pg_stat_user_tables.n_dead_tup > (pg_class.reltuples x autovacuum_vacuum_scale_factor)
+ autovacuum_vacuum_threshold
```

The view pg\_stat\_user\_tables and catalog pg\_class have multiple rows. One row can correspond to one row in your table. This formula assumes that the reltuples are for a specific table. The parameters autovacuum\_vacuum\_scale\_factor (0.20 by default) and autovacuum\_vacuum\_threshold (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

### Find tables consuming space unnecessarily

To find tables consuming more space than necessary, run the following query. When this query is run by a database user role that doesn't have the `rds_superuser` role, it returns information about only those tables that the user role has permissions to read. This query is supported by PostgreSQL version 12 and later versions.

```
WITH report AS (
  SELECT  schemaname
          ,tblname
          ,n_dead_tup
          ,n_live_tup
          ,block_size*tblpages AS real_size
          ,(tblpages-est_tblpages)*block_size AS extra_size
          ,CASE WHEN tblpages - est_tblpages > 0
                THEN 100 * (tblpages - est_tblpages)/tblpages::float
                ELSE 0
          END AS extra_ratio, fillfactor, (tblpages-est_tblpages_ff)*block_size AS
bloat_size
          ,CASE WHEN tblpages - est_tblpages_ff > 0
                THEN 100 * (tblpages - est_tblpages_ff)/tblpages::float
                ELSE 0
          END AS bloat_ratio
          ,is_na
  FROM (
    SELECT  ceil( reltuples / ( (block_size-page_hdr)/tpl_size ) ) +
ceil( toasttuples / 4 ) AS est_tblpages
            ,ceil( reltuples / ( (block_size-page_hdr)*fillfactor/
(tpl_size*100) ) ) + ceil( toasttuples / 4 ) AS est_tblpages_ff
            ,tblpages
            ,fillfactor
            ,block_size
            ,tblid
            ,schemaname
            ,tblname
            ,n_dead_tup
```

```

        ,n_live_tup
        ,heappages
        ,toastpages
        ,is_na
    FROM (
        SELECT ( 4 + tpl_hdr_size + tpl_data_size + (2*ma)
                - CASE WHEN tpl_hdr_size%ma = 0 THEN ma ELSE
tpl_hdr_size%ma END
                - CASE WHEN ceil(tpl_data_size)::int%ma = 0 THEN ma ELSE

```

## Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in

the kernel. Queries should progress faster, leading to fewer wait events. For more information, see [Amazon RDS Proxy for Aurora](#).

- Whenever possible, take advantage of reader nodes for Aurora PostgreSQL and read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the reader-only endpoint. This technique spreads application requests across all reader nodes, reducing the I/O pressure on the writer node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives Aurora PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating `IO:DataFileRead` wait events are writes.

## IO:XactSync

The `IO:XactSync` event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. A prepared transaction is part of PostgreSQL's support for a two-phase commit. This event can also occur when a query is waiting for another transaction to commit, particularly in cases where auto-commit is turned off. In such scenarios, updates might appear to be waiting on `XactSync` even though they haven't been committed yet.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

The event `IO:XactSync` indicates that the instance is spending time waiting for the Aurora storage subsystem to confirm that transaction data was processed.

## Likely causes of increased waits

When the `IO:XactSync` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Network saturation

Traffic between clients and the DB instance or traffic to the storage subsystem might be too heavy for the network bandwidth.

### CPU pressure

A heavy workload might be preventing the Aurora storage daemon from getting sufficient CPU time.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Monitor your resources](#)
- [Scale up the CPU](#)
- [Increase network bandwidth](#)
- [Reduce the number of commits](#)

### Monitor your resources

To determine the cause of the increased `IO:XactSync` events, check the following metrics:

- `WriteThroughput` and `CommitThroughput` – Changes in write throughput or commit throughput can show an increase in workload.
- `WriteLatency` and `CommitLatency` – Changes in write latency or commit latency can show that the storage subsystem is being asked to do more work.
- `CPUUtilization` – If the instance's CPU utilization is above 90 percent, the Aurora storage daemon might not be getting sufficient time on the CPU. In this case, I/O performance degrades.

For information about these metrics, see [Instance-level metrics for Amazon Aurora](#).

## Scale up the CPU

To address CPU starvation issues, consider changing to an instance type with more CPU capacity. For information about CPU capacity for a DB instance class, see [Hardware specifications for DB instance classes for Aurora](#).

## Increase network bandwidth

To determine whether the instance is reaching its network bandwidth limits, check for the following other wait events:

- `IO:DataFileRead`, `IO:BufferRead`, `IO:BufferWrite`, and `IO:XactWrite` – Queries using large amounts of I/O can generate more of these wait events.
- `Client:ClientRead` and `Client:ClientWrite` – Queries with large amounts of client communication can generate more of these wait events.

If network bandwidth is an issue, consider changing to an instance type with more network bandwidth. For information about network performance for a DB instance class, see [Hardware specifications for DB instance classes for Aurora](#).

## Reduce the number of commits

To reduce the number of commits, combine statements into transaction blocks.

## IPC:DamRecordTxAck

The `IPC:DamRecordTxAck` event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

## Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL 10.7 and higher 10 versions, 11.4 and higher 11 versions, and all 12 and 13 versions.

## Context

In synchronous mode, durability of activity stream events is favored over database performance. While waiting for a durable write of the event, the session blocks other database activity, causing the `IPC:DamRecordTxAck` wait event.

## Causes

The most common cause for the `IPC:DamRecordTxAck` event to appear in top waits is that the Database Activity Streams (DAS) feature is a holistic audit. Higher SQL activity generates activity stream events that need to be recorded.

## Actions

We recommend different actions depending on the causes of your wait event:

- Reduce the number of SQL statements or turn off database activity streams. Doing this reduces the number of events that require durable writes.
- Change to asynchronous mode. Doing this helps to reduce contention on the `IPC:DamRecordTxAck` wait event.

However, the DAS feature can't guarantee the durability of every event in asynchronous mode.

## IPC:parallel wait events

The following `IPC:parallel` wait events indicate that a session is waiting for inter-process communication related to parallel query execution operations.

- `IPC:BgWorkerStartup` - A process is waiting for a parallel worker process to complete its startup sequence. This happens when initializing workers for parallel query execution.
- `IPC:BgWorkerShutdown` - A process is waiting for a parallel worker process to complete its shutdown sequence. This occurs during the cleanup phase of parallel query execution.
- `IPC:ExecuteGather` - A process is waiting to receive data from parallel worker processes during query execution. This occurs when the leader process needs to gather results from its workers.
- `IPC:ParallelFinish` - A process is waiting for parallel workers to finish their execution and report their final results. This happens during the completion phase of parallel query execution.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

Parallel query execution in PostgreSQL involves multiple processes working together to process a single query. When a query is determined to be suitable for parallelization, a leader process coordinates with one or more parallel worker processes based on the `max_parallel_workers_per_gather` parameter setting. The leader process divides the work among workers, each worker processes its portion of data independently, and results are gathered back to the leader process.

### Note

Each parallel worker operates as a separate process with resource requirements similar to a full user session. This means a parallel query with 4 workers can consume up to 5 times the resources (CPU, memory, I/O bandwidth) compared to a non-parallel query, as both the leader process and each worker process maintain their own resource allocations. For instance, settings like `work_mem` are applied individually to each worker, potentially multiplying the total memory usage across all processes.

The parallel query architecture consists of three main components:

- **Leader process:** The main process that initiates the parallel operation, divides the workload, and coordinates with worker processes.
- **Worker processes:** Background processes that execute portions of the query in parallel.
- **Gather/Gather merge:** Operations that combine results from multiple worker processes back to the leader

During parallel execution, processes need to communicate with each other through Inter-Process Communication (IPC) mechanisms. These IPC wait events occur during different phases:

- **Worker startup:** When parallel workers are being initialized
- **Data exchange:** When workers are processing data and sending results to the leader
- **Worker shutdown:** When parallel execution completes and workers are being terminated
- **Synchronization points:** When processes need to coordinate or wait for other processes to complete their tasks

Understanding these wait events is crucial for diagnosing performance issues related to parallel query execution, especially in high-concurrency environments where multiple parallel queries may be executing simultaneously.

## Likely causes of increased waits

Several factors can contribute to an increase in parallel-related IPC wait events:

### High concurrency of parallel queries

When many parallel queries are running simultaneously, it can lead to resource contention and increased waiting times for IPC operations. This is particularly common in systems with high transaction volumes or analytical workloads.

### Suboptimal parallel query plans

If the query planner chooses inefficient parallel plans, it may result in unnecessary parallelization or poor work distribution among workers. This can lead to increased IPC waits, especially for `IPC:ExecuteGather` and `IPC:ParallelFinish` events. These planning issues often stem from outdated statistics and table/index bloat.

### Frequent startup and shutdown of parallel workers

Short-lived queries that frequently initiate and terminate parallel workers can cause an increase in `IPC:BgWorkerStartup` and `IPC:BgWorkerShutdown` events. This is often seen in OLTP workloads with many small, parallelizable queries.

### Resource constraints

Limited CPU, memory, or I/O capacity can cause bottlenecks in parallel execution, leading to increased wait times across all IPC events. For example, if CPU is saturated, worker processes may take longer to start up or process their portion of work.

## Complex query structures

Queries with multiple levels of parallelism (e.g., parallel joins followed by parallel aggregations) can lead to more complex IPC patterns and potentially increased wait times, especially for `IPC:ExecuteGather` events.

## Large result sets

Queries that produce large result sets may cause increased `IPC:ExecuteGather` wait times as the leader process spends more time collecting and processing results from worker processes.

Understanding these factors can help in diagnosing and addressing performance issues related to parallel query execution in Aurora PostgreSQL.

## Actions

When you see waits related to parallel query, it typically means that a backend process is coordinating or waiting on parallel worker processes. These waits are common during execution of parallel plans. You can investigate and mitigate the impact of these waits by monitoring parallel worker usage, reviewing the parameter settings, and tuning query execution and resource allocation.

## Topics

- [Analyze query plans for inefficient parallelism](#)
- [Monitor parallel query usage](#)
- [Review and adjust parallel query settings](#)
- [Optimize resource allocation](#)
- [Investigate connection management](#)
- [Review and optimize maintenance operations](#)
- [Utilize Query Plan Management \(QPM\)](#)

## Analyze query plans for inefficient parallelism

Parallel query execution can often lead to system instability, CPU spikes, and unpredictable query performance variance. It's crucial to thoroughly analyze whether parallelism actually improves your specific workload. Use `EXPLAIN ANALYZE` to review parallel query execution plans.

## Temporarily disable parallelism at the session level to compare plan efficiency:

```
SET max_parallel_workers_per_gather = 0;  
EXPLAIN ANALYZE <your_query>;
```

## Re-enable parallelism and compare:

```
RESET max_parallel_workers_per_gather;  
EXPLAIN ANALYZE <your_query>;
```

If disabling parallelism yields better or more consistent results, consider disabling it for specific queries at the session level using SET commands. For a broader impact, you might want to disable parallelism at the instance level by adjusting the relevant parameters in your cluster or instance parameter group. For more information, see [Amazon Aurora PostgreSQL parameters](#).

## Monitor parallel query usage

Use the following queries to gain visibility into parallel query activity and capacity:

### Check active parallel worker processes:

```
SELECT  
    COUNT(*)  
FROM  
    pg_stat_activity  
WHERE  
    backend_type = 'parallel worker';
```

This query shows the number of active parallel worker processes. A high value may indicate that your `max\_parallel\_workers` is configured with a high value and you might want to consider reducing it.

### Check concurrent parallel queries:

```
SELECT
    COUNT(DISTINCT leader_pid)
FROM
    pg_stat_activity
WHERE
    leader_pid IS NOT NULL;
```

This query returns the number of distinct leader processes that have launched parallel queries. A high number here indicates that multiple sessions are running parallel queries concurrently, which can increase demand on CPU and memory.

### Review and adjust parallel query settings

Review the following parameters to ensure they align with your workload:

- `max_parallel_workers`: Total number of parallel workers across all sessions.
- `max_parallel_workers_per_gather`: Max workers per query.

For OLAP workloads, increasing these values can improve performance. For OLTP workloads, lower values are generally preferred.

```
SHOW max_parallel_workers;
SHOW max_parallel_workers_per_gather;
```

### Optimize resource allocation

Monitor CPU utilization and consider adjusting the number of vCPUs if consistently high and if your application benefits from parallel queries. Ensure adequate memory is available for parallel operations.

- Use Performance Insights metrics to determine if the system is CPU-bound.
- Each parallel worker uses its own `work_mem`. Ensure total memory usage is within instance limits.

The parallel queries may consume very substantially more resources than non-parallel queries, because each worker process is a completely separate process which has roughly the same impact

on the system as an additional user session. This should be taken into account when choosing a value for this setting, as well as when configuring other settings that control resource utilization, such as `work_mem`. For more information, see the [PostgreSQL documentation](#). Resource limits such as `work_mem` are applied individually to each worker, which means the total utilization may be much higher across all processes than it would normally be for any single process.

Consider increasing vCPUs or tuning memory parameters if your workload is heavily parallelized.

### **Investigate connection management**

If experiencing connection exhaustion, review application connection pooling strategies. Consider implementing connection pooling at the application level if not already in use.

### **Review and optimize maintenance operations**

Coordinate index creation and other maintenance tasks to prevent resource contention. Consider scheduling these operations during off-peak hours. Avoid scheduling heavy maintenance (e.g., parallel index builds) during periods of high user query load. These operations can consume parallel workers and impact performance for regular queries.

### **Utilize Query Plan Management (QPM)**

In Aurora PostgreSQL, the Query Plan Management (QPM) feature is designed to ensure plan adaptability and stability, regardless of database environment changes that might cause query plan regression. For more information, see [Overview of Aurora PostgreSQL query plan management](#). QPM provides some control over the optimizer. Review approved plans in QPM to ensure they align with current parallelism settings. Update or remove outdated plans that may be forcing suboptimal parallel execution.

You can also fix the plans using `pg_hint_plan`. For more information, see [Fixing plans using pg\\_hint\\_plan](#). You can use the hint named `Parallel` to enforce parallel execution. For more information, see the [Hints for parallel plans](#).

## **IPC:ProcArrayGroupUpdate**

The `IPC:ProcArrayGroupUpdate` event occurs when a session is waiting for the group leader to update the transaction status at the end of that operation. While PostgreSQL generally associates IPC type wait events with parallel query operations, this particular wait event is not specific to parallel queries.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

**Understanding the process array** – The process (proc) array is a shared memory structure in PostgreSQL. It holds information about all running processes, including transaction details. During transaction completion (COMMIT or ROLLBACK), the ProcArray needs to be updated to reflect the change and clear the transactionID from the array. The session attempting to finish its transaction must acquire an exclusive lock on the ProcArray. This prevents other processes from obtaining shared or exclusive locks on it.

**Group update mechanism** – While performing a COMMIT or ROLLBACK, if a backend process cannot obtain a ProcArrayLock in exclusive mode, it updates a special field called ProcArrayGroupMember. This adds the transaction to the list of sessions that intend to end. This backend process then sleeps and the time it sleeps is instrumented as the ProcArrayGroupUpdate wait event. The first process in the ProcArray with procArrayGroupMember, referred to as the leader process, acquires the ProcArrayLock in exclusive mode. It then clears the list of processes waiting for group transactionID clearing. Once this completes, the leader releases the ProcArrayLock and then wakes up all processes in this list, notifying them that their transaction is completed.

## Likely causes of increased waits

The more processes that are running, the longer a leader will hold on to a procArrayLock in exclusive mode. Consequently, the more write transactions end up in a group update scenario causing a potential pile up of processes waiting on the ProcArrayGroupUpdate wait event. In Database Insights' Top SQL view, you will see that COMMIT is the statement with the majority of this wait event. This is expected but will require deeper investigation into the specific write SQL being run to determine what appropriate action to take.

## Actions

We recommend different actions depending on the causes of your wait event. Identify `IPC:ProcArrayGroupUpdate` events by using Amazon RDS Performance Insights or by querying the PostgreSQL system view `pg_stat_activity`.

### Topics

- [Monitoring transaction commit and rollback operations](#)
- [Reducing concurrency](#)
- [Implementing connection pooling](#)

### Monitoring transaction commit and rollback operations

**Monitor commits and rollbacks** – An increased number of commits and rollbacks can lead to increased pressure on the ProcArray. For example, if a SQL statement begins to fail due to increased duplicate key violations, you may see an increase in rollbacks which can increase ProcArray contention and table bloat.

Amazon RDS Database Insights provides the PostgreSQL metrics `xact_commit` and `xact_rollback` to report the number of commits and rollbacks per second.

### Reducing concurrency

**Batching transactions** – Where possible, batch operations in single transactions to reduce commit/rollback operations.

**Limit concurrency** – Reduce the number of concurrently active transactions to alleviate lock contention on the ProcArray. While it will require some testing, reducing the total number of concurrent connections can reduce contention and maintain throughput.

### Implementing connection pooling

**Connection pooling solutions** – Use connection pooling to manage database connections efficiently, reducing the total number of backends and therefore the workload on the ProcArray. While it will require some testing, reducing the total number of concurrent connections can reduce contention and maintain throughput.

For more information, see [Connection pooling for Aurora PostgreSQL](#).

**Reduce connection storms** – Similarly, a pattern of frequently creating and terminating connections causes additional pressure on the ProcArray. By reducing this pattern, overall contention is reduced.

## Lock:advisory

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

### Relevant engine versions

This wait event information is relevant for Aurora PostgreSQL versions 9.6 and higher.

### Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see [Advisory Locks](#) in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a `CREATE INDEX` statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see [Advisory Lock Functions](#) in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the `pg_locks` system view.

## Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from [Advisory Locks](#) in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

## Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```

SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.username AS blocked_user,
       blocking_activity.username AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type, ':', blocked_activity.wait_event) AS
blocked_wait_event,
       concat(blocking_activity.wait_event_type, ':', blocking_activity.wait_event) AS
blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
  ON blocking_locks.locktype = blocked_locks.locktype
  AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
  AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
  AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
  AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
  AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
  AND blocking_locks.transactionid IS NOT DISTINCT FROM
blocked_locks.transactionid
  AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
  AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
  AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
  AND blocking_locks.pid != blocked_locks.pid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;

```

All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.

- For the API functions with two `integer` arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one `bigint` argument; 2 means two `integer` arguments.

## Lock:extend

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. `INSERT`, `COPY`, and `UPDATE` operations can generate this event.

## Likely causes of increased waits

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

## Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Reduce concurrent inserts and updates to the same relation](#)
- [Increase network bandwidth](#)

### Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see [pg\\_stat\\_all\\_tables](#) in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```
SELECT
    blocked.pid,
    blocked.username,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';
```

```

pid | username | query | blocking_id |
      blocking_query | blocking_wait_event |
blocking_wait_event_type
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
7143 | myuser | insert into tab1 values (1); | 4600 | INSERT INTO tab1 (a)
SELECT s FROM generate_series(1,1000000) s; | DataFileExtend | IO

```

After you identify relations that contribute to increase Lock:extend events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see [Managing PostgreSQL partitions with the pg\\_partman extension](#).
- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see [CREATE TABLE](#) in the PostgreSQL documentation.

### Important

We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

## Increase network bandwidth

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora](#). For information about network performance for each DB instance class, see [Hardware specifications for DB instance classes for Aurora](#).

## Lock:Relation

The `Lock:Relation` event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the `LOCK` command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, Aurora PostgreSQL generates a `Lock:Relation` event. Some common examples are the following:

- Exclusive locks such as `ACCESS EXCLUSIVE` can block all concurrent access. Data definition language (DDL) operations such as `DROP TABLE`, `TRUNCATE`, `VACUUM FULL`, and `CLUSTER` acquire `ACCESS EXCLUSIVE` locks implicitly. `ACCESS EXCLUSIVE` is also the default lock mode for `LOCK TABLE` statements that don't specify a mode explicitly.
- Using `CREATE INDEX (without CONCURRENT)` on a table conflicts with data manipulation language (DML) statements `UPDATE`, `DELETE`, and `INSERT`, which acquire `ROW EXCLUSIVE` locks.

For more information about table-level locks and conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- **Blocking query** – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- **Blocking transaction** – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

## Likely causes of increased waits

When the `Lock:Relation` event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

### Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

### Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a `Lock:Relation` wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

### Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Reduce the impact of blocking SQL statements](#)

- [Minimize the effect of maintenance operations](#)
- [Check for reader locks](#)

## Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use SET lock\_timeout – Set a lock\_timeout value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is canceled. Set this value at the session level.

## Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see [Working with PostgreSQL autovacuum on Amazon RDS](#) in the *Amazon RDS User Guide*.

## Check for reader locks

You can see how concurrent sessions on a writer and readers might be holding locks that block each other. One way to do this is by running queries that return the lock type and relation. In the

table, you can find a sequence of queries to two such concurrent sessions, a writer session and a reader session.

The replay process waits for the duration of `max_standby_streaming_delay` before canceling the reader query. As shown in the example, the lock timeout of 100ms is well below the default `max_standby_streaming_delay` of 30 seconds. The lock times out before it's an issue.

Sequence event	Session	Command or Output
Sets an environment variable called <code>READER</code> with the specified value and tries to connect to the DB instance with this endpoint. ## Lock:transactionid

The `Lock:transactionid` event occurs when a transaction is waiting for a row-level lock.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the `Lock:transactionid` wait event is blocked because of this lock. After the blocking transaction ends in either a `COMMIT` or `ROLLBACK` statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of Aurora PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement `SELECT ... FOR KEY SHARE` is a special case. The database uses the clause `FOR KEY SHARE` to optimize the performance of referential integrity. A row-level lock on a row can block `INSERT`, `UPDATE`, and `DELETE` commands on other tables that reference the row.

## Likely causes of increased waits

When this event appears more than normal, the cause is typically `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements combined with the following conditions.

### Topics

- [High concurrency](#)
- [Idle in transaction](#)
- [Long-running transactions](#)

### High concurrency

Aurora PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

### Idle in transaction

Sometimes the `pg_stat_activity.state` column shows the value `idle in transaction`. This value appears for sessions that have started a transaction, but haven't yet issued a `COMMIT` or `ROLLBACK`. If the `pg_stat_activity.state` value isn't `active`, the query shown in `pg_stat_activity` is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event `Lock:transactionid`. To diagnose the issue, examine the output from `pg_stat_activity` and `pg_locks`.

## Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

## Actions

Row-locking is a conflict among `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

## Topics

- [Respond to high concurrency](#)
- [Respond to idle transactions](#)
- [Respond to long-running transactions](#)

## Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see [Amazon RDS Proxy for Aurora](#).
- Design the application or data model to avoid contending `UPDATE` and `SELECT ... FOR UPDATE` statements. You can also decrease the number of foreign keys accessed by `SELECT ... FOR KEY SHARE` statements.

## Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a `COMMIT` or `ROLLBACK`.
- Search for code paths that are missing `COMMIT`, `ROLLBACK`, or `END`.

- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

## Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

## Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Context

The event `Lock:tuple` indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the `Lock:tuple` event.

Time	Session 1	Session 2	Session 3
t1	Starts a transaction.		

Time	Session 1	Session 2	Session 3
t2	Updates row 1.		
t3		Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.	
t4			Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.

Or you can simulate this wait event by using the benchmarking tool `pgbench`. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation. To learn more about `pgbench`, see [pgbench](#) in the PostgreSQL documentation.

## Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running `UPDATE` or `DELETE` statements.
- Highly concurrent sessions are running a `SELECT` statement using the `FOR UPDATE` or `FOR NO KEY UPDATE` lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and `Lock:tuple` can appear.

For more information, see [Row-Level Locks](#) in the PostgreSQL documentation.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Investigate your application logic](#)
- [Find the blocker session](#)
- [Reduce concurrency when it is high](#)
- [Troubleshoot bottlenecks](#)

### Investigate your application logic

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see [Server Signaling Functions](#) in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see [Client Connection Defaults](#) in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see [SET AUTOCOMMIT](#) in the PostgreSQL documentation.

### Find the blocker session

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see [Lock dependency information](#) in the PostgreSQL wiki. To analyze past `Lock:tuple` events, use the Aurora function `aurora_stat_backend_waits`.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```
--AURORA_STAT_BACKEND_WAITS
SELECT a.pid,
       a.username,
```

```

    a.app_name,
    a.current_query,
    a.current_wait_type,
    a.current_wait_event,
    a.current_state,
    wt.type_name AS wait_type,
    we.event_name AS wait_event,
    a.waits,
    a.wait_time
FROM (SELECT pid,
            username,
            left(application_name,16) AS app_name,
            coalesce(wait_event_type,'CPU') AS current_wait_type,
            coalesce(wait_event,'CPU') AS current_wait_event,
            state AS current_state,
            left(query,80) as current_query,
            (aurora_stat_backend_waits(pid)).*
    FROM pg_stat_activity
    WHERE pid <> pg_backend_pid()
    AND username<>'rdsadmin') a
NATURAL JOIN aurora_stat_wait_type() wt
NATURAL JOIN aurora_stat_wait_event() we
WHERE we.event_name = 'tuple'
    ORDER BY a.wait_time;

```

pid	username	app_name	current_query	current_wait_type	current_wait_event	current_state	wait_type	wait_event	waits	wait_time
32136	sys	psql	/*session3*/ update tab set col=1 where col=1;	Lock	tuple	active	Lock	tuple	1	1000018
11999	sys	psql	/*session4*/ update tab set col=1 where col=1;	Lock	tuple	active	Lock	tuple	1	1000024

## Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

### Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

## LWLock:buffer\_content (BufferContent)

The `LWLock:buffer_content` event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In Aurora PostgreSQL 13 and higher, this wait event is called `BufferContent`.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `LWLock:buffer_content (BufferContent)` event indicates that multiple processes are attempting to get lightweight locks (LWLocks) on contents of a specific buffer.

## Likely causes of increased waits

When the `LWLock:buffer_content (BufferContent)` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

### Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

### Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

## Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:buffer_content (BufferContent)` events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

## Topics

- [Improve in-memory efficiency](#)

- [Reduce usage of foreign key constraints](#)
- [Remove unused indexes](#)
- [Remove duplicate indexes](#)
- [Drop or REINDEX invalid indexes](#)
- [Use partial indexes](#)
- [Remove table and index bloat](#)

## Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see [Amazon Aurora DB instance classes](#).

Monitor the `BufferCacheHitRatio` metric, which measures the percentage of requests served by the buffer cache of a DB instance in your DB cluster. This metric provides insight into the amount of data being served from memory. A high hit ratio indicates that your DB instance has sufficient memory available for your working data set, while a low ratio suggests that your queries are frequently accessing data from storage.

The cache read hit per table and cache read hit per index under Memory setting section of the [PG Collector](#) report can provide insights into the tables and indexes cache hit ratio.

## Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

## Remove unused indexes

For workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events, identify unused indexes and remove them.

The unused indexes section of the [PG Collector](#) report can provide insights into the unused indexes in the database.

## Remove duplicate indexes

Identify duplicate indexes and remove them.

The duplicate indexes section of the [PG Collector](#) report can provide insights into the duplicate indexes in the database.

### Drop or REINDEX invalid indexes

Invalid indexes typically occur when using `CREATE INDEX CONCURRENTLY` or `REINDEX CONCURRENTLY` and the command fails or is aborted.

Invalid indexes can't be used for queries, though they will still be updated and take up disk space.

The Invalid indexes section of the [PG Collector](#) report can provide insights into the invalid indexes in the database.

### Use partial indexes

Partial indexes can be leveraged to enhance query performance and reduce index size. A partial index is an index built over a subset of a table, with the subset defined by a conditional expression. As detailed in the [partial index](#) documentation, partial indexes can reduce the overhead of maintaining indexes, as PostgreSQL does not need to update the index in all cases.

### Remove table and index bloat

Excessive table and index bloat can negatively impact database performance. Bloated tables and indexes increase the active working set size, degrading in-memory efficiency. Additionally, bloat increases storage costs and slows query execution. To diagnose bloat, refer to the [Diagnosing table and index bloat](#). Further, the Fragmentation (Bloat) section of the [PG Collector](#) report can provide insights into tables and indexes bloat.

To address table and index bloat, there are a few options:

#### VACUUM FULL

`VACUUM FULL` creates a new copy of the table, copying over only the live tuples, and then replaces the old table with the new one while holding an `ACCESS EXCLUSIVE` lock. This prevents any reading or writing to the table, which can cause an outage. Additionally, `VACUUM FULL` will take longer if the table is large.

#### pg\_repack

The `pg_repack` is helpful in situations where `VACUUM FULL` might not be suitable. It creates a new table that contains the data of the bloated table, tracks the changes from the original

table, and then replaces the original table with the new one. It doesn't lock the original table for read or write operations while it's building the new table. For more information, for how to use `pg_repack`, see [Removing bloat with pg\\_repack](#) and [pg\\_repack](#).

## REINDEX

The REINDEX command can be leveraged to address index bloat. REINDEX writes a new version of the index without the dead pages or the empty or nearly-empty pages, thereby reducing the space consumption of the index. For detailed information about the [REINDEX](#) command, please refer to the REINDEX documentation.

After removing bloat from tables and indexes, it may be necessary to increase the autovacuum frequency on those tables. Implementing aggressive autovacuum settings at the table level can help prevent future bloat from occurring. For more information, please refer to the documentation on [Vacuuming and analyzing tables automatically](#).

## LWLock:buffer\_mapping

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

### Note

This event appears as `LWLock:buffer_mapping` in Aurora PostgreSQL version 12 and lower, and `LWLock:BufferMapping` in version 13 and higher.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

## Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

## Context

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. For more information, see [Shared buffers](#).

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

## Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Monitor buffer-related metrics](#)
- [Assess your indexing strategy](#)
- [Reduce the number of buffers that must be allocated quickly](#)

## Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

### `BufferCacheHitRatio`

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. You might see this metric decrease in the lead-up to the `LWLock:buffer_mapping` wait event.

### `blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

### `blks_read`

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

## Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

### Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

### Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

## Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

## LWLock:BufferIO (IPC:BufferIO)

The `LWLock:BufferIO` event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

## Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL versions. For Aurora PostgreSQL 12 and earlier versions this wait event is named as `lwlock:buffer_io` whereas in Aurora PostgreSQL 13 version it is named as `lwlock:bufferio`. From Aurora PostgreSQL 14 version `BufferIO` wait event moved from `LWLock` to `IPC` wait event type (`IPC:BufferIO`).

## Context

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

**Note**

The `LWLock:BufferIO` wait event precedes the [IO:DataFileRead](#) wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see [Locking Overview](#).

## Causes

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Sudden spikes for database connections trying to perform operations on the same page

## Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small `shared_buffers` setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.

- Restrict the maximum number of connections to the database as a best practice.

## LWLock:lock\_manager

This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

### Context

When you issue a SQL statement, Aurora PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

### Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

For more information about fast path locking, see [fast path](#) in the PostgreSQL lock manager README and [pg-locks](#) in the PostgreSQL documentation.

### Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non-fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non-fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

#### Note

The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non-fast path locks that the database must control.

### Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.

- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Use partition pruning](#)
- [Remove unnecessary indexes](#)
- [Tune your queries for fast path locking](#)
- [Tune for other wait events](#)
- [Reduce hardware bottlenecks](#)
- [Use a connection pooler](#)
- [Upgrade your Aurora PostgreSQL version](#)

## Use partition pruning

*Partition pruning* is a query optimization strategy that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their *WHERE* clause contains the column used for the partitioning. For more information, see [Partition Pruning](#) in the PostgreSQL documentation.

## Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](#) in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](#) in the Amazon Labs GitHub repository.

## Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

## Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

## Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.

- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see [Amazon RDS Instance Types](#).

### Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see [Amazon RDS Instance Types](#).

For more information about connection pooling, see the following resources:

- [Amazon RDS Proxy for Aurora](#)
- [pgbouncer](#)
- [Connection Pools and Data Sources](#) in the *PostgreSQL Documentation*

### Upgrade your Aurora PostgreSQL version

If your current version of Aurora PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and 13 have an improved partition mechanism. For more information about version 12, see [PostgreSQL 12.0 Release Notes](#). For more information about upgrading Aurora PostgreSQL, see [Database engine updates for Amazon Aurora PostgreSQL](#).

## LWLock:MultiXact

The `LWLock:MultiXactMemberBuffer`, `LWLock:MultiXactOffsetBuffer`, `LWLock:MultiXactMemberSLRU`, and `LWLock:MultiXactOffsetSLRU` wait events indicate that a session is waiting to retrieve a list of transactions that modifies the same row in a given table.

- `LWLock:MultiXactMemberBuffer` – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member.
- `LWLock:MultiXactMemberSLRU` – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member.
- `LWLock:MultiXactOffsetBuffer` – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset.

- `LWLock:MultiXactOffsetSLRU` – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

A *multixact* is a data structure that stores a list of transaction IDs (XIDs) that modify the same table row. When a single transaction references a row in a table, the transaction ID is stored in the table header row. When multiple transactions reference the same row in a table, the list of transaction IDs is stored in the multixact data structure. The multixact wait events indicate that a session is retrieving from the data structure the list of transactions that refer to a given row in a table.

## Likely causes of increased waits

Three common causes of multixact use are as follows:

- **Sub-transactions from explicit savepoints** – Explicitly creating a savepoint in your transactions spawns new transactions for the same row. For example, using `SELECT FOR UPDATE`, then `SAVEPOINT`, and then `UPDATE`.

Some drivers, object-relational mappers (ORMs), and abstraction layers have configuration options for automatically wrapping all operations with savepoints. This can generate many multixact wait events in some workloads. The PostgreSQL JDBC Driver's autosave option is an example of this. For more information, see [pgJDBC](#) in the PostgreSQL JDBC documentation. Another example is the PostgreSQL ODBC driver and its `protocol` option. For more information, see [psqlODBC Configuration Options](#) in the PostgreSQL ODBC driver documentation.

- **Sub-transactions from PL/pgSQL EXCEPTION clauses** – Each `EXCEPTION` clause that you write in your PL/pgSQL functions or procedures creates a `SAVEPOINT` internally.

- **Foreign keys** – Multiple transactions acquire a shared lock on the parent record.

When a given row is included in a multiple transaction operation, processing the row requires retrieving transaction IDs from the `multixact` listings. If lookups can't get the `multixact` from the memory cache, the data structure must be read from the Aurora storage layer. This I/O from storage means that SQL queries can take longer. Memory cache misses can start occurring with heavy usage due to a large number of multiple transactions. All these factors contribute to an increase in this wait event.

## Actions

We recommend different actions depending on the causes of your wait event. Some of these actions can help in immediate reduction of the wait events. But, others might require investigation and correction to scale your workload.

## Topics

- [Perform vacuum freeze on tables with this wait event](#)
- [Increase autovacuum frequency on tables with this wait event](#)
- [Increase memory parameters](#)
- [Reduce long-running transactions](#)
- [Long term actions](#)

### Perform vacuum freeze on tables with this wait event

If this wait event spikes suddenly and affects your production environment, you can use any of the following temporary methods to reduce its count.

- Use `VACUUM FREEZE` on the affected table or table partition to resolve the issue immediately. For more information, see [VACUUM](#).
- Use the `VACUUM (FREEZE, INDEX_CLEANUP FALSE)` clause to perform a quick vacuum by skipping the indexes. For more information, see [Vacuuming a table as quickly as possible](#).

### Increase autovacuum frequency on tables with this wait event

After scanning all tables in all databases, `VACUUM` will eventually remove `multixacts`, and their oldest `multixact` values are advanced. For more information, see [Multixacts and Wraparound](#). To

keep the LWLock:MultiXact wait events to its minimum, you must run the VACUUM as often as necessary. To do so, ensure that the VACUUM in your Aurora PostgreSQL DB cluster is configured optimally.

If using VACUUM FREEZE on the affected table or table partition resolves the wait event issue, we recommend using a scheduler, such as `pg_cron`, to perform the VACUUM instead of adjusting autovacuum at the instance level.

For the autovacuum to happen more frequently, you can reduce the value of the storage parameter `autovacuum_multixact_freeze_max_age` in the affected table. For more information, see [autovacuum\\_multixact\\_freeze\\_max\\_age](#).

### Increase memory parameters

You can optimize memory usage for multixact caches by adjusting the following parameters. These settings control how much memory is reserved for these caches, which can help reduce multixact wait events in your workload. We recommend starting with the following values:

For Aurora PostgreSQL 17 and later:

- `multixact_offset_buffers` = 128
- `multixact_member_buffers` = 256

For Aurora PostgreSQL 16 and earlier:

- `multixact_offsets_cache_size` = 128
- `multixact_members_cache_size` = 256

#### Note

In Aurora PostgreSQL 17, parameter names were changed from `multixact_offsets_cache_size` to `multixact_offset_buffers` and from `multixact_members_cache_size` to `multixact_member_buffers` to align with community PostgreSQL 17.

You can set these parameters at the cluster level so that all instances in your cluster remain consistent. We recommend you to test and adjust the values to best suit your specific workload requirements and instance class. You must reboot the writer instance for the parameter changes to take effect.

The parameters are expressed in terms of multixact cache entries. Each cache entry uses 8 KB of memory. To calculate the total memory reserved, multiply each parameter value by 8 KB. For example, if you set a parameter to 128, the total reserved memory would be  $128 * 8 \text{ KB} = 1 \text{ MB}$ .

## Reduce long-running transactions

Long-running transaction causes the vacuum to retain its information until the transaction is committed or until the read-only transaction is closed. We recommend that you proactively monitor and manage long-running transactions. For more information, see [Database has long running idle in transaction connection](#). Try to modify your application to avoid or minimize your use of long-running transactions.

## Long term actions

Examine your workload to discover the cause for the multixact spillover. You must fix the issue in order to scale your workload and reduce the wait event.

- You must analyze the DDL (data definition language) used to create your tables. Make sure that the table structures and indexes are well designed.
- When the affected tables have foreign keys, determine whether they are needed or if there is another way to enforce referential integrity.
- When a table has large unused indexes, it can cause autovacuum to not fit your workload and might block it from running. To avoid this, check for unused indexes and remove them completely. For more information, see [Managing autovacuum with large indexes](#).
- Reduce the use of savepoints in your transactions.

## LWLock:pg\_stat\_statements

The LWLock:pg\_stat\_statements wait event occurs when the pg\_stat\_statements extension takes an exclusive lock on the hash table that tracks SQL statements. This happens in the following scenarios:

- When the number of tracked statements reaches the configured `pg_stat_statements.max` parameter value and there is a need to make room for more entries, the extension performs a sort on the number of calls, removes the 5% of the least-executed statements, and re-populates the hash with the remaining entries.

- When `pg_stat_statements` performs a garbage collection operation to the `pgss_query_texts.stat` file on disk and rewrites the file.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

## Context

**Understanding the `pg_stat_statements` extension** – The `pg_stat_statements` extension tracks SQL statement execution statistics in a hash table. The extension tracks SQL statements up to the limit defined by the `pg_stat_statements.max` parameter. This parameter determines the maximum number of statements that can be tracked which corresponds to the maximum number of rows in the `pg_stat_statements` view.

**Statement statistics persistence** – The extension persists statement statistics across instance restarts by:

- Writing data to a file named `pg_stat_statements.stat`
- Using the `pg_stat_statements.save` parameter to control persistence behavior

When `pg_stat_statements.save` is set to:

- `on` (default): Statistics are saved at shutdown and reloaded at server start
- `off`: Statistics are neither saved at shutdown nor reloaded at server start

**Query text storage** – The extension stores the text of tracked queries in a file named `pgss_query_texts.stat`. This file can grow to double the average size of all tracked SQL statements before garbage collection occurs. The extension requires an exclusive lock on the hash table during cleanup operations and rewrite `pgss_query_texts.stat` file.

**Statement deallocation process** – When the number of tracked statements reaches the `pg_stat_statements.max` limit and new statements need to be tracked, the extension:

- Takes an exclusive lock (`LWLock:pg_stat_statements`) on the hash table.
- Loads existing data into local memory.
- Performs a quicksort based on the number of calls.
- Removes the least-called statements (bottom 5%).
- Re-populates the hash table with the remaining entries.

**Monitoring statement deallocation** – In PostgreSQL 14 and later, you can monitor statement deallocation using the `pg_stat_statements_info` view. This view includes a `dealloc` column that shows how many times statements were deallocated to make room for new ones

If the deallocation of statements occurs frequently, it will lead to more frequent garbage collection of the `pgss_query_texts.stat` file on disk.

## Likely causes of increased waits

The typical causes of increased `LWLock:pg_stat_statements` waits include:

- An increase in the number of unique queries used by the application.
- The `pg_stat_statements.max` parameter value being small compared to the number of unique queries being used.

## Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:pg_stat_statements` events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

Adjust the following `pg_stat_statements` parameters to control tracking behavior and reduce `LWLock:pg_stat_statements` wait events.

## Topics

- [Disable `pg\_stat\_statements.track` parameter](#)
- [Increase `pg\_stat\_statements.max` parameter](#)
- [Disable `pg\_stat\_statements.track\_utility` parameter](#)

## Disable `pg_stat_statements.track` parameter

If the `LWLock:pg_stat_statements` wait event is adversely impacting database performance, and a rapid solution is required before further analysis of the `pg_stat_statements` view to identify the root cause, the `pg_stat_statements.track` parameter can be disabled by setting it to `none`. This will disable the collection of statement statistics.

## Increase `pg_stat_statements.max` parameter

To reduce deallocation and minimize garbage collection of the `pgss_query_texts.stat` file on disk, increase the value of the `pg_stat_statements.max` parameter. The default value is `5,000`.

### Note

The `pg_stat_statements.max` parameter is static. You must restart your DB instance to apply any changes to this parameter.

## Disable `pg_stat_statements.track_utility` parameter

You can analyze the `pg_stat_statements` view to determine which utility commands are consuming the most resources tracked by `pg_stat_statements`.

The `pg_stat_statements.track_utility` parameter controls whether the module tracks utility commands, which include all commands except `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. By default, this parameter is set to `on`.

For example, when your application uses many savepoint queries, which are inherently unique, it can increase statement deallocation. To address this, you can disable the `pg_stat_statements.track_utility` parameter to stop `pg_stat_statements` from tracking savepoint queries.

### Note

The `pg_stat_statements.track_utility` parameter is a dynamic parameter. You can change its value without restarting your database instance.

## Example Example of unique save point queries in `pg_stat_statements`

query	queryid
SAVEPOINT JDBC_SAVEPOINT_495701	-7249565344517699703
SAVEPOINT JDBC_SAVEPOINT_1320	-1572997038849006629
SAVEPOINT JDBC_SAVEPOINT_26739	54791337410474486
SAVEPOINT JDBC_SAVEPOINT_1294466	8170064357463507593
ROLLBACK TO SAVEPOINT JDBC_SAVEPOINT_65016	-33608214779996400
SAVEPOINT JDBC_SAVEPOINT_14185	-2175035613806809562
SAVEPOINT JDBC_SAVEPOINT_45837	-6201592986750645383
SAVEPOINT JDBC_SAVEPOINT_1324	6388797791882029332

PostgreSQL 17 introduces several enhancements for utility command tracking:

- Savepoint names are now displayed as constants.
- Global Transaction IDs (GIDs) of two-phase commit commands are now displayed as constants.
- Names of DEALLOCATE statements are shown as constants.
- CALL parameters are now displayed as constants.

## Timeout:PgSleep

The `Timeout:PgSleep` event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

### Topics

- [Supported engine versions](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

### Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`

- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see [Delaying Execution](#) in the PostgreSQL documentation.

## Actions

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

## Tuning Aurora PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your Aurora PostgreSQL DB clusters that can cause problems, and lets you know about them before they occur. Proactive insights can alert you to a long running idle in transaction connection. For more information about troubleshooting long running idle in transaction connections, see [Database has long running idle in transaction connection](#)

DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

For more information about Amazon DevOps Guru for Amazon RDS, see [Analyzing Aurora performance anomalies with Amazon DevOps Guru for Amazon RDS](#).

# Database has long running idle in transaction connection

A connection to the database has been in the `idle in transaction` state for more than 1800 seconds.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes for this issue](#)
- [Actions](#)
- [Relevant metrics](#)

## Supported engine versions

This insight information is supported for all versions of Aurora PostgreSQL.

## Context

A transaction in the `idle in transaction` state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

## Likely causes for this issue

A transaction initiated in an interactive session with `BEGIN` or `START TRANSACTION` hasn't ended by using a `COMMIT`, `ROLLBACK`, or `END` command. This causes the transaction to move to `idle in transaction` state.

## Actions

You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in `idle in transaction` state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
  xact_duration,*
FROM pg_stat_activity
WHERE state = 'idle in transaction'
AND xact_start is not null
```

```
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

## Topics

- [End transaction](#)
- [Terminate the connection](#)
- [Configure the `idle\_in\_transaction\_session\_timeout` parameter](#)
- [Check the AUTOCOMMIT status](#)
- [Check the transaction logic in your application code](#)

### End transaction

When you initiate a transaction in an interactive session with `BEGIN` or `START TRANSACTION`, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a `COMMIT`, `ROLLBACK`, `END` command or disconnect the connection completely to roll back the transaction.

### Terminate the connection

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

`pid` is the process ID of the connection.

### Configure the `idle_in_transaction_session_timeout` parameter

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see [the PostgreSQL documentation](#).

