
- [Determine whether the number of connections increased](#)
- [Respond to workload changes](#)

### Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

## Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

### The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.

- The number of backend processes consuming CPU is greater than the number of vCPUs.

In this case, consider the following options:

- Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see [Amazon RDS Proxy for Aurora](#).
- Upgrade your instance size to get a higher number of vCPUs.
- Redirect some read-only workloads to reader nodes, if applicable.

### The connections didn't increase

Examine the blks\_hit metrics in Performance Insights. Look for a correlation between an increase in blks\_hit and CPU usage. The following scenarios are possible:

- CPU usage and blks\_hit are correlated.

In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

- Explain the plans manually and compare them to the expected execution plan.
- Look for an increase in block hits per second and local block hits per second. In the **Top SQL** section of Performance Insights dashboard, choose **Preferences**.
- CPU usage and blks\_hit aren't correlated.

In this case, determine whether any of the following occurs:

- The application is rapidly connecting to and disconnecting from the database.

Diagnose this behavior by turning on `log_connections` and `log_disconnections`, then analyzing the PostgreSQL logs. Consider using the `pgbadger` log analyzer. For more information, see <https://github.com/darold/pgbadger>.

- The OS is overloaded.

In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch `CPUUtilization` metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

- Top SQL statements are consuming too much CPU.

Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an `EXPLAIN` command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see <http://explain.dalibo.com/>.

## Respond to workload changes

If your workload has changed, look for the following types of changes:

### New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

### An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

### Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

### New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

## New operators

Check whether they perform as expected during the testing.

### An increase in running parallel queries

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

## IO:BufFileRead and IO:BufFileWrite

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when Aurora PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called *spilling to disk*. For more information about the temporary files and their usage, see [Managing temporary files with PostgreSQL](#).

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

`IO:BufFileRead` and `IO:BufFileWrite` relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see [Work memory area](#) and [Maintenance work memory area](#).

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, Aurora PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

## Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the `IO:BufFileRead` and `IO:BufFileWrite` events include the following:

### Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

### Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- CREATE INDEX
- CLUSTER

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Identify the problem](#)
- [Examine your join queries](#)
- [Examine your ORDER BY and GROUP BY queries](#)
- [Avoid using the DISTINCT operation](#)
- [Consider using window functions instead of GROUP BY functions](#)
- [Investigate materialized views and CTAS statements](#)
- [Use pg\\_repack when you create indexes](#)
- [Increase maintenance\\_work\\_mem when you cluster tables](#)
- [Tune memory to prevent IO:BufFileRead and IO:BufFileWrite](#)

### Identify the problem

You can view temporary file usage directly in Performance Insights. For more information, see [Viewing temporary file usage with Performance Insights](#). When Performance Insights is disabled, you might notice increased IO:BufFileRead and IO:BufFileWrite operations. To troubleshoot, do the following:

1. Examine the FreeLocalStorage metric in Amazon CloudWatch.
2. Look for a chainsaw pattern, which is a series of jagged spikes.

A chainsaw pattern indicates a quick consumption and release of storage, often associated with temporary files. If you notice this pattern, turn on Performance Insights. When using Performance Insights, you can identify when the wait events occur and which queries are associated with them. Your solution depends on the specific query causing the events.

Or set the parameter `log_temp_files`. This parameter logs all queries generating more than threshold KB of temporary files. If the value is 0, Aurora PostgreSQL logs all temporary files. If the

value is 1024, Aurora PostgreSQL logs all queries that produces temporary files larger than 1 MB. For more information about `log_temp_files`, see [Error Reporting and Logging](#) in the PostgreSQL documentation.