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the `idle_in_transaction` state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

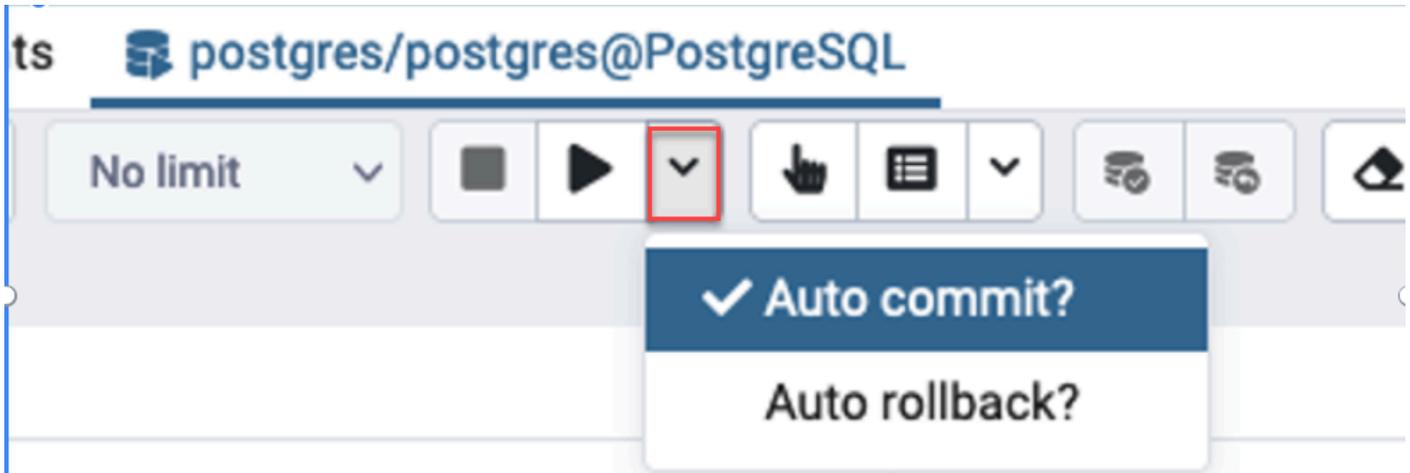

## Check the AUTOCOMMIT status

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your psql client, run the following command:

```
postgres=> \set AUTOCOMMIT on
```

- In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.

## Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit COMMIT commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

## Relevant metrics

The following PI metrics are related to this insight:

- `idle_in_transaction_count` - Number of sessions in `idle in transaction` state.
- `idle_in_transaction_max_time` - The duration of the longest running transaction in the `idle in transaction` state.

## Best practices with Amazon Aurora PostgreSQL

Following, you can find several best practices for managing your Amazon Aurora PostgreSQL DB cluster. Be sure to also review basic maintenance tasks. For more information, see [Performance and scaling for Amazon Aurora PostgreSQL](#).

### Topics

- [Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances](#)
- [Diagnosing table and index bloat](#)
- [Improved memory management in Aurora PostgreSQL](#)
- [Fast failover with Amazon Aurora PostgreSQL](#)
- [Fast recovery after failover with cluster cache management for Aurora PostgreSQL](#)

- [Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL](#)
- [Using logical replication to perform a major version upgrade for Aurora PostgreSQL](#)
- [Troubleshooting storage issues in Aurora PostgreSQL](#)

## Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances

If you're running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you're running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch, Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see [Monitoring metrics in an Amazon Aurora cluster](#).

If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see [Amazon Aurora DB instance classes](#).

## Diagnosing table and index bloat

You can use PostgreSQL Multiversion Concurrency Control (MVCC) to help preserve data integrity. PostgreSQL MVCC works by saving an internal copy of updated or deleted rows (also called *tuples*) until a transaction is either committed or rolled back. This saved internal copy is invisible to users. However, table bloat can occur when those invisible copies aren't cleaned up regularly by the VACUUM or AUTOVACUUM utilities. Unchecked, table bloat can incur increased storage costs and slow your processing speed.

In many cases, the default settings for VACUUM or AUTOVACUUM on Aurora are sufficient for handling unwanted table bloat. However, you may want to check for bloat if your application is experiencing the following conditions:

- Processes a large number of transactions in a relatively short time between VACUUM processes.
- Performs poorly and runs out of storage.

To get started, gather the most accurate information about how much space is used by dead tuples and how much you can recover by cleaning up the table and index bloat. To do so, use the `pgstattuple` extension to gather statistics on your Aurora cluster. For more information, see [pgstattuple](#). Privileges to use the `pgstattuple` extension are limited to the `pg_stat_scan_tables` role and database superusers.

To create the `pgstattuple` extension on Aurora, connect a client session to the cluster, for example, `psql` or `pgAdmin`, and use the following command:

```
CREATE EXTENSION pgstattuple;
```

Create the extension in each database that you want to profile. After creating the extension, use the command line interface (CLI) to measure how much unusable space you can reclaim. Before gathering statistics, modify the cluster parameter group by setting `AUTOVACUUM` to 0. A setting of

0 prevents Aurora from automatically cleaning up any dead tuples left behind by your application, which can impact the accuracy of the results. Enter the following command to create a simple table:

```
postgres=> CREATE TABLE lab AS SELECT generate_series (0,100000);
SELECT 100001
```

In the following example, we run the query with AUTOVACUUM turned on for the DB cluster. The `dead_tuple_count` is 0, which indicates that the AUTOVACUUM has deleted the obsolete data or tuples from the PostgreSQL database.

To use `pgstattuple` to gather information about the table, specify the name of a table or an object identifier (OID) in the query:

```
postgres=> SELECT * FROM pgstattuple('lab');
```

```
table_len | tuple_count | tuple_len | tuple_percent | dead_tuple_count |
dead_tuple_len | dead_tuple_percent | free_space | free_percent
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3629056   | 100001     | 2800028   | 77.16        | 0                |
| 0         | 16616     | 0.46       |              | 0                |
(1 row)
```

In the following query, we turn off AUTOVACUUM and enter a command that deletes 25,000 rows from the table. As a result, the `dead_tuple_count` increases to 25000.

```
postgres=> DELETE FROM lab WHERE generate_series < 25000;

DELETE 25000
```

```
SELECT * FROM pgstattuple('lab');
```

```

table_len | tuple_count | tuple_len | tuple_percent | dead_tuple_count | dead_tuple_len
| dead_tuple_percent | free_space | free_percent
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
3629056 | 75001 | 2100028 | 57.87 | 25000 | 700000 | 19.29 | 16616 | 0.46
(1 row)

```

To reclaim those dead tuples, start a `VACUUM` process.

## Observing bloat without interrupting your application

Settings on an Aurora cluster are optimized to provide the best practices for most workloads. However, you might want to optimize a cluster to better suit your applications and use patterns. In this case, you can use the `pgstattuple` extension without disrupting a busy application. To do so, perform the following steps:

1. Clone your Aurora instance.
2. Modify the parameter file to turn off `AUTOVACUUM` in the clone.
3. Perform a `pgstattuple` query while testing the clone with a sample workload or with `pgbench`, which is a program for running benchmark tests on PostgreSQL. For more information, see [pgbench](#).

After running your applications and viewing the result, use `pg_repack` or `VACUUM FULL` on the restored copy and compare the differences. If you see a significant drop in the `dead_tuple_count`, `dead_tuple_len`, or `dead_tuple_percent`, then adjust the vacuum schedule on your production cluster to minimize the bloat.

## Avoiding bloat in temporary tables

If your application creates temporary tables, make sure that your application removes those temporary tables when they're no longer needed. Autovacuum processes don't locate temporary tables. Left unchecked, temporary tables can quickly create database bloat. Moreover, the bloat

can extend into the system tables, which are the internal tables that track PostgreSQL objects and attributes, like `pg_attribute` and `pg_depend`.

When a temporary table is no longer needed, you can use a `TRUNCATE` statement to empty the table and free up the space. Then, manually vacuum the `pg_attribute` and `pg_depend` tables. Vacuuming these tables ensures that creating and truncating/deleting temporary tables continually isn't adding tuples and contributing to system bloat.

You can avoid this problem while creating a temporary table by including the following syntax that deletes the new rows when content is committed:

```
CREATE TEMP TABLE IF NOT EXISTS table_name(table_description) ON COMMIT DELETE ROWS;
```

The `ON COMMIT DELETE ROWS` clause truncates the temporary table when the transaction is committed.

## Avoiding bloat in indexes

When you change an indexed field in a table, the index update results in one or more dead tuples in that index. By default, the autovacuum process cleans up bloat in indexes, but that cleanup uses a significant amount of time and resources. To specify index cleanup preferences when you create a table, include the `vacuum_index_cleanup` clause. By default, at table creation time, the clause is set to `AUTO`, which means that the server decides if your index requires cleanup when it vacuums the table. You can set the clause to `ON` to turn on index cleanup for a specific table, or `OFF` to turn off index cleanup for that table. Remember, turning off index cleanup might save time, but can potentially lead to a bloated index.

You can manually control index cleanup when you `VACUUM` a table at the command line. To vacuum a table and remove dead tuples from the indexes, include the `INDEX_CLEANUP` clause with a value of `ON` and the table name:

```
acctg=> VACUUM (INDEX_CLEANUP ON) receivables;

INFO: aggressively vacuuming "public.receivables"
VACUUM
```

To vacuum a table without cleaning the indexes, specify a value of `OFF`:

```
acctg=> VACUUM (INDEX_CLEANUP OFF) receivables;
```

```
INFO: aggressively vacuuming "public.receivables"  
VACUUM
```

## Improved memory management in Aurora PostgreSQL

Aurora PostgreSQL now includes advanced memory management capabilities to optimize database performance and resilience under varying workloads. These improvements help Aurora PostgreSQL maintain consistent availability and responsiveness, even during periods of high memory demand.

This feature is available and enabled by default in the following Aurora PostgreSQL versions for provisioned instances:

- 15.3 and all higher minor versions
- 14.8 and higher minor versions
- 13.11 and higher minor versions
- 12.15 and higher minor versions
- 11.20 and higher minor versions

This feature is available and enabled by default in the following Aurora PostgreSQL for Aurora Serverless instances:

- 16.3 and all higher minor versions
- 15.7 and all higher minor versions
- 14.12 and higher minor versions
- 13.15 and higher minor versions

When customer workloads use up all available free memory, the operating system may restart the database to protect resources, leading to temporary unavailability. The new memory management improvements in Aurora PostgreSQL proactively cancel certain transactions when the system experiences high memory pressure, helping to maintain database stability.

The key features of improved memory management is as follows:

- Cancelling database transactions that request more memory when the system is approaching critical memory pressure.
- The system is said to be under critical memory pressure, when it exhausts all the physical memory and is about to exhaust the swap. In these circumstances, any transaction that requests

memory will be cancelled in an effort to immediately reduce memory pressure in the DB instance.

- Essential PostgreSQL launchers and background workers such as autovacuum workers are always protected.

## Handling memory management parameters

### To turn on memory management

This feature is turned on by default. An error message is displayed when a transaction is cancelled due to insufficient memory as shown in the following example:

```
ERROR: out of memory Detail: Failed on request of size 16777216.
```

### To turn off memory management

To turn off this feature, connect to the Aurora PostgreSQL DB cluster with psql and use the SET statement for the parameter values as mentioned below.

#### Note

We recommend that you keep memory management enabled. This helps prevent potential out-of-memory errors that may lead to workload-induced database restarts due to memory exhaustion.

The following table shows how to turn off the memory management feature for the different Aurora PostgreSQL versions:

Aurora PostgreSQL versions	Parameter	Default	Command to turn off memory management at session level
11.20, 11.21, 12.15, 12.16, 13.11, 13.12, 14.8, 14.9, 15.3, 15.4	rds.memory_allocation_guard	false	SET rds.memory_allocation_guard

Aurora PostgreSQL versions	Parameter	Default	Command to turn off memory management at session level
			<code>ion_guard = true;</code>
12.17, 13.13, 14.10, 15.5, and higher versions	<code>rds.enable_memory_management</code>	true	<code>SET rds.enable_memory_management = false;</code>

### Note

The `rds.memory_allocation_guard` parameter has been deprecated in Aurora PostgreSQL 12.17, 13.13, 14.10, 15.5, and higher versions.

Setting the values of these parameters in the DB cluster parameter group prevents the queries from being canceled. For more information about DB cluster parameter group, see [Parameter groups for Amazon Aurora](#).

## Limitation

- This feature is not supported in `db.t3.medium` instance class.

## Fast failover with Amazon Aurora PostgreSQL

Following, you can learn how to make sure that failover occurs as fast as possible. To recover quickly after failover, you can use cluster cache management for your Aurora PostgreSQL DB cluster. For more information, see [Fast recovery after failover with cluster cache management for Aurora PostgreSQL](#).

Some of the steps that you can take to make failover perform fast include the following:

- Set Transmission Control Protocol (TCP) keepalives with short time frames, to stop longer running queries before the read timeout expires if there's a failure.

- Set timeouts for Java Domain Name System (DNS) caching aggressively. Doing this helps ensure the Aurora read-only endpoint can properly cycle through read-only nodes on later connection attempts.
- Set the timeout variables used in the JDBC connection string as low as possible. Use separate connection objects for short- and long-running queries.
- Use the read and write Aurora endpoints that are provided to connect to the cluster.
- Use RDS API operations to test application response on server-side failures. Also, use a packet dropping tool to test application response for client-side failures.
- Use the Amazon JDBC Driver to take full advantage of the failover capabilities of Aurora PostgreSQL. For more information about the Amazon JDBC Driver and complete instructions for using it, see the [Amazon Web Services \(Amazon\) JDBC Driver GitHub repository](#).

These are covered in more detail following.

## Topics

- [Setting TCP keepalives parameters](#)
- [Configuring your application for fast failover](#)
- [Testing failover](#)
- [Fast failover example in Java](#)

## Setting TCP keepalives parameters

When you set up a TCP connection, a set of timers is associated with the connection. When the keepalive timer reaches zero, a keepalive probe packet is sent to the connection endpoint. If the probe receives a reply, you can assume that the connection is still up and running.

Turning on TCP keepalive parameters and setting them aggressively ensures that if your client can't connect to the database, any active connections are quickly closed. The application can then connect to a new endpoint.

Make sure to set the following TCP keepalive parameters:

- `tcp_keepalives_idle` controls the time, in seconds, after which a keepalive packet is sent when no data has been sent by the socket. ACKs aren't considered data. We recommend the following setting:

```
tcp_keepalives_idle = 1
```

- `tcp_keepalives_interval` controls the time, in seconds, between sending subsequent keepalive packets after the initial packet is sent. Set this time by using the `tcp_keepalives_idle` parameter. We recommend the following setting:

```
tcp_keepalives_interval = 1
```

- `tcp_keepalives_count` is the number of unacknowledged keepalive probes that occur before the application is notified. We recommend the following setting:

```
tcp_keepalives_count = 5
```

These settings should notify the application within five seconds when the database stops responding. If keepalive packets are often dropped within the application's network, you can set a higher `tcp_keepalives_count` value. Doing this allows for more buffer in less reliable networks, although it increases the time that it takes to detect an actual failure.

### To set TCP keepalive parameters on Linux

1. Test how to configure your TCP keepalive parameters.

We recommend doing so by using the command line with the following commands. This suggested configuration is system-wide. In other words, it also affects all other applications that create sockets with the `SO_KEEPALIVE` option on.

```
sudo sysctl net.ipv4.tcp_keepalive_time=1
sudo sysctl net.ipv4.tcp_keepalive_intvl=1
sudo sysctl net.ipv4.tcp_keepalive_probes=5
```

2. After you've found a configuration that works for your application, persist these settings by adding the following lines to `/etc/sysctl.conf`, including any changes you made:

```
tcp_keepalive_time = 1
tcp_keepalive_intvl = 1
tcp_keepalive_probes = 5
```

## Configuring your application for fast failover

Following, you can find a discussion of several configuration changes for Aurora PostgreSQL that you can make for fast failover. To learn more about PostgreSQL JDBC driver setup and configuration, see the [PostgreSQL JDBC Driver](#) documentation.

### Topics

- [Reducing DNS cache timeouts](#)
- [Setting an Aurora PostgreSQL connection string for fast failover](#)
- [Other options for obtaining the host string](#)

### Reducing DNS cache timeouts

When your application tries to establish a connection after a failover, the new Aurora PostgreSQL writer will be a previous reader. You can find it by using the Aurora read-only endpoint before DNS updates have fully propagated. Setting the java DNS time to live (TTL) to a low value, such as under 30 seconds, helps cycle between reader nodes on later connection attempts.

```
// Sets internal TTL to match the Aurora R0 Endpoint TTL
java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
```

### Setting an Aurora PostgreSQL connection string for fast failover

To use Aurora PostgreSQL fast failover, make sure that your application's connection string has a list of hosts instead of just a single host. Following is an example connection string that you can use to connect to an Aurora PostgreSQL cluster. In this example, the hosts are in bold.

```
jdbc:postgresql://myauroracluster.cluster-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432,  
myauroracluster.cluster-ro-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432  
/postgres?user=<primaryuser>&password=<primarypw>&loginTimeout=2  
&connectTimeout=2&cancelSignalTimeout=2&socketTimeout=60  
&tcpKeepAlive=true&targetServerType=primary
```

For best availability and to avoid a dependency on the RDS API, we recommend that you maintain a file to connect with. This file contains a host string that your application reads from when you establish a connection to the database. This host string has all the Aurora endpoints available

for the cluster. For more information about Aurora endpoints, see [Amazon Aurora endpoint connections](#).

For example, you might store your endpoints in a local file as shown following.

```
myauroracluster.cluster-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432,  
myauroracluster.cluster-ro-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432
```

Your application reads from this file to populate the host section of the JDBC connection string. Renaming the DB cluster causes these endpoints to change. Make sure that your application handles this event if it occurs.

Another option is to use a list of DB instance nodes, as follows.

```
my-node1.cksc6x1mwcyw.us-east-1-beta.rds.amazonaws.com:5432,  
my-node2.cksc6x1mwcyw.us-east-1-beta.rds.amazonaws.com:5432,  
my-node3.cksc6x1mwcyw.us-east-1-beta.rds.amazonaws.com:5432,  
my-node4.cksc6x1mwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The benefit of this approach is that the PostgreSQL JDBC connection driver loops through all nodes on this list to find a valid connection. In contrast, when you use the Aurora endpoints only two nodes are tried in each connection attempt. However, there's a downside to using DB instance nodes. If you add or remove nodes from your cluster and the list of instance endpoints becomes stale, the connection driver might never find the correct host to connect to.

To help ensure that your application doesn't wait too long to connect to any one host, set the following parameters aggressively:

- `targetServerType` – Controls whether the driver connects to a write or read node. To ensure that your applications reconnect only to a write node, set the `targetServerType` value to `primary`.

Values for the `targetServerType` parameter include `primary`, `secondary`, `any`, and `preferSecondary`. The `preferSecondary` value attempts to establish a connection to a reader first. It connects to the writer if no reader connection can be established.

- `loginTimeout` – Controls how long your application waits to log in to the database after a socket connection has been established.
- `connectTimeout` – Controls how long the socket waits to establish a connection to the database.

You can modify other application parameters to speed up the connection process, depending on how aggressive you want your application to be:

- `cancelSignalTimeout` – In some applications, you might want to send a "best effort" cancel signal on a query that has timed out. If this cancel signal is in your failover path, consider setting it aggressively to avoid sending this signal to a dead host.
- `socketTimeout` – This parameter controls how long the socket waits for read operations. This parameter can be used as a global "query timeout" to ensure no query waits longer than this value. A good practice is to have two connection handlers. One connection handler runs short-lived queries and sets this value lower. Another connection handler, for long-running queries, has this value set much higher. With this approach, you can rely on TCP keepalive parameters to stop long-running queries if the server goes down.
- `tcpKeepAlive` – Turn on this parameter to ensure the TCP keepalive parameters that you set are respected.
- `loadBalanceHosts` – When set to `true`, this parameter has the application connect to a random host chosen from a list of candidate hosts.

### Other options for obtaining the host string

You can get the host string from several sources, including the `aurora_replica_status` function and by using the Amazon RDS API.

In many cases, you need to determine who the writer of the cluster is or to find other reader nodes in the cluster. To do this, your application can connect to any DB instance in the DB cluster and query the `aurora_replica_status` function. You can use this function to reduce the amount of time it takes to find a host to connect to. However, in certain network failure scenarios the `aurora_replica_status` function might show out-of-date or incomplete information.

A good way to ensure that your application can find a node to connect to is to try to connect to the cluster writer endpoint and then the cluster reader endpoint. You do this until you can establish a readable connection. These endpoints don't change unless you rename your DB cluster. Thus, you can generally leave them as static members of your application or store them in a resource file that your application reads from.

After you establish a connection using one of these endpoints, you can get information about the rest of the cluster. To do this, call the `aurora_replica_status` function. For example, the following command retrieves information with `aurora_replica_status`.

```
postgres=> SELECT server_id, session_id, highest_lsn_rcvd, cur_replay_latency_in_usec,
now(), last_update_timestamp
FROM aurora_replica_status();
```

```
server_id | session_id | highest_lsn_rcvd | cur_replay_latency_in_usec | now |
last_update_timestamp
```

```
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
mynode-1 | 3e3c5044-02e2-11e7-b70d-95172646d6ca | 594221001 | 201421 | 2017-03-07
19:50:24.695322+00 | 2017-03-07 19:50:23+00
mynode-2 | 1efdd188-02e4-11e7-becd-f12d7c88a28a | 594221001 | 201350 | 2017-03-07
19:50:24.695322+00 | 2017-03-07 19:50:23+00
mynode-3 | MASTER_SESSION_ID | | | 2017-03-07 19:50:24.695322+00 | 2017-03-07
19:50:23+00
(3 rows)
```

For example, the hosts section of your connection string might start with both the writer and reader cluster endpoints, as shown following.

```
myauroracluster.cluster-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hj1rd.us-east-1-beta.rds.amazonaws.com:5432
```

In this scenario, your application attempts to establish a connection to any node type, primary or secondary. When your application is connected, a good practice is to first examine the read/write status of the node. To do this, query for the result of the command `SHOW transaction_read_only`.

If the return value of the query is `OFF`, then you successfully connected to the primary node. However, suppose that the return value is `ON` and your application requires a read/write connection. In this case, you can call the `aurora_replica_status` function to determine the `server_id` that has `session_id= 'MASTER_SESSION_ID'`. This function gives you the name of the primary node. You can use this with the `endpointPostfix` described following.

Make sure that you're aware when you connect to a replica that has stale data. When this happens, the `aurora_replica_status` function might show out-of-date information. You can set a threshold for staleness at the application level. To check this, you can look at the difference between the server time and the `last_update_timestamp` value. In general, your application should avoid flipping between two hosts due to conflicting information returned by the `aurora_replica_status` function. Your application should try all known hosts first instead of following the data returned by `aurora_replica_status`.

## Listing instances using the DescribeDBClusters API operation, example in Java

You can programmatically find the list of instances by using the [Amazon SDK for Java](#), specifically the [DescribeDBClusters](#) API operation.

Following is a small example of how you might do this in Java 8.

```
AmazonRDS client = AmazonRDSClientBuilder.defaultClient();
DescribeDBClustersRequest request = new DescribeDBClustersRequest()
    .withDBClusterIdentifier(clusterName);
DescribeDBClustersResult result =
rdsClient.describeDBClusters(request);

DBCluster singleClusterResult = result.getDBClusters().get(0);

String pgJDBCEndpointStr =
singleClusterResult.getDBClusterMembers().stream()
    .sorted(Comparator.comparing(DBClusterMember::getIsClusterWriter)
    .reversed()) // This puts the writer at the front of the list
    .map(m -> m.getDBInstanceIdentifier() + endpointPostfix + ":" +
singleClusterResult.getPort())
    .collect(Collectors.joining(","));
```

Here, `pgJDBCEndpointStr` contains a formatted list of endpoints, as shown following.

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The variable `endpointPostfix` can be a constant that your application sets. Or your application can get it by querying the `DescribeDBInstances` API operation for a single instance in your cluster. This value remains constant within an Amazon Web Services Region and for an individual customer. So it saves an API call to simply keep this constant in a resource file that your application reads from. In the example preceding, it's set to the following.

```
.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com
```

For availability purposes, a good practice is to default to using the Aurora endpoints of your DB cluster if the API isn't responding or takes too long to respond. The endpoints are guaranteed to be up to date within the time it takes to update the DNS record. Updating the DNS record with an endpoint typically takes less than 30 seconds. You can store the endpoint in a resource file that your application consumes.

## Testing failover

In all cases you must have a DB cluster with two or more DB instances in it.

From the server side, certain API operations can cause an outage that can be used to test how your applications responds:

- [FailoverDBCluster](#) – This operation attempts to promote a new DB instance in your DB cluster to writer.

The following code example shows how you can use `failoverDBCluster` to cause an outage. For more details about setting up an Amazon RDS client, see [Using the Amazon SDK for Java](#).

```
public void causeFailover() {  
  
    final AmazonRDS rdsClient = AmazonRDSClientBuilder.defaultClient();  
  
    FailoverDBClusterRequest request = new FailoverDBClusterRequest();  
    request.setDBClusterIdentifier("cluster-identifier");  
  
    rdsClient.failoverDBCluster(request);  
}
```

- [RebootDBInstance](#) – Failover isn't guaranteed with this API operation. It shuts down the database on the writer, however. You can use it to test how your application responds to connections dropping. The `ForceFailover` parameter doesn't apply for Aurora engines. Instead, use the `FailoverDBCluster` API operation.
- [ModifyDBCluster](#) – Modifying the `Port` parameter causes an outage when the nodes in the cluster begin listening on a new port. In general, your application can respond to this failure first by ensuring that only your application controls port changes. Also, ensure that it can appropriately update the endpoints it depends on. You can do this by having someone manually update the port when they make modifications at the API level. Or you can do this by using the RDS API in your application to determine if the port has changed.
- [ModifyDBInstance](#) – Modifying the `DBInstanceClass` parameter causes an outage.
- [DeleteDBInstance](#) – Deleting the primary (writer) causes a new DB instance to be promoted to writer in your DB cluster.

From the application or client side, if you use Linux, you can test how the application responds to sudden packet drops. You can do this based on whether port, host, or if TCP keepalive packets are sent or received by using the `iptables` command.

## Fast failover example in Java

The following code example shows how an application might set up an Aurora PostgreSQL driver manager.

The application calls the `getConnection` function when it needs a connection. A call to `getConnection` can fail to find a valid host. An example is when no writer is found but the `targetServerType` parameter is set to `primary`. In this case, the calling application should simply retry calling the function.

To avoid pushing the retry behavior onto the application, you can wrap this retry call into a connection pooler. With most connection poolers, you can specify a JDBC connection string. So your application can call into `getJdbcConnectionString` and pass that to the connection pooler. Doing this means you can use faster failover with Aurora PostgreSQL.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.ArrayList;
import java.util.List;
import java.util.stream.Collectors;
import java.util.stream.IntStream;

import org.joda.time.Duration;

public class FastFailoverDriverManager {
    private static Duration LOGIN_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CONNECT_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CANCEL_SIGNAL_TIMEOUT = Duration.standardSeconds(1);
    private static Duration DEFAULT_SOCKET_TIMEOUT = Duration.standardSeconds(5);

    public FastFailoverDriverManager() {
        try {
            Class.forName("org.postgresql.Driver");
        } catch (ClassNotFoundException e) {
            e.printStackTrace();
        }
    }
}
```

```

    /*
     * R0 endpoint has a TTL of 1s, we should honor that here. Setting this
    aggressively makes sure that when
     * the PG JDBC driver creates a new connection, it will resolve a new different
    R0 endpoint on subsequent attempts
     * (assuming there is > 1 read node in your cluster)
    */
    java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
    // If the lookup fails, default to something like small to retry
    java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
}

public Connection getConnection(String targetServerType) throws SQLException {
    return getConnection(targetServerType, DEFAULT_SOCKET_TIMEOUT);
}

public Connection getConnection(String targetServerType, Duration queryTimeout)
throws SQLException {
    Connection conn =
    DriverManager.getConnection(getJdbcConnectionString(targetServerType, queryTimeout));

    /*
     * A good practice is to set socket and statement timeout to be the same thing
    since both
     * the client AND server will stop the query at the same time, leaving no
    running queries
     * on the backend
    */
    Statement st = conn.createStatement();
    st.execute("set statement_timeout to " + queryTimeout.getMillis());
    st.close();

    return conn;
}

private static String urlFormat = "jdbc:postgresql://%s"
    + "/postgres"
    + "?user=%s"
    + "&password=%s"
    + "&loginTimeout=%d"
    + "&connectTimeout=%d"
    + "&cancelSignalTimeout=%d"
    + "&socketTimeout=%d"

```

```
        + "&targetServerType=%s"
        + "&tcpKeepAlive=true"
        + "&ssl=true"
        + "&loadBalanceHosts=true";
    public String getJdbcConnectionString(String targetServerType, Duration
queryTimeout) {
        return String.format(urlFormat,
            getFormattedEndpointList(getLocalEndpointList()),
            CredentialManager.getUsername(),
            CredentialManager.getPassword(),
            LOGIN_TIMEOUT.getStandardSeconds(),
            CONNECT_TIMEOUT.getStandardSeconds(),
            CANCEL_SIGNAL_TIMEOUT.getStandardSeconds(),
            queryTimeout.getStandardSeconds(),
            targetServerType
        );
    }

    private List<String> getLocalEndpointList() {
        /*
         * As mentioned in the best practices doc, a good idea is to read a local
resource file and parse the cluster endpoints.
         * For illustration purposes, the endpoint list is hardcoded here
         */
        List<String> newEndpointList = new ArrayList<>();
        newEndpointList.add("myauroracluster.cluster-c9bfei4hjlr.us-east-1-
beta.rds.amazonaws.com:5432");
        newEndpointList.add("myauroracluster.cluster-ro-c9bfei4hjlr.us-east-1-
beta.rds.amazonaws.com:5432");

        return newEndpointList;
    }

    private static String getFormattedEndpointList(List<String> endpoints) {
        return IntStream.range(0, endpoints.size())
            .mapToObj(i -> endpoints.get(i).toString())
            .collect(Collectors.joining(","));
    }
}
```

# Fast recovery after failover with cluster cache management for Aurora PostgreSQL

For fast recovery of the writer DB instance in your Aurora PostgreSQL clusters if there's a failover, use cluster cache management for Amazon Aurora PostgreSQL. Cluster cache management ensures that application performance is maintained if there's a failover.

In a typical failover situation, you might see a temporary but large performance degradation after failover. This degradation occurs because when the failover DB instance starts, the buffer cache is empty. An empty cache is also known as a *cold cache*. A cold cache degrades performance because the DB instance has to read from the slower disk, instead of taking advantage of values stored in the buffer cache.

With cluster cache management, you set a specific reader DB instance as the failover target. Cluster cache management ensures that the data in the designated reader's cache is kept synchronized with the data in the writer DB instance's cache. The designated reader's cache with prefilled values is known as a *warm cache*. If a failover occurs, the designated reader uses values in its warm cache immediately when it's promoted to the new writer DB instance. This approach provides your application much better recovery performance.

Cluster cache management requires that the designated reader instance have the same instance class type and size (`db.r5.2xlarge` or `db.r5.xlarge`, for example) as the writer. Keep this in mind when you create your Aurora PostgreSQL DB clusters so that your cluster can recover during a failover. For a listing of instance class types and sizes, see [Hardware specifications for DB instance classes for Aurora](#).

## Note

Cluster cache management isn't supported for Aurora PostgreSQL secondary DB cluster that are part of Aurora global databases. For primary clusters where this feature is supported, it's recommended that no workload should run on the designated tier-0 reader.

## Contents

- [Configuring cluster cache management](#)
- [Enabling cluster cache management](#)
- [Setting the promotion tier priority for the writer DB instance](#)

- [Setting the promotion tier priority for a reader DB instance](#)
- [Monitoring the buffer cache](#)
- [Troubleshooting CCM configuration](#)

## Configuring cluster cache management

To configure cluster cache management, do the following processes in order.

### Topics

- [Enabling cluster cache management](#)
- [Setting the promotion tier priority for the writer DB instance](#)
- [Setting the promotion tier priority for a reader DB instance](#)

#### Note

Allow at least 1 minute after completing these steps for cluster cache management to be fully operational.

## Enabling cluster cache management

To enable cluster cache management, take the steps described following.

### Console

#### To enable cluster cache management

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group for your Aurora PostgreSQL DB cluster.

The DB cluster must use a parameter group other than the default, because you can't change values in a default parameter group.

4. For **Parameter group actions**, choose **Edit**.
5. Set the value of the `apg_ccm_enabled` cluster parameter to **1**.

## 6. Choose **Save changes**.

### Amazon CLI

To enable cluster cache management for an Aurora PostgreSQL DB cluster, use the Amazon CLI [modify-db-cluster-parameter-group](#) command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name my-db-cluster-parameter-group \  
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name my-db-cluster-parameter-group ^  
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

### Setting the promotion tier priority for the writer DB instance

For cluster cache management, make sure that the promotion priority is **tier-0** for the writer DB instance of the Aurora PostgreSQL DB cluster. The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority. For more information about the promotion tier, see [Fault tolerance for an Aurora DB cluster](#).

### Console

#### To set the promotion priority for the writer DB instance to tier-0

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.

3. Choose the **Writer** DB instance of the Aurora PostgreSQL DB cluster.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

## Amazon CLI

To set the promotion tier priority to 0 for the writer DB instance using the Amazon CLI, call the [modify-db-instance](#) command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier writer-db-instance \  
  --promotion-tier 0 \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier writer-db-instance ^  
  ---promotion-tier 0 ^  
  --apply-immediately
```

## Setting the promotion tier priority for a reader DB instance

You must set only one reader DB instance for cluster cache management. To do so, choose a reader from the Aurora PostgreSQL cluster that is the same instance class and size as the writer

DB instance. For example, if the writer uses `db.r5.xlarge`, choose a reader that uses this same instance class type and size. Then set its promotion tier priority to 0.

The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority.

## Console

### To set the promotion priority of the reader DB instance to tier-0

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose a **Reader** DB instance of the Aurora PostgreSQL DB cluster that is the same instance class as the writer DB instance.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

## Amazon CLI

To set the promotion tier priority to 0 for the reader DB instance using the Amazon CLI, call the [modify-db-instance](#) command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier reader-db-instance \  
  --promotion-tier 0 \  
  --apply-immediately
```

```
--promotion-tier 0 \  
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier reader-db-instance ^  
  ---promotion-tier 0 ^  
  --apply-immediately
```

## Monitoring the buffer cache

After setting up cluster cache management, you can monitor the state of synchronization between the writer DB instance's buffer cache and the designated reader's warm buffer cache. To examine the buffer cache contents on both the writer DB instance and the designated reader DB instance, use the PostgreSQL `pg_buffercache` module. For more information, see the [PostgreSQL `pg\_buffercache` documentation](#).

### Using the `aurora_ccm_status` Function

Cluster cache management also provides the `aurora_ccm_status` function. Use the `aurora_ccm_status` function on the writer DB instance to get the following information about the progress of cache warming on the designated reader:

- `buffers_sent_last_minute` – How many buffers have been sent to the designated reader in the last minute.
- `buffers_found_last_minute` – The number of frequently accessed buffers identified during the past minute.
- `buffers_sent_last_scan` – How many buffers have been sent to the designated reader during the last complete scan of the buffer cache.
- `buffers_found_last_scan` – How many buffers have been identified as frequently accessed and needed to be sent during the last complete scan of the buffer cache. Buffers already cached on the designated reader aren't sent.
- `buffers_sent_current_scan` – How many buffers have been sent so far during the current scan.
- `buffers_found_current_scan` – How many buffers have been identified as frequently accessed in the current scan.

- `current_scan_progress` – How many buffers have been visited so far during the current scan.

The following example shows how to use the `aurora_ccm_status` function to convert some of its output into a warm rate and warm percentage.

```
SELECT buffers_sent_last_minute*8/60 AS warm_rate_kbps,  
       100*(1.0-buffers_sent_last_scan::float/buffers_found_last_scan) AS warm_percent  
FROM aurora_ccm_status();
```

## Troubleshooting CCM configuration

When you enable `apg_ccm_enabled` cluster parameter, cluster cache management is automatically turned on at the instance level on the writer DB instance and one reader DB instance on the Aurora PostgreSQL DB cluster. The writer and reader instance should use the same instance class type and size. Their promotion tier priority is set to 0. Other reader instances in the DB cluster should have a non-zero promotion tier and cluster cache management is disabled for those instances.

The following reasons may lead to issues in the configuration and disable cluster cache management:

- When there is no single reader DB instance set to promotion tier 0.
- When the writer DB instance is not set to promotion tier 0.
- When more than one reader DB instances are set to promotion tier 0.
- When the writer and one reader DB instances with promotion tier 0 doesn't have the same instance size.

## Managing Aurora PostgreSQL connection churn with pooling

When client applications connect and disconnect so often that Aurora PostgreSQL DB cluster response time slows, the cluster is said to be experiencing *connection churn*. Each new connection to the Aurora PostgreSQL DB cluster endpoint consumes resources, thus reducing the resources that can be used to process the actual workload. Connection churn is an issue that we recommend that you manage by following some of the best practices discussed following.

For starters, you can improve response times on Aurora PostgreSQL DB clusters that have high rates of connection churn. To do this, you can use a connection pooler, such as RDS Proxy. A

*connection pooler* provides a cache of ready to use connections for clients. Almost all versions of Aurora PostgreSQL support RDS Proxy. For more information, see [Amazon RDS Proxy with Aurora PostgreSQL](#).

If your specific version of Aurora PostgreSQL doesn't support RDS Proxy, you can use another PostgreSQL-compatible connection pooler, such as PgBouncer. To learn more, see the [PgBouncer](#) website.

To see if your Aurora PostgreSQL DB cluster can benefit from connection pooling, you can check the `postgresql.log` file for connections and disconnections. You can also use Performance Insights to find out how much connection churn your Aurora PostgreSQL DB cluster is experiencing. Following, you can find information about both topics.

## Logging connections and disconnections

The PostgreSQL `log_connections` and `log_disconnections` parameters can capture connections and disconnections to the writer instance of the Aurora PostgreSQL DB cluster. By default, these parameters are turned off. To turn these parameters on, use a custom parameter group and turn on by changing the value to 1. For more information about custom parameter groups, see [DB cluster parameter groups for Amazon Aurora DB clusters](#). To check the settings, connect to your DB cluster endpoint for Aurora PostgreSQL by using `psql` and query as follows.

```
labdb=> SELECT setting FROM pg_settings
  WHERE name = 'log_connections';
  setting
  -----
on
(1 row)
labdb=> SELECT setting FROM pg_settings
  WHERE name = 'log_disconnections';
  setting
  -----
on
(1 row)
```

With both of these parameters turned on, the log captures all new connections and disconnections. You see the user and database for each new authorized connection. At disconnection time, the session duration is also logged, as shown in the following example.

```
2022-03-07 21:44:53.978 UTC [16641] LOG: connection authorized: user=labtek
  database=labdb application_name=psql
```

```
2022-03-07 21:44:55.718 UTC [16641] LOG: disconnection: session time: 0:00:01.740
user=labtek database=labdb host=[local]
```

To check your application for connection churn, turn on these parameters if they're not on already. Then gather data in the PostgreSQL log for analysis by running your application with a realistic workload and time period. You can view the log file in the RDS console. Choose the writer instance of your Aurora PostgreSQL DB cluster, and then choose the **Logs & events** tab. For more information, see [Viewing and listing database log files](#).

Or you can download the log file from the console and use the following command sequence. This sequence finds the total number of connections authorized and dropped per minute.

```
grep "connection authorized\|disconnection: session time:"
  postgresql.log.2022-03-21-16|\
awk {'print $1,$2'} |\
sort |\
uniq -c |\
sort -n -k1
```

In the example output, you can see a spike in authorized connections followed by disconnections starting at 16:12:10.

```
.....
,.....
.....
5 2022-03-21 16:11:55 connection authorized:
9 2022-03-21 16:11:55 disconnection: session
5 2022-03-21 16:11:56 connection authorized:
5 2022-03-21 16:11:57 connection authorized:
5 2022-03-21 16:11:57 disconnection: session
32 2022-03-21 16:12:10 connection authorized:
30 2022-03-21 16:12:10 disconnection: session
31 2022-03-21 16:12:11 connection authorized:
27 2022-03-21 16:12:11 disconnection: session
27 2022-03-21 16:12:12 connection authorized:
27 2022-03-21 16:12:12 disconnection: session
41 2022-03-21 16:12:13 connection authorized:
47 2022-03-21 16:12:13 disconnection: session
46 2022-03-21 16:12:14 connection authorized:
41 2022-03-21 16:12:14 disconnection: session
24 2022-03-21 16:12:15 connection authorized:
```

```
29 2022-03-21 16:12:15 disconnection: session
28 2022-03-21 16:12:16 connection authorized:

With this information, you can decide if your workload can benefit from a connection pooler. For more detailed analysis, you can use Performance Insights.

## Detecting connection churn with Performance Insights

You can use Performance Insights to assess the amount of connection churn on your Aurora PostgreSQL-Compatible Edition DB cluster. When you create an Aurora PostgreSQL DB cluster, the setting for Performance Insights is turned on by default. If you cleared this choice when you created your DB cluster, modify your cluster to turn on the feature. For more information, see [Modifying an Amazon Aurora DB cluster](#).

With Performance Insights running on your Aurora PostgreSQL DB cluster, you can choose the metrics that you want to monitor. You can access Performance Insights from the navigation pane in the console. You can also access Performance Insights from the **Monitoring** tab of the writer instance for your Aurora PostgreSQL DB cluster, as shown in the following image.

RDS > Databases > docs-lab-apg-hq-main > docs-lab-apg-hq-main-instance-1

## docs-lab-apg-hq-main-instance-1

Add instance to compare

From the Performance Insights console, choose **Manage metrics**. To analyze your Aurora PostgreSQL DB cluster's connection and disconnection activity, choose the following metrics. These are all metrics from PostgreSQL.

- `xact_commit` – The number of committed transactions.
- `total_auth_attempts` – The number of attempted authenticated user connections per minute.
- `numbackends` – The number of backends currently connected to the database.

Cancel Update graph

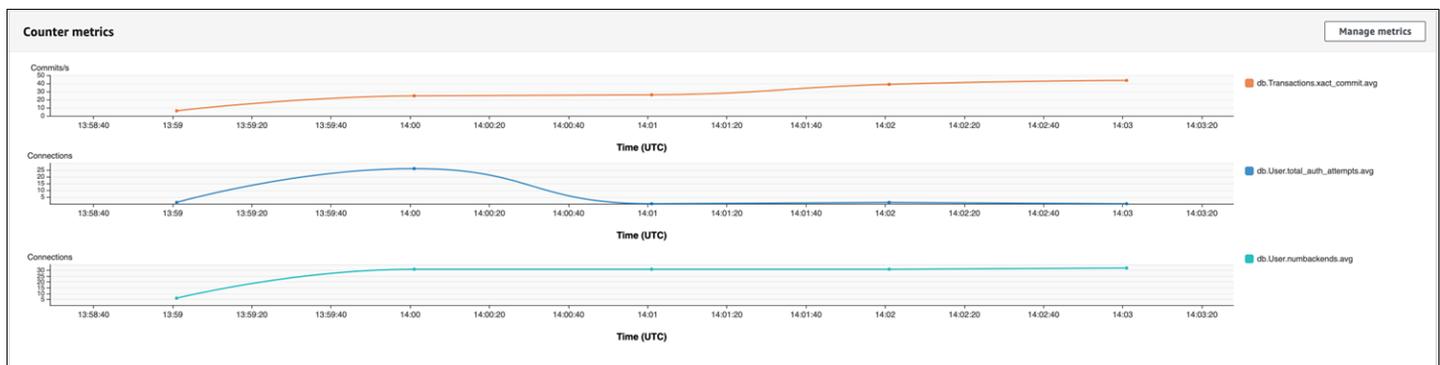

To save the settings and display connection activity, choose **Update graph**.

In the following image, you can see the impact of running pgbench with 100 users. The line showing connections is on a consistent upward slope. To learn more about pgbench and how to use it, see [pgbench](#) in PostgreSQL documentation.

The image shows that running a workload with as few as 100 users without a connection pooler can cause a significant increase in the number of `total_auth_attempts` throughout the duration of workload processing. Note that it's best to keep `total_auth_attempts` as close to zero as possible.

With RDS Proxy connection pooling, the connection attempts increase at the start of the workload. After setting up the connection pool, the average declines. The resources used by transactions and backend use stays consistent throughout workload processing.

For more information about using Performance Insights with your Aurora PostgreSQL DB cluster, see [Monitoring DB load with Performance Insights on Amazon Aurora](#). To analyze the metrics, see [Analyzing metrics with the Performance Insights dashboard](#).

## Demonstrating the benefits of connection pooling

As mentioned previously, if you determine that your Aurora PostgreSQL DB cluster has a connection churn problem, you can use RDS Proxy for improved performance. Following, you can find an example that shows the differences in processing a workload when connections are pooled and when they're not. The example uses `pgbench` to model a transaction workload.

As is `psql`, `pgbench` is a PostgreSQL client application that you can install and run from your local client machine. You can also install and run it from the Amazon EC2 instance that you use

for managing your Aurora PostgreSQL DB cluster. For more information, see [pgbench](#) in the PostgreSQL documentation.

To step through this example, you first create the pgbench environment in your database. The following command is the basic template for initializing the pgbench tables in the specified database. This example uses the default main user account, `postgres`, for the login. Change it as needed for your Aurora PostgreSQL DB cluster. You create the pgbench environment in a database on the writer instance of your cluster.

**Note**

The pgbench initialization process drops and recreates tables named `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`. Be sure that the database that you choose for `dbname` when you initialize pgbench doesn't use these names.

```
pgbench -U postgres -h db-cluster-instance-1.111122223333.aws-region.rds.amazonaws.com
-p 5432 -d -i -s 50 dbname
```

For pgbench, specify the following parameters.

**-d**

Outputs a debugging report as pgbench runs.

**-h**

Specifies the endpoint of the Aurora PostgreSQL DB cluster's writer instance.

**-i**

Initializes the pgbench environment in the database for the benchmark tests.

**-p**

Identifies the port used for database connections. The default for Aurora PostgreSQL is typically 5432 or 5433.

**-S**

Specifies the scaling factor to use for populating the tables with rows. The default scaling factor is 1, which generates 1 row in the `pgbench_branches` table, 10 rows in the `pgbench_tellers` table, and 100000 rows in the `pgbench_accounts` table.

**-U**

Specifies the user account for the Aurora PostgreSQL DB cluster's writer instance.

After the `pgbench` environment is set up, you can then run benchmarking tests with and without connection pooling. The default test consists of a series of five `SELECT`, `UPDATE`, and `INSERT` commands per transaction that run repeatedly for the time specified. You can specify scaling factor, number of clients, and other details to model your own use cases.

As an example, the command that follows runs the benchmark for 60 seconds (`-T` option, for time) with 20 concurrent connections (the `-c` option). The `-C` option makes the test run using a new connection each time, rather than once per client session. This setting gives you an indication of the connection overhead.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U
postgres -p 5432 -T 60 -c 20 -C labdb
Password:*****
pgbench (14.3, server 13.3)
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 50
query mode: simple
number of clients: 20
number of threads: 1
duration: 60 s
number of transactions actually processed: 495
latency average = 2430.798 ms
average connection time = 120.330 ms
tps = 8.227750 (including reconnection times)
```

Running `pgbench` on the writer instance of an Aurora PostgreSQL DB cluster without reusing connections shows that only about 8 transactions are processed each second. This gives a total of 495 transactions during the 1-minute test.

If you reuse connections, the response from Aurora PostgreSQL DB cluster for the number of users is almost 20 times faster. With reuse, a total of 9,042 transactions is processed compared to 495 in the same amount of time and for the same number of user connections. The difference is that in the following, each connection is being reused.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U
postgres -p 5432 -T 60 -c 20 labdb
Password:*****
pgbench (14.3, server 13.3)
  starting vacuum...end.
  transaction type: <builtin: TPC-B (sort of)>
  scaling factor: 50
  query mode: simple
  number of clients: 20
  number of threads: 1
  duration: 60 s
  number of transactions actually processed: 9042
  latency average = 127.880 ms
  initial connection time = 2311.188 ms
  tps = 156.396765 (without initial connection time)
```

This example shows you that pooling connections can significantly improve response times. For information about setting up RDS Proxy for your Aurora PostgreSQL DB cluster, see [Amazon RDS Proxy for Aurora](#).

## Dead connection handling in PostgreSQL

Dead connections occur when a database session remains active on the server despite the client application having abandoned or terminated abnormally. This situation typically arises when client processes crash or terminate unexpectedly without properly closing their database connections or canceling ongoing requests.

PostgreSQL efficiently identifies and cleans up dead connections when server processes are idle or attempt to send data to clients. However, detection is challenging for sessions that are idle, waiting for client input, or actively running queries. To handle these scenarios, PostgreSQL provides `tcp_keepalives_*`, `tcp_user_timeout`, and `client_connection_check_interval` parameters.

### Topics

- [Understanding TCP keepalive](#)

- [Key TCP keepalive parameters in Aurora PostgreSQL](#)
- [Use cases for TCP keepalive settings](#)
- [Best practices](#)

## Understanding TCP keepalive

TCP Keepalive is a protocol-level mechanism that helps maintain and verify connection integrity. Each TCP connection maintains kernel-level settings that govern keepalive behavior. When the keepalive timer expires, the system does the following:

- Sends a probe packet with no data and the ACK flag set.
- Expects a response from the remote endpoint according to TCP/IP specifications.
- Manages connection state based on the response or lack thereof.

## Key TCP keepalive parameters in Aurora PostgreSQL

Parameter	Description	Default values
<code>tcp_keepalives_idle</code>	Specifies number of seconds of inactivity before sending keepalive message.	300
<code>tcp_keepalives_interval</code>	Specifies number of seconds between retransmissions of unacknowledged keepalive messages.	30
<code>tcp_keepalives_count</code>	Maximum lost keepalive messages before declaring connection dead	2
<code>tcp_user_timeout</code>	Specifies how long (in Milliseconds) unacknowledged data can remain before forcibly closing the connection.	0

Parameter	Description	Default values
<code>client_connection_check_interval</code>	Sets the interval (in Milliseconds) for checking client connection status during long-running queries. This ensures quicker detection of closed connections.	0

## Use cases for TCP keepalive settings

### Keeping idle sessions alive

To prevent idle connections from being terminated by firewalls or routers due to inactivity:

- Configure `tcp_keepalives_idle` to send keepalive packets at regular intervals.

### Detecting dead connections

To detect dead connections promptly:

- Adjust `tcp_keepalives_idle`, `tcp_keepalives_interval`, and `tcp_keepalives_count`. For example, with Aurora PostgreSQL defaults, it takes about a minute (2 probes × 30 seconds) to detect a dead connection. Lowering these values can speed up detection.
- Use `tcp_user_timeout` to specify the maximum wait time for an acknowledgment.

TCP keepalive settings help the kernel detect dead connections, but PostgreSQL may not act until the socket is used. If a session is running a long query, dead connections might only be detected after query completion. In PostgreSQL 14 and higher versions, `client_connection_check_interval` can expedite dead connection detection by periodically polling the socket during query execution.

## Best practices

- **Set reasonable keepalive intervals:** Tune `tcp_user_timeout`, `tcp_keepalives_idle`, `tcp_keepalives_count` and `tcp_keepalives_interval` to balance detection speed and resource use.

- **Optimize for your environment:** Align settings with network behavior, firewall policies, and session needs.
- **Leverage PostgreSQL features:** Use `client_connection_check_interval` in PostgreSQL 14 and higher versions for efficient connection checks.

## Tuning memory parameters for Aurora PostgreSQL

In Amazon Aurora PostgreSQL, you can use several parameters that control the amount of memory used for various processing tasks. If a task takes more memory than the amount set for a given parameter, Aurora PostgreSQL uses other resources for processing, such as by writing to disk. This can cause your Aurora PostgreSQL DB cluster to slow or potentially halt, with an out-of-memory error.

The default setting for each memory parameter can usually handle its intended processing tasks. However, you can also tune your Aurora PostgreSQL DB cluster's memory-related parameters. You do this tuning to ensure that enough memory is allocated for processing your specific workload.

Following, you can find information about parameters that control memory management. You can also learn how to assess memory utilization.

### Checking and setting parameter values

The parameters that you can set to manage memory and assess your Aurora PostgreSQL DB cluster's memory usage include the following:

- `work_mem` – Specifies the amount of memory that the Aurora PostgreSQL DB cluster uses for internal sort operations and hash tables before it writes to temporary disk files.
- `log_temp_files` – Logs temporary file creation, file names, and sizes. When this parameter is turned on, a log entry is stored for each temporary file that gets created. Turn this on to see how frequently your Aurora PostgreSQL DB cluster needs to write to disk. Turn it off again after you've gathered information about your Aurora PostgreSQL DB cluster's temporary file generation, to avoid excessive logging.
- `logical_decoding_work_mem` – Specifies the amount of memory (in kilobytes) to be used by each internal reorder buffer before spilling to disk. This memory is used for *Logical decoding*, which is the process to create a replica. It is done by converting data from the write-ahead log (WAL) file to the logical streaming output needed by the target.

The value of this parameter creates a single buffer of the size specified for each replication connection. By default, it's 65536 KB. After this buffer is filled, the excess is written to disk as a file. To minimize disk activity, you can set the value of this parameter to a much higher value than that of `work_mem`.

These are all dynamic parameters, so you can change them for the current session. To do this, connect to the Aurora PostgreSQL DB cluster with `psql` and using the `SET` statement, as shown following.

```
SET parameter_name TO parameter_value;
```

Session settings last for the duration of the session only. When the session ends, the parameter reverts to its setting in the DB cluster parameter group. Before changing any parameters, first check the current values by querying the `pg_settings` table, as follows.

```
SELECT unit, setting, max_val
FROM pg_settings WHERE name='parameter_name';
```

For example, to find the value of the `work_mem` parameter, connect to the Aurora PostgreSQL DB cluster's writer instance and run the following query.

```
SELECT unit, setting, max_val, pg_size_pretty(max_val::numeric)
FROM pg_settings WHERE name='work_mem';
unit | setting | max_val | pg_size_pretty
-----+-----+-----+-----
kB   | 1024    | 2147483647 | 2048 MB
(1 row)
```

Changing parameter settings so that they persist requires using a custom DB cluster parameter group. After exercising your Aurora PostgreSQL DB cluster with different values for these parameters using the `SET` statement, you can create a custom parameter group and apply to your Aurora PostgreSQL DB cluster. For more information, see [Parameter groups for Amazon Aurora](#).

## Understanding the working memory parameter

The working memory parameter (`work_mem`) specifies the maximum amount of memory that Aurora PostgreSQL can use to process complex queries. Complex queries include those that involve sorting or grouping operations—in other words, queries that use the following clauses:

- ORDER BY
- DISTINCT
- GROUP BY
- JOIN (MERGE and HASH)

The query planner indirectly affects how your Aurora PostgreSQL DB cluster uses working memory. The query planner generates execution plans for processing SQL statements. A given plan might break up a complex query into multiple units of work that can be run in parallel. When possible, Aurora PostgreSQL uses the amount of memory specified in the `work_mem` parameter for each session before writing to disk for each parallel process.

Multiple database users running multiple operations concurrently and generating multiple units of work in parallel can exhaust your Aurora PostgreSQL DB cluster's allocated working memory. This can lead to excessive temporary file creation and disk I/O, or worse, it can lead to an out-of-memory error.

## Identifying temporary file use

Whenever the memory required to process queries exceeds the value specified in the `work_mem` parameter, the working data is offloaded to disk in a temporary file. You can see how often this occurs by turning on the `log_temp_files` parameter. By default, this parameter is off (it's set to -1). To capture all temporary file information, set this parameter to 0. Set `log_temp_files` to any other positive integer to capture temporary file information for files equal to or greater than that amount of data (in kilobytes). In the following image, you can see an example from Amazon Web Services Management Console.

The screenshot shows the AWS Management Console interface for a parameter group named 'docs-lab-apg14-custom-db-cluster-param-group'. The 'Parameters' section is active, displaying a search bar with 'log\_temp\_files' entered. Below the search bar is a table of parameters. The table has columns for Name, Values, Allowed values, Modifiable, Source, Apply type, Data type, and Description. The 'log\_temp\_files' parameter is listed with a value of 1024, allowed values from -1 to 2147483647, is modifiable, has a user source, is dynamic, and is an integer type. The description indicates it logs the use of temporary files larger than the specified number of kilobytes.

Name	Values	Allowed values	Modifiable	Source	Apply type	Data type	Description
log_temp_files	1024	-1-2147483647	true	user	dynamic	integer	(kB) Log the use of temporary files larger than this number of kilobytes.

After configuring temporary file logging, you can test with your own workload to see if your working memory setting is sufficient. You can also simulate a workload by using `pgbench`, a simple benchmarking application from the PostgreSQL community.

The following example initializes (`-i`) `pgbench` by creating the necessary tables and rows for running the tests. In this example, the scaling factor (`-s 50`) creates 50 rows in the `pgbench_branches` table, 500 rows in `pgbench_tellers`, and 5,000,000 rows in the `pgbench_accounts` table in the `labdb` database.

```
pgbench -U postgres -h your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com
-p 5432 -i -s 50 labdb
Password:
dropping old tables...
NOTICE: table "pgbench_accounts" does not exist, skipping
NOTICE: table "pgbench_branches" does not exist, skipping
NOTICE: table "pgbench_history" does not exist, skipping
NOTICE: table "pgbench_tellers" does not exist, skipping
creating tables...
generating data (client-side)...
5000000 of 5000000 tuples (100%) done (elapsed 15.46 s, remaining 0.00 s)
vacuuming...
creating primary keys...
done in 61.13 s (drop tables 0.08 s, create tables 0.39 s, client-side generate 54.85
s, vacuum 2.30 s, primary keys 3.51 s)
```

After initializing the environment, you can run the benchmark for a specific time (`-T`) and the number of clients (`-c`). This example also uses the `-d` option to output debugging information as the transactions are processed by the Aurora PostgreSQL DB cluster.

```
pgbench -h -U postgres your-cluster-instance-1.111122223333.aws-regionrds.amazonaws.com
-p 5432 -d -T 60 -c 10 labdb
Password:*****
pgbench (14.3)
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 50
query mode: simple
number of clients: 10
number of threads: 1
duration: 60 s
number of transactions actually processed: 1408
latency average = 398.467 ms
```

```
initial connection time = 4280.846 ms
tps = 25.096201 (without initial connection time)
```

For more information about `pgbench`, see [pgbench](#) in the PostgreSQL documentation.

You can use the `psql` metacommand `\d` to list the relations such as tables, views, and indexes created by `pgbench`.

```
labdb=> \d pgbench_accounts
Table "public.pgbench_accounts"
 Column |      Type      | Collation | Nullable | Default
-----+-----+-----+-----+-----
 aid    | integer        |           | not null |
 bid    | integer        |           |         |
 abalance | integer        |           |         |
 filler | character(84)  |           |         |
Indexes:
    "pgbench_accounts_pkey" PRIMARY KEY, btree (aid)
```

As shown in the output, the `pgbench_accounts` table is indexed on the `aid` column. To ensure that this next query uses working memory, query any nonindexed column, such as that shown in the following example.

```
postgres=> SELECT * FROM pgbench_accounts ORDER BY bid;
```

Check the log for the temporary files. To do so, open the Amazon Web Services Management Console, choose the Aurora PostgreSQL DB cluster instance, and then choose the **Logs & Events** tab. View the logs in the console or download for further analysis. As shown in the following image, the size of the temporary files needed to process the query indicates that you should consider increasing the amount specified for the `work_mem` parameter.

```

2022-07-07 23:14:02 UTC:[local]:[unknown]:[unknown]:[17375]:LOG: connection received: host=[local]
2022-07-07 23:16:02 UTC:[local]:[unknown]:[unknown]:[22962]:LOG: connection received: host=[local]
2022-07-07 23:18:02 UTC:[local]:[unknown]:[unknown]:[28804]:LOG: connection received: host=[local]
2022-07-07 23:20:02 UTC:[local]:[unknown]:[unknown]:[2012]:LOG: connection received: host=[local]
2022-07-07 23:22:02 UTC:[local]:[unknown]:[unknown]:[8000]:LOG: connection received: host=[local]
```

You can configure this parameter differently for individuals and groups, based on your operational needs. For example, you can set the `work_mem` parameter to 8 GB for the role named `dev_team`.

```
postgres=> ALTER ROLE dev_team SET work_mem='8GB';
```

With this setting for `work_mem`, any role that's a member of the `dev_team` role is allotted up to 8 GB of working memory.

## Using indexes for faster response time

If your queries are taking too long to return results, you can verify that your indexes are being used as expected. First, turn on `\timing`, the `psql` metacommand, as follows.

```
postgres=> \timing on
```

After turning on timing, use a simple `SELECT` statement.

```
postgres=> SELECT COUNT(*) FROM
  (SELECT * FROM pgbench_accounts
   ORDER BY bid)
 AS accounts;
count
-----
5000000
(1 row)
Time: 3119.049 ms (00:03.119)
```

As shown in the output, this query took just over 3 seconds to complete. To improve the response time, create an index on `pgbench_accounts`, as follows.

```
postgres=> CREATE INDEX ON pgbench_accounts(bid);
CREATE INDEX
```

Rerun the query, and notice the faster response time. In this example, the query completed about 5 times faster, in about half a second.

```
postgres=> SELECT COUNT(*) FROM (SELECT * FROM pgbench_accounts ORDER BY bid) AS
accounts;
count
```

```

-----
 5000000
(1 row)
Time: 567.095 ms

```

## Adjusting working memory for logical decoding

Logical replication has been available in all versions of Aurora PostgreSQL since its introduction in PostgreSQL version 10. When you configure logical replication, you can also set the `logical_decoding_work_mem` parameter to specify the amount of memory that the logical decoding process can use for the decoding and streaming process.

During logical decoding, write-ahead log (WAL) records are converted to SQL statements that are then sent to another target for logical replication or another task. When a transaction is written to the WAL and then converted, the entire transaction must fit into the value specified for `logical_decoding_work_mem`. By default, this parameter is set to 65536 KB. Any overflow is written to disk. This means that it must be reread from the disk before it can be sent to its destination, thus slowing the overall process.

You can assess the amount of transaction overflow in your current workload at a specific point in time by using the `aurora_stat_file` function as shown in the following example.

```

SELECT split_part (filename, '/', 2)
       AS slot_name, count(1) AS num_spill_files,
       sum(used_bytes) AS slot_total_bytes,
       pg_size_pretty(sum(used_bytes)) AS slot_total_size
FROM aurora_stat_file()
WHERE filename like '%spill%'
GROUP BY 1;
 slot_name | num_spill_files | slot_total_bytes | slot_total_size
-----+-----+-----+-----
 slot_name |           590   | 411600000       | 393 MB
(1 row)

```

This query returns the count and size of spill files on your Aurora PostgreSQL DB cluster when the query is invoked. Longer running workloads might not have any spill files on disk yet. To profile long-running workloads, we recommend that you create a table to capture the spill file information as the workload runs. You can create the table as follows.

```
CREATE TABLE spill_file_tracking AS
```

```
SELECT now() AS spill_time,*
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';
```

To see how spill files are used during logical replication, set up a publisher and subscriber and then start a simple replication. For more information, see [Setting up logical replication for your Aurora PostgreSQL DB cluster](#). With replication under way, you can create a job that captures the result set from the `aurora_stat_file()` spill file function, as follows.

```
INSERT INTO spill_file_tracking
SELECT now(),*
FROM aurora_stat_file()
WHERE filename LIKE '%spill%';
```

Use the following `psql` command to run the job once per second.

```
\watch 0.5
```

As the job is running, connect to the writer instance from another `psql` session. Use the following series of statements to run a workload that exceeds the memory configuration and causes Aurora PostgreSQL to create a spill file.

```
labdb=> CREATE TABLE my_table (a int PRIMARY KEY, b int);
CREATE TABLE
labdb=> INSERT INTO my_table SELECT x,x FROM generate_series(0,10000000) x;
INSERT 0 10000001
labdb=> UPDATE my_table SET b=b+1;
UPDATE 10000001
```

These statements take several minutes to complete. When finished, press the Ctrl key and the C key together to stop the monitoring function. Then use the following command to create a table to hold the information about the Aurora PostgreSQL DB cluster's spill file usage.

```
SELECT spill_time, split_part (filename, '/', 2)
AS slot_name, count(1)
AS spills, sum(used_bytes)
AS slot_total_bytes, pg_size_pretty(sum(used_bytes))
AS slot_total_size FROM spill_file_tracking
GROUP BY 1,2 ORDER BY 1;
```

```

                spill_time | slot_name           | spills | slot_total_bytes |
slot_total_size
-----+-----+-----+-----
+-----
2022-04-15 13:42:52.528272+00 | replication_slot_name | 1      | 142352280        | 136
MB
2022-04-15 14:11:33.962216+00 | replication_slot_name | 4      | 467637996        | 446
MB
2022-04-15 14:12:00.997636+00 | replication_slot_name | 4      | 569409176        | 543
MB
2022-04-15 14:12:03.030245+00 | replication_slot_name | 4      | 569409176        | 543
MB
2022-04-15 14:12:05.059761+00 | replication_slot_name | 5      | 618410996        | 590
MB
2022-04-15 14:12:07.22905+00  | replication_slot_name | 5      | 640585316        | 611
MB
(6 rows)

```

The output shows that running the example created five spill files that used 611 MB of memory. To avoid writing to disk, we recommend setting the `logical_decoding_work_mem` parameter to the next highest memory size, 1024.

## Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL

Aurora automatically sends metric data to CloudWatch in 1-minute periods. You can analyze resource usage for Aurora PostgreSQL using CloudWatch metrics. You can evaluate the network throughput and the network usage with the metrics.

### Evaluating network throughput with CloudWatch

When your system usage approaches the resource limits for your instance type, the processing can slow down. You can use CloudWatch **Logs Insights** to monitor your storage resource usage and ensure that sufficient resources are available. When needed, you can modify the DB instance to a larger instance class.

Aurora storage processing may be slow because of:

- Insufficient network bandwidth between the client and DB instance.
- Insufficient network bandwidth to the storage subsystem.

- A workload that is large for your instance type.

You can query CloudWatch **Logs Insights** to generate a graph of Aurora storage resource usage to monitor the resources. The graph shows the CPU utilization and metrics to help you decide whether to scale up to a larger instance size. For information about the query syntax for CloudWatch **Logs Insights**, see [CloudWatch Logs Insights query syntax](#)

To use CloudWatch, you need to export your Aurora PostgreSQL log files to CloudWatch. You can also modify your existing cluster to export logs to CloudWatch. For information about exporting logs to CloudWatch, see [Turning on the option to publish logs to Amazon CloudWatch](#).

You need the **Resource ID** of your DB instance to query the CloudWatch **Logs Insights**. The **Resource ID** is available in the **Configuration** tab in your console:

The screenshot shows the Amazon Aurora console Configuration tab for a DB instance. The instance details are as follows:

Configuration	Instance class	Storage	Performance Insights
DB instance ID bbf-instance-1	Instance class db.serverless	Encryption Enabled	Performance Insights enabled Turned on
Engine version 13.6	vCPU -	KMS key aws/rds	KMS key aws/rds
DB name -	RAM 0 GB	Storage type	Retention period 7 days
Option groups default:aurora-postgresql-13 In sync	Availability		Database activity stream
Amazon Resource Name (ARN) arn:aws:rds:us-east-1:035920430668:db:bbf-instance-1	Fallover priority 1		Status KMS key aws/rds
<b>Resource ID</b> db-PEPQNGT75VIYGKBUFU5A34JIRA			Kinesis data stream -
Created time Mon Sep 26 2022 14:05:25 GMT-0400 (Eastern Daylight Time)			
Parameter group default:aurora-postgresql13 In sync			

### To query your log files for resource storage metrics:

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.

The CloudWatch overview home page appears.

2. If necessary, change the Amazon Web Services Region. In the navigation bar, choose the Amazon Web Services Region where your Amazon resources are located. For more information, see [Regions and endpoints](#).
3. In the navigation pane, choose **Logs** and then **Logs Insights**.

The **Logs Insights** page appears.

- Select the log files from the drop-down list to analyze.
- Enter the following query in the field, replacing <resource ID> with the resource ID of your DB cluster:

```
filter @logStream = <resource ID> | parse @message "\"Aurora Storage Daemon\"*memoryUsedPc\":*,\"cpuUsedPc\":*,\" as a,memoryUsedPc,cpuUsedPc
| display memoryUsedPc,cpuUsedPc #| stats avg(xcpu) as avgCpu by
bin(5m) | limit 10000
```

- Click **Run query**.

The storage utilization graph is displayed.

The following image provides the **Logs Insights** page and the graph display.

The screenshot displays the Amazon CloudWatch Logs Insights interface. At the top, the title is "Logs Insights" with a subtitle "Select log groups, and then run a query or choose a sample query." There are time range filters: 5m, 30m, 1h (selected), 3h, 12h, and Custom. A dropdown menu shows "RDSOSMetrics" selected. The query editor contains the following query:

```
1 filter @LogStream = 'db-5T2GJC'
2 | parse processList.2 "name\":" as name
3 | parse processList.2 "cpuUsedPc\":" as xcpu
4 #| stats avg(xcpu) as avgCpu by bin(5m)
5 | limit 10000
```

Buttons for "Run query", "Save", and "History" are visible. Below the query editor, it states "Queries are allowed to run for up to 15 minutes." The interface has tabs for "Logs" and "Visualization". On the right, there are buttons for "Export results", "Add to dashboard", and a settings icon. The main area shows a histogram with the text "Showing 59 of 59 records matched" and "410 records (5.1 MB) scanned in 2.8s @ 148 records/s (1.9 MB/s)". The x-axis represents time from 12:45 to 01:45. Below the histogram is a table of results:

#	name	xcpu
▶ 1	"Aurora Storage Daemon"	0.07
▶ 2	"Aurora Storage Daemon"	0.06
▶ 3	"Aurora Storage Daemon"	0.06
▶ 4	"Aurora Storage Daemon"	0.06
▶ 5	"Aurora Storage Daemon"	0.06
▶ 6	"Aurora Storage Daemon"	0.07

## Evaluating DB instance usage for Aurora PostgreSQL with CloudWatch metrics

You can use CloudWatch metrics to watch your instance throughput and discover if your instance class provides sufficient resources for your applications. For information about your DB instance class limits, go to [Hardware specifications for DB instance classes for Aurora](#) and locate the specifications for your DB instance class to find your network performance.

If your DB instance usage is near the instance class limit, then performance may begin to slow. The CloudWatch metrics can confirm this situation so you can plan to manually scale-up to a larger instance class.

Combine the following CloudWatch metrics values to find out if you are nearing the instance class limit:

- **NetworkThroughput** – The amount of network throughput received and transmitted by the clients for each instance in the Aurora DB cluster. This throughput value doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **StorageNetworkThroughput** – The amount of network throughput received and sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.

Add the **NetworkThroughput** to the **StorageNetworkThroughput** to find the network throughput received from and sent to the Aurora storage subsystem by each instance in your Aurora DB cluster. The instance class limit for your instance should be greater than the sum of these two combined metrics.

You can use the following metrics to review additional details of the network traffic from your client applications when sending and receiving:

- **NetworkReceiveThroughput** – The amount of network throughput received from clients by each instance in the Aurora PostgreSQL DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **NetworkTransmitThroughput** – The amount of network throughput sent to clients by each instance in the Aurora DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.
- **StorageNetworkReceiveThroughput** – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.
- **StorageNetworkTransmitThroughput** – The amount of network throughput sent to the Aurora storage subsystem by each instance in the DB cluster.

Add all of these metrics together to evaluate how your network usage compares to the instance class limit. The instance class limit should be greater than the sum of these combined metrics.

The network limits and CPU utilization for storage are mutual. When the network throughput increases, then the CPU utilization also increases. Monitoring the CPU and network usage provides information about how and why the resources are being exhausted.

To help minimize network usage, you can consider:

- Using a larger instance class.
- Using `pg_partman` partitioning strategies.
- Dividing the write requests in batches to reduce overall transactions.
- Directing the read-only workload to a read-only instance.
- Deleting any unused indexes.
- Checking for bloated objects and `VACUUM`. In the case of severe bloat, use the PostgreSQL extension `pg_repack`. For more information about `pg_repack`, see [Reorganize tables in PostgreSQL databases with minimal locks](#).

## Using logical replication to perform a major version upgrade for Aurora PostgreSQL

Using logical replication and Aurora fast cloning, you can perform a major version upgrade that uses the current version of Aurora PostgreSQL database while gradually migrating the changing data to the new major version database. This low downtime upgrade process is referred to as a blue/green upgrade. The current version of the database is referred as the "blue" environment and the new database version is referred as the "green" environment.

Aurora fast cloning fully loads the existing data by taking a snapshot of the source database. Fast cloning uses a copy-on-write protocol built on top of the Aurora storage layer, which allows you to create a clone of database in a short time. This method is very effective when upgrading to a large database.

Logical replication in PostgreSQL tracks and transfers your data changes from initial instance to a new instance running in parallel until you move to the newer version of PostgreSQL. Logical replication uses a publish and subscribe model. For more information about Aurora PostgreSQL logical replication, see [Replication with Amazon Aurora PostgreSQL](#).

**Tip**

You can minimize the downtime required for a major version upgrade by using the managed Amazon RDS Blue/Green Deployment feature. For more information, see [Using Amazon Aurora Blue/Green Deployments for database updates](#).

**Topics**

- [Requirements](#)
- [Limitations](#)
- [Setting and checking parameter values](#)
- [Upgrading Aurora PostgreSQL to a new major version](#)
- [Performing post-upgrade tasks](#)

**Requirements**

You must meet the following requirements to perform this low downtime upgrade process:

- You must have `rds_superuser` permissions.
- The Aurora PostgreSQL DB cluster you intend to upgrade must be running a supported version that can perform major version upgrades using logical replication. Make sure to apply any minor version updates and patches to your DB cluster. The `aurora_volume_logical_start_lsn` function that is used in this technique is supported in the following versions of Aurora PostgreSQL:
  - 15.2 and higher 15 versions
  - 14.3 and higher 14 versions
  - 13.6 and higher 13 versions
  - 12.10 and higher 12 versions
  - 11.15 and higher 11 versions
  - 10.20 and higher 10 versions

For more information on `aurora_volume_logical_start_lsn` function, see [aurora\\_volume\\_logical\\_start\\_lsn](#).

- All of your tables must have a primary key or include a [PostgreSQL identity column](#).

- Configure the security group for your VPC to allow inbound and outbound access between the two Aurora PostgreSQL DB clusters, both old and new. You can grant access to a specific classless inter-domain routing (CIDR) range or to another security group in your VPC or in a peer VPC. (Peer VPC requires a VPC peering connection.)

**Note**

For detailed information about the permissions required to configure and manage a running logical replication scenario, see the [PostgreSQL core documentation](#).

## Limitations

When you are performing low downtime upgrade on your Aurora PostgreSQL DB cluster to upgrade it to a new major version, you are using the native PostgreSQL logical replication feature. It has the same capabilities and limitations as the PostgreSQL logical replication. For more information, see [PostgreSQL logical replication](#).

- Data definition language (DDL) commands are not replicated.
- Replication doesn't support schema changes in a live database. The schema is recreated in its original form during the cloning process. If you change the schema after cloning, but before completing the upgrade, it isn't reflected in the upgraded instance.
- Large objects are not replicated, but you can store data in normal tables.
- Replication is only supported by tables, including partitioned tables. Replication to other types of relations, such as views, materialized views, or foreign tables, is not supported.
- Sequence data is not replicated and requires a manual update post-failover.

**Note**

This upgrade doesn't support auto-scripting. You should perform all the steps manually.

## Setting and checking parameter values

Before upgrading, configure the writer instance of your Aurora PostgreSQL DB cluster to act as a publication server. The instance should use a custom DB cluster parameter group with the following settings:

- `rds.logical_replication` – Set this parameter to 1. The `rds.logical_replication` parameter serves the same purpose as a standalone PostgreSQL server's `wal_level` parameter and other parameters that control the write-ahead log file management.
- `max_replication_slots` – Set this parameter to the total number of subscriptions that you plan to create. If you are using Amazon DMS, set this parameter to the number of Amazon DMS tasks that you plan to use for changed data capture from this DB cluster.
- `max_wal_senders` – Set to the number of concurrent connections, plus a few extra, to make available for management tasks and new sessions. If you are using Amazon DMS, the number of `max_wal_senders` should be equal to the number of concurrent sessions plus the number of Amazon DMS tasks that may be working at any given time.
- `max_logical_replication_workers` – Set to the number of logical replication workers and table synchronization workers that you expect. It's generally safe to set the number of replication workers to the same value used for `max_wal_senders`. The workers are taken from the pool of background processes (`max_worker_processes`) allocated for the server.
- `max_worker_processes` – Set to the number of background processes for the server. This number should be large enough to allocate workers for replication, auto-vacuum processes, and other maintenance processes that may take place concurrently.

When you upgrade to a newer version of Aurora PostgreSQL, you need to duplicate any parameters that you modified in the earlier version of the parameter group. These parameters are applied to the upgraded version. You can query the `pg_settings` table to get a list of parameter settings so that you can re-create them on your new Aurora PostgreSQL DB cluster.

For example, to get the settings for replication parameters, run the following query:

```
SELECT name, setting FROM pg_settings WHERE name in
('rds.logical_replication', 'max_replication_slots',
'max_wal_senders', 'max_logical_replication_workers',
'max_worker_processes');
```

## Upgrading Aurora PostgreSQL to a new major version

### To prepare the publisher (blue)

1. In the example that follows, the source writer instance (blue) is an Aurora PostgreSQL DB cluster running PostgreSQL version 11.15. This is the publication node in our replication scenario. For this demonstration, our source writer instance hosts a sample table that holds a series of values:

```
CREATE TABLE my_table (a int PRIMARY KEY);  
INSERT INTO my_table VALUES (generate_series(1,100));
```

2. To create a publication on the source instance, connect to the writer node of the instance with psql (the CLI for PostgreSQL) or with the client of your choice). Enter the following command in each database:

```
CREATE PUBLICATION publication_name FOR ALL TABLES;
```

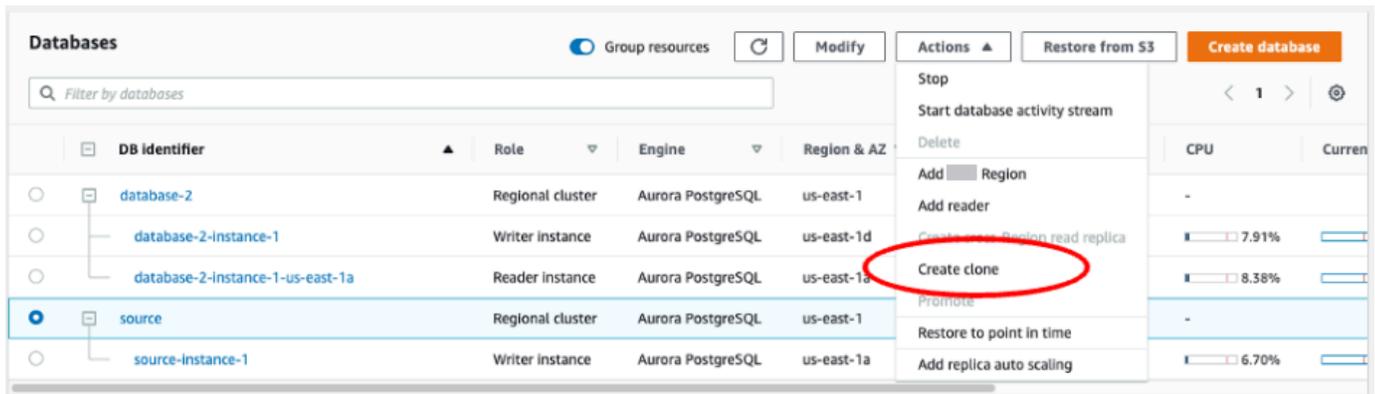

The `publication_name` specifies the name of the publication.

3. You also need to create a replication slot on the instance. The following command creates a replication slot and loads the pgoutput [logical decoding plug-in](#). The plug-in changes content read from write-ahead logging (WAL) to the logical replication protocol, and filters the data according to the publication specification.

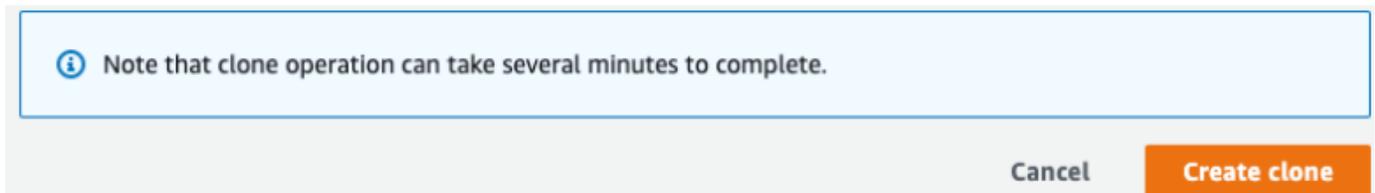

```
SELECT pg_create_logical_replication_slot('replication_slot_name', 'pgoutput');
```

### To clone the publisher

1. Use the Amazon RDS Console to create a clone of the source instance. Highlight the instance name in the Amazon RDS Console, and then choose **Create clone** in the **Actions** menu.

2. Provide a unique name for the instance. Most of the settings are defaults from the source instance. When you've made changes required for the new instance, choose **Create clone**.

3. While the target instance is initiating, the **Status** column of the writer node displays **Creating** in the **Status** column. When the instance is ready, the status changes to **Available**.

### To prepare the clone for an upgrade

1. The clone is the 'green' instance in the deployment model. It is the host of the replication subscription node. When the node becomes available, connect with psql and query the new writer node to obtain the log sequence number (LSN). The LSN identifies the beginning of a record in the WAL stream.

```
SELECT aurora_volume_logical_start_lsn();
```

2. In the response from the query, you find the LSN number. You need this number later in the process, so make a note of it.

```
postgres=> SELECT aurora_volume_logical_start_lsn();
aurora_volume_logical_start_lsn
-----
0/402E2F0
(1 row)
```

3. Before upgrading the clone, drop the clone's replication slot.

```
SELECT pg_drop_replication_slot('replication_slot_name');
```

## To upgrade the cluster to a new major version

- After cloning the provider node, use the Amazon RDS Console to initiate a major version upgrade on the subscription node. Highlight the instance name in the RDS console, and select the **Modify** button. Select the updated version and your updated parameter groups, and apply the settings immediately to upgrade the target instance.

### Modify DB cluster: target-cluster

**Settings**

**DB engine version**  
Version number of the database engine to be used for this database

- Aurora PostgreSQL (Compatible with PostgreSQL 13.6)
- Aurora PostgreSQL (Compatible with PostgreSQL 11.15)
- Aurora PostgreSQL (Compatible with PostgreSQL 12.10)
- Aurora PostgreSQL (Compatible with PostgreSQL 13.6)**

target-cluster

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

- You can also use the CLI to perform an upgrade:

```
aws rds modify-db-cluster --db-cluster-identifier $TARGET_Aurora_ID --engine-version 13.6 --allow-major-version-upgrade --apply-immediately
```

## To prepare the subscriber (green)

1. When the clone becomes available after the upgrade, connect with psql and define the subscription. To do so, you need to specify the following options in the CREATE SUBSCRIPTION command:
  - `subscription_name` – The name of the subscription.
  - `admin_user_name` – The name of an administrative user with `rds_superuser` permissions.

- `admin_user_password` – The password associated with the administrative user.
- `source_instance_URL` – The URL of the publication server instance.
- `database` – The database that the subscription server will connect with.
- `publication_name` – The name of the publication server.
- `replication_slot_name` – The name of the replication slot.

```
CREATE SUBSCRIPTION subscription_name
CONNECTION 'postgres://admin_user_name:admin_user_password@source_instance_URL/
database' PUBLICATION publication_name
WITH (copy_data = false, create_slot = false, enabled = false, connect = true,
slot_name = 'replication_slot_name');
```

2. After creating the subscription, query the [pg\\_replication\\_origin](#) view to retrieve the `roname` value, which is the identifier of the replication origin. Each instance has one `roname`:

```
SELECT * FROM pg_replication_origin;
```

For example:

```
postgres=>
SELECT * FROM pg_replication_origin;

roident | roname
-----+-----
1 | pg_24586
```

3. Provide the LSN that you saved from the earlier query of the publication node and the `roname` returned from the subscription node [INSTANCE] in the command. This command uses the [pg\\_replication\\_origin\\_advance](#) function to specify the starting point in the log sequence for replication.

```
SELECT pg_replication_origin_advance('roname', 'log_sequence_number');
```

`roname` is the identifier returned by the `pg_replication_origin` view.

`log_sequence_number` is the value returned by the earlier query of the `aurora_volume_logical_start_lsn` function.

- Then, use the `ALTER SUBSCRIPTION . . . ENABLE` clause to turn on logical replication.

```
ALTER SUBSCRIPTION subscription_name ENABLE;
```

- At this point, you can confirm that replication is working. Add a value to the publication instance, then confirm that the value is replicated to the subscription node.

Then, use the following command to monitor replication lag on the publication node:

```
SELECT now() AS CURRENT_TIME, slot_name, active, active_pid,
       pg_size_pretty(pg_wal_lsn_diff(pg_current_wal_lsn(),
                                     confirmed_flush_lsn)) AS diff_size, pg_wal_lsn_diff(pg_current_wal_lsn(),
                                     confirmed_flush_lsn) AS diff_bytes FROM pg_replication_slots WHERE slot_type =
       'logical';
```

For example:

```
postgres=> SELECT now() AS CURRENT_TIME, slot_name, active, active_pid,
                pg_size_pretty(pg_wal_lsn_diff(pg_current_wal_lsn(),
                                                confirmed_flush_lsn)) AS diff_size, pg_wal_lsn_diff(pg_current_wal_lsn(),
                                                confirmed_flush_lsn) AS diff_bytes FROM pg_replication_slots WHERE slot_type =
                'logical';
```

```
current_time          | slot_name          | active | active_pid |
diff_size | diff_bytes
-----+-----+-----+-----
+-----+-----
2022-04-13 15:11:00.243401+00 | replication_slot_name | t      | 21854      | 136
bytes | 136
(1 row)
```

You can monitor the replication lag using `diff_size` and `diff_bytes` values. When these values reach 0, the replica has caught up to the source DB instance.

## Performing post-upgrade tasks

When the upgrade is complete, the instance status displays as **Available** in the **Status** column of the console dashboard. On the new instance, we recommend you do the following:

- Redirect your applications to point to the writer node.

- Add reader nodes to manage the caseload and provide high-availability in the event of an issue with the writer node.
- Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in [Collations supported in Aurora PostgreSQL](#).
- Update user permissions on the new instance to ensure access.

After testing your application and data on the new instance, we recommend that you make a final backup of your initial instance before removing it. For more information about using logical replication on an Aurora host, see [Setting up logical replication for your Aurora PostgreSQL DB cluster](#).

## Troubleshooting storage issues in Aurora PostgreSQL

If the amount of working memory needed for sort or index-creation operations exceeds the amount allocated by the `work_mem` parameter, Aurora PostgreSQL writes the excess data to temporary disk files. When it writes the data, Aurora PostgreSQL uses the same storage space that it uses for storing error and message logs, that is, *local storage*. Each instance in your Aurora PostgreSQL DB cluster has an amount of local storage available. The amount of storage is based on its DB instance class. To increase the amount of local storage, you need to modify the instance to use a larger DB instance class. For DB instance class specifications, see [Hardware specifications for DB instance classes for Aurora](#).

You can monitor your Aurora PostgreSQL DB cluster's local storage space by watching the Amazon CloudWatch metric for `FreeLocalStorage`. This metric reports the amount of storage available to each DB instance in the Aurora DB cluster for temporary tables and logs. For more information, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#).

Sorting, indexing, and grouping operations start in working memory but often must be offloaded to local storage. If your Aurora PostgreSQL DB cluster runs out of local storage because of these types of operations, you can resolve the issue by taking one of the following actions.

- Increase the amount of working memory. This reduces the need to use local storage. By default, PostgreSQL allocates 4 MB for each sort, group, and index operation. To check the current working memory value for your Aurora PostgreSQL DB cluster's writer instance, connect to the instance using `psql` and run the following command.

```
postgres=> SHOW work_mem;
```

```
work_mem
-----
 4MB
(1 row)
```

You can increase the working memory at the session level before sort, group, and other operations, as follows.