## Examine your join queries

Your application probably use joins. For example, the following query joins four tables.

```
SELECT *
  FROM order
 INNER JOIN order_item
   ON (order.id = order_item.order_id)
 INNER JOIN customer
   ON (customer.id = order.customer_id)
 INNER JOIN customer_address
   ON (customer_address.customer_id = customer.id AND
       order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
  FROM order
 INNER JOIN order_item
   ON (order.id = order_item.order_id)
 INNER JOIN customer
   ON (customer.id = customer.id)
 INNER JOIN customer_address
   ON (customer_address.customer_id = customer.id AND
       order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.

- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

### Examine your `ORDER BY` and `GROUP BY` queries

In some cases, an `ORDER BY` clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an `ORDER BY` clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the `ORDER BY` clause.
- Considering creating indexes to accelerate `ORDER BY` clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use `WITH` clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

- If you don't need to obtain the full result set, use the `LIMIT` clause. For example, if you only want the top five rows, a query using the `LIMIT` clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a `GROUP BY` clause can also require temporary files. `GROUP BY` queries summarize values by using functions such as the following:

- `COUNT`
- `AVG`
- `MIN`
- `MAX`

- SUM
- STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

### **Avoid using the DISTINCT operation**

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use Amazon Aurora PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

### **Consider using window functions instead of GROUP BY functions**

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY\_AGG
- ROW\_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
       , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
```

```
FROM empsalary;
```

You can rewrite the query with the `WINDOW` clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
       , avg(salary) OVER w as_avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the Aurora PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

### Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as `GROUP BY`, `ORDER BY`, or `DISTINCT`. During a refresh, you might observe large numbers of temporary files and the wait events `IO:BufFileWrite` and `IO:BufFileRead`. Similarly, when you create a table based on a `SELECT` statement, the `CREATE TABLE` statement runs a query. To reduce the temporary files needed, optimize the query.

### Use `pg_repack` when you create indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information, see [Maintenance work memory area](#).

A possible workaround when recreating a large index is to use the `pg_repack` tool. For more information, see [Reorganize tables in PostgreSQL databases with minimal locks](#) in the `pg_repack` documentation.

### Increase `maintenance_work_mem` when you cluster tables

The `CLUSTER` command clusters the table specified by `table_name` based on an existing index specified by `index_name`. Aurora PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster

tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

### **Tune memory to prevent `IO:BufFileRead` and `IO:BufFileWrite`**

In some situation, you need to tune memory. Your goal is to balance the following requirements:

- The `work_mem` value (see [Work memory area](#))
- The memory remaining after discounting the `shared_buffers` value (see [Buffer pool](#))
- The maximum connections opened and in use, which is limited by `max_connections`

### **Increase the size of the work memory area**

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value. For more information, see [Work memory area](#).

To find out how many temporary files a query generates, set `log_temp_files` to 0. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

### **Reserve sufficient memory for the shared buffer pool**

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`. For more information about the buffer pool, see [Buffer pool](#).

For example, assume that your Aurora PostgreSQL instance class is `db.r5.2xlarge`. This class has 64 GiB of memory. By default, 75 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the Aurora PostgreSQL automation services automatically restart.

## Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

## IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see [Buffer pool](#).

## Likely causes of increased waits

Common causes for the `IO:DataFileRead` event include the following:

### Connection spikes

You might find multiple connections generating the same number of `IO:DataFileRead` wait events. In this case, a spike (sudden and large increase) in `IO:DataFileRead` events can occur.

### `SELECT` and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater `seq_scan` value. Find them by querying `pg_stat_user_tables`. To track queries that are generating more read operations, use the extension `pg_stat_statements`.

### `CTAS` and `CREATE INDEX` for large data sets

A `CTAS` is a `CREATE TABLE AS SELECT` statement. If you run a `CTAS` using a large data set as a source, or create an index on a large table, the `IO:DataFileRead` event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A `CTAS` generates `IO:DataFile` reads when pages aren't in memory.

### Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the `IO:DataFileRead` waits increase. After space is reclaimed, the vacuum time spent on `IO:DataFileRead` decreases.

## Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the `default_statistics_target` value. For more information, see the [PostgreSQL documentation](#). The `default_statistics_target` parameter accepts values between 1 and 10,000, where the default is 100.

## Resource starvation

If instance network bandwidth or CPU are consumed, the `IO:DataFileRead` event might occur more frequently.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Check predicate filters for queries that generate waits](#)
- [Minimize the effect of maintenance operations](#)
- [Respond to high numbers of connections](#)

## Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating `IO:DataFileRead` wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension `pg_stat_statements`
- The catalog view `pg_stat_all_tables`, if it periodically shows an increased number of physical reads
- The `pg_statio_all_tables` view, if it shows that `_read` counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.

Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

### Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

```