```
SET work_mem TO '1 GB';
```

For more information about working memory, see [Resource Consumption](#) in the PostgreSQL documentation.

- Change the log retention period so that logs are stored for shorter timeframes. To learn how, see [Aurora PostgreSQL database log files](#).

For Aurora PostgreSQL DB clusters larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes. We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more information, see [DB instance class types](#).

## Replication with Amazon Aurora PostgreSQL

Following, you can find information about replication with Amazon Aurora PostgreSQL, including how to monitor and use logical replication.

### Topics

- [Using Aurora Replicas](#)
- [Improving the read availability of Aurora Replicas](#)
- [Monitoring Aurora PostgreSQL replication](#)
- [Overview of PostgreSQL logical replication with Aurora](#)
- [Setting up logical replication for your Aurora PostgreSQL DB cluster](#)
- [Turning off logical replication](#)

- [Configuring IAM authentication for logical replication connections](#)

## Using Aurora Replicas

An *Aurora Replica* is an independent endpoint in an Aurora DB cluster, best used for scaling read operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located throughout the Availability Zones of the Aurora DB cluster's Amazon Region.

The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary writer DB instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see [Aurora Replicas](#).

Aurora Replicas work well for read scaling because they're fully dedicated to read operations on your cluster volume. The writer DB instance manages write operations. The cluster volume is shared among all instances in your Aurora PostgreSQL DB cluster. Thus, no extra work is needed to replicate a copy of the data for each Aurora Replica.

With Aurora PostgreSQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

Aurora PostgreSQL DB clusters support Aurora Replicas in different Amazon Regions, using Aurora global database. For more information, see [Using Amazon Aurora Global Database](#).

### Note

With the read availability feature, if you want to reboot the Aurora Replicas in the DB cluster, you have to perform it manually. For the DB clusters created prior to this feature rebooting the writer DB instance automatically reboots the Aurora Replicas. The automatic reboot re-establishes an entry point that guarantees read/write consistency across the DB cluster.

## Improving the read availability of Aurora Replicas

Aurora PostgreSQL improves the read availability in the DB cluster by continuously serving the read requests when the writer DB instance restarts or when the Aurora Replica is unable to keep up with the write traffic.

The read availability feature is available by default on the following versions of Aurora PostgreSQL:

- 16.1 and all higher versions
- 15.2 and higher 15 versions
- 14.7 and higher 14 versions
- 13.10 and higher 13 versions
- 12.14 and higher 12 versions

The read availability feature is supported by Aurora global database in the following versions:

- 16.1 and all higher versions
- 15.4 and higher 15 versions
- 14.9 and higher 14 versions
- 13.12 and higher 13 versions
- 12.16 and higher 12 versions

To use the read availability feature for a DB cluster created on one of these versions prior to this launch, restart the writer instance of the DB cluster.

When you modify static parameters of your Aurora PostgreSQL DB cluster, you must restart the writer instance so that the parameter changes take effect. For example, you must restart the writer instance when you set the value of `shared_buffers`. With the read availability feature of Aurora Replicas, the DB cluster maintains improved availability, reducing the impact on it when the writer instance restarts. The reader instances don't restart and continue to respond to the read requests. To apply static parameter changes, reboot each individual reader instance.

An Aurora PostgreSQL DB cluster's Aurora Replica can recover from replication errors such as writer restarts, failover, slow replication, and network issues by quickly recovering to in-memory database state after it reconnects with the writer. This approach allows Aurora Replica instances to reach consistency with the latest storage updates while the client database is still available.

The in-progress transactions that conflict with replication recovery might receive an error but the client can retry these transactions, after the readers catch up with the writer.

## Monitoring Aurora Replicas

You can monitor the Aurora Replicas when recovering from a writer disconnect. Use the metrics below to check for the latest information about the reader instance and to track in-process read-only transactions.

- The `aurora_replica_status` function is updated to return the most up-to-date information for the reader instance when it is still connected. The last update time stamp in `aurora_replica_status` is always empty for the row corresponding to the DB instance that the query is executed on. This indicates that the reader instance has the latest data.
- When the Aurora replica disconnects from the writer instance and reconnects back, the following database event is emitted:

```
Read replica has been disconnected from the writer instance and
reconnected.
```

- When a read-only query is canceled due to a recovery conflict, you might see one or more of the following error messages in the database error log:

```
Canceling statement due to conflict with recovery.
```

```
User query may not have access to page data to replica disconnect.
```

```
User query might have tried to access a file that no longer exists.
```

```
When the replica reconnects, you will be able to repeat your command.
```

## Limitations

The following limitations apply to Aurora Replicas with the read availability feature:

- Aurora Replicas of secondary DB cluster can restart if the data can't be streamed from the writer instance during replication recovery.
- Aurora Replicas don't support online replication recovery if one is already in progress and will restart.
- Aurora Replicas will restart when your DB instance is nearing the transaction ID wraparound. For more information on transaction ID wraparound, see [Preventing Transaction ID Wraparound Failures](#).
- Aurora Replicas can restart when the replication process is blocked under certain circumstances.

## Monitoring Aurora PostgreSQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the writer DB instance of your Aurora PostgreSQL DB cluster by monitoring the Amazon CloudWatch `ReplicaLag` metric. Because Aurora Replicas read from the same cluster volume as the writer DB instance, the `ReplicaLag` metric has a different meaning for an Aurora PostgreSQL DB cluster. The `ReplicaLag` metric for an Aurora Replica indicates the lag for the page cache of the Aurora Replica compared to that of the writer DB instance.

For more information on monitoring RDS instances and CloudWatch metrics, see [Monitoring metrics in an Amazon Aurora cluster](#).

## Overview of PostgreSQL logical replication with Aurora

By using PostgreSQL's logical replication feature with your Aurora PostgreSQL DB cluster, you can replicate and synchronize individual tables rather than the entire database instance. Logical replication uses a publish and subscribe model to replicate changes from a source to one or more recipients. It works by using change records from the PostgreSQL write-ahead log (WAL). The source, or *publisher*, sends WAL data for the specified tables to one or more recipients (*subscriber*), thus replicating the changes and keeping a subscriber's table synchronized with the publisher's table. The set of changes from the publisher are identified using a *publication*. Subscribers get the changes by creating a *subscription* that defines the connection to the publisher's database and its publications. A *replication slot* is the mechanism used in this scheme to track progress of a subscription.

For Aurora PostgreSQL DB clusters, the WAL records are saved on Aurora storage. The Aurora PostgreSQL DB cluster that's acting as the publisher in a logical replication scenario reads the WAL data from Aurora storage, decodes it, and sends it to the subscriber so that the changes can be applied to the table on that instance. The publisher uses a *logical decoder* to decode the data for use by subscribers. By default, Aurora PostgreSQL DB clusters use the native PostgreSQL `pgoutput` plugin when sending data. Other logical decoders are available. For example, Aurora PostgreSQL also supports the [wal2json](#) plugin that converts WAL data to JSON.

As of Aurora PostgreSQL version 14.5, 13.8, 12.12, and 11.17, Aurora PostgreSQL augments the PostgreSQL logical replication process with a *write-through cache* to improve performance. The WAL transaction logs are cached locally, in a buffer, to reduce the amount of disk I/O, that is, reading from Aurora storage during logical decoding. The write-through cache is used by default whenever you use logical replication for your Aurora PostgreSQL DB cluster. Aurora provides

several functions that you can use to manage the cache. For more information, see [Monitoring the Aurora PostgreSQL logical replication write-through cache](#).

Logical replication is supported by all currently available Aurora PostgreSQL versions. For more information, [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

Logical replication is supported by BabelFish for Aurora PostgreSQL from the following versions:

- 15.7 and higher versions
- 16.3 and higher versions

**Note**

In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, Aurora PostgreSQL also supports the `pglogical` extension. For more information, see [Using pglogical to synchronize data across instances](#).

For more information about PostgreSQL logical replication, see [Logical replication](#) and [Logical decoding concepts](#) in the PostgreSQL documentation.

**Note**

PostgreSQL 16 added support for logical decoding from read replicas. This feature isn't supported on Aurora PostgreSQL.

## Setting up logical replication for your Aurora PostgreSQL DB cluster

Setting up logical replication requires `rds_superuser` privileges. Your Aurora PostgreSQL DB cluster must be configured to use a custom DB cluster parameter group so that you can set the necessary parameters as detailed in the procedure following. For more information, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

### To set up PostgreSQL logical replication for an Aurora PostgreSQL DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

2. In the navigation pane, choose your Aurora PostgreSQL DB cluster.
3. Open the **Configuration** tab. Among the Instance details, find the **Parameter group** link with **DB cluster parameter group** for **Type**.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `rds` to find the `rds.logical_replication` parameter. The default value for this parameter is `0`, meaning that it's turned off by default.
6. Choose **Edit parameters** to access the property values, and then choose `1` from the selector to turn on the feature. Depending on your expected usage, you might also need to change the settings for the following parameters. However, in many cases, the default values are sufficient.
  - `max_replication_slots` – Set this parameter to a value that's at least equal to your planned total number of logical replication publications and subscriptions. If you are using Amazon DMS, this parameter should equal at least your planned change data capture tasks from the cluster, plus logical replication publications and subscriptions.
  - `max_wal_senders` and `max_logical_replication_workers` – Set these parameters to a value that's at least equal to the number of logical replication slots that you intend to be active, or the number of active Amazon DMS tasks for change data capture. Leaving a logical replication slot inactive prevents the vacuum from removing obsolete tuples from tables, so we recommend that you monitor replication slots and remove inactive slots as needed.
  - `max_worker_processes` – Set this parameter to a value that's at least equal to the total of the `max_logical_replication_workers`, `autovacuum_max_workers`, and `max_parallel_workers` values. On small DB instance classes, background worker processes can affect application workloads, so monitor the performance of your database if you set `max_worker_processes` higher than the default value. (The default value is the result of `GREATEST({DBInstanceVCPU*2}, 8)`, which means that, by default, this is either 8 or twice the CPU equivalent of the DB instance class, whichever is greater).
7. Choose **Save changes**.

 **Note**

You can modify parameter values in a customer-created DB parameter group. you can't change the parameter values in a default DB parameter group.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes takes effect. In the Amazon RDS console, choose the primary DB instance of the cluster and choose **Reboot** from the **Actions** menu.
9. When the instance is available, you can verify that logical replication is turned on, as follows.
  - a. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=your-db-cluster-instance-1.aws-region.rds.amazonaws.com --port=5432
--username=postgres --password --dbname=labdb
```

- b. Verify that logical replication has been enabled by using the following command.

```
labdb=> SHOW rds.logical_replication;
 rds.logical_replication
-----
 on
(1 row)
```

- c. Verify that the `wal_level` is set to logical.

```
labdb=> SHOW wal_level;
 wal_level
-----
 logical
(1 row)
```

For an example of using logical replication to keep a database table synchronized with changes from a source Aurora PostgreSQL DB cluster, see [Example: Using logical replication with Aurora PostgreSQL DB clusters](#).

## Turning off logical replication

After completing your replication tasks, you should stop the replication process, drop replication slots, and turn off logical replication. Before dropping slots, make sure that they're no longer needed. Active replication slots can't be dropped.

### To turn off logical replication

1. Drop all replication slots.

To drop all of the replication slots, connect to the publisher and run the following SQL command.

```
SELECT pg_drop_replication_slot(slot_name)
FROM pg_replication_slots
WHERE slot_name IN (SELECT slot_name FROM pg_replication_slots);
```

The replication slots can't be active when you run this command.

2. Modify the custom DB cluster parameter group associated with the publisher as detailed in [Setting up logical replication for your Aurora PostgreSQL DB cluster](#), but set the `rds.logical_replication` parameter to 0.

For more information about custom parameter groups, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

3. Restart the publisher Aurora PostgreSQL DB cluster for the change to the `rds.logical_replication` parameter to take effect.

## Monitoring the write-through cache and logical slots for Aurora PostgreSQL logical replication

Monitor the logical replication write-through cache and manage logical slots to improve performance for your Aurora PostgreSQL DB cluster. Following, find more information about the write-through cache and logical slots.

### Topics

- [Monitoring the Aurora PostgreSQL logical replication write-through cache](#)
- [Managing logical slots for Aurora PostgreSQL](#)

## Monitoring the Aurora PostgreSQL logical replication write-through cache

By default, Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 and higher use a write-through cache to improve the performance for logical replication. Without the write-through cache, Aurora PostgreSQL uses the Aurora storage layer in its implementation of the native PostgreSQL logical replication process. It does so by writing WAL data to storage and then reading

the data back from storage to decode it and send (replicate) to its targets (subscribers). This can result in bottlenecks during logical replication for Aurora PostgreSQL DB clusters.

The write-through cache minimizes reliance on the Aurora storage layer. Instead of consistently writing to and reading from this layer, Aurora PostgreSQL uses a buffer to cache the logical WAL stream for use during the replication process, reducing the need to access disk. This buffer is the native PostgreSQL cache used in logical replication and is identified in Aurora PostgreSQL DB cluster parameters as `rds.logical_wal_cache`.

When you use logical replication with your Aurora PostgreSQL DB cluster (for the versions that support the write-through cache), you can monitor the cache hit ratio to see how well it's working for your use case. To do so, connect to your Aurora PostgreSQL DB cluster's write instance using `psql` and then use the Aurora function, `aurora_stat_logical_wal_cache`, as shown in the following example.

```
SELECT * FROM aurora_stat_logical_wal_cache();
```

The function returns output such as the following.

name	active_pid	cache_hit	cache_miss	blks_read	hit_rate	last_reset_timestamp
test_slot1	79183	24	0	24	100.00%	2022-08-05 17:39...
test_slot2		1	0	1	100.00%	2022-08-05 17:34...

(2 rows)

The `last_reset_timestamp` values have been shortened for readability. For more information about this function, see [aurora\\_stat\\_logical\\_wal\\_cache](#).

Aurora PostgreSQL provides the following two functions for monitoring the write-through cache.

- The `aurora_stat_logical_wal_cache` function – For reference documentation, see [aurora\\_stat\\_logical\\_wal\\_cache](#).
- The `aurora_stat_reset_wal_cache` function – For reference documentation, see [aurora\\_stat\\_reset\\_wal\\_cache](#).

If you find that the automatically adjusted WAL cache size isn't sufficient for your workloads, you can change the value of the `rds.logical_wal_cache` manually. Consider the following:

- When the `rds.logical_replication` parameter is disabled, `rds.logical_wal_cache` is set to zero (0).
- When the `rds.logical_replication` parameter is enabled, `rds.logical_wal_cache` has a default value of 16 MB.
- The `rds.logical_wal_cache` parameter is static and requires a database instance reboot for changes to take effect. This parameter is defined in terms of 8 Kb blocks. Note that any positive value less than 32 Kb is treated as 32 Kb. For more information about `wal_buffers` see [Write Ahead Log](#) in the PostgreSQL documentation.

## Managing logical slots for Aurora PostgreSQL

Streaming activity is captured in the `pg_replication_origin_status` view. To see the contents of this view, you can use the `pg_show_replication_origin_status()` function, as shown following:

```
SELECT * FROM pg_show_replication_origin_status();
```

You can get a list of your logical slots by using the following SQL query.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the `pg_drop_replication_slot` with the name of the slot, as shown in the following command.

```
SELECT pg_drop_replication_slot('test_slot');
```

## Example: Using logical replication with Aurora PostgreSQL DB clusters

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. Both the publisher and the subscriber must be configured for logical replication as detailed in [Setting up logical replication for your Aurora PostgreSQL DB cluster](#).

The Aurora PostgreSQL DB cluster that's the designated publisher must also allow access to the replication slot. To do so, modify the security group associated with the Aurora PostgreSQL DB

cluster's virtual public cloud (VPC) based on the Amazon VPC service. Allow inbound access by adding the security group associated with the subscriber's VPC to the publisher's security group. For more information, see [Control traffic to resources using security groups](#) in the *Amazon VPC User Guide*.

With these preliminary steps complete, you can use PostgreSQL commands CREATE PUBLICATION on the publisher and the CREATE SUBSCRIPTION on the subscriber, as detailed in the following procedure.

## To start the logical replication process between two Aurora PostgreSQL DB clusters

These steps assume that your Aurora PostgreSQL DB clusters have a writer instance with a database in which to create the example tables.

### 1. On the publisher Aurora PostgreSQL DB cluster

- a. Create a table using the following SQL statement.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

- b. Insert data into the publisher database by using the following SQL statement.

```
INSERT INTO LogicalReplicationTest VALUES (generate_series(1,10000));
```

- c. Verify that data exists in the table by using the following SQL statement.

```
SELECT count(*) FROM LogicalReplicationTest;
```

- d. Create a publication for this table by using the CREATE PUBLICATION statement, as follows.

```
CREATE PUBLICATION testpub FOR TABLE LogicalReplicationTest;
```

### 2. On the subscriber Aurora PostgreSQL DB cluster

- a. Create the same LogicalReplicationTest table on the subscriber that you created on the publisher, as follows.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

- b. Verify that this table is empty.

```
SELECT count(*) FROM LogicalReplicationTest;
```

- c. Create a subscription to get the changes from the publisher. You need to use the following details about the publisher Aurora PostgreSQL DB cluster.
- **host** – The publisher Aurora PostgreSQL DB cluster's writer DB instance.
  - **port** – The port on which the writer DB instance is listening. The default for PostgreSQL is 5432.
  - **dbname** – The name of the database.

```
CREATE SUBSCRIPTION testsub CONNECTION
  'host=publisher-cluster-writer-endpoint port=5432 dbname=db-name user=user
  password=password'
  PUBLICATION testpub;
```

 **Note**

Specify a password other than the prompt shown here as a security best practice.

After the subscription is created, a logical replication slot is created at the publisher.

- d. To verify for this example that the initial data is replicated on the subscriber, use the following SQL statement on the subscriber database.

```
SELECT count(*) FROM LogicalReplicationTest;
```

Any further changes on the publisher are replicated to the subscriber.

Logical replication affects performance. We recommend that you turn off logical replication after your replication tasks are complete.

## Example: Logical replication using Aurora PostgreSQL and Amazon Database Migration Service

You can use the Amazon Database Migration Service (Amazon DMS) to replicate a database or a portion of a database. Use Amazon DMS to migrate your data from an Aurora PostgreSQL database

to another open source or commercial database. For more information about Amazon DMS, see the [Amazon Database Migration Service User Guide](#).

The following example shows how to set up logical replication from an Aurora PostgreSQL database as the publisher and then use Amazon DMS for migration. This example uses the same publisher and subscriber that were created in [Example: Using logical replication with Aurora PostgreSQL DB clusters](#).

To set up logical replication with Amazon DMS, you need details about your publisher and subscriber from Amazon RDS. In particular, you need details about the publisher's writer DB instance and the subscriber's DB instance.

Get the following information for the publisher's writer DB instance:

- The virtual private cloud (VPC) identifier
- The subnet group
- The Availability Zone (AZ)
- The VPC security group
- The DB instance ID

Get the following information for the subscriber's DB instance:

- The DB instance ID
- The source engine

### **To use Amazon DMS for logical replication with Aurora PostgreSQL**

1. Prepare the publisher database to work with Amazon DMS.

To do this, PostgreSQL 10.x and later databases require that you apply Amazon DMS wrapper functions to the publisher database. For details on this and later steps, see the instructions in [Using PostgreSQL version 10.x and later as a source for Amazon DMS](#) in the *Amazon Database Migration Service User Guide*.

2. Sign in to the Amazon Web Services Management Console and open the Amazon DMS console at <https://console.amazonaws.cn/dms/v2>. At top right, choose the same Amazon Region in which the publisher and subscriber are located.
3. Create an Amazon DMS replication instance.

Choose values that are the same as for your publisher's writer DB instance. These include the following settings:

- For **VPC**, choose the same VPC as for the writer DB instance.
  - For **Replication Subnet Group**, choose a subnet group with the same values as the writer DB instance. Create a new one if necessary.
  - For **Availability zone**, choose the same zone as for the writer DB instance.
  - For **VPC Security Group**, choose the same group as for the writer DB instance.
4. Create an Amazon DMS endpoint for the source.

Specify the publisher as the source endpoint by using the following settings:

- For **Endpoint type**, choose **Source endpoint**.
  - Choose **Select RDS DB Instance**.
  - For **RDS Instance**, choose the DB identifier of the publisher's writer DB instance.
  - For **Source engine**, choose **postgres**.
5. Create an Amazon DMS endpoint for the target.

Specify the subscriber as the target endpoint by using the following settings:

- For **Endpoint type**, choose **Target endpoint**.
  - Choose **Select RDS DB Instance**.
  - For **RDS Instance**, choose the DB identifier of the subscriber DB instance.
  - Choose a value for **Source engine**. For example, if the subscriber is an RDS PostgreSQL database, choose **postgres**. If the subscriber is an Aurora PostgreSQL database, choose **aurora-postgresql**.
6. Create an Amazon DMS database migration task.

You use a database migration task to specify what database tables to migrate, to map data using the target schema, and to create new tables on the target database. At a minimum, use the following settings for **Task configuration**:

- For **Replication instance**, choose the replication instance that you created in an earlier step.
- For **Source database endpoint**, choose the publisher source that you created in an earlier step.

- For **Target database endpoint**, choose the subscriber target that you created in an earlier step.

The rest of the task details depend on your migration project. For more information about specifying all the details for DMS tasks, see [Working with Amazon DMS tasks](#) in the *Amazon Database Migration Service User Guide*.

After Amazon DMS creates the task, it begins migrating data from the publisher to the subscriber.

## Configuring IAM authentication for logical replication connections

Starting with Aurora PostgreSQL versions 11 and higher, you can use Amazon Identity and Access Management (IAM) authentication for replication connections. This feature enhances security by allowing you to manage database access using IAM roles instead of passwords. It works at the cluster level and follows the same security model as standard IAM authentication.

IAM authentication for replication connections is an opt-in feature. To enable it, set the `rds.iam_auth_for_replication` parameter to 1 in your DB cluster parameter group. As this is a dynamic parameter, your DB cluster doesn't need to restart, enabling you to leverage IAM authentication with existing workloads without downtime. Before enabling this feature, you must meet the [Prerequisites](#) listed below.

### Prerequisites

To use IAM authentication for replication connections, you need to meet all of the following requirements:

- Your Aurora PostgreSQL DB cluster must be version 11 or later.
- On your publisher Aurora PostgreSQL DB cluster:
  - Enable IAM database authentication.

For more information, see [Enabling and disabling IAM database authentication](#).

- Enable logical replication by setting the `rds.logical_replication` parameter to 1.

For more information, see [Setting up logical replication for your Aurora PostgreSQL DB cluster](#).

In logical replication, the publisher is the source Aurora PostgreSQL DB cluster that sends data to subscriber clusters. For more information, see [Overview of PostgreSQL logical replication with Aurora](#).

### Note

Both IAM authentication and logical replication must be enabled on your publisher Aurora PostgreSQL DB cluster. If either one isn't enabled, you can't use IAM authentication for replication connections.

## Enabling IAM authentication for replication connections

Complete the following steps to enable IAM authentication for replication connection.

1. Verify that your Aurora PostgreSQL DB cluster meets all prerequisites for IAM authentication with replication connections. For details, see [Prerequisites](#).
2. Configure the `rds.iam_auth_for_replication` parameter by modifying your DB cluster parameter group:
  - Set the `rds.iam_auth_for_replication` parameter to 1. This dynamic parameter doesn't require a reboot.
3. Connect to your database and grant the necessary roles to your replication user:

The following SQL commands grant the necessary roles to enable IAM authentication for replication connections:

```
-- Grant IAM authentication role
GRANT rds_iam TO replication_user_name;
-- Grant replication privileges
ALTER USER replication_user_name WITH REPLICATION;
```

After you complete these steps, the specified user must use IAM authentication for replication connections.

**⚠ Important**

When you enable the feature, users with both `rds_iam` and `rds_replication` roles must use IAM authentication for replication connections. This applies whether the roles are assigned directly to the user or inherited through other roles.

## Disabling IAM authentication for replication connections

You can disable IAM authentication for replication connections by using any of the following methods:

- Set the `rds.iam_auth_for_replication` parameter to `0` in your DB cluster parameter group
- Alternatively, you can disable either of these features on your Aurora PostgreSQL DB cluster:
  - Disable logical replication by setting the `rds.logical_replication` parameter to `0`
  - Disable IAM authentication

When you disable the feature, replication connections can use database passwords for authentication if configured.

**📘 Note**

Replication connections for users without the `rds_iam` role can use password authentication even when the feature is enabled.

## Limitations and considerations

The following limitations and considerations apply when using IAM authentication for replication connections.

- IAM authentication for replication connections is only available for Aurora PostgreSQL versions 11 and higher.
- The publisher must support IAM authentication for replication connections.
- The IAM authentication token expires after 15 minutes by default. You might need to refresh long-running replication connections before the token expires.

# Local write forwarding in Aurora PostgreSQL

*Local (in-cluster) write forwarding* allows your applications to issue read/write transactions directly on an Aurora Replica. The write commands are then forwarded to the writer DB instance to be committed. You can use local write forwarding for your applications that have occasional writes and require *read-after-write consistency*, which is the ability to read the latest write in a transaction.

Without write forwarding, your applications must fully split all read and write traffic, maintaining two sets of database connections to send the traffic to the appropriate endpoint. Read replicas receive updates asynchronously from the writer instance. In addition, because replication lag can differ among read replicas, achieving global read consistency across all replicas is difficult. You must transact any reads requiring read-after-write consistency on the writer database instance. Alternatively, you would need to develop complex custom application logic to take advantage of multiple read replicas for scalability while ensuring consistency.

With write forwarding, you avoid the need to split those transactions or send them exclusively to the writer instance. You also don't have to develop complex application logic to achieve *read-after-write consistency*.

Local write forwarding is available in every Region where Aurora PostgreSQL is available. It is supported in the following Aurora PostgreSQL versions:

- 16.4 and higher 16 versions
- 15.8 and higher 15 versions
- 14.13 and higher 14 versions

Local write forwarding is used to forward writes from in-Region replicas. To forward writes from a global replica, see [Using write forwarding in an Amazon Aurora global database](#).

## Topics

- [Limitations and considerations of local write forwarding in Aurora PostgreSQL](#)
- [Configuring Aurora PostgreSQL for Local write forwarding](#)
- [Working with local write forwarding for Aurora PostgreSQL](#)
- [Monitoring local write forwarding in Aurora PostgreSQL](#)

## Limitations and considerations of local write forwarding in Aurora PostgreSQL

The following limitations currently apply to local write forwarding in Aurora PostgreSQL:

- Local write forwarding is not supported with RDS Proxy.
- Certain statements aren't allowed or can produce stale results when you use them in Aurora PostgreSQL with write forwarding. In addition, user defined functions and user defined procedures aren't supported. Thus, the `EnableLocalWriteForwarding` setting is turned off by default for DB clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.
- The following kinds of SQL statements aren't supported with write forwarding:

### Note

These statements can be implicitly used by you in your application or inferred by the PostgreSQL protocol. For example, PL/SQL exception handling can result in the use of `SAVEPOINT`, which is not a supported statement.

- ANALYZE
- CLUSTER
- COPY
- Cursors – Cursors aren't supported, so make sure to close them before using local write forwarding.
- Data definition language (DDL) statements
- GRANT|REVOKE|REASSIGN OWNED|SECURITY LABEL
- LISTEN / NOTIFY
- LOCK
- SAVEPOINT
- SELECT INTO
- SET CONSTRAINTS
- Sequence updates: `nextval()`, `setval()`

### • TRUNCATE

- Two-phase commit commands: `PREPARE TRANSACTION`, `COMMIT PREPARED`, `ROLLBACK PREPARED`
- User defined functions and user defined procedures.
- `VACUUM`

You can consider using the following SQL statements with write forwarding:

- A DML statement might consist of multiple parts, such as an `INSERT . . . SELECT` statement or a `DELETE . . . WHERE` statement. In this case, the entire statement is forwarded to the writer DB instance and run there.
- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`.
- `EXPLAIN` statements with the statements in this list.
- `PREPARE` and `EXECUTE` statements.
- `SELECT FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE }` statements.

## Configuring Aurora PostgreSQL for Local write forwarding

Using the following sections, you can enable local write forwarding for your Amazon Aurora PostgreSQL DB cluster, configuring consistency levels, and managing transactions with write forwarding.

### Enabling local write forwarding

By default, local write forwarding isn't enabled for Aurora PostgreSQL DB clusters. You enable local write forwarding at the cluster level, not at the instance level.

#### Console

Using the Amazon Web Services Management Console, select the **Turn on local write forwarding** check box under **Read replica write forwarding** when you create or modify a DB cluster.

#### Amazon CLI

To enable local write forwarding with the Amazon CLI, use the `--enable-local-write-forwarding` option. This option works when you create a new DB cluster using the `create-db-cluster` command. It also works when you modify an existing DB cluster using the `modify-db-`

cluster command. You can disable local write forwarding by using the `--no-enable-local-write-forwarding` option with these same CLI commands.

The following example creates an Aurora PostgreSQL DB cluster with local write forwarding enabled.

```
aws rds create-db-cluster \  
--db-cluster-identifier write-forwarding-test-cluster \  
--enable-local-write-forwarding \  
--engine aurora-postgresql \  
--engine-version 16.4 \  
--master-username myuser \  
--master-user-password mypassword \  
--backup-retention 1
```

You then create writer and reader DB instances so that you can use write forwarding. For more information, see [Creating an Amazon Aurora DB cluster](#).

## RDS API

To enable local write forwarding using the Amazon RDS API, set the `EnableLocalWriteForwarding` parameter to `true`. This parameter works when you create a new DB cluster using the `CreateDBCluster` operation. It also works when you modify an existing DB cluster using the `ModifyDBCluster` operation. You can disable local write forwarding by setting the `EnableLocalWriteForwarding` parameter to `false`.

## Enabling local write forwarding for database sessions

The `apg_write_forward.consistency_mode` parameter is a DB parameter and DB cluster parameter that enables write forwarding. You can specify `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF` for the read consistency level. To learn more about consistency levels, see [Consistency and isolation for local write forwarding in Aurora PostgreSQL](#).

The following rules apply to this parameter:

- The default value is `SESSION`.
- Local write forwarding is available only if you set `apg_write_forward.consistency_mode` to `EVENTUAL`, `SESSION`, or `GLOBAL`. This parameter is relevant only in reader instances of DB clusters that have local write forwarding enabled.

- Setting the value to OFF disables local write forwarding in the session.

## Consistency and isolation for local write forwarding in Aurora PostgreSQL

You can control the degree of read consistency on a read replica. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the read replica before any subsequent queries. You can also use this setting to ensure that queries on the read replica always see the most current updates from the writer DB instance. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose the appropriate value for the session-level parameter `apg_write_forward.consistency_mode`. The `apg_write_forward.consistency_mode` parameter has an effect only on read replicas that have local write forwarding enabled.

### Note

For the `apg_write_forward.consistency_mode` parameter, you can specify the value `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF`. By default, the value is set to `SESSION`. Setting the value to `OFF` disables write forwarding.

As you increase the consistency level, your application spends more time waiting for changes to be propagated to read replicas. You can choose the balance between lower latency and ensuring that changes made in other locations are fully available before your queries run.

With each available consistency mode setting, the effect is as follows:

- `SESSION` – A session on a read replica that uses local write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current reader DB instance. It doesn't wait for updated results from write operations performed in other sessions within the current DB cluster.
- `EVENTUAL` – A session on a read replica that uses local write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the writer DB instance and replicated to the read replica. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

- GLOBAL – A session on a read replica sees changes made by that session. It also sees all committed changes from both the writer DB instance and other read replicas. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the read replica is up-to-date with all committed data from the writer DB instance, as of the time that the query began.

**Note**

The global consistency mode impacts the latency of queries executed within a session. It will perform a wait even when the session has not sent any write queries.

- OFF – Local write forwarding is disabled.

In sessions that use write forwarding, you can use the REPEATABLE READ and READ COMMITTED isolation levels. However, the SERIALIZABLE isolation level isn't supported.

For more information about all the parameters involved with write forwarding, see [Default parameter settings for write forwarding](#).

## Transaction access modes with write forwarding

If the transaction access mode is set to read only, local write forwarding isn't used. You can set the access mode to read write only while you're connected to a DB cluster and session that has local write forwarding enabled.

For more information on the transaction access modes, see [SET TRANSACTION](#).

## Working with local write forwarding for Aurora PostgreSQL

Using the following sections, you can check if a database cluster has local write forwarding enabled, view compatibility considerations, and see configurable parameters and authentication setup. This information equips you with the details to utilize local write forwarding feature in Aurora PostgreSQL effectively.

**Note**

When a writer instance in a cluster using local write forwarding is restarted, any active, forwarded transactions and queries on reader instances using local write forwarding

are automatically closed. After the writer instance is available again, you can retry these transactions.

## Checking if a DB cluster has local write forwarding enabled

To determine that you can use local write forwarding in a DB cluster, confirm that the cluster has the attribute `LocalWriteForwardingStatus` set to `enabled`.

In the Amazon Web Services Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Local read replica write forwarding**.

To see the status of the local write forwarding setting for all of your clusters, run the following Amazon CLI command.

### Example

```
aws rds describe-db-clusters \
--query '*[*].
{DBClusterIdentifier:DBClusterIdentifier,LocalWriteForwardingStatus:LocalWriteForwardingStatus}

[
{
"LocalWriteForwardingStatus": "enabled",
"DBClusterIdentifier": "write-forwarding-test-cluster-1"
},
{
"LocalWriteForwardingStatus": "disabled",
"DBClusterIdentifier": "write-forwarding-test-cluster-2"
},
{
"LocalWriteForwardingStatus": "requested",
"DBClusterIdentifier": "test-global-cluster-2"
},
{
"LocalWriteForwardingStatus": "null",
"DBClusterIdentifier": "aurora-postgresql-v2-cluster"
}
]
```

A DB cluster can have the following values for `LocalWriteForwardingStatus`:

- `disabled` – Local write forwarding is disabled.
- `disabling` – Local write forwarding is in the process of being disabled.
- `enabled` – Local write forwarding is enabled.
- `enabling` – Local write forwarding is in the process of being enabled.
- `null` – Local write forwarding isn't available for this DB cluster.
- `requested` – Local write forwarding has been requested, but is not yet active.

## Default parameter settings for write forwarding

The Aurora cluster parameter groups include settings for the local write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Parameter	Scope	Type	Default value	Valid values
<code>apg_write_forward.connect_timeout</code>	Session	seconds	30	0–2147483647
<code>apg_write_forward.consistency_mode</code>	Session	enum	Session	SESSION, EVENTUAL, GLOBAL, and OFF
<code>apg_write_forward.idle_in_transaction_session_timeout</code>	Session	milliseconds	86400000	0–2147483647
<code>apg_write_forward.idle_session_timeout</code>	Session	milliseconds	300000	0–2147483647
<code>apg_write_forward.max_forwarding_connections_percent</code>	Global	int	25	1–100

The `apg_write_forward.max_forwarding_connections_percent` parameter is the upper limit on database connection slots that can be used to handle queries forwarded from readers. It is expressed as a percentage of the `max_connections` setting for the writer DB instance. For example, if `max_connections` is 800 and `apg_write_forward.max_forwarding_connections_percent` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting. This setting applies only on the writer DB instance when the cluster has local write forwarding enabled.

Use the following settings to control local write forwarding requests:

- `apg_write_forward.consistency_mode` – A session-level parameter that controls the degree of read consistency on a read replica. Valid values are `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF`. By default, the value is set to `SESSION`. Setting the value to `OFF` disables local write forwarding in the session. To learn more about consistency levels, see [Consistency and isolation for local write forwarding in Aurora PostgreSQL](#). This parameter is relevant only in reader instances that have local write forwarding enabled.
- `apg_write_forward.connect_timeout` – The maximum number of seconds the read replica waits when establishing a connection to the writer DB instance before giving up. A value of 0 means to wait indefinitely.
- `apg_write_forward.idle_in_transaction_session_timeout` – The number of milliseconds the writer DB instance waits for activity on a connection that's forwarded from a read replica that has an open transaction before closing it. If the session remains idle in transaction beyond this period, Aurora terminates the session. A value of 0 disables the timeout.
- `apg_write_forward.idle_session_timeout` – The number of milliseconds the writer DB instance waits for activity on a connection that's forwarded from a read replica before closing it. If the session remains idle beyond this period, Aurora terminates the session. A value of 0 disables the timeout.

## **rdswriteforwarduser**

The `rdswriteforwarduser` is a user that we will use to establish a connection between the read replica and the writer DB instance.

**Note**

`rdswriteforwarduser` inherits its `CONNECT` privileges to customer databases via the `PUBLIC` role. If the privileges for the `PUBLIC` role are revoked, you will need to `GRANT CONNECT` privileges for the databases you need to forward writes to.

## Monitoring local write forwarding in Aurora PostgreSQL

Using the following sections you can monitor local write forwarding in Aurora PostgreSQL clusters, including relevant CloudWatch metrics and wait events to track performance and identify potential issues.

### Amazon CloudWatch metrics and Aurora PostgreSQL status variables for write forwarding

The following Amazon CloudWatch metrics apply to the writer DB instances when you use write forwarding on one or more read replicas.

CloudWatch Metric	Units and description
<code>AuroraLocal ForwardingWriterDMLThroughput</code>	Count (per second). Number of forwarded DML statements processed each second by this writer DB instance.
<code>AuroraLocalForwardingWriterOpenSessions</code>	Count. Number of open sessions on this writer DB instance processing forwarded queries.
<code>AuroraLocal ForwardingWriterTotalSessions</code>	Count. Total number of forwarded sessions on this writer DB instance.

The following CloudWatch metrics apply to each read replica. These metrics are measured on each reader DB instance in the DB cluster with local write forwarding enabled.

CloudWatch Metric	Unit and description
AuroraForwardingReplicaCommitThroughput	Count (per second). Number of commits in sessions forwarded by this replica each second.
AuroraForwardingReplicaDMLLatency	Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.
AuroraForwardingReplicaDMLThroughput	Count (per second). Number of forwarded DML statements processed on this replica each second.
AuroraForwardingReplicaErrorSessionsLimit	Count. Number of sessions rejected by the writer DB instance because the limit for max connections or max write forward connections was reached.
AuroraForwardingReplicaOpenSessions	Count. The number of sessions that are using local write forwarding on a replica instance.
AuroraForwardingReplicaReadWaitLatency	Milliseconds. Average wait time in milliseconds that the replica waits to be consistent with the LSN of the writer DB instance. The degree to which the reader DB instance waits depends on the <code>apg_write_forward.consistency_mode</code> setting. For information about this setting, see <a href="#">the section called “Configuration parameters for write forwarding in Aurora PostgreSQL”</a> .

## Wait events for local write forwarding in Aurora PostgreSQL

Amazon Aurora generates the following wait events when you use write forwarding with Aurora PostgreSQL.

### Topics

- [IPC:AuroraWriteForwardConnect](#)
- [IPC:AuroraWriteForwardConsistencyPoint](#)
- [IPC:AuroraWriteForwardExecute](#)
- [IPC:AuroraWriteForwardGetGlobalConsistencyPoint](#)
- [IPC:AuroraWriteForwardXactAbort](#)
- [IPC:AuroraWriteForwardXactCommit](#)
- [IPC:AuroraWriteForwardXactStart](#)

### **IPC:AuroraWriteForwardConnect**

The `IPC:AuroraWriteForwardConnect` event occurs when a backend process on the read replica is waiting for a connection to the writer DB instance to be opened.

#### **Likely causes of increased waits**

This event increases as the number of connection attempts from a read replica to the writer node increases.

#### **Actions**

Reduce the number of simultaneous connections from a read replica to the writer node.

### **IPC:AuroraWriteForwardConsistencyPoint**

The `IPC:AuroraWriteForwardConsistencyPoint` event describes how long a query from a node on the read replica will wait for the results of forwarded write operations to be replicated to the current Region. This event is only generated if the session-level parameter `apg_write_forward.consistency_mode` is set to one of the following:

- `SESSION` – queries on a read replica wait for the results of all changes made in that session.
- `GLOBAL` – queries on a read replica wait for the results of changes made by that session, plus all committed changes from both the writer DB instance and read replica.

For more information about the `apg_write_forward.consistency_mode` parameter settings, see [the section called “Configuration parameters for write forwarding in Aurora PostgreSQL”](#).

#### **Likely causes of increased waits**

Common causes for longer wait times include the following:

- Increased replica lag, as measured by the Amazon CloudWatch ReplicaLag metric. For more information about this metric, see [Monitoring Aurora PostgreSQL replication](#).
- Increased load on the writer DB instance or read replica.

## Actions

Change your consistency mode, depending on your application's requirements.

## IPC:AuroraWriteForwardExecute

The `IPC:AuroraWriteForwardExecute` event occurs when a backend process on the read replica is waiting for a forwarded query to complete and obtain results from the writer node of the DB cluster.

## Likely causes of increased waits

Common causes for increased waits include the following:

- Fetching a large number of rows from the writer node.
- Increased network latency between the writer node and read replica increases the time it takes the read replica to receive data from the writer node.
- Increased load on the read replica can delay transmission of the query request from the read replica to the writer node.
- Increased load on the writer node can delay transmission of data from the writer node to the read replica.

## Actions

We recommend different actions depending on the causes of your wait event.

- Optimize queries to retrieve only necessary data.
- Optimize data manipulation language (DML) operations to only modify necessary data.
- If the read replica or writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## **IPC:AuroraWriteForwardGetGlobalConsistencyPoint**

The `IPC:AuroraWriteForwardGetGlobalConsistencyPoint` event occurs when a backend process on the read replica that's using the GLOBAL consistency mode is waiting to obtain the global consistency point from the writer node before executing a query.

### **Likely causes of increased waits**

Common causes for increased waits include the following:

- Increased network latency between the read replica and writer node increases the time it takes the read replica to receive data from the writer node.
- Increased load on the read replica can delay transmission of the query request from the read replica to the writer node.
- Increased load on the writer node can delay transmission of data from the writer node to the read replica.

### **Actions**

We recommend different actions depending on the causes of your wait event.

- Change your consistency mode, depending on your application's requirements.
- If the read replica or writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## **IPC:AuroraWriteForwardXactAbort**

The `IPC:AuroraWriteForwardXactAbort` event occurs when a backend process on the read replica is waiting for the result of a remote cleanup query. Cleanup queries are issued to return the process to the appropriate state after a write-forwarded transaction is aborted. Amazon Aurora performs them either because an error was found or because an user issued an explicit ABORT command or cancelled a running query.

### **Likely causes of increased waits**

Common causes for increased waits include the following:

- Increased network latency between the read replica and writer node increases the time it takes the read replica to receive data from the writer node.

- Increased load on the read replica can delay transmission of the cleanup query request from the read replica to the writer node.
- Increased load on the writer node can delay transmission of data from the writer node to the read replica.

## Actions

We recommend different actions depending on the causes of your wait event.

- Investigate the cause of the aborted transaction.
- If the read replica or writer DB instance is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## IPC:AuroraWriteForwardXactCommit

The `IPC:AuroraWriteForwardXactCommit` event occurs when a backend process on the read replica is waiting for the result of a forwarded commit transaction command.

## Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the read replica and writer node increases the time it takes the read replica to receive data from the writer node.
- Increased load on the read replica can delay transmission of the query request from the read replica to the writer node.
- Increased load on the writer node can delay transmission of data from the writer node to the read replica.

## Actions

If the read replica or writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## IPC:AuroraWriteForwardXactStart

The `IPC:AuroraWriteForwardXactStart` event occurs when a backend process on the read replica is waiting for the result of a forwarded start transaction command.

## Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the read replica and writer node increases the time it takes the read replica to receive data from the writer node.
- Increased load on the read replica can delay transmission of the query request from the read replica to the writer node.
- Increased load on the writer node can delay transmission of data from the writer node to the read replica.

## Actions

If the read replica or writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

# Using Aurora PostgreSQL as a Knowledge Base for Amazon Bedrock

You can use an Aurora PostgreSQL DB cluster as a Knowledge Base for Amazon Bedrock. For more information, see [Create a vector store in Amazon Aurora](#). A Knowledge Base automatically takes unstructured text data stored in an Amazon S3 bucket, converts it to text chunks and vectors, and stores it in a PostgreSQL database. With the generative AI applications, you can use Agents for Amazon Bedrock to query the data stored in the Knowledge Base and use the results of those queries to augment answers provided by foundational models. This workflow is called Retrieval Augmented Generation (RAG). For more information on RAG, see [Retrieval Augmented Generation \(RAG\)](#).

For detailed information about using Aurora PostgreSQL to build generative AI applications using RAG, see this [blog post](#).

## Topics

- [Prerequisites](#)
- [Preparing Aurora PostgreSQL to be used as a Knowledge Base for Amazon Bedrock](#)
- [Creating a Knowledge Base in the Bedrock console](#)
- [Quick create an Aurora PostgreSQL Knowledge Base for Amazon Bedrock](#)

## Prerequisites

Familiarize yourself with the following prerequisites to use Aurora PostgreSQL cluster as a Knowledge Base for Amazon Bedrock. At a high level, you need to configure the following services for use with Bedrock:

- Amazon Aurora PostgreSQL DB cluster created in any of the following versions:
  - 16.1 and all higher versions
  - 15.4 and higher versions
  - 14.9 and higher versions
  - 13.12 and higher versions
  - 12.16 and higher versions

### Note

You must enable the `pgvector` extension in your target database and use version 0.5.0 or higher. For more information, see [pgvector v0.5.0 with HNSW indexing](#).

- RDS Data API
- A user managed in Amazon Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#).

## Preparing Aurora PostgreSQL to be used as a Knowledge Base for Amazon Bedrock

Follow the steps explained in the below sections to prepare Aurora PostgreSQL to be used as a Knowledge Base for Amazon Bedrock.

### Creating and configuring Aurora PostgreSQL

To configure Amazon Bedrock with an Aurora PostgreSQL DB cluster, you must first create an Aurora PostgreSQL DB cluster and take note of the important fields for configuring it with Amazon Bedrock. For more information about creating Aurora PostgreSQL DB cluster, see [Creating and connecting to an Aurora PostgreSQL DB cluster](#).

- Enable Data API while creating Aurora PostgreSQL DB cluster. For more information on the versions supported, see [Using the Amazon RDS Data API](#).

- Make sure to note down the Amazon Resource Names (ARN) of your Aurora PostgreSQL DB cluster. You'll need it to configure the DB cluster for use with Amazon Bedrock. For more information, see [Amazon Resource Names \(ARNs\)](#).

## Connecting to a database and installing pgvector

You can connect to Aurora PostgreSQL using any of the connection utilities. For more detailed information on these utilities, see [Connecting to an Amazon Aurora PostgreSQL DB cluster](#). Alternatively, you can use the RDS console query editor to run the queries. You need an Aurora DB cluster with the RDS Data API enabled to use the query editor.

1. Log in to the database with your master user and set up pgvector. Use the following command if the extension is not installed:

```
CREATE EXTENSION IF NOT EXISTS vector;
```

Use pgvector 0.5.0 and higher version that supports HNSW indexing. For more information, see [pgvector v0.5.0 with HNSW indexing](#).

2. Use the following command to check the version of the pg\_vector installed:

```
SELECT extversion FROM pg_extension WHERE extname='vector';
```

## Setting up database objects and privileges

1. Create a specific schema that Bedrock can use to query the data. Use the following command to create a schema:

```
CREATE SCHEMA bedrock_integration;
```

2. Create a new role that Bedrock can use to query the database. Use the following command to create a new role:

```
CREATE ROLE bedrock_user WITH PASSWORD 'password' LOGIN;
```

**Note**

Make a note of this password as you will need it later to create a Secrets Manager password.

If you are using `psql` client, then use the following commands to create a new role:

```
CREATE ROLE bedrock_user LOGIN;  
\PASSWORD password;
```

3. Grant the `bedrock_user` permissions to manage the `bedrock_integration` schema. This will provide the ability to create tables or indexes within the schema.

```
GRANT ALL ON SCHEMA bedrock_integration to bedrock_user;
```

4. Login as the `bedrock_user` and create a table in the `bedrock_integration` schema.

```
CREATE TABLE bedrock_integration.bedrock_kb (id uuid PRIMARY KEY, embedding  
vector(n), chunks text, metadata json, custom_metadata jsonb);
```

This command will create the `bedrock_kb` table in the `bedrock_integration` schema with Titan embeddings.

Replace `n` in the `vector(n)` data type with the appropriate dimension for the embedding model you are using. Use the recommendations below to help select your dimensions:

- For the Titan v2 model, use `vector(1024)`, or `vector(512)`, or `vector (256)`. To learn more, see [Amazon Titan Embeddings Text](#).
- For the Titan v1.2 model, use `vector(1536)`. To learn more, see [Amazon Titan Multimodal Embeddings G1](#).
- For the Cohere Embed model, use `vector(1024)`. To learn more, see [Cohere Embed models](#).
- For the Cohere Embed Multilingual v3, use `vector(1024)`.

The first four columns are mandatory. For metadata handling, Bedrock writes data from your metadata files to the `custom_metadata` column. We recommend creating this column if

you plan to use metadata and filtering. If you don't create a `custom_metadata` column, add individual columns for each metadata attribute in your table before you begin ingestion. For more information, see [Configure and customize queries and response generation](#).

5. Follow these steps to create the required indexes that Bedrock uses to query your data:

- Create an index with the cosine operator which the bedrock can use to query the data.

```
CREATE INDEX ON bedrock_integration.bedrock_kb USING hnsw (embedding
vector_cosine_ops);
```

- We recommend you to set the value of `ef_construction` to 256 for `pgvector` 0.6.0 and higher version that use parallel index building.

```
CREATE INDEX ON bedrock_integration.bedrock_kb USING hnsw (embedding
vector_cosine_ops) WITH (ef_construction=256);
```

- Create an index which Bedrock can use to query the text data.

```
CREATE INDEX ON bedrock_integration.bedrock_kb USING gin (to_tsvector('simple',
chunks));
```

- If you created a column for custom metadata, create an index which Bedrock can use to query the metadata.

```
CREATE INDEX ON bedrock_integration.bedrock_kb USING gin (custom_metadata);
```

## Create a secret in Secrets Manager

Secrets Manager lets you store your Aurora credentials so that they can be securely transmitted to applications. If you didn't choose the Amazon secrets manager option when creating Aurora PostgreSQL DB cluster, you can create a secret now. For more information about creating Amazon Secrets Manager database secret, see [Amazon Secrets Manager database secret](#).

## Creating a Knowledge Base in the Bedrock console

While preparing Aurora PostgreSQL to be used as the vector store for a Knowledge Base, you must gather the following details that you need to provide to Amazon Bedrock console.

- **Amazon Aurora DB cluster ARN** – The ARN of your DB cluster.

- **Secret ARN** – The ARN of the Amazon Secrets Manager key for your DB cluster.
- **Database name** – The name of your database. For example, you can use the default database *postgres*.
- **Table name** – We recommend you to provide a schema qualified name while creating the table using the command similar to the following:

```
CREATE TABLE bedrock_integration.bedrock_kb;
```

This command will create the `bedrock_kb` table in the `bedrock_integration` schema.

- When creating the table, make sure to configure it with the specified columns and data types. You can use your preferred column names instead of those listed in the table. Remember to take a note of the names you chose for reference during the Knowledge Base set up.

Column name	Data type	Description
id	UUID primary key	Contains unique identifiers for each record.
chunks	Text	Contains the chunks of raw text from your data sources.
embedding	Vector	Contains the vector embeddings of the data sources.
metadata	JSON	Contains metadata required to carry out source attribution and to enable data ingestion and querying.
custom_metadata	JSONB	(Optional) Defines the target column where Amazon Bedrock writes metadata details from your data sources.

With these details, you can now create a Knowledge Base in the Bedrock console. For more detailed information on setting up a vector index and creating a Knowledge Base information, see [Create a vector store in Amazon Aurora](#) and [Create a vector store in Amazon Aurora](#).

After adding Aurora as your Knowledge Base, you can now ingest your data sources for searching and querying. For more information, see [Ingest your data sources into the Knowledge Base](#).

## Quick create an Aurora PostgreSQL Knowledge Base for Amazon Bedrock

Amazon Bedrock's retrieval augmented generation (RAG) workflow relies on vector data stored in an Aurora PostgreSQL database to power content retrieval. Previously, setting up Aurora PostgreSQL as the vector data store for Bedrock Knowledge Bases was a multi-step process, requiring numerous manual actions across different user interfaces. This made it challenging for data scientists and developers to leverage Aurora for their Bedrock projects.

To improve the user experience, Amazon has created a new CloudFormation-based quick create option that simplifies the setup process. With Aurora quick create, you can now provision a pre-configured Aurora PostgreSQL DB cluster as the vector store for your Amazon Bedrock Knowledge Bases with a single click.

### Topics

- [Supported regions and Aurora PostgreSQL versions](#)
- [Understanding the quick create process](#)
- [Benefits of using Aurora quick create](#)
- [Limitations of Aurora quick create process](#)

## Supported regions and Aurora PostgreSQL versions

The Aurora quick create option is available in all the Amazon regions that support Amazon Bedrock Knowledge Bases. By default, it creates an Aurora PostgreSQL DB cluster with version 15.7. For more information about supported Regions, see [Supported models and regions for Amazon Bedrock Knowledge Bases](#).

## Understanding the quick create process

The quick create process automatically provisions the following resources to set up an Amazon Aurora PostgreSQL database as the vector data store for your Bedrock Knowledge Base:

An Aurora PostgreSQL DB cluster in your account, configured with default settings.

- ACUs (Aurora Capacity Units) are set from 0 to 16. This lets your vector store scale down to zero when not in use, saving on compute costs. The ACUs can be adjusted later in the Amazon RDS console.
- (Hierarchical Navigable Small World) HNSW index using Euclidean distance as a similarity measure for the Bedrock vector embeddings stored in Aurora.
- The DB instance is a serverless v2 instance.
- The cluster is associated with the default VPC and subnets, and has the RDS Data API enabled.
- The cluster admin credentials are managed by Amazon Secrets Manager.

Besides the default settings, the following settings are set up for you. As you go through the process, you'll see screens that explains the workflow.

- Seeding the Aurora cluster with the necessary database objects:
  - Create the pgvector extension, schema, role, and tables required for the Bedrock Knowledge Base.
  - Register a limited-privilege database user for Bedrock to interact with the cluster.
- A progress banner will be displayed throughout the resource provisioning process, allowing you to track the status of the following sub-events:
  - Aurora cluster creation
  - Seeding the Aurora cluster
  - Knowledge Base creation

The banner stays visible until the knowledge base is fully created, even if you navigate away from the page and return.

- You can click [View details](#) on the progress banner to see the status of each step. For more information about events during knowledge base creation, choose the CloudFormation link in the view details screen. Once the process is complete, your new Bedrock Knowledge Base will be ready to use.
- The stack IDs for all the quick create resources can be found in the tags of the Bedrock Knowledge Base, should you need to reference them.

A Bedrock Knowledge Base, with the configuration to the newly provisioned Aurora cluster as the vector store is created.

## Benefits of using Aurora quick create

- The CloudFormation-based quick create process significantly reduces the time and complexity required to use Aurora as the vector store.
- Aurora offers excellent performance, vector scalability and cost benefits with the ability to scale to zero compute charges when not in use.
- The quick create process streamlines the end-to-end experience, allowing you to easily create and configure your Bedrock Knowledge Bases using Aurora.
- Customers can build upon CloudFormation template to customize the provisioning with their own configurations.

## Limitations of Aurora quick create process

- With Aurora quick create option, the DB cluster is provisioned with default configurations. However, these default settings may not meet your specific requirements or intended use case. Quick create does not offer options to modify the configurations during the provisioning process. The configurations are set automatically to streamline the deployment experience. If you need to customize the Aurora DB cluster configuration, you can do so after the initial deployment by quick create in the Amazon RDS console.
- While quick create flow simplifies the setup process, the time to create the Aurora DB cluster is still approximately 10 minutes, the same as a manual deployment. This is due to the time required to provision the Aurora infrastructure.
- The quick create option is designed for experimentation and quick setup. The resources created through quick create may not be suitable for production use, and you won't be able to directly migrate them to a production environment in your VPC.

## Integrating Amazon Aurora PostgreSQL with other Amazon services

Amazon Aurora integrates with other Amazon services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the Amazon Cloud. Your Aurora PostgreSQL DB cluster can use Amazon services to do the following:

- Quickly collect, view, and assess performance for your Aurora PostgreSQL DB instances with Amazon RDS Performance Insights. Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information about Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).
- Configure your Aurora PostgreSQL DB cluster to publish log data to Amazon CloudWatch Logs. CloudWatch Logs provide highly durable storage for your log records. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. For more information, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](#).
- Import data from an Amazon S3 bucket to an Aurora PostgreSQL DB cluster, or export data from an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster](#) and [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).
- Add machine learning-based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the Amazon machine learning (ML) services SageMaker AI and Amazon Comprehend. For more information, see [Using Amazon Aurora machine learning with Aurora PostgreSQL](#).
- Invoke Amazon Lambda functions from an Aurora PostgreSQL DB cluster. To do this, use the `aws_lambda` PostgreSQL extension provided with Aurora PostgreSQL. For more information, see [Invoking an Amazon Lambda function from an Aurora PostgreSQL DB cluster](#).
- Integrate queries from Amazon Redshift and Aurora PostgreSQL. For more information, see [Getting started with using federated queries to PostgreSQL](#) in the *Amazon Redshift Database Developer Guide*.

## Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster

You can import data that's been stored using Amazon Simple Storage Service into a table on an Aurora PostgreSQL DB cluster instance. To do this, you first install the Aurora PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A *bucket* is an Amazon S3 container for objects and files. The data can be in a comma-separated value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into Aurora PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the *Amazon Simple Storage Service User Guide*.

- [Create a bucket](#)
- [Add an object to a bucket](#)

Cross-account import from Amazon S3 is supported. For more information, see [Granting cross-account permissions](#) in the *Amazon Simple Storage Service User Guide*.

You can use the customer managed key for encryption while importing data from S3. For more information, see [KMS keys stored in Amazon KMS](#) in the *Amazon Simple Storage Service User Guide*.

#### Note

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

## Topics

- [Installing the aws\\_s3 extension](#)
- [Overview of importing data from Amazon S3 data](#)
- [Setting up access to an Amazon S3 bucket](#)
- [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster](#)
- [Function reference](#)

## Installing the aws\_s3 extension

Before you can use Amazon S3 with your Aurora PostgreSQL DB cluster, you need to install the aws\_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#). The aws\_s3 extension depends on some of the helper functions in the aws\_commons extension, which is installed automatically when needed.

## To install the `aws_s3` extension

1. Use `psql` (or `pgAdmin`) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the `psql \dx` metacommand.

```
postgres=> \dx
      List of installed extensions
  Name      | Version | Schema  | Description
-----+-----+-----+-----
aws_commons | 1.2     | public  | Common data types across Amazon services
aws_s3      | 1.1     | public  | Amazon S3 extension for importing data from
S3
plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Overview of importing data from Amazon S3 data

### To import S3 data into Aurora PostgreSQL

First, gather the details that you need to supply to the function. These include the name of the table on your Aurora PostgreSQL DB cluster's instance, and the bucket name, file path, file type, and Amazon Web Services Region where the Amazon S3 data is stored. For more information, see [View an object](#) in the *Amazon Simple Storage Service User Guide*.

**Note**

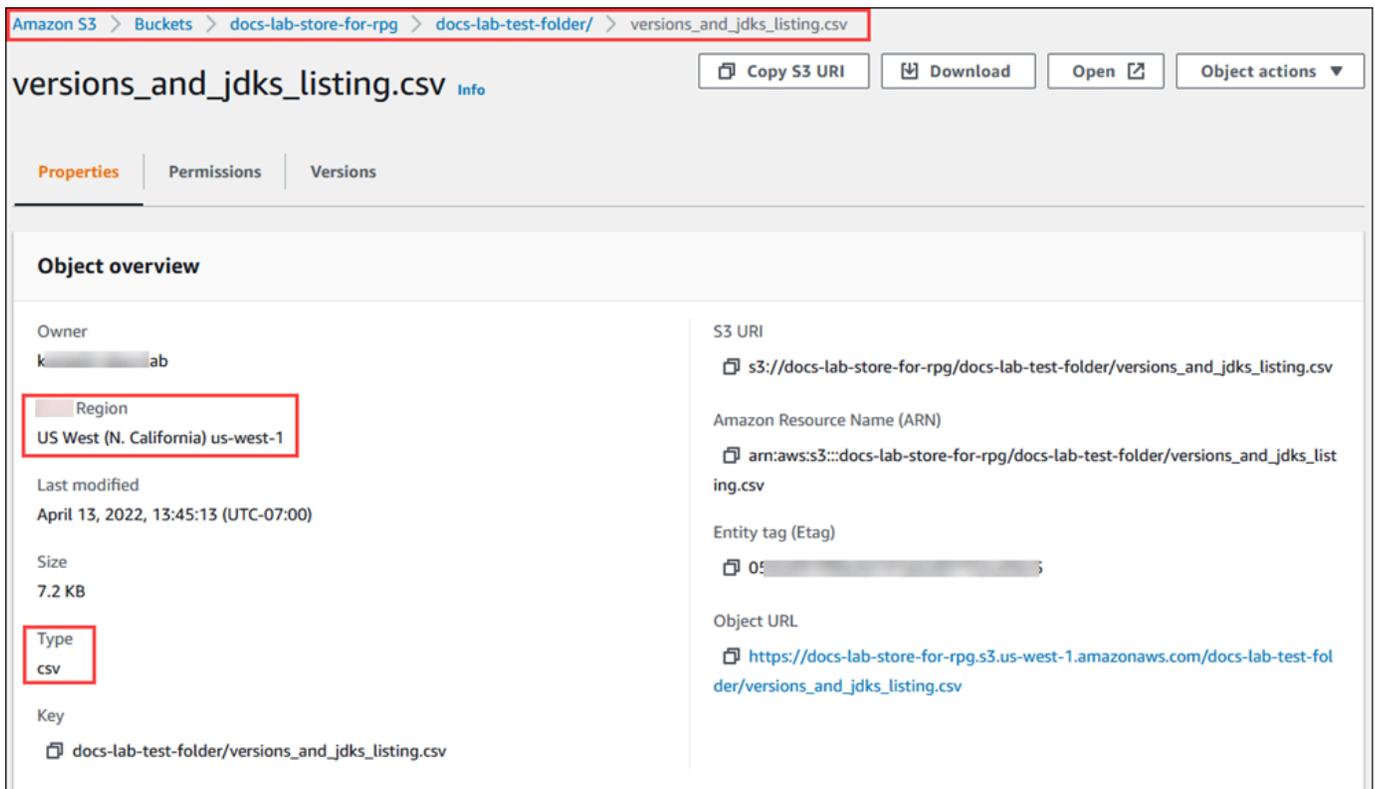

Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

```
postgres=> CREATE TABLE t1
  (col1 varchar(80),
   col2 varchar(80),
   col3 varchar(80));
```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at <https://console.amazonaws.cn/s3/>, and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

Make a note of the bucket name, path, the Amazon Web Services Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more information, see [Setting up access to an Amazon S3 bucket](#). The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the Amazon CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://amzn-s3-demo-bucket/sample_file_path ./
```

4. Set up permissions on your Aurora PostgreSQL DB cluster to allow access to the file on the Amazon S3 bucket. To do so, you use either an Amazon Identity and Access Management (IAM) role or security credentials. For more information, see [Setting up access to an Amazon S3 bucket](#).
5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see [aws\\_commons.create\\_s3\\_uri](#). The following is an example of constructing this object during a `psql` session.

```
postgres=> SELECT aws_commons.create_s3_uri(
    'docs-lab-store-for-rpg',
    'versions_and_jdks_listing.csv',
    'us-west-1'
) AS s3_uri \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3](#). For examples, see [Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster](#).

## Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

### Topics

- [Using an IAM role to access an Amazon S3 bucket](#)
- [Using security credentials to access an Amazon S3 bucket](#)
- [Troubleshooting access to Amazon S3](#)

### Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB cluster.

#### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

### To give an Aurora PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your Aurora PostgreSQL DB cluster to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Aurora PostgreSQL:

- `s3:GetObject`
- `s3:ListBucket`

Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws-cn:s3:::amzn-s3-demo-bucket`
- `arn:aws-cn:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following Amazon CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `amzn-s3-demo-bucket`.

#### Note

Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

## Example

For Linux, macOS, or Unix:

```
aws iam create-policy \  
  --policy-name rds-s3-import-policy \  
  --policy-document '{  
    "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Sid": "s3import",
    "Action": [
      "s3:GetObject",
      "s3:ListBucket"
    ],
    "Effect": "Allow",
    "Resource": [
      "arn:aws-cn:s3:::amzn-s3-demo-bucket",
      "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
    ]
  }
]
}'

```

For Windows:

```

aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3import",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws-cn:s3:::amzn-s3-demo-bucket",
        "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
      ]
    }
  ]
}'

```

## 2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the Amazon CLI command to create a role named `rds-s3-import-role`.

## Example

For Linux, macOS, or Unix:

```
aws iam create-role \  
  --role-name rds-s3-import-role \  
  --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
      {  
        "Effect": "Allow",  
        "Principal": {  
          "Service": "rds.amazonaws.com"  
        },  
        "Action": "sts:AssumeRole",  
        "Condition": {  
          "StringEquals": {  
            "aws:SourceAccount": "111122223333",  
            "aws:SourceArn": "arn:aws:rds:us-  
east-1:111122223333:cluster:clustername"  
          }  
        }  
      }  
    ]  
  }
```

```
}'
```

### For Windows:

```
aws iam create-role ^
  --role-name rds-s3-import-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
            "aws:SourceArn": "arn:aws:rds:us-
east-1:111122223333:cluster:clustername"
          }
        }
      }
    ]
  }'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following Amazon CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role`. Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

### Example

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
  --policy-arn your-policy-arn \
  --role-name rds-s3-import-role
```

### For Windows:

```
aws iam attach-role-policy ^
  --policy-arn your-policy-arn ^
  --role-name rds-s3-import-role
```

4. Add the IAM role to the DB cluster.

You do so by using the Amazon Web Services Management Console or Amazon CLI, as described following.

## Console

### To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this cluster**.
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

## Amazon CLI

### To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named `my-db-cluster`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \  
  --db-cluster-identifier my-db-cluster \  
  --feature-name s3Import \  
  --role-arn your-role-arn \  
  --
```

```
--region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^  
  --db-cluster-identifier my-db-cluster ^  
  --feature-name s3Import ^  
  --role-arn your-role-arn ^  
  --region your-region
```

## RDS API

To add an IAM role for a PostgreSQL DB cluster using the Amazon RDS API, call the [AddRoleToDBCluster](#) operation.

### Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the [aws\\_s3.table\\_import\\_from\\_s3](#) function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains Amazon credentials. Use the [aws\\_commons.create\\_aws\\_credentials](#) function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(  
  'sample_access_key', 'sample_secret_key', '')  
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the [aws\\_s3.table\\_import\\_from\\_s3](#) function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(  
  't', '', '(format csv)',  
  :'s3_uri',  
  :'creds'  
);
```

Or you can include the [aws\\_commons.create\\_aws\\_credentials](#) function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  't', '', '(format csv)',
  :'s3_uri',
  aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- [Troubleshooting Amazon Aurora identity and access](#)
- [Troubleshooting Amazon S3](#) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](#) in the *IAM User Guide*

## Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3](#).

### Note

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  't1',
  '',
  '(format csv)',
  :'s3_uri'
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB cluster to copy the data into.
- `' '` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see [Importing an Amazon S3 file that uses a custom delimiter](#).
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the [PostgreSQL COPY](#) command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the [aws\\_commons.create\\_s3\\_uri](#) function to create an `s3_uri` structure, see [Overview of importing data from Amazon S3 data](#).

For more information about this function, see [aws\\_s3.table\\_import\\_from\\_s3](#).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

 **Note**

Importing 0 bytes file will cause an error.

## Topics

- [Importing an Amazon S3 file that uses a custom delimiter](#)
- [Importing an Amazon S3 compressed \(gzip\) file](#)
- [Importing an encoded Amazon S3 file](#)

## Importing an Amazon S3 file that uses a custom delimiter

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

## To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

```
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the [aws\\_s3.table\\_import\\_from\\_s3](#) function to import data from the Amazon S3 file.

You can include the [aws\\_commons.create\\_s3\\_uri](#) function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    'test',
    'a,b,d,e',
    'DELIMITER '|' | ''',
    aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'pipeDelimitedSampleFile', 'us-
east-2')
);
```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
a | b | c | d | e
---+-----+---+---+-----+-----
1 | foo1 | | bar1 | elephant1
2 | foo2 | | bar2 | elephant2
3 | foo3 | | bar3 | elephant3
4 | foo4 | | bar4 | elephant4
```

## Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: Content-Encoding
- Value: gzip

If you upload the file using the Amazon Web Services Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the Amazon Web Services Management Console, the Amazon CLI, or the API, see [Uploading objects](#) in the *Amazon Simple Storage Service User Guide*.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](#) in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your Aurora PostgreSQL DB cluster as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_gzip', '', '(format csv)',
  'amzn-s3-demo-bucket', 'test-data.gz', 'us-east-2'
);
```

## Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_table', '', 'encoding ''WIN1252''',
  aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'SampleFile', 'us-east-2')
);
```

## Function reference

### Functions

- [aws\\_s3.table\\_import\\_from\\_s3](#)
- [aws\\_commons.create\\_s3\\_uri](#)
- [aws\\_commons.create\\_aws\\_credentials](#)

## aws\_s3.table\_import\_from\_s3

Imports Amazon S3 data into an Aurora PostgreSQL table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

### Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB cluster.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1  
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1,  
    credentials aws_commons._aws_credentials_1  
)
```

### Parameters

#### *table\_name*

A required text string containing the name of the PostgreSQL database table to import the data into.

### *column\_list*

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see [Importing an Amazon S3 file that uses a custom delimiter](#).

### *options*

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the [PostgreSQL COPY documentation](#).

### *s3\_info*

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The Amazon Region that the file is in. For a listing of Amazon Region names and associated values, see [Regions and Availability Zones](#).

### *credentials*

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see [aws\\_commons.create\\_aws\\_credentials](#).

## **Alternate syntax**

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text  
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text,  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

## Alternate parameters

### *bucket*

A text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A text string containing the Amazon S3 file name including the path of the file.

### *region*

A text string identifying the Amazon Web Services Region location of the file. For a listing of Amazon Web Services Region names and associated values, see [Regions and Availability Zones](#).

### *access\_key*

A text string containing the access key to use for the import operation. The default is NULL.

### *secret\_key*

A text string containing the secret key to use for the import operation. The default is NULL.

### *session\_token*

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

## **aws\_commons.create\_s3\_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

### **Syntax**

```
aws_commons.create_s3_uri(  
    bucket text,  
    file_path text,  
    region text  
)
```

### **Parameters**

#### *bucket*

A required text string containing the Amazon S3 bucket name for the file.

#### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

#### *region*

A required text string containing the Amazon Web Services Region that the file is in. For a listing of Amazon Web Services Region names and associated values, see [Regions and Availability Zones](#).

## `aws_commons.create_aws_credentials`

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

### Syntax

```
aws_commons.create_aws_credentials(  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

### Parameters

#### *access\_key*

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

#### *secret\_key*

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

#### *session\_token*

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

## Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the Aurora PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

**Note**

Cross-account export to Amazon S3 isn't supported.

All currently available versions of Aurora PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

If you don't have a bucket set up for your export, see the following topics in the *Amazon Simple Storage Service User Guide*.

- [Setting up Amazon S3](#)
- [Creating a bucket](#)

By default, the data exported from Aurora PostgreSQL to Amazon S3 uses server-side encryption with Amazon managed key. You can alternatively use customer managed key that you have already created. If you are using bucket encryption, the Amazon S3 bucket must be encrypted with Amazon Key Management Service (Amazon KMS) key (SSE-KMS). Currently, buckets encrypted with Amazon S3 managed keys (SSE-S3) are not supported.

**Note**

You can save DB and DB cluster snapshot data to Amazon S3 using the Amazon Web Services Management Console, Amazon CLI, or Amazon RDS API. For more information, see [Exporting DB cluster snapshot data to Amazon S3](#).

**Topics**

## Installing the aws\_s3 extension

Before you can use Amazon Simple Storage Service with your Aurora PostgreSQL DB cluster, you need to install the `aws_s3` extension. This extension provides functions for exporting data from the writer instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster](#). The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

### To install the aws\_s3 extension

1. Use `psql` (or `pgAdmin`) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the `psql \dx` metacommand.

```
postgres=> \dx  
      List of installed extensions  
  Name      | Version | Schema  | Description  
-----+-----+-----+-----  
aws_commons | 1.2     | public  | Common data types across Amazon services  
aws_s3      | 1.1     | public  | Amazon S3 extension for importing data from  
S3  
plpgsql    | 1.0     | pg_catalog | PL/pgSQL procedural language  
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Verify that your Aurora PostgreSQL version supports exports to Amazon S3

You can verify that your Aurora PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example checks to see if version 10.14 can export to Amazon S3.

```
aws rds describe-db-engine-versions --region us-east-1 \  
--engine aurora-postgresql --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

## Overview of exporting data to Amazon S3

To export data stored in an Aurora PostgreSQL database to an Amazon S3 bucket, use the following procedure.

### To export Aurora PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see [Specifying the Amazon S3 file path to export to](#).
2. Provide permission to access the Amazon S3 bucket.

To export data to an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB cluster .

For details about this process, see [Setting up access to an Amazon S3 bucket](#).

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export query results to Amazon S3. For details about this process, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

## Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- Bucket name – A *bucket* is a container for Amazon S3 objects or files.

For more information on storing data with Amazon S3, see [Creating a bucket](#) and [Working with objects](#) in the *Amazon Simple Storage Service User Guide*.

- File path – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- Amazon Region (optional) – The Amazon Region where the Amazon S3 bucket is located. If you don't specify an Amazon Region value, then Aurora saves your files into Amazon S3 in the same Amazon Region as the exporting DB cluster.

### Note

Currently, the Amazon Region must be the same as the region of the exporting DB cluster.

For a listing of Amazon Region names and associated values, see [Regions and Availability Zones](#).

To hold the Amazon S3 file information about where the export is to be stored, you can use the [aws\\_commons.create\\_s3\\_uri](#) function to create an `aws_commons._s3_uri_1` composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(  
    'amzn-s3-demo-bucket',  
    'sample-filepath',  
    'us-west-2'  
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the [aws\\_s3.query\\_export\\_to\\_s3](#) function. For examples, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

## Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB cluster permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

### To give a PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your PostgreSQL DB cluster to access Amazon S3.

As part of creating this policy, take the following steps:

- a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB cluster to an Amazon S3 bucket:
  - `s3:PutObject`
  - `s3:AbortMultipartUpload`
- b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws-cn:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following Amazon CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `amzn-s3-demo-bucket`.

### Warning

We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see [Using endpoint policies for Amazon S3](#) in the Amazon VPC User Guide.

We strongly recommend that you do not create a policy with all-resource access.

This access can pose a threat for data security. If you create a policy that gives `S3:PutObject` access to all resources using `"Resource": "*"` , then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to *any publicly writable bucket within your Amazon Region*.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3export",
      "Action": [
        "s3:PutObject*",
        "s3:ListBucket",
        "s3:GetObject*",
        "s3:DeleteObject*",
        "s3:GetBucketLocation",
        "s3:AbortMultipartUpload"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
      ]
    }
  ]
}
```

```
    }  
  ]  
}'
```

## 2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the Amazon CLI command to create a role named `rds-s3-export-role`.

### Example

For Linux, macOS, or Unix:

```
aws iam create-role \  
  --role-name rds-s3-export-role \  
  --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
      {  
        "Effect": "Allow",  
        "Principal": {  
          "Service": "rds.amazonaws.com"  
        },  
        "Action": "sts:AssumeRole",
```

```

    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": "111122223333",
        "aws:SourceArn": "arn:aws:rds:us-
east-1:111122223333:cluster:dbname"
      }
    }
  ]
}'

```

### For Windows:

```

aws iam create-role ^
--role-name rds-s3-export-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "aws:SourceArn": "arn:aws:rds:us-
east-1:111122223333:cluster:dbname"
        }
      }
    }
  ]
}'

```

3. Attach the IAM policy that you created to the IAM role that you created.

The following Amazon CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace ***your-policy-arn*** with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB cluster. You do so by using the Amazon Web Services Management Console or Amazon CLI, as described following.

## Console

### To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

## Amazon CLI

### To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named `my-db-cluster`. Replace *your-role-arn* with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \  
  --db-cluster-identifier my-db-cluster \  
  --feature-name s3Export \  
  --role-arn your-role-arn \  
  --region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
  --db-cluster-identifier my-db-cluster ^
  --feature-name s3Export ^
  --role-arn your-role-arn ^
  --region your-region
```

## Exporting query data using the `aws_s3.query_export_to_s3` function

Export your PostgreSQL data to Amazon S3 by calling the [aws\\_s3.query\\_export\\_to\\_s3](#) function.

### Topics

- [Prerequisites](#)
- [Calling `aws\_s3.query\_export\_to\_s3`](#)
- [Exporting to a CSV file that uses a custom delimiter](#)
- [Exporting to a binary file with encoding](#)

### Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in [Overview of exporting data to Amazon S3](#).
- Determine where to export your data to Amazon S3 as described in [Specifying the Amazon S3 file path to export to](#).
- Make sure that the DB cluster has export access to Amazon S3 as described in [Setting up access to an Amazon S3 bucket](#).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `amzn-s3-demo-bucket`. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,
'Wednesday');
```

## Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the [aws\\_s3.query\\_export\\_to\\_s3](#) function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the [aws\\_commons.create\\_s3\\_uri](#) function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(  
    'amzn-s3-demo-bucket',  
    'sample-filepath',  
    'us-west-2'  
) AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called *amzn-s3-demo-bucket*.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM  
sample_table', :s3_uri_1);  
  
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM  
sample_table', :s3_uri_1, options :='format text');
```

The parameters are described as follows:

- 'SELECT \* FROM sample\_table' – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- :s3\_uri\_1 – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',  
    aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2')  
);
```

- `options := 'format text'` – The options parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the [PostgreSQL COPY](#) command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix  
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part2  
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see [aws\\_s3.query\\_export\\_to\\_s3](#). For more about accessing files in Amazon S3, see [View an object](#) in the *Amazon Simple Storage Service User Guide*.

### Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export data to a file that uses a custom delimiter. The example uses arguments of the [PostgreSQL COPY](#) command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',  
options := 'format csv, delimiter $$:$$');
```

### Exporting to a binary file with encoding

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',
options :='format binary, encoding WIN1253');
```

## Function reference

### Functions

- [aws\\_s3.query\\_export\\_to\\_s3](#)
- [aws\\_commons.create\\_s3\\_uri](#)

### aws\_s3.query\_export\_to\_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

### Syntax

```
aws_s3.query_export_to_s3(  
    query text,  
    s3_info aws_commons._s3_uri_1,  
    options text,  
    kms_key text  
)
```

### Input parameters

#### *query*

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

#### *s3\_info*

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket to contain the file.
- `file_path` – The Amazon S3 file name and path.
- `region` – The Amazon Region that the bucket is in. For a listing of Amazon Region names and associated values, see [Regions and Availability Zones](#).

Currently, this value must be the same Amazon Region as that of the exporting DB cluster . The default is the Amazon Region of the exporting DB cluster .

To create an `aws_commons._s3_uri_1` composite structure, see the [aws\\_commons.create\\_s3\\_uri](#) function.

### *options*

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

### *kms\_key text*

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

## **Alternate input parameters**

To help with testing, you can use an expanded set of parameters instead of the `s3_info` parameter. Following are additional syntax variations for the `aws_s3.query_export_to_s3` function.

Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```
aws_s3.query_export_to_s3(  
  query text,  
  bucket text,  
  file_path text,  
  region text,  
  options text,  
  kms_key text  
)
```

### *query*

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

### *bucket*

A required text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

### *region*

An optional text string containing the Amazon Region that the bucket is in. For a listing of Amazon Region names and associated values, see [Regions and Availability Zones](#).

Currently, this value must be the same Amazon Region as that of the exporting DB cluster. The default is the Amazon Region of the exporting DB cluster.

### *options*

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

### *kms\_key text*

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

## **Output parameters**

```
aws_s3.query_export_to_s3(  
    OUT rows_uploaded bigint,  
    OUT files_uploaded bigint,  
    OUT bytes_uploaded bigint  
)
```

### *rows\_uploaded*

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

### *files\_uploaded*

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_partXX` appended to the name. The `XX` represents 2, then 3, and so on as needed.

### *bytes\_uploaded*

The total number of bytes uploaded to Amazon S3.

## Examples

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2', 'format text');
```

### **aws\_commons.create\_s3\_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.query\\_export\\_to\\_s3](#) function. For an example of using the `aws_commons.create_s3_uri` function, see [Specifying the Amazon S3 file path to export to](#).

## Syntax

```
aws_commons.create_s3_uri(
  bucket text,
  file_path text,
  region text
)
```

## Input parameters

### *bucket*

A required text string containing the Amazon S3 bucket name for the file.

### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

## *region*

A required text string containing the Amazon Region that the file is in. For a listing of Amazon Region names and associated values, see [Regions and Availability Zones](#).

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see [Provide access to the DB cluster in the VPC by creating a security group](#).

See also the following for recommendations:

- [Troubleshooting Amazon Aurora identity and access](#)
- [Troubleshooting Amazon S3](#) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](#) in the *IAM User Guide*

## Invoking an Amazon Lambda function from an Aurora PostgreSQL DB cluster

Amazon Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many Amazon services, including Aurora PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see [What is Amazon Lambda?](#) in the *Amazon Lambda Developer Guide*.

### Note

Invoking Amazon Lambda functions is supported in Aurora PostgreSQL 11.9 and higher (including Aurora Serverless v2).

Setting up Aurora PostgreSQL to work with Lambda functions is a multi-step process involving Amazon Lambda, IAM, your VPC, and your Aurora PostgreSQL DB cluster. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see [Getting started with Lambda](#) and [Amazon Lambda foundations](#) in the *Amazon Lambda Developer Guide*.

## Topics

- [Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to Amazon Lambda](#)
- [Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and Amazon Lambda](#)
- [Step 3: Install the aws\\_lambda extension for an Aurora PostgreSQL DB cluster](#)
- [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\)](#)
- [Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster](#)
- [Step 6: Grant other users permission to invoke Lambda functions](#)
- [Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster](#)
- [Lambda function error messages](#)
- [Amazon Lambda function and parameter reference](#)

## Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to Amazon Lambda

Lambda functions always run inside an Amazon VPC that's owned by the Amazon Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your Aurora PostgreSQL DB cluster sends network traffic to the Lambda service's VPC. How you configure this depends on whether your Aurora DB cluster's primary DB instance is public or private.

- **Public Aurora PostgreSQL DB cluster** – A DB cluster's primary DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is `true`. To find the value of this property, you can use the [describe-db-instances](#) Amazon CLI command. Or, you can use the Amazon Web Services Management Console to open the **Connectivity & security** tab and check that **Publicly accessible** is **Yes**. To verify that the instance is in the public subnet of your VPC, you can use the Amazon Web Services Management Console or the Amazon CLI.

To set up access to Lambda, you use the Amazon Web Services Management Console or the Amazon CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private Aurora PostgreSQL DB cluster** – In this case, the instance's "PubliclyAccessible" property is false or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation (NAT) gateway. For more information, see [NAT gateways](#). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](#) in the *Amazon VPC User Guide*. The endpoint responds to calls made by your Aurora PostgreSQL DB cluster to your Lambda functions.

Your VPC can now interact with the Amazon Lambda VPC at the network level. Next, you configure the permissions using IAM.

## Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and Amazon Lambda

Invoking Lambda functions from your Aurora PostgreSQL DB cluster requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB cluster. This approach gives the DB cluster privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the Amazon CLI.

### To configure IAM permissions for using your cluster with Lambda

1. Use the [create-policy](#) Amazon CLI command to create an IAM policy that allows your Aurora PostgreSQL DB cluster to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your Aurora DB cluster the minimum permissions needed to invoke the specified Lambda function.

```
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"
    }
  ]
}'
```

Alternatively, you can use the predefined `AWSLambdaRole` policy that allows you to invoke any of your Lambda functions. For more information, see [Identity-based IAM policies for Lambda](#)

2. Use the [create-role](#) Amazon CLI command to create an IAM role that the policy can assume at runtime.

```
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

3. Apply the policy to the role by using the [attach-role-policy](#) Amazon CLI command.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
  --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your Aurora PostgreSQL DB cluster by using the [add-role-to-db-cluster](#) Amazon CLI command. This last step allows your DB cluster's database users to invoke Lambda functions.

```
aws rds add-role-to-db-cluster \
  --db-cluster-identifier my-cluster-name \
  --feature-name Lambda \
  --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \
  --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your Aurora PostgreSQL DB cluster's capabilities.)

### Step 3: Install the `aws_lambda` extension for an Aurora PostgreSQL DB cluster

To use Amazon Lambda with your Aurora PostgreSQL DB cluster, add the `aws_lambda` PostgreSQL extension to your Aurora PostgreSQL DB cluster. This extension provides your Aurora PostgreSQL DB cluster with the ability to call Lambda functions from PostgreSQL.

#### To install the `aws_lambda` extension in your Aurora PostgreSQL DB cluster

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your Aurora PostgreSQL DB cluster .

1. Connect to your Aurora PostgreSQL DB cluster instance as a user with `rds_superuser` privileges. The default postgres user is shown in the example.

```
psql -h cluster-instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your Aurora PostgreSQLDB cluster , it's installed with `aws_lambda` as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

The `aws_lambda` extension is installed in your Aurora PostgreSQL DB cluster's primary DB instance. You can now create convenience structures for invoking your Lambda functions.

### Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional)

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in [Step 2: Configure IAM for your cluster and Lambda](#) requires the ARN, so we recommend that you use your function's ARN.

- **Amazon Region** – (Optional) The Amazon Region where the Lambda function is located if it's not in the same Region as your Aurora PostgreSQL DB cluster.

To hold the Lambda function name information, you use the [aws\\_commons.create\\_lambda\\_function\\_arn](#) function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the `invoke` function. Following, you can find three alternative approaches to setting up this composite structure.

```
SELECT aws_commons.create_lambda_function_arn(  
    'my-function',  
    'aws-region'  
) AS aws_lambda_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(  
    '111122223333:function:my-function',  
    'aws-region'  
) AS lambda_partial_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(  
    'arn:aws-cn:lambda:aws-region:111122223333:function:my-function'  
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the [aws\\_lambda.invoke](#) function. For examples, see [Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster](#).

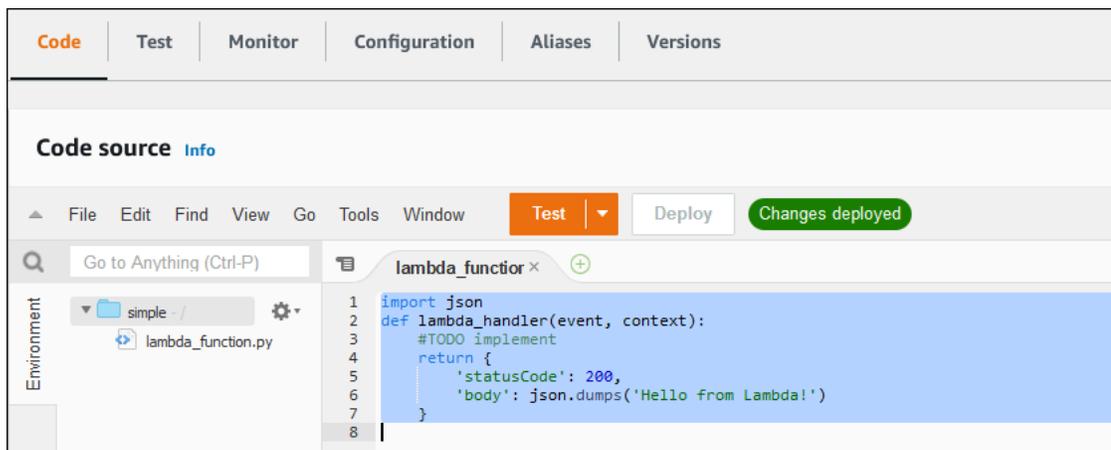

## Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **RequestResponse** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.

- **Event** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

## To invoke an example function

1. Connect to your primary DB instance using `psql` or pgAdmin.

```
psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Invoke the function using its ARN.

```

SELECT * from
  aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-
region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from
Postgres!}':::json );

```

The response looks as follows.

```

status_code |                               payload                               |
executed_version | log_result
-----+-----
+-----+-----
          200 | {"statusCode": 200, "body": "\"Hello from Lambda!\\""} | $LATEST
|

```

```
(1 row)
```

If your invocation attempt doesn't succeed, see [Lambda function error messages](#).

## Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

### To grant others permission to invoke Lambda functions

1. Connect to your primary DB instance using `psql` or `pgAdmin`.

```
psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Run the following SQL commands:

```
postgres=> GRANT USAGE ON SCHEMA aws_lambda TO db_username;  
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
```

## Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster

Following, you can find several examples of calling the [aws\\_lambda.invoke](#) function. Most of the examples use the composite structure `aws_lambda_arn_1` that you create in [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\)](#) to simplify passing the function details. For an example of asynchronous invocation, see [Example: Asynchronous \(Event\) invocation of Lambda functions](#). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see [Invoking Lambda functions](#) in the *Amazon Lambda Developer Guide*. For more information about `aws_lambda_arn_1`, see [aws\\_commons.create\\_lambda\\_function\\_arn](#).

### Examples list

- [Example: Synchronous \(RequestResponse\) invocation of Lambda functions](#)
- [Example: Asynchronous \(Event\) invocation of Lambda functions](#)
- [Example: Capturing the Lambda execution log in a function response](#)
- [Example: Including client context in a Lambda function](#)

- [Example: Invoking a specific version of a Lambda function](#)

### Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json);
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse');
```

The parameters are described as follows:

- `'aws_lambda_arn_1'` – This parameter identifies the composite structure created in [Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster \(Optional\)](#), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}'::json);
```

- `'{"body": "Hello from PostgreSQL!"}'::json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

### Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'Event');
```

## Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the `log_type` parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to `None`, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':::json,
'RequestResponse', 'Tail');
```

Set the [aws\\_lambda.invoke](#) function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is `None`.

The `log_result` that's returned is a base64 encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about `log_type`, see [aws\\_lambda.invoke](#).

## Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a `context` parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':::json,
'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the [aws\\_lambda.invoke](#) function's `context` parameter.

For more information about the `context` parameter, see the [aws\\_lambda.invoke](#) reference.

## Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using `'custom_version'` as an alias for the version.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
Postgres!"}':::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-  
function:custom_version', 'us-west-2'),  
'{"body": "Hello from Postgres!"}'::json);
```

For more information about `qualifier` and other parameters, see the [aws\\_lambda.invoke](#) reference.

## Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

VPC configuration issues can raise the following error messages when trying to connect:

```
ERROR: invoke API failed  
DETAIL: Amazon Lambda client returned 'Unable to connect to endpoint'.  
CONTEXT: SQL function "invoke" statement 1
```

A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

- **Lack of permissions needed to invoke Lambda functions**

If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

```
ERROR: permission denied for schema aws_lambda
```

```
ERROR: permission denied for function invoke
```

A user (role) must be given specific grants to invoke Lambda functions. For more information, see [Step 6: Grant other users permission to invoke Lambda functions](#).

- **Improper handling of errors in your Lambda functions**

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
Postgres!"}':::json);
ERROR:  lambda invocation failed
DETAIL:  "arn:aws-cn:lambda:us-west-2:555555555555:function:my-function" returned
error "Unhandled", details: "<Error details string>".
```

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

## Amazon Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with Aurora PostgreSQL .

### Functions and parameters

- [aws\\_lambda.invoke](#)
- [aws\\_commons.create\\_lambda\\_function\\_arn](#)
- [aws\\_lambda parameters](#)

### aws\_lambda.invoke

Runs a Lambda function for an Aurora PostgreSQL DB cluster .

For more details about invoking Lambda functions, see also [Invoke](#) in the *Amazon Lambda Developer Guide*.

### Syntax

#### JSON

```
aws_lambda.invoke(
  IN function_name TEXT,
  IN payload JSON,
  IN region TEXT DEFAULT NULL,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSON DEFAULT NULL,
```

```
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSON,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

```
aws_lambda.invoke(  
IN function_name aws_commons._lambda_function_arn_1,  
IN payload JSON,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSON DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSON,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

## JSONB

```
aws_lambda.invoke(  
IN function_name TEXT,  
IN payload JSONB,  
IN region TEXT DEFAULT NULL,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSONB DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSONB,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

```
aws_lambda.invoke(  
IN function_name aws_commons._lambda_function_arn_1,  
IN payload JSONB,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSONB DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSONB,
```

```
OUT executed_version TEXT,  
OUT log_result TEXT  
)
```

## Input parameters

### *function\_name*

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see [Lambda function name formats](#) in the *Amazon Lambda Developer Guide*.

### *payload*

The input for the Lambda function. The format can be JSON or JSONB. For more information, see [JSON Types](#) in the PostgreSQL documentation.

### *region*

(Optional) The Lambda Region for the function. By default, Aurora resolves the Amazon Region from the full ARN in the `function_name` or it uses the Aurora PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the `function_name` ARN, an error is raised.

### *invocation\_type*

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- `RequestResponse` – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the `RequestResponse` invocation type when your workflow depends on receiving the Lambda function result immediately.
- `Event` – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the `Event` invocation type when you don't need results of the Lambda function before your workflow moves on.
- `DryRun` – This type of invocation tests access without running the Lambda function.

### *log\_type*

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- **Tail** – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- **None** – No Lambda log information is returned.

#### *context*

Client context in JSON or JSONB format. Fields to use include `custom` and `env`.

#### *qualifier*

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

## Output parameters

#### *status\_code*

An HTTP status response code. For more information, see [Lambda Invoke response elements](#) in the *Amazon Lambda Developer Guide*.

#### *payload*

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

#### *executed\_version*

The version of the Lambda function that ran.

#### *log\_result*

The execution log information returned if the `log_type` value is `Tail` when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

## **aws\_commons.create\_lambda\_function\_arn**

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the `aws_lambda.invoke` [aws\\_lambda.invoke](#) function.

## Syntax

```
aws_commons.create_lambda_function_arn(
```

```
function_name TEXT,
region TEXT DEFAULT NULL
)
RETURNS aws_commons._lambda_function_arn_1
```

## Input parameters

### *function\_name*

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

### *region*

An optional text string containing the Amazon Region that the Lambda function is in. For a listing of Region names and associated values, see [Regions and Availability Zones](#).

## aws\_lambda parameters

In this table, you can find parameters associated with the `aws_lambda` function.

Parameter	Description
<code>aws_lambda.connect_timeout_ms</code>	This is a dynamic parameter and it sets the maximum wait time while connecting to Amazon Lambda. The default values is 1000. Allowed values for this parameter are 1 - 900000.
<code>aws_lambda.request_timeout_ms</code>	This is a dynamic parameter and it sets the maximum wait time while waiting for response from Amazon Lambda. The default values is 3000. Allowed values for this parameter are 1 - 900000.
<code>aws_lambda.endpoint_override</code>	Specifies the endpoint that can be used to connect to Amazon Lambda. An empty string selects the default Amazon Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.

## Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs

You can configure your Aurora PostgreSQL DB cluster to export log data to Amazon CloudWatch Logs on a regular basis. When you do so, events from your Aurora PostgreSQL DB cluster's PostgreSQL log are automatically *published* to Amazon CloudWatch, as Amazon CloudWatch Logs. In CloudWatch, you can find the exported log data in a *Log group* for your Aurora PostgreSQL DB cluster. The log group contains one or more *log streams* that contain the events from the PostgreSQL log from each instance in the cluster.

Publishing the logs to CloudWatch Logs allows you to keep your cluster's PostgreSQL log records in highly durable storage. With the log data available in CloudWatch Logs, you can evaluate and improve your cluster's operations. You can also use CloudWatch to create alarms and view metrics. To learn more, see [Monitoring log events in Amazon CloudWatch](#).

### Note

Publishing your PostgreSQL logs to CloudWatch Logs consumes storage, and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.

Turning the export log option off for an existing Aurora PostgreSQL DB cluster doesn't affect any data that's already held in CloudWatch Logs. Existing logs remain available in CloudWatch Logs based on your log retention settings. To learn more about CloudWatch Logs, see [What is Amazon CloudWatch Logs?](#)

Aurora PostgreSQL supports publishing logs to CloudWatch Logs for the following versions.

- 16.1 and all higher versions
- 15.2 and higher 15 versions
- 14.3 and higher 14 versions
- 13.3 and higher 13 versions
- 12.8 and higher 12 versions
- 11.9 and higher 11 versions

For information about turning on the option to publish logs to CloudWatch Logs, monitoring log events in CloudWatch Logs, and analyzing logs using CloudWatch Logs Insights, see the following topics.

## Topics

- [Turning on the option to publish logs to Amazon CloudWatch](#)
- [Monitoring log events in Amazon CloudWatch](#)
- [Analyzing PostgreSQL logs using CloudWatch Logs Insights](#)

## Turning on the option to publish logs to Amazon CloudWatch

To publish your Aurora PostgreSQL DB cluster's PostgreSQL log to CloudWatch Logs, choose the **Log export** option for the cluster. You can choose the Log export setting when you create your Aurora PostgreSQL DB cluster. Or, you can modify the cluster later on. When you modify an existing cluster, its PostgreSQL logs from each instance are published to CloudWatch cluster from that point on. For Aurora PostgreSQL, the PostgreSQL log (`postgresql.log`) is the only log that gets published to Amazon CloudWatch.

You can use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API to turn on the Log export feature for your Aurora PostgreSQL DB cluster.

### Console

You choose the Log exports option to start publishing the PostgreSQL logs from your Aurora PostgreSQL DB cluster to CloudWatch Logs.

### To turn on the Log export feature from the console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora PostgreSQL DB cluster whose log data you want to publish to CloudWatch Logs.
4. Choose **Modify**.
5. In the **Log exports** section, choose **PostgreSQL log**.
6. Choose **Continue**, and then choose **Modify cluster** on the summary page.

### Amazon CLI

You can turn on the log export option to start publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs with the Amazon CLI. To do so, run the [modify-db-cluster](#) Amazon CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be set for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs by running one of the following Amazon CLI commands:

- [create-db-cluster](#)
- [restore-db-cluster-from-s3](#)
- [restore-db-cluster-from-snapshot](#)
- [restore-db-cluster-to-point-in-time](#)

Run one of these Amazon CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the Amazon CLI command that you run.

### Example

The following command creates an Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier my-db-cluster \  
  --engine aurora-postgresql \  
  --enable-cloudwatch-logs-exports postgresql
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier my-db-cluster ^  
  --engine aurora-postgresql ^
```

```
--enable-cloudwatch-logs-exports postgresql
```

## Example

The following command modifies an existing Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is `postgresql`, and `instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier my-db-cluster \  
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":  
["postgresql","instance"]}'
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier my-db-cluster ^  
  --cloudwatch-logs-export-configuration '{"EnableLogTypes\":[\"postgresql\  
\"instance\"]}'
```

### Note

When using the Windows command prompt, make sure to escape double quotation marks (") in JSON code by prefixing them with a backslash (\).

## Example

The following example modifies an existing Aurora PostgreSQL DB cluster to disable publishing log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is `postgresql` and `instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbinstance \  
  --cloudwatch-logs-export-configuration '{"DisableLogTypes":  
["postgresql","instance"]}'
```

## For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql",
  \instance\']}]}'
```

### Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

## RDS API

You can turn on the log export option to start publishing Aurora PostgreSQL logs with the RDS API. To do so, run the [ModifyDBCluster](#) operation with the following options:

- `DBClusterIdentifier` – The DB cluster identifier.
- `CloudwatchLogsExportConfiguration` – The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs with the RDS API by running one of the following RDS API operations:

- [CreateDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

Run the RDS API action with the following parameters:

- `DBClusterIdentifier`—The DB cluster identifier.
- `Engine`—The database engine.
- `EnableCloudwatchLogsExports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the Amazon CLI command that you run.

## Monitoring log events in Amazon CloudWatch

With Aurora PostgreSQL log events published and available as Amazon CloudWatch Logs, you can view and monitor events using Amazon CloudWatch. For more information about monitoring, see [View log data sent to CloudWatch Logs](#).

When you turn on Log exports, a new log group is automatically created using the prefix `/aws/rds/cluster/` with the name of your Aurora PostgreSQL and the log type, as in the following pattern.

```
/aws/rds/cluster/your-cluster-name/postgresql
```

As an example, suppose that an Aurora PostgreSQL DB cluster named `docs-lab-apg-small` exports its log to Amazon CloudWatch Logs. Its log group name in Amazon CloudWatch is shown following.

```
/aws/rds/cluster/docs-lab-apg-small/postgresql
```

If a log group with the specified name exists, Aurora uses that log group to export log data for the Aurora DB cluster. Each DB instance in the Aurora PostgreSQL DB cluster uploads its PostgreSQL log to the log group as a distinct log stream. You can examine the log group and its log streams using the various graphical and analytical tools available in Amazon CloudWatch.

For example, you can search for information within the log events from your Aurora PostgreSQL DB cluster, and filter events by using the CloudWatch Logs console, the Amazon CLI, or the CloudWatch Logs API. For more information, see [Searching and filtering log data](#) in the *Amazon CloudWatch Logs User Guide*.

By default, new log groups are created using **Never expire** for their retention period. You can use the CloudWatch Logs console, the Amazon CLI, or the CloudWatch Logs API to change the log retention period. To learn more, see [Change log data retention in CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

### Tip

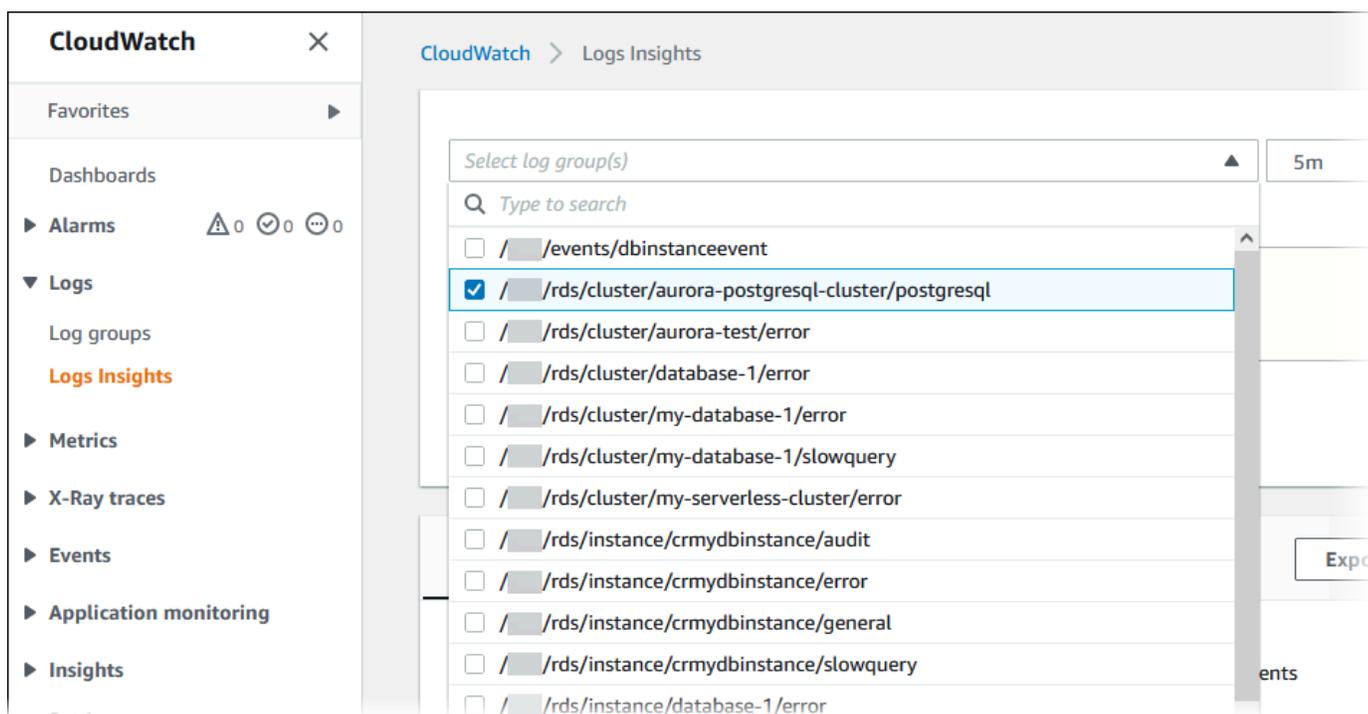

You can use automated configuration, such as Amazon CloudFormation, to create log groups with predefined log retention periods, metric filters, and access permissions.

## Analyzing PostgreSQL logs using CloudWatch Logs Insights

With the PostgreSQL logs from your Aurora PostgreSQL DB cluster published as CloudWatch Logs, you can use CloudWatch Logs Insights to interactively search and analyze your log data in Amazon CloudWatch Logs. CloudWatch Logs Insights includes a query language, sample queries, and other tools for analyzing your log data so that you can identify potential issues and verify fixes. To learn more, see [Analyzing log data with CloudWatch Logs Insights](#) in the *Amazon CloudWatch Logs User Guide*.

### To analyze PostgreSQL logs with CloudWatch Logs Insights

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. In the navigation pane, open **Logs** and choose **Log insights**.
3. In **Select log group(s)**, select the log group for your Aurora PostgreSQL DB cluster.

4. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
##Autovacuum execution time in seconds per 5 minute
fields @message
| parse @message "elapsed: * s" as @duration_sec
| filter @message like / automatic vacuum /
| display @duration_sec
```

```

| sort @timestamp
| stats avg(@duration_sec) as avg_duration_sec,
max(@duration_sec) as max_duration_sec
by bin(5 min)

```

The screenshot shows the AWS CloudWatch Logs Insights interface. On the left is a navigation sidebar with options like Favorites, Dashboards, Alarms, Logs, Metrics, X-Ray traces, Events, Application monitoring, and Insights. The main area is titled 'CloudWatch > Logs Insights'. It features a search bar for log groups, currently set to '/rds/cluster/aurora-postgresql-cluster/postgresql'. Below the search bar is a query editor with the following SQL query:

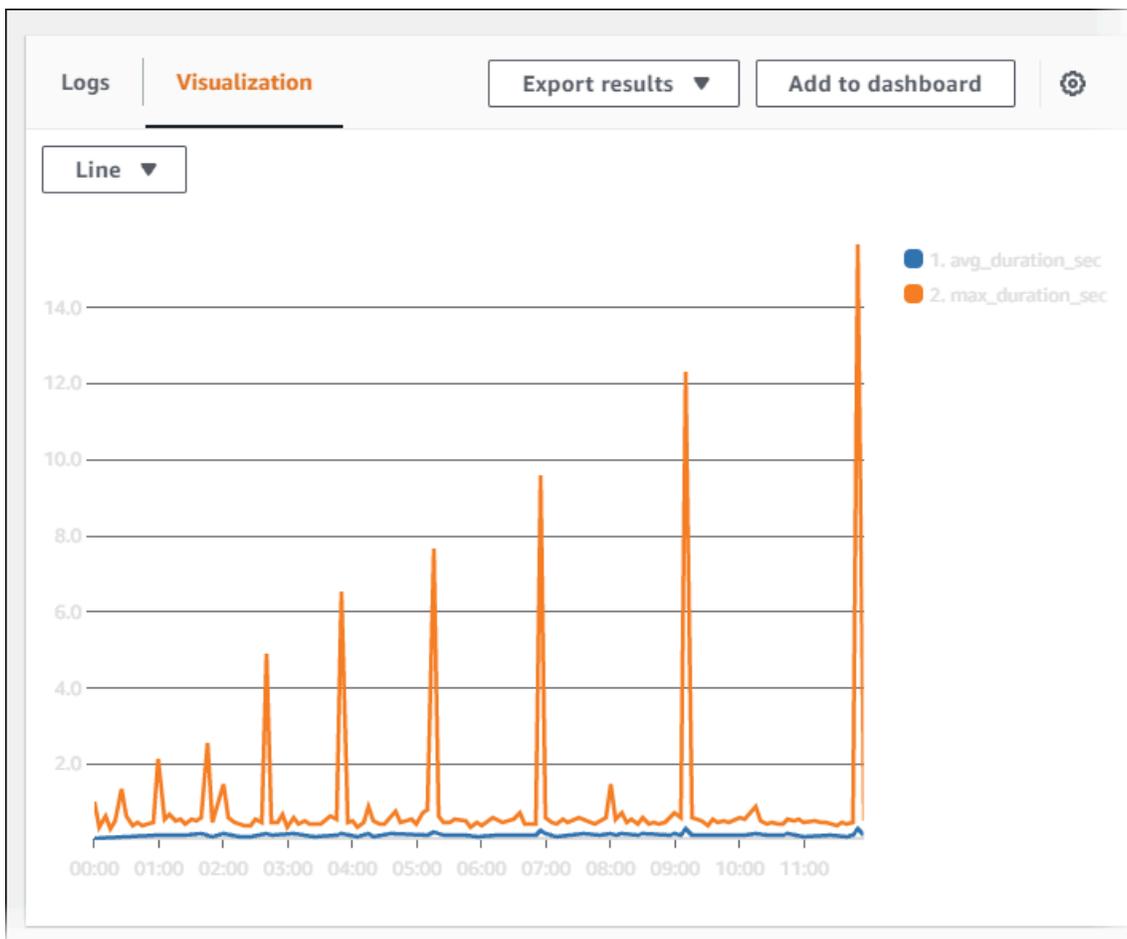

```

1 ##Autovacuum execution time in seconds per 5 minute
2 fields @message
3 | parse @message "elapsed: * s" as @duration_sec
4 | filter @message like / automatic vacuum /
5 | display @duration_sec
6 | sort @timestamp
7 | stats avg(@duration_sec) as avg_duration_sec,
8 max(@duration_sec) as max_duration_sec
9 by bin(5 min)

```

Below the query editor are buttons for 'Run query', 'Save', and 'History'. A note at the bottom states: 'Queries are allowed to run for up to 15 minutes.'

## 5. Choose the **Visualization** tab.

6. Choose **Add to dashboard**.
7. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.
8. In **Widget type**, choose a widget type for your visualization.

### Add to dashboard ✕

**Select a dashboard**  
Select an existing dashboard or create a new one.

✕

Create new

**Widget type**  
Select a widget type to add to the dashboard.

Line

**Customize widget title**  
Widgets get an automatic title. You can optionally customize the title here.

Autovacuum Duration - Avg and Max

**Preview**  
This is how your chart will appear in your dashboard.

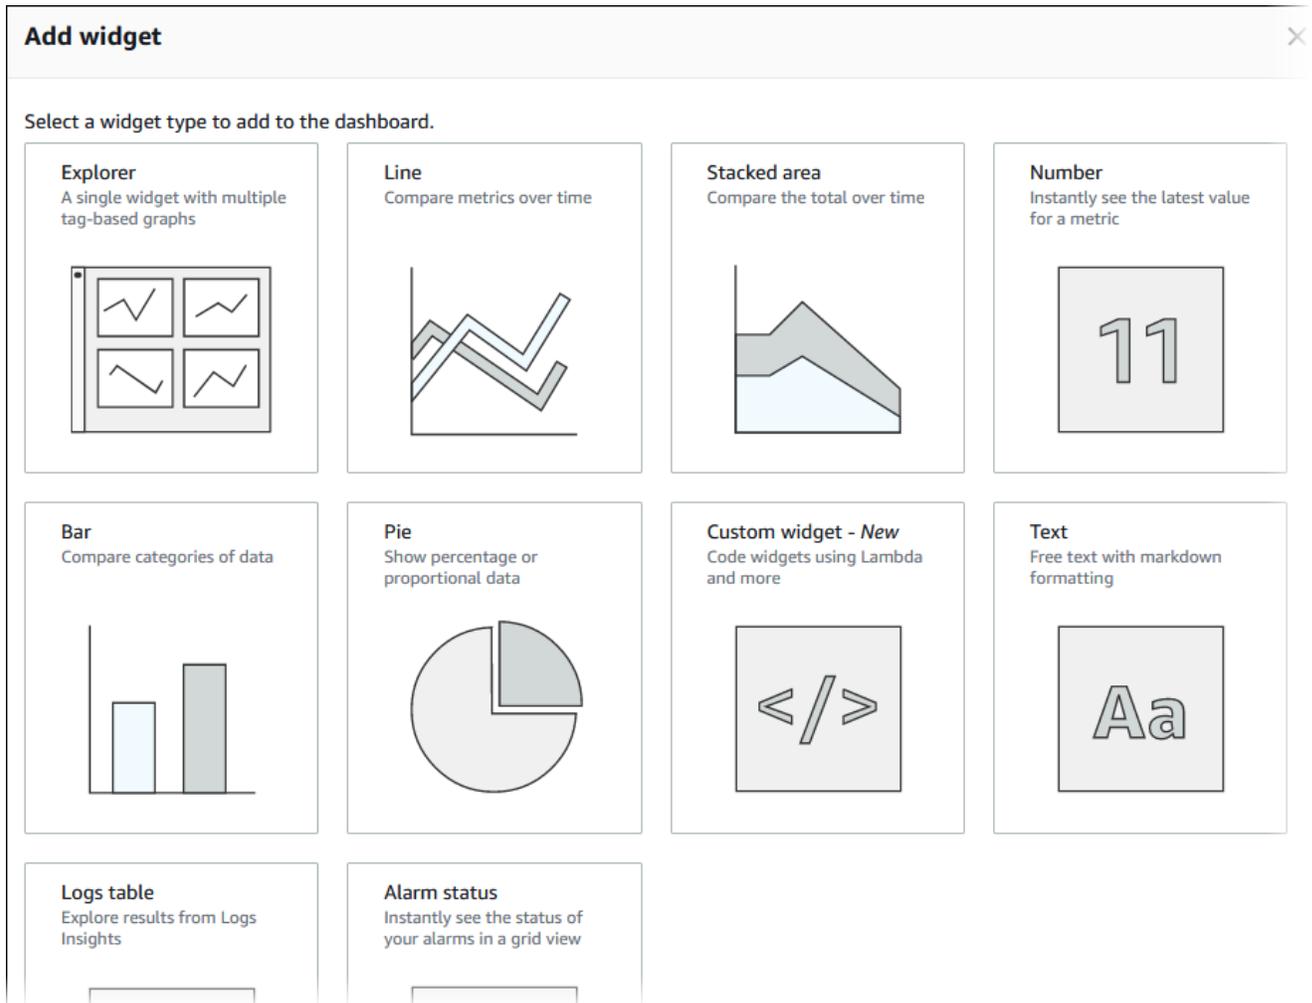

**Autovacuum Duration - Avg and Max**

● 1. avg\_duration\_sec  
● 2. max\_duration\_sec

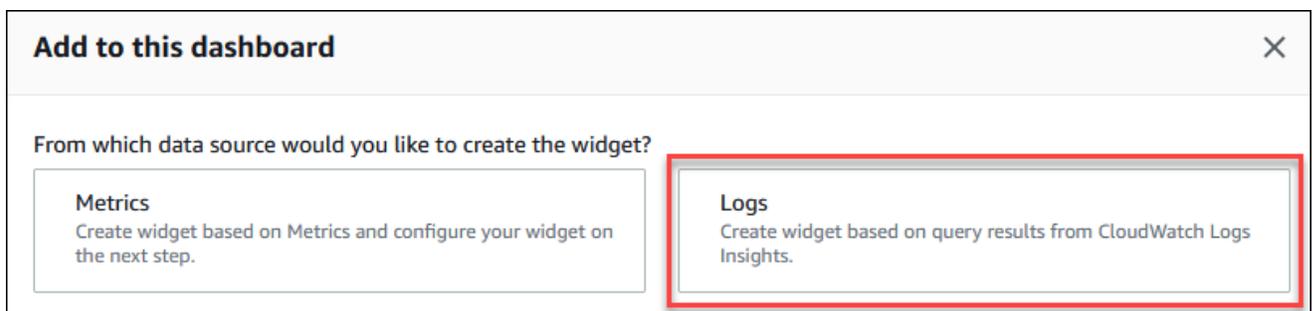

00:00 03:00 06:00 09:00

Cancel
Add to dashboard

9. (Optional) Add more widgets based on your log query results.
  - a. Choose **Add widget**.
  - b. Choose a widget type, such as **Line**.

- c. In the **Add to this dashboard** window, choose **Logs**.

- d. In **Select log group(s)**, select the log group for your DB cluster.
- e. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
##Autovacuum tuples statistics per 5 min
fields @timestamp, @message
| parse @message "tuples: " as @tuples_temp
```

```

| parse @tuples_temp "* removed," as @tuples_removed
| parse @tuples_temp "remain, * are dead but not yet removable, " as
  @tuples_not_removable
| filter @message like / automatic vacuum /
| sort @timestamp
| stats avg(@tuples_removed) as avg_tuples_removed,
  avg(@tuples_not_removable) as avg_tuples_not_removable
  by bin(5 min)

```

The screenshot shows the AWS CloudWatch Logs Insights interface. On the left is a navigation sidebar with options like Favorites, Dashboards, Alarms, Logs, Metrics, X-Ray traces, Events, Application monitoring, and Insights. The main area is titled 'Logs Insights' and shows a selected log group: `/rds/cluster/aurora-postgresql-cluster/postgresql`. A query is entered in the text area:

```

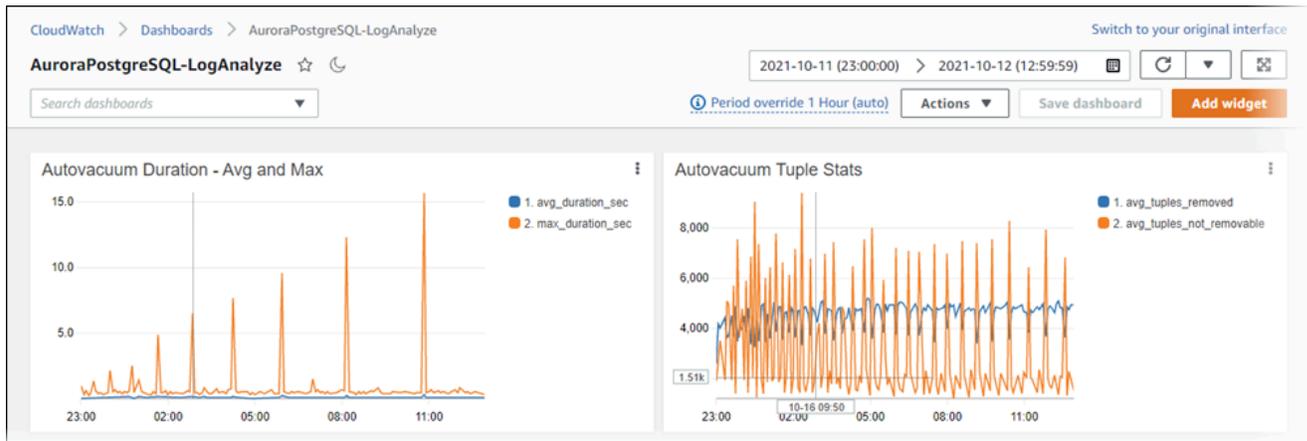

1 ##Autovacuum tuples statistics per 5 min
2 fields @timestamp, @message
3 | parse @message "tuples:" as @tuples_temp
4 | parse @tuples_temp "* removed," as @tuples_removed
5 | parse @tuples_temp "remain, * are dead but not yet removable," as @tuples_not_removable
6 | filter @message like / automatic vacuum /
7 | sort @timestamp
8 | stats avg(@tuples_removed) as avg_tuples_removed,
9   avg(@tuples_not_removable) as avg_tuples_not_removable
10 by bin(5 min)

```

Below the query are buttons for 'Run query', 'Save', and 'History'. A note at the bottom states: 'Queries are allowed to run for up to 15 minutes.'

f. Choose **Create widget**.

Your dashboard should look similar to the following image.

# Monitoring query execution plans and peak memory for Aurora PostgreSQL

You can monitor query execution plans in your Aurora PostgreSQL DB instance to detect the execution plans contributing to current database load and to track performance statistics of execution plans over time using the `aurora_compute_plan_id` parameter. Whenever a query executes, the execution plan used by the query is assigned an identifier and the same identifier is used by subsequent executions of the same plan.

The `aurora_compute_plan_id` is turned OFF by default in DB parameter group from Aurora PostgreSQL versions 14.10, 15.5, and higher versions. To assign a plan identifier, set `aurora_compute_plan_id` to ON in the parameter group.

This plan identifier is used in several utilities that serve a different purpose.

You can monitor query peak memory usage in your DB instance to detect queries contributing to high database memory use from the following versions:

- 16.3 and all higher versions
- 15.7 and higher versions
- 14.12 and higher versions

Whenever a query runs, the peak memory used by the query is tracked. Queries typically run many times; the average, minimum and maximum memory usage values across all runs can be viewed for each query.

## Topics

- [Accessing query execution plans and peak memory using Aurora functions](#)
- [Parameter reference for Aurora PostgreSQL query execution plans](#)

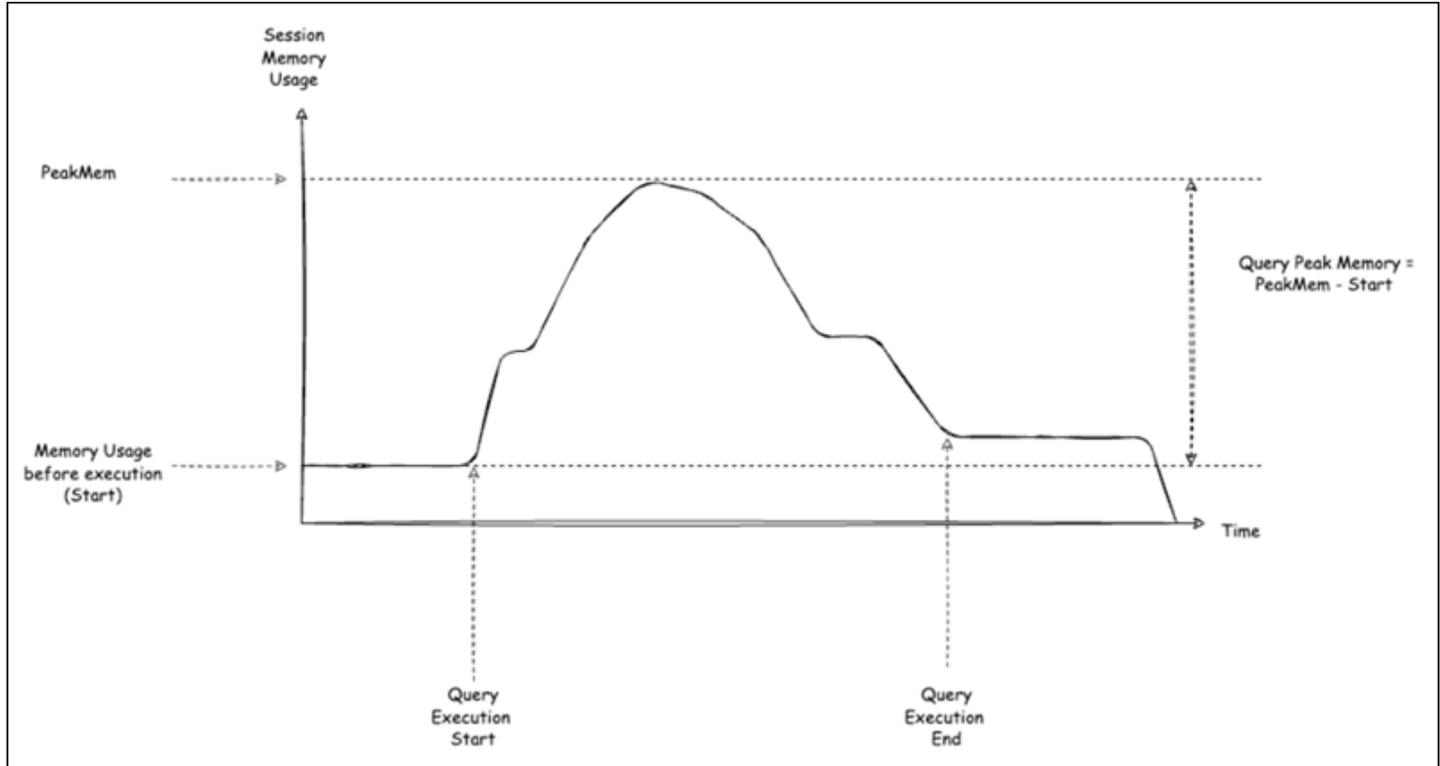

## Accessing query execution plans and peak memory using Aurora functions

With `aurora_compute_plan_id`, you can access the execution plans using the following functions:

- `aurora_stat_activity`

- `aurora_stat_plans`

The query peak memory does not include memory that is allocated before query processing starts. Peak memory usage is tracked and reported separately for the planning and execution phases of each query.

You can access the query peak memory statistics using the following functions:

- `aurora_stat_statements`
- `aurora_stat_plans`

For more information on these functions, see [Aurora PostgreSQL functions reference](#).

## Parameter reference for Aurora PostgreSQL query execution plans

You can monitor the query execution plans using the below parameters in a DB parameter group.

### Parameters

- [aurora\\_compute\\_plan\\_id](#)
- [aurora\\_stat\\_plans.minutes\\_until\\_recapture](#)

- [aurora\\_stat\\_plans.calls\\_until\\_recapture](#)
- [aurora\\_stat\\_plans.with\\_costs](#)
- [aurora\\_stat\\_plans.with\\_analyze](#)
- [aurora\\_stat\\_plans.with\\_timing](#)
- [aurora\\_stat\\_plans.with\\_buffers](#)
- [aurora\\_stat\\_plans.with\\_wal](#)
- [aurora\\_stat\\_plans.with\\_triggers](#)

### Note

The configuration for `aurora_stat_plans.with_*` parameters takes effect only for newly captured plans.

## aurora\_compute\_plan\_id

The `aurora_compute_plan_id` is a configuration parameter that controls whether a plan identifier is assigned during query execution.

Default	Allowed values	Description
off	0(off)	Set to off to prevent a plan identifier from being assigned.
	1(on)	Set to on to assign a plan identifier.

## aurora\_stat\_plans.minutes\_until\_recapture

The number of minutes to pass before a plan is recaptured. Default is 0 which will disable recapturing a plan. When the `aurora_stat_plans.calls_until_recapture` threshold is passed, the plan will be recaptured.

Default	Allowed values	Description
0	0-1073741823	Set the number of minutes to pass before a plan is recaptured.

## aurora\_stat\_plans.calls\_until\_recapture

The number of calls to a plan before it is recaptured. Default is 0 which will disable recapturing a plan after a number of calls. When the `aurora_stat_plans.minutes_until_recapture` threshold is passed, the plan will be recaptured.

Default	Allowed values	Description
0	0-1073741823	Set the number of calls before a plan is recaptured.

## aurora\_stat\_plans.with\_costs

Captures an EXPLAIN plan with estimated costs. The allowed values are on and off. The default is on.

Default	Allowed values	Description
on	0(off)	Doesn't show estimated cost and rows for each plan node.
	1(on)	Shows estimated cost and rows for each plan node.

## aurora\_stat\_plans.with\_analyze

Controls the EXPLAIN plan with ANALYZE. This mode is only used the first time a plan is captured. The allowed values are on and off. The default is off.

Default	Allowed values	Description
off	0(off)	Doesn't include actual run time statistics for the plan.
	1(on)	Includes actual run time statistics for the plan.

## aurora\_stat\_plans.with\_timing

Plan timing will be captured in the explain when ANALYZE is used. The default is on.

Default	Allowed values	Description
on	0(off)	Doesn't include actual start up time and time spent in each plan node.
	1(on)	Includes actual start up time and time spent in each plan node.

### **aurora\_stat\_plans.with\_buffers**

Plan buffer usage statistics will be captured in the explain when ANALYZE is used. The default is off.

Default	Allowed values	Description
off	0(off)	Doesn't include information on buffer usage.
	1(on)	Includes information on buffer usage.

### **aurora\_stat\_plans.with\_wal**

Plan wal usage statistics will be captured in the explain when ANALYZE is used. The default is off.

Default	Allowed values	Description
off	0(off)	Doesn't include information on WAL record generation.
	1(on)	Includes information on WAL record generation.

### **aurora\_stat\_plans.with\_triggers**

Plan trigger execution statistics will be captured in the explain when ANALYZE is used. The default is off.

Default	Allowed values	Description
off	0(off)	Doesn't include triggers execution statistics.

Default	Allowed values	Description
	1(on)	Includes triggers execution statistics.

# Managing query execution plans for Aurora PostgreSQL

Aurora PostgreSQL query plan management is an optional feature that you can use with your Amazon Aurora PostgreSQL-Compatible Edition DB cluster. This feature is packaged as the `apg_plan_mgmt` extension that you can install in your Aurora PostgreSQL DB cluster. Query plan management allows you to manage the query execution plans generated by the optimizer for your SQL applications. The `apg_plan_mgmt` Amazon extension builds on the native query processing functionality of the PostgreSQL database engine.

Following, you can find information about Aurora PostgreSQL query plan management features, how to set it up, and how to use it with your Aurora PostgreSQL DB cluster. Before you get started, we recommend that you review any release notes for the specific version of the `apg_plan_mgmt` extension available for your Aurora PostgreSQL version. For more information, see [Aurora PostgreSQL `apg\_plan\_mgmt` extension versions](#) in the *Release Notes for Aurora PostgreSQL*.

## Overview of Aurora PostgreSQL query plan management

Aurora PostgreSQL query plan management is designed to ensure plan stability regardless of changes to the database that might cause query plan regression. *Query plan regression* occurs when

the optimizer chooses a sub-optimal plan for a given SQL statement after system or database changes. Changes to statistics, constraints, environment settings, query parameter bindings, and upgrades to the PostgreSQL database engine can all cause plan regression.

With Aurora PostgreSQL query plan management, you can control how and when query execution plans change. The benefits of Aurora PostgreSQL query plan management include the following.

- Improve plan stability by forcing the optimizer to choose from a small number of known, good plans.
- Optimize plans centrally and then distribute the best plans globally.
- Identify indexes that aren't used and assess the impact of creating or dropping an index.
- Automatically detect a new minimum-cost plan discovered by the optimizer.
- Try new optimizer features with less risk, because you can choose to approve only the plan changes that improve performance.

You can use the tools provided by query plan management proactively, to specify the best plan for certain queries. Or you can use query plan management to react to changing circumstances and avoid plan regressions. For more information, see [Best practices for Aurora PostgreSQL query plan management](#).

## Topics

- [Supported SQL statements](#)
- [Query plan management limitations](#)
- [Query plan management terminology](#)
- [Aurora PostgreSQL query plan management versions](#)
- [Turning on Aurora PostgreSQL query plan management](#)
- [Upgrading Aurora PostgreSQL query plan management](#)
- [Turning off Aurora PostgreSQL query plan management](#)

## Supported SQL statements

Query plan management supports the following types of SQL statements.

- Any SELECT, INSERT, UPDATE, or DELETE statement, regardless of complexity.
- Prepared statements. For more information, see [PREPARE](#) in the PostgreSQL documentation.

- Dynamic statements, including those run in immediate-mode. For more information, see [Dynamic SQL](#) and [EXECUTE IMMEDIATE](#) in PostgreSQL documentation.
- Embedded SQL commands and statements. For more information, see [Embedded SQL Commands](#) in the PostgreSQL documentation.
- Statements inside named functions. For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.
- Statements containing temp tables.
- Statements inside procedures and DO-blocks.

You can use query plan management with EXPLAIN in manual mode to capture a plan without actually running it. For more information, see [Analyzing the optimizer's chosen plan](#). To learn more about query plan management's modes (manual, automatic), see [Capturing Aurora PostgreSQL execution plans](#).

Aurora PostgreSQL query plan management supports all PostgreSQL language features, including partitioned tables, inheritance, row-level security, and recursive common table expressions (CTEs). To learn more about these PostgreSQL language features, see [Table Partitioning](#), [Row Security Policies](#), and [WITH Queries \(Common Table Expressions\)](#) and other topics in the PostgreSQL documentation.

For information about different versions of the Aurora PostgreSQL query plan management feature, see [Aurora PostgreSQL apg\\_plan\\_mgmt extension versions](#) in the *Release Notes for Aurora PostgreSQL*.

## Query plan management limitations

The current release of Aurora PostgreSQL query plan management has the following limitations.

- **Plans aren't captured for statements that reference system relations** – Statements that reference system relations, such as `pg_class`, aren't captured. This is by design, to prevent a large number of system-generated plans that are used internally from being captured. This also applies to system tables inside views.
- **Larger DB instance class might be needed for your Aurora PostgreSQL DB cluster** – Depending on the workload, query plan management might need a DB instance class that has more than 2 vCPUs. The number of `max_worker_processes` is limited by the DB instance class size. The number of `max_worker_processes` provided by a 2-vCPU DB instance class (`db.t3.medium`,

for example) might not be sufficient for a given workload. We recommend that you choose a DB instance class with more than 2 vCPUs for your Aurora PostgreSQL DB cluster if you use query plan management.

When the DB instance class can't support the workload, query plan management raises an error message such as the following.

```
WARNING: could not register plan insert background process
HINT: You may need to increase max_worker_processes.
```

In this case, you should scale up your Aurora PostgreSQL DB cluster to a DB instance class size with more memory. For more information, see [Supported DB engines for DB instance classes](#).

- **Plans already stored in sessions aren't affected** – Query plan management provides a way to influence query plans without changing the application code. However, when a generic plan is already stored in an existing session and if you want to change its query plan, then you must first set `plan_cache_mode` to `force_custom_plan` in the DB cluster parameter group.
- `queryid` in `apg_plan_mgmt.dba_plans` and `pg_stat_statements` can diverge when:
  - Objects are dropped and recreated after storing in `apg_plan_mgmt.dba_plans`.
  - `apg_plan_mgmt.plans` table is imported from another cluster.

For information about different versions of the Aurora PostgreSQL query plan management feature, see [Aurora PostgreSQL apg\\_plan\\_mgmt extension versions](#) in the *Release Notes for Aurora PostgreSQL*.

## Query plan management terminology

The following terms are used throughout this topic.

### managed statement

A SQL statement captured by the optimizer under query plan management. A managed statement has one or more query execution plans stored in the `apg_plan_mgmt.dba_plans` view.

### plan baseline

The set of approved plans for a given managed statement. That is, all the plans for the managed statement that have "Approved" for their `status` column in the `dba_plan` view.

## plan history

The set of all captured plans for a given managed statement. The plan history contains all plans captured for the statement, regardless of status.

## query plan regression

The case when the optimizer chooses a less optimal plan than it did before a given change to the database environment, such as a new PostgreSQL version or changes to statistics.

## Aurora PostgreSQL query plan management versions

Query plan management is supported by all currently available Aurora PostgreSQL releases. For more information, see the list of [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

Query plan management functionality is added to your Aurora PostgreSQL DB cluster when you install the `apg_plan_mgmt` extension. Different versions of Aurora PostgreSQL support different versions of the `apg_plan_mgmt` extension. We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.

### Note

For release notes for each `apg_plan_mgmt` extension versions, see [Aurora PostgreSQL `apg\_plan\_mgmt` extension versions](#) in the *Release Notes for Aurora PostgreSQL*.

You can identify the version running on your cluster by connecting to an instance using `psql` and using the metacommand `\dx` to list extensions as shown following.

```
labdb=> \dx
                                List of installed extensions
  Name          | Version | Schema          | Description
-----+-----+-----+-----
apg_plan_mgmt | 1.0     | apg_plan_mgmt | Amazon Aurora with PostgreSQL compatibility
Query Plan Management
plpgsql        | 1.0     | pg_catalog     | PL/pgSQL procedural language
(2 rows)
```

The output shows that this cluster is using 1.0 version of the extension. Only certain `apg_plan_mgmt` versions are available for a given Aurora PostgreSQL version. In some cases, you might need to upgrade the Aurora PostgreSQL DB cluster to a new minor release or apply a patch so that you can upgrade to the most recent version of query plan management. The `apg_plan_mgmt` version 1.0 shown in the output is from an Aurora PostgreSQL version 10.17 DB cluster, which doesn't have a newer version of `apg_plan_mgmt` available. In this case, the Aurora PostgreSQL DB cluster should be upgraded to a more recent version of PostgreSQL.

For more information about upgrading your Aurora PostgreSQL DB cluster to a new version of PostgreSQL, see [Database engine updates for Amazon Aurora PostgreSQL](#).

To learn how to upgrade the `apg_plan_mgmt` extension, see [Upgrading Aurora PostgreSQL query plan management](#).

## Turning on Aurora PostgreSQL query plan management

Setting up query plan management for your Aurora PostgreSQL DB cluster involves installing an extension and changing several DB cluster parameter settings. You need `rds_superuser` permissions to install the `apg_plan_mgmt` extension and to turn on the feature for the Aurora PostgreSQL DB cluster.

Installing the extension creates a new role, `apg_plan_mgmt`. This role allows database users to view, manage, and maintain query plans. As an administrator with `rds_superuser` privileges, be sure to grant the `apg_plan_mgmt` role to database users as needed.

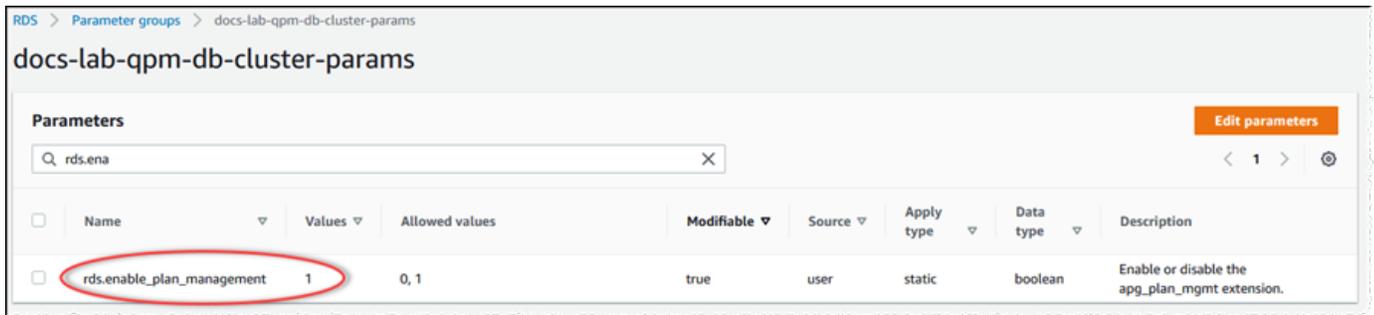

Only users with the `rds_superuser` role can complete the following procedure. The `rds_superuser` is required for creating the `apg_plan_mgmt` extension and its `apg_plan_mgmt` role. Users must be granted the `apg_plan_mgmt` role to administer the `apg_plan_mgmt` extension.

### To turn on query plan management for your Aurora PostgreSQL DB cluster

The following steps turn on query plan management for all SQL statements that get submitted to the Aurora PostgreSQL DB cluster. This is known as *automatic* mode. To learn more about the difference between modes, see [Capturing Aurora PostgreSQL execution plans](#).

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Create a custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You need to change certain parameters to activate query plan management and to set its behavior. For more information, see [Creating a DB parameter group in Amazon Aurora](#).

- Open the custom DB cluster parameter group and set the `rds.enable_plan_management` parameter to 1, as shown in the following image.

For more information, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

- Create a custom DB parameter group that you can use to set query plan parameters at the instance level. For more information, see [Creating a DB cluster parameter group in Amazon Aurora](#).
- Modify the writer instance of the Aurora PostgreSQL DB cluster to use the custom DB parameter group. For more information, see [Modifying a DB instance in a DB cluster](#).
- Modify the Aurora PostgreSQL DB cluster to use the custom DB cluster parameter group. For more information, see [Modifying the DB cluster by using the console, CLI, and API](#).
- Reboot your DB instance to enable the custom parameter group settings.
- Connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using `psql` or `pgAdmin`. The following example uses the default `postgres` account for the `rds_superuser` role.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
port=5432 --username=postgres --password --dbname=my-db
```

- Create the `apg_plan_mgmt` extension for your DB instance, as shown following.

```
labdb=> CREATE EXTENSION apg_plan_mgmt;
CREATE EXTENSION
```

### Tip

Install the `apg_plan_mgmt` extension in the template database for your application. The default template database is named `template1`. To learn more, see [Template Databases](#) in the PostgreSQL documentation.

10. Change the `apg_plan_mgmt.capture_plan_baselines` parameter to `automatic`. This setting causes the optimizer to generate plans for every SQL statement that is either planned or executed two or more times.

**Note**

Query plan management also has a *manual* mode that you can use for specific SQL statements. To learn more, see [Capturing Aurora PostgreSQL execution plans](#).

11. Change the value of `apg_plan_mgmt.use_plan_baselines` parameter to "on." This parameter causes the optimizer to choose a plan for the statement from its plan baseline. To learn more, see [Using Aurora PostgreSQL managed plans](#).

**Note**

You can modify the value of either of these dynamic parameters for the session without needing to reboot the instance.

When your query plan management set up is complete, be sure to grant the `apg_plan_mgmt` role to any database users that need to view, manage, or maintain query plans.

## Upgrading Aurora PostgreSQL query plan management

We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.

1. Connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`. This example shows how to use `psql`, but you can also use `pgAdmin` if you prefer.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. Run the following query to upgrade the extension.

```
ALTER EXTENSION apg_plan_mgmt UPDATE TO '2.1';
```

3. Use the [apg\\_plan\\_mgmt.validate\\_plans](#) function to update the hashes of all plans. The optimizer validates all Approved, Unapproved, and Rejected plans to ensure that they're still viable plans for new version of the extension.

```
SELECT apg_plan_mgmt.validate_plans('update_plan_hash');
```

To learn more about using this function, see [Validating plans](#).

4. Use the [apg\\_plan\\_mgmt.reload](#) function to refresh any plans in the shared memory with the validated plans from the `dba_plans` view.

```
SELECT apg_plan_mgmt.reload();
```

To learn more about all functions available for query plan management, see [Function reference for Aurora PostgreSQL query plan management](#).

## Turning off Aurora PostgreSQL query plan management

You can disable query plan management at any time by turning off the `apg_plan_mgmt.use_plan_baselines` and `apg_plan_mgmt.capture_plan_baselines`.

```
labdb=> SET apg_plan_mgmt.use_plan_baselines = off;

labdb=> SET apg_plan_mgmt.capture_plan_baselines = off;
```

## Best practices for Aurora PostgreSQL query plan management

Query plan management lets you control how and when query execution plans change. As a DBA, your main goals when using QPM include preventing regressions when there are changes to your database, and controlling whether to allow the optimizer to use a new plan. In the following, you can find some recommended best practices for using query plan management. Proactive and reactive plan management approaches differ in how and when new plans get approved for use.

### Contents

- [Proactive plan management to help prevent performance regression](#)
  - [Ensuring plan stability after a major version upgrade](#)
- [Reactive plan management to detect and repair performance regressions](#)

## Proactive plan management to help prevent performance regression

To prevent plan performance regressions from occurring, you *evolve* plan baselines by running a procedure that compares the performance of newly discovered plans to the performance of the existing baseline of Approved plans, and then automatically approves the fastest set of plans as the new baseline. In this way, the baseline of plans improves over time as faster plans are discovered.

1. In a development environment, identify the SQL statements that have the greatest impact on performance or system throughput. Then capture the plans for these statements as described in [Manually capturing plans for specific SQL statements](#) and [Automatically capturing plans](#).
2. Export the captured plans from the development environment and import them into the production environment. For more information, see [Exporting and importing managed plans for Aurora PostgreSQL](#).
3. In production, run your application and enforce the use of approved managed plans. For more information, see [Using Aurora PostgreSQL managed plans](#). While the application runs, also add new plans as the optimizer discovers them. For more information, see [Automatically capturing plans](#).
4. Analyze the unapproved plans and approve those that perform well. For more information, see [Evaluating plan performance](#).
5. While your application continues to run, the optimizer begins to use the new plans as appropriate.

### Ensuring plan stability after a major version upgrade

Each major version of PostgreSQL includes enhancements and changes to the query optimizer that are designed to improve performance. However, query execution plans generated by the optimizer in earlier versions might cause performance regressions in newer upgraded versions. You can use query plan management to resolve these performance issues and to ensure plan stability after a major version upgrade.

The optimizer always uses a minimum-cost Approved plan, even if more than one Approved plan for the same statement exists. After an upgrade the optimizer might discover new plans but they will be saved as Unapproved plans. These plans are performed only if approved using the reactive style of plan management with the `unapproved_plan_execution_threshold` parameter. You can maximize plan stability using the proactive style of plan management with the `evolve_plan_baselines` parameter. This compares the performance of the new plans to the old plans and approves or rejects plans that are at least 10% faster than the next best plan.

After upgrading, you can use the `evolve_plan_baselines` function to compare plan performance before and after the upgrade using your query parameter bindings. The following steps assume that you have been using approved managed plans in your production environment, as detailed in [Using Aurora PostgreSQL managed plans](#).

1. Before upgrading, run your application with the query plan manager running. While the application runs, add new plans as the optimizer discovers them. For more information, see [Automatically capturing plans](#).
2. Evaluate each plan's performance. For more information, see [Evaluating plan performance](#).
3. After upgrading, analyze your approved plans again using the `evolve_plan_baselines` function. Compare performance before and after using your query parameter bindings. If the new plan is fast, you can add it to your approved plans. If it's faster than another plan for the same parameter bindings, then you can mark the slower plan as Rejected.

For more information, see [Approving better plans](#). For reference information about this function, see [apg\\_plan\\_mgmt.evolve\\_plan\\_baselines](#).

For more information, see [Ensuring consistent performance after major version upgrades with Amazon Aurora PostgreSQL-Compatible Edition Query Plan Management](#).

#### Note

When you perform a major version upgrade using logical replication or Amazon DMS, make sure that you replicate the `apg_plan_mgmt` schema to ensure existing plans are copied to the upgraded instance. For more information on logical replication, see [Using logical replication to perform a major version upgrade for Aurora PostgreSQL](#).

## Reactive plan management to detect and repair performance regressions

By monitoring your application as it runs, you can detect plans that cause performance regressions. When you detect regressions, you manually reject or fix the bad plans by following these steps:

1. While your application runs, enforce the use of managed plans and automatically add newly discovered plans as unapproved. For more information, see [Using Aurora PostgreSQL managed plans](#) and [Automatically capturing plans](#).
2. Monitor your running application for performance regressions.

3. When you discover a plan regression, set the plan's status to `rejected`. The next time the optimizer runs the SQL statement, it automatically ignores the rejected plan and uses a different approved plan instead. For more information, see [Rejecting or disabling slower plans](#).

In some cases, you might prefer to fix a bad plan rather than reject, disable, or delete it. Use the `pg_hint_plan` extension to experiment with improving a plan. With `pg_hint_plan`, you use special comments to tell the optimizer to override how it normally creates a plan. For more information, see [Fixing plans using `pg\_hint\_plan`](#).

## Aurora PostgreSQL query plan management

With query plan management turned on for your Aurora PostgreSQL DB cluster, the optimizer generates and stores query execution plans for any SQL statement that it processes more than once. The optimizer always sets the status of a managed statement's first generated plan to `Approved`, and stores it in the `dba_plans` view.

The set of approved plans saved for a managed statement is known as its *plan baseline*. As your application runs, the optimizer might generate additional plans for managed statements. The optimizer sets additional captured plans to a status of `Unapproved`.

Later, you can decide if the `Unapproved` plans perform well and change them to `Approved`, `Rejected`, or `Preferred`. To do so, you use the `apg_plan_mgmt.evolve_plan_baselines` function or the `apg_plan_mgmt.set_plan_status` function.

When the optimizer generates a plan for a SQL statement, query plan management saves the plan in the `apg_plan_mgmt.plans` table. Database users that have been granted the `apg_plan_mgmt` role can see the plan details by querying the `apg_plan_mgmt.dba_plans` view. For example, the following query lists details for plans currently in the view for a non-production Aurora PostgreSQL DB cluster.

- `sql_hash` – An identifier for the SQL statement that's the hash value for the normalized text of the SQL statement.
- `plan_hash` – A unique identifier for the plan that's a combination of the `sql_hash` and a hash of the plan.
- `status` – The status of the plan. The optimizer can run an approved plan.
- `enabled` – Indicates whether the plan is ready to use (`true`) or not (`false`).

- `plan_outline` – A representation of the plan that's used to recreate the actual execution plan. Operators in the tree structure map to operators in EXPLAIN output.

The `apg_plan_mgmt.dba_plans` view has many more columns that contain all details of the plan, such as when the plan was last used. For complete details, see [Reference for the `apg\_plan\_mgmt.dba\_plans` view for Aurora PostgreSQL-Compatible Edition](#).

## Normalization and the SQL hash

In the `apg_plan_mgmt.dba_plans` view, you can identify a managed statement by its SQL hash value. The SQL hash is calculated on a normalized representation of the SQL statement that removes some differences, such as literal values.

The *normalization* process for each SQL statement preserves space and case, so that you can still read and understand the gist of the SQL statement. Normalization removes or replaces the following items.

- Leading block comments
- The EXPLAIN keyword and EXPLAIN options, and EXPLAIN ANALYZE
- Trailing spaces
- All literals

As an example, take the following statement.

```
/*Leading comment*/ EXPLAIN SELECT /* Query 1 */ * FROM t WHERE x > 7 AND y = 1;
```

The query plan management normalizes this statement as shown:

```
SELECT /* Query 1 */ * FROM t WHERE x > CONST AND y = CONST;
```

Normalization allows the same SQL hash to be used for similar SQL statements that might differ only in their literal or parameter values. In other words, multiple plans for the same SQL hash can exist, with a different plan that's optimal under different conditions.

**Note**

A single SQL statement that's used with different schemas has different plans because it's bound to the specific schema at runtime. The planner uses the statistics for schema binding to choose the optimal plan.

To learn more about how the optimizer chooses a plan, see [Using Aurora PostgreSQL managed plans](#). In that section, you can learn how to use EXPLAIN and EXPLAIN ANALYZE to preview a plan before it's actually used. For details, see [Analyzing the optimizer's chosen plan](#). For an image that outlines the process for choosing a plan, see [How the optimizer chooses which plan to run](#).

## Capturing Aurora PostgreSQL execution plans

Aurora PostgreSQL query plan management offers two different modes for capturing query execution plans, automatic or manual. You choose the mode by setting the value of the `apg_plan_mgmt.capture_plans_baselines` to `automatic` or to `manual`. You can capture execution plans for specific SQL statements by using manual plan capture. Alternatively, you can capture all (or the slowest) plans that are executed two or more times as your application runs by using automatic plan capture.

When capturing plans, the optimizer sets the status of a managed statement's first captured plan to `approved`. The optimizer sets the status of any additional plans captured for a managed statement to `unapproved`. However, more than one plan might occasionally be saved with the `approved` status. This can happen when multiple plans are created for a statement in parallel and before the first plan for the statement is committed.

To control the maximum number of plans that can be captured and stored in the `dba_plans` view, set the `apg_plan_mgmt.max_plans` parameter in your DB instance-level parameter group. A change to the `apg_plan_mgmt.max_plans` parameter requires a DB instance reboot for a new value to take effect. For more information, see the [apg\\_plan\\_mgmt.max\\_plans](#) parameter.

### Manually capturing plans for specific SQL statements

If you have a known set of SQL statements to manage, put the statements into a SQL script file and then manually capture plans. The following shows a `psql` example of how to capture query plans manually for a set of SQL statements.

```
psql> SET apg_plan_mgmt.capture_plan_baselines = manual;
```

```
psql> \i my-statements.sql
psql> SET apg_plan_mgmt.capture_plan_baselines = off;
```

After capturing a plan for each SQL statement, the optimizer adds a new row to the `apg_plan_mgmt.dba_plans` view.

We recommend that you use either `EXPLAIN` or `EXPLAIN EXECUTE` statements in the SQL script file. Make sure that you include enough variations in parameter values to capture all the plans of interest.

If you know of a better plan than the optimizer's minimum cost plan, you might be able to force the optimizer to use the better plan. To do so, specify one or more optimizer hints. For more information, see [Fixing plans using pg\\_hint\\_plan](#). To compare the performance of the unapproved and approved plans and approve, reject, or delete them, see [Evaluating plan performance](#).

## Automatically capturing plans

Use automatic plan capture for situations such as the following:

- You don't know the specific SQL statements that you want to manage.
- You have hundreds or thousands of SQL statements to manage.
- Your application uses a client API. For example, JDBC uses unnamed prepared statements or bulk-mode statements that can't be expressed in `psql`.

### To capture plans automatically

1. Turn on automatic plan capture by setting `apg_plan_mgmt.capture_plan_baselines` to `automatic` in the DB instance-level parameter group. For more information, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).
2. As the application runs, the optimizer captures plans for each SQL statement that runs at least twice.

As the application runs with default query plan management parameter settings, the optimizer captures plans for each SQL statement that runs at least twice. Capturing all plans while using the defaults has very little run-time overhead and can be enabled in production.

## To turn off automatic plan capture

- Set the `apg_plan_mgmt.capture_plan_baselines` parameter to `off` from the DB instance-level parameter group.

To measure the performance of the unapproved plans and approve, reject, or delete them, see [Evaluating plan performance](#).

## Using Aurora PostgreSQL managed plans

To get the optimizer to use captured plans for your managed statements, set the parameter `apg_plan_mgmt.use_plan_baselines` to `true`. The following is a local instance example.

```
SET apg_plan_mgmt.use_plan_baselines = true;
```

While the application runs, this setting causes the optimizer to use the minimum-cost, preferred, or approved plan that is valid and enabled for each managed statement.

### Analyzing the optimizer's chosen plan

When the `apg_plan_mgmt.use_plan_baselines` parameter is set to `true`, you can use `EXPLAIN ANALYZE SQL` statements to cause the optimizer to show the plan it would use if it were to run the statement. The following is an example.

```
EXPLAIN ANALYZE EXECUTE rangeQuery (1,10000);
```

```

                                     QUERY PLAN
-----
Aggregate (cost=393.29..393.30 rows=1 width=8) (actual time=7.251..7.251 rows=1
 loops=1)
  ->  Index Only Scan using t1_pkey on t1 t (cost=0.29..368.29 rows=10000 width=0)
      (actual time=0.061..4.859 rows=10000 loops=1)
      Index Cond: ((id >= 1) AND (id <= 10000))
           Heap Fetches: 10000
      Planning time: 1.408 ms
      Execution time: 7.291 ms
      Note: An Approved plan was used instead of the minimum cost plan.
      SQL Hash: 1984047223, Plan Hash: 512153379
```

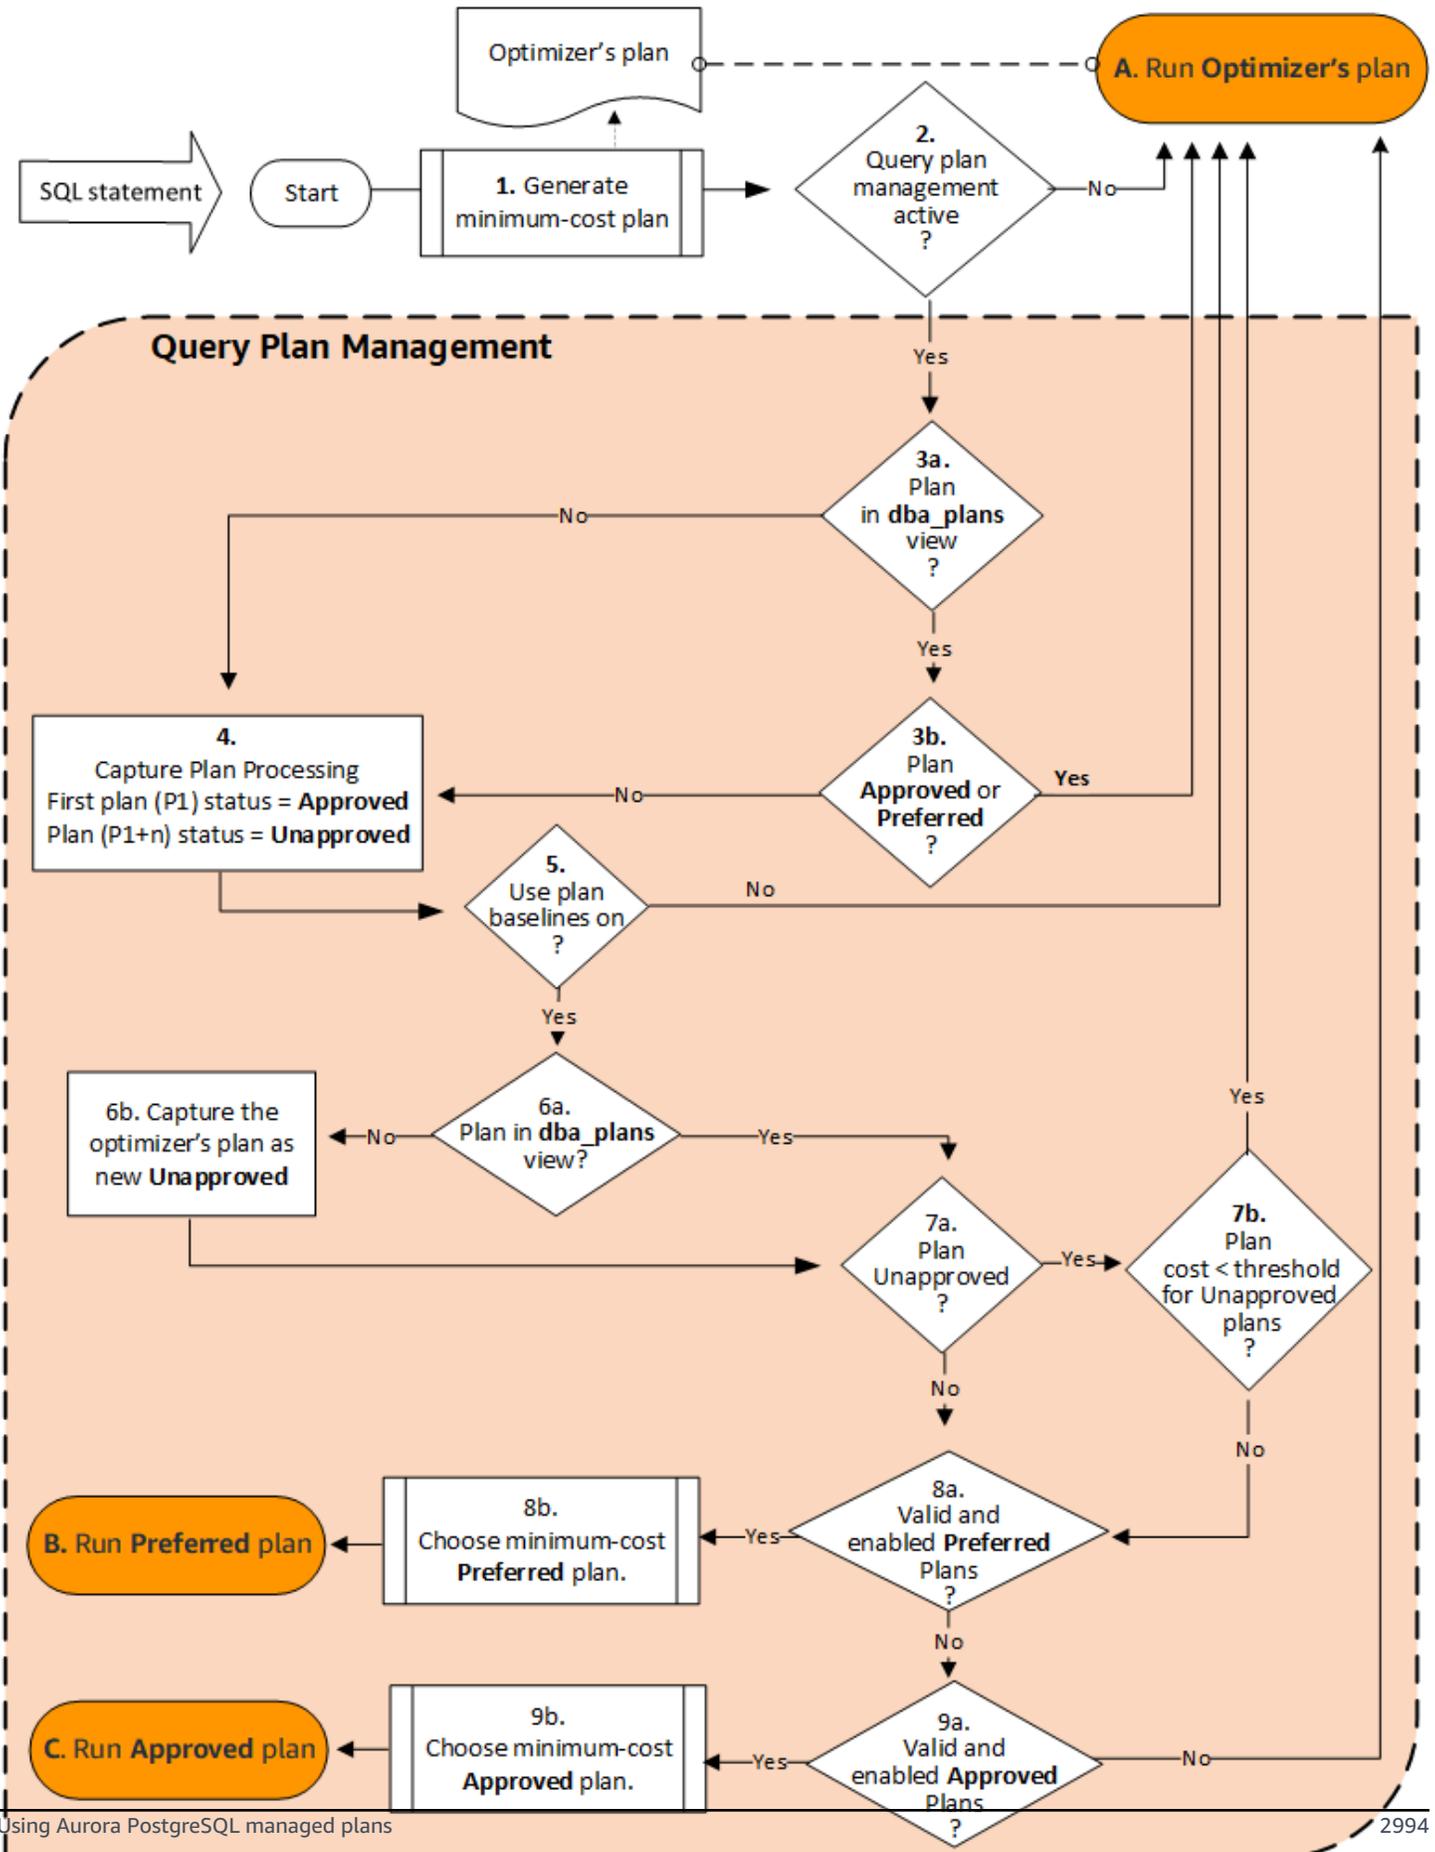

The output shows the Approved plan from the baseline that would run. However, the output also shows that it found a lower-cost plan. In this case, you capture this new minimum cost plan by turning on automatic plan capture as described in [Automatically capturing plans](#).

New plans are always captured by the optimizer as Unapproved. Use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans and change them to approved, rejected, or disabled. For more information, see [Evaluating plan performance](#).

## How the optimizer chooses which plan to run

The cost of an execution plan is an estimate that the optimizer makes to compare different plans. When calculating a plan's cost, the optimizer includes factors such as CPU and I/O operations required by that plan. To learn more about PostgreSQL query planner cost estimates, see [Query Planning](#) in the PostgreSQL documentation.

The following image shows how a plan is chosen for a given SQL statement when query plan management is active, and when it's not.

The flow is as follows:

1. The optimizer generates a minimum-cost plan for the SQL statement.
2. If query plan management isn't active, the optimizer's plan is run immediately (A. Run Optimizer's plan). Query plan management is inactive when the `apg_plan_mgmt.capture_plan_baselines` and the `apg_plan_mgmt.use_plan_baselines` parameters are both at their default settings ("off" and "false," respectively).

Otherwise, query plan management is active. In this case, the SQL statement and the optimizer's plan for it are further assessed before a plan is chosen.

 **Tip**

Database users with the `apg_plan_mgmt` role can pro-actively compare plans, change status of plans, and force the use of specific plans as needed. For more information, see [Improving Aurora PostgreSQL query plans](#).

3. The SQL statement might already have plans that were stored by query plan management in the past. Plans are stored in the `apg_plan_mgmt.dba_plans`, along with information about the SQL statements that were used to create them. Information about a plan includes its status. A plan's status can determine whether it's used or not, as follows.
  - a. If the plan isn't among the stored plans for the SQL statement, it means that it's the first time this particular plan was generated by the optimizer for the given SQL statement. The plan is sent to Capture Plan Processing (4).
  - b. If the plan is among the stored plans and its status is Approved or Preferred, the plan is run (A. Run Optimizer's plan).

If the plan is among the stored plans but it's neither Approved nor Preferred, the plan is sent to Capture Plan Processing (4).

4. When a plan is captured for the first time for a given SQL statement, the plan's status is always set to Approved (P1). If the optimizer subsequently generates the same plan for the same SQL statement, the status of that plan is changed to Unapproved (P1+n).

With the plan captured and its status updated, the evaluation continues at the next step (5).

5. A plan's *baseline* consists of the history of the SQL statement and its plans at various states. Query plan management can take the baseline into account when choosing a plan, depending on whether the use plan baselines option is turned on or not, as follows.
  - Use plan baselines is "off" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to its default value (`false`). The plan isn't compared to the baseline before it's run (A. Run Optimizer's plan).
  - Use plan baselines is "on" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to `true`. The plan is further assessed using the baseline (6).
6. The plan is compared to other plans for the statement in the baseline.
  - a. If the optimizer's plan is among the plans in the baseline, its status is checked (7a).
  - b. If the optimizer's plan isn't among plans in the baseline, the plan is added to the plans for the statement as a new Unapproved plan.
7. The plan's status is checked to determine only if it's Unapproved.
  - a. If the plan's status is Unapproved, the plan's estimated cost is compared to the cost estimate specified for the unapproved execution plan threshold.
    - If the plan's estimated cost is below the threshold, the optimizer uses it even though it's an Unapproved plan (A. Run Optimizer's plan). Generally, the optimizer won't run an Unapproved plan. However, when the `apg_plan_mgmt.unapproved_plan_execution_threshold` parameter specifies a cost threshold value, the optimizer compares the Unapproved plan's cost to the threshold. If the estimated cost is less than the threshold, the optimizer runs the plan. For more information, see [apg\\_plan\\_mgmt.unapproved\\_plan\\_execution\\_threshold](#).
    - If the plan's estimated cost isn't below the threshold, the plan's other attributes are checked (8a).
  - b. If the plan's status is anything other than Unapproved, its other attributes are checked (8a).
8. The optimizer won't use a plan that's disabled. That is, the plan that has its `enable` attribute set to 'f' (`false`). The optimizer also won't use a plan that has a status of Rejected.

The optimizer can't use any plans that aren't valid. Plans can become invalid over time when the objects that they depend on, such as indexes and table partitions, are removed or deleted.

- a. If the statement has any enabled and valid Preferred plans, the optimizer chooses the minimum-cost plan from among the Preferred plans stored for this SQL statement. The optimizer then runs the minimum-cost Preferred plan.

- b. If the statement doesn't have any enabled and valid Preferred plans, it's assessed in the next step (9).
9. If the statement has any enabled and valid Approved plans, the optimizer chooses the minimum-cost plan from among the Approved plans stored for this SQL statement. The optimizer then runs the minimum-cost Approved plan.

If the statement doesn't have any valid and enabled Approved plans, the optimizer uses the minimum cost plan (A. Run Optimizer's plan).

## Examining Aurora PostgreSQL query plans in the `dba_plans` view

Database users and administrators that have been granted the `apg_plan_mgmt` role can view and manage the plans stored in the `apg_plan_mgmt.dba_plans`. An Aurora PostgreSQL DB cluster's administrator (someone with `rds_superuser` permissions) must explicitly grant this role to the database users who need to work with query plan management.

The `apg_plan_mgmt` view contains the plan history for all managed SQL statements for every database on the writer instance of the Aurora PostgreSQL DB cluster. This view lets you examine plans, their state, when last used, and all other relevant details.

As discussed in [Normalization and the SQL hash](#), each managed plan is identified by the combined SQL hash value and a plan hash value. With these identifiers, you can use tools such as Amazon RDS Performance Insights to track individual plan performance. For more information about Performance Insights, see [Using Amazon RDS performance insights](#).

### Listing managed plans

To list the managed plans, use a `SELECT` statement on the `apg_plan_mgmt.dba_plans` view. The following example displays some columns in the `dba_plans` view such as the status, which identifies the approved and unapproved plans.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

sql_hash	plan_hash	status	enabled	stmt_name
1984047223	512153379	Approved	t	rangequery
1984047223	512284451	Unapproved	t	rangequery

(2 rows)

For readability, the query and the output shown list just a few of the columns from the `dba_plans` view. For complete information, see [Reference for the `apg\_plan\_mgmt.dba\_plans` view for Aurora PostgreSQL-Compatible Edition](#).

## Improving Aurora PostgreSQL query plans

Improve query plan management by evaluating plan performance and fixing plans. For more information about improving your query plans, see the following topics.

### Topics

- [Evaluating plan performance](#)
- [Fixing plans using `pg\_hint\_plan`](#)

## Evaluating plan performance

After the optimizer captures plans as unapproved, use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans based on their actual performance. Depending on the outcome of your performance experiments, you can change a plan's status from unapproved to either approved or rejected. You can instead decide to use the `apg_plan_mgmt.evolve_plan_baselines` function to temporarily disable a plan if it does not meet your requirements.

### Approving better plans

The following example demonstrates how to change the status of managed plans to approved using the `apg_plan_mgmt.evolve_plan_baselines` function.

```
SELECT apg_plan_mgmt.evolve_plan_baselines (  
    sql_hash,  
    plan_hash,  
    min_speedup_factor := 1.0,  
    action := 'approve'  
)  
FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved';
```

```
NOTICE:      rangequery (1,10000)  
NOTICE:      Baseline [ Planning time 0.761 ms, Execution time 13.261 ms]  
NOTICE:      Baseline+1 [ Planning time 0.204 ms, Execution time 8.956 ms]
```

```
NOTICE:      Total time benefit: 4.862 ms, Execution time benefit: 4.305 ms
NOTICE:      Unapproved -> Approved
evolve_plan_baselines
-----
0
(1 row)
```

The output shows a performance report for the rangequery statement with parameter bindings of 1 and 10,000. The new unapproved plan (Baseline+1) is better than the best previously approved plan (Baseline). To confirm that the new plan is now Approved, check the `apg_plan_mgmt.dba_plans` view.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

```
sql_hash | plan_hash | status | enabled | stmt_name
-----+-----+-----+-----+-----
1984047223 | 512153379 | Approved | t      | rangequery
1984047223 | 512284451 | Approved | t      | rangequery
(2 rows)
```

The managed plan now includes two approved plans that are the statement's plan baseline. You can also call the `apg_plan_mgmt.set_plan_status` function to directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred'.

## Rejecting or disabling slower plans

To reject or disable plans, pass 'reject' or 'disable' as the action parameter to the `apg_plan_mgmt.evolve_plan_baselines` function. This example disables any captured Unapproved plan that is slower by at least 10 percent than the best Approved plan for the statement.

```
SELECT apg_plan_mgmt.evolve_plan_baselines(
  sql_hash, -- The managed statement ID
  plan_hash, -- The plan ID
  1.1,      -- number of times faster the plan must be
  'disable' -- The action to take. This sets the enabled field to false.
)
FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND -- plan is Unapproved
```

```
origin = 'Automatic';      -- plan was auto-captured
```

You can also directly set a plan to rejected or disabled. To directly set a plan's enabled field to true or false, call the `apg_plan_mgmt.set_plan_enabled` function. To directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred', call the `apg_plan_mgmt.set_plan_status` function.

To delete plans that aren't valid and that you expect to remain invalid, use the `apg_plan_mgmt.validate_plans` function. This function lets you delete or disable invalid plans. For more information, see [Validating plans](#).

## Fixing plans using `pg_hint_plan`

The query optimizer is well-designed to find an optimal plan for all statements, and in most cases the optimizer finds a good plan. However, occasionally you might know that a much better plan exists than that generated by the optimizer. Two recommended ways to get the optimizer to generate a desired plan include using the `pg_hint_plan` extension or setting Grand Unified Configuration (GUC) variables in PostgreSQL:

- `pg_hint_plan` extension – Specify a "hint" to modify how the planner works by using PostgreSQL's `pg_hint_plan` extension. To install and learn more about how to use the `pg_hint_plan` extension, see the [pg\\_hint\\_plan documentation](#).
- GUC variables – Override one or more cost model parameters or other optimizer parameters, such as the `from_collapse_limit` or `GEQO_threshold`.

When you use one of these techniques to force the query optimizer to use a plan, you can also use query plan management to capture and enforce use of the new plan.

You can use the `pg_hint_plan` extension to change the join order, the join methods, or the access paths for a SQL statement. You use a SQL comment with special `pg_hint_plan` syntax to modify how the optimizer creates a plan. For example, assume the problem SQL statement has a two-way join.

```
SELECT *  
FROM t1, t2  
WHERE t1.id = t2.id;
```

Then suppose that the optimizer chooses the join order (t1, t2), but you know that the join order (t2, t1) is faster. The following hint forces the optimizer to use the faster join order, (t2, t1). Include

EXPLAIN so that the optimizer generates a plan for the SQL statement but without running the statement. (Output not shown.)

```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *  
FROM t1, t2  
WHERE t1.id = t2.id;
```

The following steps show how to use `pg_hint_plan`.

### To modify the optimizer's generated plan and capture the plan using `pg_hint_plan`

1. Turn on the manual capture mode.

```
SET apg_plan_mgmt.capture_plan_baselines = manual;
```

2. Specify a hint for the SQL statement of interest.

```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *  
FROM t1, t2  
WHERE t1.id = t2.id;
```

After this runs, the optimizer captures the plan in the `apg_plan_mgmt.dba_plans` view. The captured plan doesn't include the special `pg_hint_plan` comment syntax because query plan management normalizes the statement by removing leading comments.

3. View the managed plans by using the `apg_plan_mgmt.dba_plans` view.

```
SELECT sql_hash, plan_hash, status, sql_text, plan_outline  
FROM apg_plan_mgmt.dba_plans;
```

4. Set the status of the plan to `Preferred`. Doing so makes sure that the optimizer chooses to run it, instead of selecting from the set of approved plans, when the minimum-cost plan isn't already `Approved` or `Preferred`.

```
SELECT apg_plan_mgmt.set_plan_status(sql-hash, plan-hash, 'preferred' );
```

5. Turn off manual plan capture and enforce the use of managed plans.

```
SET apg_plan_mgmt.capture_plan_baselines = false;  
SET apg_plan_mgmt.use_plan_baselines = true;
```

Now, when the original SQL statement runs, the optimizer chooses either an `Approved` or `Preferred` plan. If the minimum-cost plan isn't `Approved` or `Preferred`, then the optimizer chooses the `Preferred` plan.

## Deleting Aurora PostgreSQL query plans

Delete execution plans that you aren't using or plans that aren't valid. For more information about deleting plans, see the following sections.

### Topics

- [Deleting plans](#)
- [Validating plans](#)

### Deleting plans

Plans are automatically deleted if they haven't been used in over a month, specifically, 32 days. That's the default setting for the `apg_plan_mgmt.plan_retention_period` parameter. You can change the plan retention period to a longer period of time, or to a shorter period of time starting from the value of 1. Determining the number of days since a plan was last used is calculated by subtracting the `last_used` date from the current date. The `last_used` date is the most recent date that the optimizer chose the plan as the minimum cost plan or that the plan was run. The date is stored for the plan in the `apg_plan_mgmt.dba_plans` view.

We recommend that you delete plans that haven't been used for a long time or that aren't useful. Every plan has a `last_used` date that the optimizer updates each time it executes a plan or chooses the plan as the minimum-cost plan for a statement. Check the last `last_used` dates to identify the plans that you can safely delete.

The following query returns a three column table with the count on the total number of plans, plans failed to delete, and the plans successfully deleted. It has a nested query that is an example of how to use the `apg_plan_mgmt.delete_plan` function to delete all plans that haven't been chosen as the minimum-cost plan in the last 31 days and its status is not `Rejected`.

```
SELECT (SELECT COUNT(*) from apg_plan_mgmt.dba_plans) total_plans,  
       COUNT(*) FILTER (WHERE result = -1) failed_to_delete,  
       COUNT(*) FILTER (WHERE result = 0) successfully_deleted  
FROM (
```

```
SELECT apg_plan_mgmt.delete_plan(sql_hash, plan_hash) as result
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '31 days')
AND status <> 'Rejected'
) as dba_plans ;
```

```
total_plans | failed_to_delete | successfully_deleted
-----+-----+-----
          3 |                0 |                   2
```

For more information, see [apg\\_plan\\_mgmt.delete\\_plan](#).

To delete plans that aren't valid and that you expect to remain invalid, use the `apg_plan_mgmt.validate_plans` function. This function lets you delete or disable invalid plans. For more information, see [Validating plans](#).

### Important

If you don't delete extraneous plans, you might eventually run out of shared memory that's set aside for query plan management. To control how much memory is available for managed plans, use the `apg_plan_mgmt.max_plans` parameter. Set this parameter in your custom DB parameter group and reboot your DB instance for changes to take effect. For more information, see the [apg\\_plan\\_mgmt.max\\_plans](#) parameter.

## Validating plans

Use the `apg_plan_mgmt.validate_plans` function to delete or disable plans that are invalid.

Plans can become invalid or stale when objects that they depend on are removed, such as an index or a table. However, a plan might be invalid only temporarily if the removed object gets recreated. If an invalid plan can become valid later, you might prefer to disable an invalid plan or do nothing rather than delete it.

To find and delete all plans that are invalid and haven't been used in the past week, use the `apg_plan_mgmt.validate_plans` function as follows.

```
SELECT apg_plan_mgmt.validate_plans(sql_hash, plan_hash, 'delete')
FROM apg_plan_mgmt.dba_plans
```

```
WHERE last_used < (current_date - interval '7 days');
```

To enable or disabled a plan directly, use the `apg_plan_mgmt.set_plan_enabled` function.

## Exporting and importing managed plans for Aurora PostgreSQL

You can export your managed plans and import them into another DB instance.

### To export managed plans

An authorized user can copy any subset of the `apg_plan_mgmt.plans` table to another table, and then save it using the `pg_dump` command. The following is an example.

```
CREATE TABLE plans_copy AS SELECT *  
FROM apg_plan_mgmt.plans [ WHERE predicates ] ;
```

```
% pg_dump --table apg_plan_mgmt.plans_copy -Ft mysourcedatabase > plans_copy.tar
```

```
DROP TABLE apg_plan_mgmt.plans_copy;
```

### To import managed plans

1. Copy the `.tar` file of the exported managed plans to the system where the plans are to be restored.
2. Use the `pg_restore` command to copy the tar file into a new table.

```
% pg_restore --dbname mytargetdatabase -Ft plans_copy.tar
```

3. Merge the `plans_copy` table with the `apg_plan_mgmt.plans` table, as shown in the following example.

#### Note

In some cases, you might dump from one version of the `apg_plan_mgmt` extension and restore into a different version. In these cases, the columns in the `plans` table might be different. If so, name the columns explicitly instead of using `SELECT *`.

```
INSERT INTO apg_plan_mgmt.plans SELECT * FROM plans_copy
```

```
ON CONFLICT ON CONSTRAINT plans_pkey
DO UPDATE SET
status = EXCLUDED.status,
enabled = EXCLUDED.enabled,
-- Save the most recent last_used date
--
last_used = CASE WHEN EXCLUDED.last_used > plans.last_used
THEN EXCLUDED.last_used ELSE plans.last_used END,
-- Save statistics gathered by evolve_plan_baselines, if it ran:
--
estimated_startup_cost = EXCLUDED.estimated_startup_cost,
estimated_total_cost = EXCLUDED.estimated_total_cost,
planning_time_ms = EXCLUDED.planning_time_ms,
execution_time_ms = EXCLUDED.execution_time_ms,
total_time_benefit_ms = EXCLUDED.total_time_benefit_ms,
execution_time_benefit_ms = EXCLUDED.execution_time_benefit_ms;
```

4. Reload the managed plans into shared memory and remove the temporary plans table.

```
SELECT apg_plan_mgmt.reload(); -- refresh shared memory
DROP TABLE plans_copy;
```

## Parameter reference for Aurora PostgreSQL query plan management

You can set your preferences for the `apg_plan_mgmt` extension by using the parameters listed in this section. These are available in the custom DB cluster parameter and the DB parameter group associated with your Aurora PostgreSQL DB cluster. These parameters control the behavior of the query plan management feature and how it affects the optimizer. For information about setting up query plan management, see [Turning on Aurora PostgreSQL query plan management](#). Changing the parameters following has no effect if the `apg_plan_mgmt` extension isn't set up as detailed in that section. For information about modifying parameters, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#) and [DB parameter groups for Amazon Aurora DB instances](#).

### Parameters

- [apg\\_plan\\_mgmt.capture\\_plan\\_baselines](#)
- [apg\\_plan\\_mgmt.plan\\_capture\\_threshold](#)
- [apg\\_plan\\_mgmt.explain\\_hashes](#)
- [apg\\_plan\\_mgmt.log\\_plan\\_enforcement\\_result](#)

- [apg\\_plan\\_mgmt.max\\_databases](#)
- [apg\\_plan\\_mgmt.max\\_plans](#)
- [apg\\_plan\\_mgmt.plan\\_hash\\_version](#)
- [apg\\_plan\\_mgmt.plan\\_retention\\_period](#)
- [apg\\_plan\\_mgmt.unapproved\\_plan\\_execution\\_threshold](#)
- [apg\\_plan\\_mgmt.use\\_plan\\_baselines](#)
- [auto\\_explain.hashes](#)

## apg\_plan\_mgmt.capture\_plan\_baselines

Captures query execution plans generated by the optimizer for each SQL statement and stores them in the `dba_plans` view. By default, the maximum number of plans that can be stored is 10,000 as specified by the `apg_plan_mgmt.max_plans` parameter. For reference information, see [apg\\_plan\\_mgmt.max\\_plans](#).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
off	automatic	Apply this setting at either the session level or in a parameter group to capture plans that are used two or more times.
	manual	Apply this setting at either the session level or in a parameter group to capture plans that are used one or more times.
	off	Turns off plan capture.

For more information, see [Capturing Aurora PostgreSQL execution plans](#).

## apg\_plan\_mgmt.plan\_capture\_threshold

Specifies a threshold so that if the total cost of the query execution plan is below the threshold, the plan won't be captured in the `apg_plan_mgmt.dba_plans` view.

Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
0	0 - 1.79769e+308	Sets the threshold of the <code>apg_plan_mgmt_query_plan_total_execution_cost</code> for capturing plans.

For more information, see [Examining Aurora PostgreSQL query plans in the `dba\_plans` view](#).

## `apg_plan_mgmt.explain_hashes`

Specifies if the EXPLAIN [ANALYZE] shows `sql_hash` and `plan_hash` at the end of its output. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
0	0 (off)	EXPLAIN does not show <code>sql_hash</code> and <code>plan_hash</code> without <code>hashes true</code> option.
	1 (on)	EXPLAIN shows <code>sql_hash</code> and <code>plan_hash</code> without <code>hashes true</code> option.

## `apg_plan_mgmt.log_plan_enforcement_result`

Specifies if the results has to be recorded to see if the QPM managed plans are used properly. When a stored generic plan is used, there will be no records written in the log files. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
none	none	Does not show any plan enforcement result in log files.
	on_error	Only shows plan enforcement result in log files when QPM fails to use managed plans.
	all	Shows all plan enforcement results in log files including both successes and failures.

## apg\_plan\_mgmt.max\_databases

Specifies the maximum number of databases on your Aurora PostgreSQL DB cluster's Writer instance that can use query plan management. By default, up to 10 databases can use query plan management. If you have more than 10 databases on the instance, you can change the value of this setting. To find out how many databases are on a given instance, connect to the instance using `psql`. Then, use the `psql` metacommand, `\l`, to list the databases.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
10	10-2147483647	Maximum number of databases that can use query plan management on the instance.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group.

## apg\_plan\_mgmt.max\_plans

Sets the maximum number of SQL statements that the query plan manager can maintain in the `apg_plan_mgmt.dba_plans` view. We recommend setting this parameter to 10000 or higher for all Aurora PostgreSQL versions.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
10000	10-2147483647	Maximum number of plans that can be stored in the <code>apg_plan_mgmt.dba_plans</code> view.  Default for Aurora PostgreSQL version 10 and older versions is 1000.

For more information, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view](#).

## apg\_plan\_mgmt.plan\_hash\_version

Specifies the use cases that the plan\_hash calculation is designed to cover. A higher version of apg\_plan\_mgmt.plan\_hash\_version covers all the functionality of the lower version. For example, version 3 covers the use cases supported by version 2.

Changing the value of this parameter must be followed by a call to apg\_plan\_mgmt.validate\_plans('update\_plan\_hash'). It updates the plan\_hash values in each database with apg\_plan\_mgmt installed and entries in the plans table. For more information, see [Validating plans](#)

Default	Allowed values	Description
1	1	Default plan_hash calculation.
	2	plan_hash calculation modified for multi-schema support.
	3	plan_hash calculation modified for multi-schema support and partitioned table support.
	4	plan_hash calculation modified for parallel operators and to support materialize nodes.

## apg\_plan\_mgmt.plan\_retention\_period

Specifies the number of days to keep plans in the apg\_plan\_mgmt.dba\_plans view, after which they're automatically deleted. By default, a plan is deleted when 32 days have elapsed since the plan was last used (the last\_used column in the apg\_plan\_mgmt.dba\_plans view). You can change this setting to any number, 1 and over.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

Default	Allowed values	Description
32	1-2147483647	Maximum number of days since a plan was last used before it's deleted.

For more information, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view](#).

## **apg\_plan\_mgmt.unapproved\_plan\_execution\_threshold**

Specifies a cost threshold below which an Unapproved plan can be used by the optimizer. By default the threshold is 0, so the optimizer doesn't run Unapproved plans. Setting this parameter to a trivially low cost threshold such as 100 avoids plan enforcement overhead on trivial plans. You can also set this parameter to an extremely large value like 10000000 using the reactive style of plan management. This allows the optimizer to use all chosen plans with no plan enforcement overhead. But, when a bad plan is found, you can manually mark it as "rejected" so that it is not used next time.

The value of this parameter represents a cost estimate for running a given plan. If an Unapproved plan is below that estimated cost, the optimizer uses it for the SQL statement. You can see captured plans and their status (Approved, Unapproved) in the dba\_plans view. To learn more, see [Examining Aurora PostgreSQL query plans in the dba\\_plans view](#).

Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
0	0-2147483647	Estimated plan cost below which an Unapproved plan is used.

For more information, see [Using Aurora PostgreSQL managed plans](#).

## **apg\_plan\_mgmt.use\_plan\_baselines**

Specifies that the optimizer should use one of the Approved plans captured and stored in the apg\_plan\_mgmt.dba\_plans view. By default, this parameter is off (false), causing the optimizer to use the minimum-cost plan that it generates without any further assessment. Turning this parameter on (setting it to true) forces the optimizer to choose a query execution plan for the statement from its plan baseline. For more information, see [Using Aurora PostgreSQL managed plans](#). To find an image detailing this process, see [How the optimizer chooses which plan to run](#).

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
false	true	Use an Approved, Preferred, or Unapproved plan from the <code>apg_plan_mgmt.dba_plans</code> . If none of those meet all evaluation criterion for the optimizer, it can then use its own generated minimum-cost plan. For more information, see <a href="#">How the optimizer chooses which plan to run</a> .
	false	Use the minimum cost plan generated by the optimizer.

You can evaluate response times of different captured plans and change plan status, as needed. For more information, see [Improving Aurora PostgreSQL query plans](#).

## auto\_explain.hashes

Specifies if the auto\_explain output shows sql\_hash and plan\_hash. Changing the value of this parameter doesn't require a reboot.

Default	Allowed values	Description
0(off)	0(off)	auto_explain result does not show sql_hash and plan_hash .
	1(on)	auto_explain result shows sql_hash and plan_hash .

## Function reference for Aurora PostgreSQL query plan management

The `apg_plan_mgmt` extension provides the following functions.

### Functions

- [apg\\_plan\\_mgmt.copy\\_outline](#)
- [apg\\_plan\\_mgmt.delete\\_plan](#)
- [apg\\_plan\\_mgmt.evolve\\_plan\\_baselines](#)
- [apg\\_plan\\_mgmt.get\\_explain\\_plan](#)
- [apg\\_plan\\_mgmt.plan\\_last\\_used](#)

- [apg\\_plan\\_mgmt.reload](#)
- [apg\\_plan\\_mgmt.set\\_plan\\_enabled](#)
- [apg\\_plan\\_mgmt.set\\_plan\\_status](#)
- [apg\\_plan\\_mgmt.update\\_plans\\_last\\_used](#)
- [apg\\_plan\\_mgmt.validate\\_plans](#)

## apg\_plan\_mgmt.copy\_outline

Copy a given SQL plan hash and plan outline to a target SQL plan hash and outline, thereby overwriting the target's plan hash and outline. This function is available in `apg_plan_mgmt` 2.3 and higher releases.

### Syntax

```
apg_plan_mgmt.copy_outline(  
    source_sql_hash,  
    source_plan_hash,  
    target_sql_hash,  
    target_plan_hash,  
    force_update_target_plan_hash  
)
```

### Return value

Returns 0 when the copy is successful. Raises exceptions for invalid inputs.

### Parameters

Parameter	Description
<code>source_sql_hash</code>	The <code>sql_hash</code> ID associated with the <code>plan_hash</code> to copy to the target query.
<code>source_plan_hash</code>	The <code>plan_hash</code> ID to copy to the target query.
<code>target_sql_hash</code>	The <code>sql_hash</code> ID of the query to update with the source plan hash and outline.

Parameter	Description
<code>target_plan_hash</code>	The <code>plan_hash</code> ID of the query to update with the source plan hash and outline.
<code>force_update_target_plan_hash</code>	(Optional) The <code>target_plan_hash</code> ID of the query is updated even if the source plan isn't reproducible for the <code>target_sql_hash</code> . When set to true, the function can be used to copy plans across schemas where relation names and columns are consistent.

### Usage notes

This function allows you to copy a plan hash and plan outline that uses hints to other, similar statements, and thus saves you from needing to use in-line hint statements at every occurrence in the target statements. If the updated target query results in an invalid plan, this function raises an error and rolls back the attempted update.

### `apg_plan_mgmt.delete_plan`

Delete a managed plan.

### Syntax

```
apg_plan_mgmt.delete_plan(  
    sql_hash,  
    plan_hash  
)
```

### Return value

Returns 0 if the delete was successful or -1 if the delete failed.

### Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.
plan_hash	The managed plan's plan_hash ID.

## apg\_plan\_mgmt.evolve\_plan\_baselines

Verifies whether an already approved plan is faster or whether a plan identified by the query optimizer as a minimum cost plan is faster.

### Syntax

```
apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor,
    action
)
```

### Return value

The number of plans that were not faster than the best approved plan.

### Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.
plan_hash	The managed plan's plan_hash ID. Use NULL to mean all plans that have the same sql_hash ID value.
min_speedup_factor	The <i>minimum speedup factor</i> can be the number of times faster that a plan must be than the best of the already approved plans to approve it. Alternatively, this factor can be the number of times slower that a plan must be to reject or disable it.

Parameter	Description
	This is a positive float value.
<code>action</code>	<p>The action the function is to perform. Valid values include the following . Case does not matter.</p> <ul style="list-style-type: none"><li>• <code>'disable'</code> – Disable each matching plan that does not meet the minimum speedup factor.</li><li>• <code>'approve'</code> – Enable each matching plan that meets the minimum speedup factor and set its status to approved.</li><li>• <code>'reject'</code> – For each matching plan that does not meet the minimum speedup factor, set its status to rejected.</li><li>• <code>NULL</code> – The function simply returns the number of plans that have no performance benefit because they do not meet the minimum speedup factor.</li></ul>

## Usage notes

Set specified plans to approved, rejected, or disabled based on whether the planning plus execution time is faster than the best approved plan by a factor that you can set. The action parameter might be set to `'approve'` or `'reject'` to automatically approve or reject a plan that meets the performance criteria. Alternatively, it might be set to `''` (empty string) to do the performance experiment and produce a report, but take no action.

You can avoid pointlessly rerunning of the `apg_plan_mgmt.evolve_plan_baselines` function for a plan on which it was recently run. To do so, restrict the plans to just the recently created unapproved plans. Alternatively, you can avoid running the `apg_plan_mgmt.evolve_plan_baselines` function on any approved plan that has a recent `last_verified` timestamp.

Conduct a performance experiment to compare the planning plus execution time of each plan relative to the other plans in the baseline. In some cases, there is only one plan for a statement and the plan is approved. In such a case, compare the planning plus execution time of the plan to the planning plus execution time of using no plan.

The incremental benefit (or disadvantage) of each plan is recorded in the `apg_plan_mgmt.dba_plans` view in the `total_time_benefit_ms` column. When this value is positive, there is a measurable performance advantage to including this plan in the baseline.

In addition to collecting the planning and execution time of each candidate plan, the `last_verified` column of the `apg_plan_mgmt.dba_plans` view is updated with the `current_timestamp`. The `last_verified` timestamp might be used to avoid running this function again on a plan that recently had its performance verified.

## `apg_plan_mgmt.get_explain_plan`

Generates the text of an EXPLAIN statement for the specified SQL statement.

### Syntax

```
apg_plan_mgmt.get_explain_plan(  
    sql_hash,  
    plan_hash,  
    [explainOptionList]  
)
```

### Return value

Returns runtime statistics for the specified SQL statements. Use without `explainOptionList` to return a simple EXPLAIN plan.

### Parameters

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID.
<code>explainOptionList</code>	A comma-separated list of explain options. Valid values include 'analyze' , 'verbose' , 'buffers' , 'hashes', and 'format json'. If the <code>explainOptionList</code> is NULL

Parameter	Description
	or an empty string ("), this function generates an EXPLAIN statement, without any statistics.

## Usage notes

For the `explainOptionList`, you can use any of the same options that you would use with an EXPLAIN statement. The Aurora PostgreSQL optimizer concatenates the list of options that you provide to the EXPLAIN statement.

## `apg_plan_mgmt.plan_last_used`

Returns the `last_used` date of the specified plan from shared memory.

### Note

The value in shared memory is always current on the primary DB instance in the DB cluster. The value is only periodically flushed to the `last_used` column of the `apg_plan_mgmt.dba_plans` view.

## Syntax

```
apg_plan_mgmt.plan_last_used(
    sql_hash,
    plan_hash
)
```

## Return value

Returns the `last_used` date.

## Parameters

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.

Parameter	Description
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID.

## `apg_plan_mgmt.reload`

Reload plans into shared memory from the `apg_plan_mgmt.dba_plans` view.

### Syntax

```
apg_plan_mgmt.reload()
```

### Return value

None.

### Parameters

None.

### Usage notes

Call `reload` for the following situations:

- Use it to refresh the shared memory of a read-only replica immediately, rather than wait for new plans to propagate to the replica.
- Use it after importing managed plans.

## `apg_plan_mgmt.set_plan_enabled`

Enable or disable a managed plan.

### Syntax

```
apg_plan_mgmt.set_plan_enabled(  
    sql_hash,  
    plan_hash,  
    [true | false]  
)
```

## Return value

Returns 0 if the setting was successful or -1 if the setting failed.

## Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.
plan_hash	The managed plan's plan_hash ID.
enabled	Boolean value of true or false: <ul style="list-style-type: none"><li>A value of true enables the plan.</li><li>A value of false disables the plan.</li></ul>

## apg\_plan\_mgmt.set\_plan\_status

Set a managed plan's status to Approved, Unapproved, Rejected, or Preferred.

## Syntax

```
apg_plan_mgmt.set_plan_status(  
    sql_hash,  
    plan_hash,  
    status  
)
```

## Return value

Returns 0 if the setting was successful or -1 if the setting failed.

## Parameters

Parameter	Description
sql_hash	The sql_hash ID of the plan's managed SQL statement.

Parameter	Description
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID.
<code>status</code>	<p>A string with one of the following values:</p> <ul style="list-style-type: none"><li>'Approved'</li><li>'Unapproved'</li><li>'Rejected'</li><li>'Preferred'</li></ul> <p>The case you use does not matter, however the status value is set to initial uppercase in the <code>apg_plan_mgmt.dba_plans</code> view. For more information about these values, see status in <a href="#">Reference for the <code>apg_plan_mgmt.dba_plans</code> view for Aurora PostgreSQL-Compatible Edition</a>.</p>

## `apg_plan_mgmt.update_plans_last_used`

Immediately updates the plans table with the `last_used` date stored in shared memory.

### Syntax

```
apg_plan_mgmt.update_plans_last_used()
```

### Return value

None.

### Parameters

None.

### Usage notes

Call `update_plans_last_used` to make sure queries against the `dba_plans.last_used` column use the most current information. If the `last_used` date isn't updated immediately,

a background process updates the plans table with the `last_used` date once every hour (by default).

For example, if a statement with a certain `sql_hash` begins to run slowly, you can determine which plans for that statement were executed since the performance regression began. To do that, first flush the data in shared memory to disk so that the `last_used` dates are current, and then query for all plans of the `sql_hash` of the statement with the performance regression. In the query, make sure the `last_used` date is greater than or equal to the date on which the performance regression began. The query identifies the plan or set of plans that might be responsible for the performance regression. You can use `apg_plan_mgmt.get_explain_plan` with `explainOptionList` set to `verbose`, hashes. You can also use `apg_plan_mgmt.evolve_plan_baselines` to analyze the plan and any alternative plans that might perform better.

The `update_plans_last_used` function has an effect only on the primary DB instance of the DB cluster.

## **apg\_plan\_mgmt.validate\_plans**

Validate that the optimizer can still recreate plans. The optimizer validates `Approved`, `Unapproved`, and `Preferred` plans, whether the plan is enabled or disabled. Rejected plans are not validated. Optionally, you can use the `apg_plan_mgmt.validate_plans` function to delete or disable invalid plans.

### **Syntax**

```
apg_plan_mgmt.validate_plans(  
    sql_hash,  
    plan_hash,  
    action)  
  
apg_plan_mgmt.validate_plans(  
    action)
```

### **Return value**

The number of invalid plans.

### **Parameters**

Parameter	Description
<code>sql_hash</code>	The <code>sql_hash</code> ID of the plan's managed SQL statement.
<code>plan_hash</code>	The managed plan's <code>plan_hash</code> ID. Use NULL to mean all plans for the same <code>sql_hash</code> ID value.
<code>action</code>	<p>The action the function is to perform for invalid plans. Valid string values include the following. Case does not matter.</p> <ul style="list-style-type: none"> <li>'disable' – Each invalid plan is disabled.</li> <li>'delete' – Each invalid plan is deleted.</li> <li>'update_plan_hash' – Updates the <code>plan_hash</code> ID for plans that can't be reproduced exactly. It also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an Approved plan for the original SQL.</li> <li>NULL – The function simply returns the number of invalid plans. No other action is performed.</li> <li>" – An empty string produces a message indicating the number of both valid and invalid plans.</li> </ul> <p>Any other value is treated like the empty string.</p>

## Usage notes

Use the form `validate_plans(action)` to validate all the managed plans for all the managed statements in the entire `apg_plan_mgmt.dba_plans` view.

Use the form `validate_plans(sql_hash, plan_hash, action)` to validate a managed plan specified with `plan_hash`, for a managed statement specified with `sql_hash`.

Use the form `validate_plans(sql_hash, NULL, action)` to validate all the managed plans for the managed statement specified with `sql_hash`.

## Reference for the `apg_plan_mgmt.dba_plans` view for Aurora PostgreSQL-Compatible Edition

The columns of plan information in the `apg_plan_mgmt.dba_plans` view include the following.

dba_plans column	Description
cardinality_error	<p>A measure of the error between the estimated cardinality versus the actual cardinality. <i>Cardinality</i> is the number of table rows that the plan is to process. If the cardinality error is large, then it increases the likelihood that the plan isn't optimal. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.</p>
compatibility_level	<p>This parameter shows when a query plan was last validated. In Aurora PostgreSQL versions 12.19, 13.15, 14.12, 15.7, 16.3, and later, it displays the Aurora version number. For earlier versions, it displays a feature specific version number.</p> <div data-bbox="594 793 1507 1010" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p> <b>Note</b></p> <p>Keep this parameter value at its default setting. Aurora PostgreSQL automatically sets and updates this value.</p> </div>
created_by	<p>The authenticated user (<code>session_user</code> ) who created the plan.</p>
enabled	<p>An indicator of whether the plan is enabled or disabled. All plans are enabled by default. You can disable plans to prevent them from being used by the optimizer. To modify this value, use the <a href="#">apg_plan_mgmt.set_plan_enabled</a> function.</p>
environment_variables	<p>The PostgreSQL Grand Unified Configuration (GUC) parameter s and values that the optimizer has overridden at the time the plan was captured.</p>
estimated_startup_cost	<p>The estimated optimizer setup cost before the optimizer delivers rows of a table.</p>
estimated_total_cost	<p>The estimated optimizer cost to deliver the final table row.</p>

dba_plans column	Description
execution_time_benefit_ms	The execution time benefit in milliseconds of enabling the plan. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.
execution_time_ms	The estimated time in milliseconds that the plan would run. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.
has_side_effects	A value that indicates that the SQL statement is a data manipulation language (DML) statement or a SELECT statement that contains a VOLATILE function.
last_used	This value is updated to the current date whenever the plan is either executed or when the plan is the query optimizer's minimum-cost plan. This value is stored in shared memory and periodically flushed to disk. To get the most up-to-date value, read the date from shared memory by calling the function <code>apg_plan_mgmt.plan_last_used(sql_hash, plan_hash)</code> instead of reading the <code>last_used</code> value. For additional information, see the <a href="#">apg_plan_mgmt.plan_retention_period</a> parameter.
last_validated	The most recent date and time when it was verified that the plan could be recreated by either the <a href="#">apg_plan_mgmt.validate_plans</a> function or the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.
last_verified	The most recent date and time when a plan was verified to be the best-performing plan for the specified parameters by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.

dba_plans column	Description
origin	<p>How the plan was captured with the <a href="#">apg_plan_mgmt.capture_plan_baselines</a> parameter. Valid values include the following:</p> <p>M – The plan was captured with manual plan capture.</p> <p>A – The plan was captured with automatic plan capture.</p>
param_list	<p>The parameter values that were passed to the statement if this is a prepared statement.</p>
plan_created	<p>The date and time the plan that was created.</p>
plan_hash	<p>The plan identifier. The combination of <code>plan_hash</code> and <code>sql_hash</code> uniquely identifies a specific plan.</p>
plan_outline	<p>A representation of the plan that is used to recreate the actual execution plan, and that is database-independent. Operators in the tree correspond to operators that appear in the EXPLAIN output.</p>
planning_time_ms	<p>The actual time to run the planner, in milliseconds. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.</p>
queryId	<p>A statement hash, as calculated by the <code>pg_stat_statements</code> extension. This isn't a stable or database-independent identifier because it depends on object identifiers (OIDs). The value will be 0 if <code>compute_query_id</code> is off when capturing the query plan.</p>
sql_hash	<p>A hash value of the SQL statement text, normalized with literals removed.</p>
sql_text	<p>The full text of the SQL statement.</p>

dba_plans column	Description
status	<p>A plan's status, which determines how the optimizer uses a plan. Valid values include the following.</p> <ul style="list-style-type: none"> <li>• <b>Approved</b> – A usable plan that the optimizer can choose to run. The optimizer runs the least-cost plan from a managed statement's set of approved plans (baseline). To reset a plan to approved, use the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.</li> <li>• <b>Unapproved</b> – A captured plan that you have not verified for use. For more information, see <a href="#">Evaluating plan performance</a>.</li> <li>• <b>Rejected</b> – A plan that the optimizer won't use. For more information, see <a href="#">Rejecting or disabling slower plans</a>.</li> <li>• <b>Preferred</b> – A plan that you have determined is a preferred plan to use for a managed statement.</li> </ul> <p>If the optimizer's minimum-cost plan isn't an approved or preferred plan, you can reduce plan enforcement overhead. To do so, make a subset of the approved plans Preferred . When the optimizer's minimum cost isn't an Approved plan, a Preferred plan is chosen before an Approved plan.</p> <p>To reset a plan to Preferred , use the <a href="#">apg_plan_mgmt.set_plan_status</a> function.</p>
stmt_name	<p>The name of the SQL statement within a PREPARE statement . This value is an empty string for an unnamed prepared statement. This value is NULL for a nonprepared statement.</p>
total_time_benefit_ms	<p>The total time benefit in milliseconds of enabling this plan. This value considers both planning time and execution time.</p> <p>If this value is negative, there is a disadvantage to enabling this plan. This column is populated by the <a href="#">apg_plan_mgmt.evolve_plan_baselines</a> function.</p>

## Advanced features in Query Plan Management

Following you can find information about the advanced Aurora PostgreSQL Query Plan Management (QPM) features:

### Topics

- [Capturing Aurora PostgreSQL execution plans in Replicas](#)
- [Supporting table partition](#)

## Capturing Aurora PostgreSQL execution plans in Replicas

QPM (Query Plan Management) allows you to capture the query plans generated by Aurora Replicas and stores them on the primary DB instance of the Aurora DB cluster. You can collect the query plans from all the Aurora Replicas, and maintain a set of optimal plans in a central persistent table on the primary instance. You can then apply these plans on other Replicas when needed. This helps you to maintain the stability of execution plans and improve performance of the queries across the DB clusters and engine versions.

### Topics

- [Prerequisites](#)
- [Managing plan capture for Aurora Replicas](#)
- [Troubleshooting](#)

### Prerequisites

**Turn on `capture_plan_baselines` parameter in Aurora Replica** - Set `capture_plan_baselines` parameter to `automatic` or `manual` to capture plans in Aurora Replicas. For more information, see [apg\\_plan\\_mgmt.capture\\_plan\\_baselines](#).

**Install `postgres_fdw` extension** - You must install `postgres_fdw` foreign data wrapper extension to capture plans in Aurora Replicas. Run the following command in each database, to install the extension.

```
postgres=> CREATE EXTENSION IF NOT EXISTS postgres_fdw;
```

### Managing plan capture for Aurora Replicas

#### Turn on plan capture for Aurora Replicas

You must have `rds_superuser` privileges to create or remove Plan Capture in Aurora Replicas. For more information on user roles and permissions, see [Understanding PostgreSQL roles and permissions](#).

To capture plans, call the function `apg_plan_mgmt.create_replica_plan_capture` in the writer DB instance, as shown in the following:

```
postgres=> CALL apg_plan_mgmt.create_replica_plan_capture('endpoint', 'password');
```

- `endpoint` - Aurora Global Database writer endpoint or `cluster_endpoint` provides failover support for Plan Capture in Aurora Replicas.

For more information on the Aurora Global Database writer endpoint, see [Viewing the endpoints of an Amazon Aurora global database](#).

For more information about cluster endpoints, see [Cluster endpoints for Amazon Aurora](#).

- `password` - We recommend you to follow the below guidelines while creating the password to enhance the security:
  - It must contain at least 8 characters.
  - It must contain at least one uppercase, one lowercase letter, and one number.
  - It must have at least one special character (`?`, `!`, `#`, `<`, `>`, `*`, and so on).

#### Note

If you change the endpoint, password, or port number, you must run `apg_plan_mgmt.create_replica_plan_capture()` again with the endpoint and password to re-initialize the plan capture. If not, capturing plans from Aurora Replicas will fail.

## Turn off plan capture for Aurora Replicas

You can turn off `capture_plan_baselines` parameter in Aurora Replica by setting its value to off in the Parameter group.

## Remove plan capture for Aurora Replicas

You can completely remove Plan Capture in Aurora Replicas but make sure before you do. To remove plan capture, call `apg_plan_mgmt.remove_replica_plan_capture` as shown:

```
postgres=> CALL apg_plan_mgmt.remove_replica_plan_capture();
```

You must call `apg_plan_mgmt.create_replica_plan_capture()` again to turn on plan capture in Aurora Replicas with the endpoint and password.

## Troubleshooting

Following, you can find troubleshooting ideas and workarounds if the plan is not captured in Aurora Replicas as expected.

- **Parameter settings** - Check if the `capture_plan_baselines` parameter is set to proper value to turn on plan capture.
- **postgres\_fdw extension is installed** - Use the following query to check if `postgres_fdw` is installed.

```
postgres=> SELECT * FROM pg_extension WHERE extname = 'postgres_fdw'
```

- **create\_replica\_plan\_capture() is called** - Use the following command to check if the user mapping exists. Otherwise, call `create_replica_plan_capture()` to initialize the feature.

```
postgres=> SELECT * FROM pg_foreign_server WHERE srvname =  
'apg_plan_mgmt_writer_foreign_server';
```

- **Endpoint and port number** - Check if the endpoint and port number are appropriate. There won't be any error message displayed if these values are incorrect.

Use the following command to verify if the endpoint used in the `create()` and to check which database it resides in:

```
postgres=> SELECT srvoptions FROM pg_foreign_server WHERE srvname =  
'apg_plan_mgmt_writer_foreign_server';
```

- **reload()** - You must call `apg_plan_mgmt.reload()` after calling `apg_plan_mgmt.delete_plan()` in Aurora Replicas to make the delete function effective. This ensures that the change has been successfully implemented.

- **Password** - You must enter password in `create_replica_plan_capture()` as per the guidelines mentioned. Otherwise, you will receive an error message. For more information, see [Managing plan capture for Aurora Replicas](#). Use another password that aligns with the requirements.
- **Cross-Region connection** - Plan capture in Aurora Replicas is also supported in Aurora global database, where writer instance and Aurora Replicas can be in different regions. Ensure that you use the Aurora Global Database writer endpoint to maintain connectivity after failover or switchover events. For more information on the Aurora Global Database endpoints, see [Viewing the endpoints of an Amazon Aurora Global Database](#). The writer instance and cross-Region Replica must be able to communicate, using VPC Peering. For more information, see [VPC peering](#). If a cross-Region failover happens, you must reconfigure the endpoint to new primary DB cluster endpoint.

 **Note**

When using a cluster endpoint instead of an Aurora Global Database writer endpoint, you'll need to update the cluster endpoint after performing either a global failover or switchover operation.

## Supporting table partition

Aurora PostgreSQL Query Plan Management (QPM) supports declarative table partitioning in the following versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions

For more information, see [Table Partitioning](#).

### Topics

- [Setting up table partition](#)
- [Capturing plans for table partition](#)
- [Enforcing a table partition plan](#)
- [Naming Convention](#)

## Setting up table partition

To set up table partition in Aurora PostgreSQL QPM, do as follows:

1. Set `apg_plan_mgmt.plan_hash_version` to 3 or more in the DB cluster parameter group.
2. Navigate to a database that uses Query Plan Management and has entries in `apg_plan_mgmt.dba_plans` view.
3. Call `apg_plan_mgmt.validate_plans('update_plan_hash')` to update the `plan_hash` value in the plans table.
4. Repeat steps 2-3 for all databases with Query Plan Management enabled that have entries in `apg_plan_mgmt.dba_plans` view.

For more information on these parameters, see [Parameter reference for Aurora PostgreSQL query plan management](#).

## Capturing plans for table partition

In QPM, different plans are distinguished by their `plan_hash` value. To understand how the `plan_hash` changes, you must first understand similar kind of plans.

The combination of access methods, digit-stripped index names and digit-stripped partition names, accumulated at the Append node level must be constant for plans to be considered the same. The specific partitions accessed in the plans are not significant. In the following example, a table `tbl_a` is created with 4 partitions.

```
postgres=>create table tbl_a(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=>create table tbl_a1 partition of tbl_a for values from (0) to (1000);
CREATE TABLE
postgres=>create table tbl_a2 partition of tbl_a for values from (1001) to (2000);
CREATE TABLE
postgres=>create table tbl_a3 partition of tbl_a for values from (2001) to (3000);
CREATE TABLE
postgres=>create table tbl_a4 partition of tbl_a for values from (3001) to (4000);
CREATE TABLE
postgres=>create index t_i on tbl_a using btree (i);
CREATE INDEX
postgres=>create index t_j on tbl_a using btree (j);
CREATE INDEX
```

```
postgres=>create index t_k on tbl_a using btree (k);
CREATE INDEX
```

The following plans are considered the same because a single scan method is being used to scan `tbl_a` irrespective of the number of partitions that the query looks up.

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 999 and j < 9910 and k > 50;
```

QUERY PLAN

```
-----
Seq Scan on tbl_a1 tbl_a
  Filter: ((i >= 990) AND (i <= 999) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
(3 rows)
```

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 1100 and j < 9910 and k > 50;
```

QUERY PLAN

```
-----
Append
-> Seq Scan on tbl_a1 tbl_a_1
  Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
(6 rows)
```

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 2100 and j < 9910 and k > 50;
```

QUERY PLAN

```
-----
Append
-> Seq Scan on tbl_a1 tbl_a_1
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a3 tbl_a_3
  Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
```

(8 rows)

The following 3 plans are also considered the same because at the parent level, the access methods, digit-stripped index names and digit-stripped partition names are SeqScan tbl\_a, IndexScan (i\_idx) tbl\_a.

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 1100 and j < 9910 and k > 50;
```

QUERY PLAN

-----

Append

```
-> Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a2_i_idx on tbl_a2 tbl_a_2
    Index Cond: ((i >= 990) AND (i <= 1100))
    Filter: ((j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(7 rows)
```

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 2100 and j < 9910 and k > 50;
```

QUERY PLAN

-----

Append

```
-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(10 rows)
```

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 3100 and j < 9910 and k > 50;
```

QUERY PLAN

-----

## Append

```

-> Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a3 tbl_a_3
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a4_i_idx on tbl_a4 tbl_a_4
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(11 rows)

```

Irrespective of different order and number of occurrences in child partitions, the access methods, digit-stripped index names and digit-stripped partition names are constant at the parent level for each of the above plans.

However, the plans would be considered different if any of the following conditions are met:

- Any additional access methods are used in the plan.

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between
990 and 2100 and j < 9910 and k > 50;

```

## QUERY PLAN

-----  
Append

```

-> Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Bitmap Heap Scan on tbl_a3 tbl_a_3
    Recheck Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
    -> Bitmap Index Scan on tbl_a3_i_idx
        Index Cond: ((i >= 990) AND (i <= 2100))
SQL Hash: 1553185667, Plan Hash: 1134525070
(11 rows)

```

- Any of the access methods in the plan are not used anymore.

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between
990 and 1100 and j < 9910 and k > 50;

```

QUERY PLAN

-----

Append

```
-> Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
```

SQL Hash: 1553185667, Plan Hash: -694232056  
(6 rows)

- The index associated with an index method is changed.

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between
990 and 1100 and j < 9910 and k > 50;
```

QUERY PLAN

-----

Append

```
-> Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a2_j_idx on tbl_a2 tbl_a_2
    Index Cond: (j < 9910)
    Filter: ((i >= 990) AND (i <= 1100) AND (k > 50))
```

SQL Hash: 1553185667, Plan Hash: -993343726  
(7 rows)

## Enforcing a table partition plan

Approved plans for partitioned tables are enforced with positional correspondence. The plans are not specific to the partitions, and can be enforced on partitions other than the plans referenced in the original query. Plans also have the capability of being enforced for queries accessing a different number of partitions than the original approved outline.

For example, if the approved outline is for the following plan:

```
postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 2100 and j < 9910 and k > 50;
```

QUERY PLAN

-----

Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -993736942
(10 rows)

```

Then, this plan can be enforced on SQL queries referencing 2, 4, or more partitions as well. The possible plans that could arise from these scenarios for 2 and 4 partition access are:

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 1100 and j < 9910 and k > 50;

```

#### QUERY PLAN

##### Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 1100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
(8 rows)

```

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 3100 and j < 9910 and k > 50;

```

#### QUERY PLAN

##### Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))

```

```

-> Seq Scan on tbl_a4 tbl_a_4
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
(12 rows)

```

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 3100 and j < 9910 and k > 50;

```

#### QUERY PLAN

---

##### Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
-> Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))
-> Index Scan using tbl_a4_i_idx on tbl_a4 tbl_a_4
    Index Cond: ((i >= 990) AND (i <= 3100))
    Filter: ((j < 9910) AND (k > 50))
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
(14 rows)

```

Consider another approved plan with different access methods for each partition:

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 2100 and j < 9910 and k > 50;

```

#### QUERY PLAN

---

##### Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
-> Bitmap Heap Scan on tbl_a3 tbl_a_3
    Recheck Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))

```

```

-> Bitmap Index Scan on tbl_a3_i_idx
      Index Cond: ((i >= 990) AND (i <= 2100))
SQL Hash: 1553185667, Plan Hash: 2032136998
(12 rows)

```

In this case, any plan that reads from two partitions would fail to be enforced. Unless all of the (access method, index name) combinations from the approved plan are usable, the plan cannot be enforced. For example, the following plans have different plan hashes and the approved plan can't be enforced in these cases:

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 1900 and j < 9910 and k > 50;

```

#### QUERY PLAN

---

##### Append

```

-> Bitmap Heap Scan on tbl_a1 tbl_a_1
      Recheck Cond: ((i >= 990) AND (i <= 1900))
      Filter: ((j < 9910) AND (k > 50))
  -> Bitmap Index Scan on tbl_a1_i_idx
        Index Cond: ((i >= 990) AND (i <= 1900))
-> Bitmap Heap Scan on tbl_a2 tbl_a_2
      Recheck Cond: ((i >= 990) AND (i <= 1900))
      Filter: ((j < 9910) AND (k > 50))
  -> Bitmap Index Scan on tbl_a2_i_idx
        Index Cond: ((i >= 990) AND (i <= 1900))
Note: This is not an Approved plan. No usable Approved plan was found.
SQL Hash: 1553185667, Plan Hash: -568647260
(13 rows)

```

```

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990
and 1900 and j < 9910 and k > 50;

```

#### QUERY PLAN

---

##### Append

```

-> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 1900))
      Filter: ((j < 9910) AND (k > 50))
-> Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 1900) AND (j < 9910) AND (k > 50))
Note: This is not an Approved plan. No usable Approved plan was found.

```

```
SQL Hash: 1553185667, Plan Hash: -496793743
(8 rows)
```

## Naming Convention

For QPM to enforce a plan with declarative partitioned tables, you must follow specific naming rules for parent tables, table partitions, and indexes:

- **Parent table names** – These names must differ by alphabets or special characters, and not by just digits. For example, tA, tB, and tC are acceptable names for separate parent tables while t1, t2, and t3 are not.
- **Individual partition table names** – Partitions of the same parent should differ from one another by digits only. For example, acceptable partition names of tA could be tA1, tA2 or t1A, t2A or even multiple digits.

Any other differences (letters, special characters) will not guarantee plan enforcement.

- **Index names** – In partition table hierarchy, make sure that all indexes have unique names. This means that the non-numeric parts of the names must be different. For example, if you have a partitioned table named tA with an index named tA\_col1\_idx1, you can't have another index named tA\_col1\_idx2. However, you can have an index called tA\_a\_col1\_idx2 because the non-numeric part of the name is unique. This rule applies to indexes created on both the parent table and individual partition tables.

Failure to adhere to the above naming conventions may result in failure of approved plans enforcement. The following example illustrates such a failed enforcement:

```
postgres=>create table t1(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=>create table t1a partition of t1 for values from (0) to (1000);
CREATE TABLE
postgres=>create table t1b partition of t1 for values from (1001) to (2000);
CREATE TABLE
postgres=>SET apg_plan_mgmt.capture_plan_baselines TO 'manual';
SET
postgres=>explain (hashes true, costs false) select count(*) from t1 where i > 0;
```

QUERY PLAN

```
-----
Aggregate
-> Append
```

```
-> Seq Scan on t1a t1_1
    Filter: (i > 0)
-> Seq Scan on t1b t1_2
    Filter: (i > 0)
SQL Hash: -1720232281, Plan Hash: -1010664377
(7 rows)
```

```
postgres=>SET app_plan_mgmt.use_plan_baselines TO 'on';
SET
postgres=>explain (hashes true, costs false) select count(*) from t1 where i > 1000;
```

#### QUERY PLAN

```
-----
Aggregate
  -> Seq Scan on t1b t1
      Filter: (i > 1000)
Note: This is not an Approved plan. No usable Approved plan was found.
SQL Hash: -1720232281, Plan Hash: 335531806
(5 rows)
```

Even though the two plans might appear identical, their Plan Hash values are different due to the names of the child tables. The table names vary by alpha characters instead of just digits leading to an enforcement failure.

## Working with extensions and foreign data wrappers

To extend the functionality to your Aurora PostgreSQL-Compatible Edition DB cluster, you can install and use various PostgreSQL *extensions*. For example, if your use case calls for intensive data entry across very large tables, you can install the [pg\\_partman](#) extension to partition your data and thus spread the workload.

### Note

As of Aurora PostgreSQL 14.5, Aurora PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your Aurora PostgreSQL. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements, as well as much of the preliminary testing for new extensions. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

In some cases, rather than installing an extension, you might add a specific *module* to the list of `shared_preload_libraries` in your Aurora PostgreSQL DB cluster's custom DB cluster parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in [Scheduling maintenance with the PostgreSQL pg\\_cron extension](#). As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see [Logging execution plans of queries](#) in the Amazon knowledge center.

An extension that provides access to external data is more specifically known as a *foreign data wrapper* (FDW). As one example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB cluster to work with Oracle databases.

You can also specify precisely which extensions can be installed on your Aurora PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Restricting installation of PostgreSQL extensions](#).

Following, you can find information about setting up and using some of the extensions, modules, and FDWs available for Aurora PostgreSQL. For simplicity's sake, these are all referred to as "extensions." You can find listings of extensions that you can use with the currently available

Aurora PostgreSQL versions, see [Extension versions for Amazon Aurora PostgreSQL](#) in the *Release Notes for Aurora PostgreSQL*.

- [Working with Oracle databases by using the oracle\\_fdw extension](#)
- [Working with SQL Server databases by using the tds\\_fdw extension](#)

## Using Amazon Aurora delegated extension support for PostgreSQL

Using Amazon Aurora delegated extension support for PostgreSQL, you can delegate the extension management to a user who need not be an `rds_superuser`. With this delegated extension support, a new role called `rds_extension` is created and you must assign this to a user to manage other extensions. This role can create, update, and drop extensions.

You can specify the extensions that can be installed on your Aurora PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Using PostgreSQL extensions with Amazon RDS for PostgreSQL](#).

You can restrict the list of extensions available that can be managed by the user with the `rds_extension` role using `rds.allowed_delegated_extensions` parameter.

The delegated extension support is available in the following versions:

- All higher versions
- 15.5 and higher 15 versions
- 14.10 and higher 14 versions
- 13.13 and higher 13 versions
- 12.17 and higher 12 versions

### Topics

- [Turning on delegate extension support to a user](#)

- [Configuration used in Aurora delegated extension support for PostgreSQL](#)
- [Turning off the support for the delegated extension](#)

- [Permissions required for certain extensions](#)
- [Security Considerations](#)
- [Drop extension cascade disabled](#)
- [Example extensions that can be added using delegated extension support](#)

## Turning on delegate extension support to a user

You must perform the following to enable delegate extension support to a user:

1. **Grant `rds_extension` role to a user** – Connect to the database as `rds_superuser` and execute the following command:

```
Postgres => grant rds_extension to user_name;
```

2. **Set the list of extensions available for delegated users to manage** – The `rds.allowed_delegated_extensions` allows you to specify a subset of the available extensions using `rds.allowed_extensions` in the DB cluster parameter. You can perform this at one of the following levels:

- In the cluster or the instance parameter group, through the Amazon Web Services Management Console or API. For more information, see [Parameter groups for Amazon Aurora](#).
- Use the following command at the database level:

```
alter database database_name set rds.allowed_delegated_extensions =  
'extension_name_1,  
   extension_name_2,...extension_name_n';
```

- Use the following command at the user level:

```
alter user user_name set rds.allowed_delegated_extensions = 'extension_name_1,  
   extension_name_2,...extension_name_n';
```

**Note**

You need not restart the database after changing the `rds.allowed_delegated_extensions` dynamic parameter.

**3. Allow access to the delegated user to objects created during the extension creation process**

– Certain extensions create objects that require additional permissions to be granted before the user with `rds_extension` role can access them. The `rds_superuser` must grant the delegated user access to those objects. One of the options is to use an event trigger to automatically grant permission to the delegated user.

**Example of event trigger**

If you want to allow a delegated user with `rds_extension` to use extensions that require setting permissions on their objects created by the extension creation, you can customize the below example of an event trigger and add only the extensions for which you want the delegated users to have access to the full functionality. This event trigger can be created on `template1` (the default template), therefore all database created from `template1` will have that event trigger. When a delegated user installs the extension, this trigger will automatically grant ownership on the objects created by the extension.

```
CREATE OR REPLACE FUNCTION create_ext()  
  
    RETURNS event_trigger AS $$  
  
DECLARE  
  
    schemaname TEXT;  
    databaseowner TEXT;  
  
    r RECORD;  
  
BEGIN  
  
    IF tg_tag = 'CREATE EXTENSION' and current_user != 'rds_superuser' THEN  
        RAISE NOTICE 'SECURITY INVOKER';  
        RAISE NOTICE 'user: %', current_user;  
        FOR r IN SELECT * FROM pg_catalog.pg_event_trigger_ddl_commands()
```

```

LOOP
    CONTINUE WHEN r.command_tag != 'CREATE EXTENSION' OR r.object_type !=
'extension';

    schemaname = (
        SELECT n.nspname
        FROM pg_catalog.pg_extension AS e
        INNER JOIN pg_catalog.pg_namespace AS n
        ON e.extnamespace = n.oid
        WHERE e.oid = r.objid
    );

    databaseowner = (
        SELECT pg_catalog.pg_get_userbyid(d.datdba)
        FROM pg_catalog.pg_database d
        WHERE d.datname = current_database()
    );

    RAISE NOTICE 'Record for event trigger %, objid: %,tag: %, current_user: %,
schema: %, database_owenr: %', r.object_identity, r.objid, tg_tag, current_user,
schemaname, databaseowner;

    IF r.object_identity = 'address_standardizer_data_us' THEN
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON
TABLE %I.us_gaz TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON
TABLE %I.us_lex TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON
TABLE %I.us_rules TO %I WITH GRANT OPTION;', schemaname, databaseowner);
    ELSIF r.object_identity = 'dict_int' THEN
        EXECUTE pg_catalog.format('ALTER TEXT SEARCH DICTIONARY %I.intdict
OWNER TO %I;', schemaname, databaseowner);
    ELSIF r.object_identity = 'pg_partman' THEN
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON
TABLE %I.part_config TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON
TABLE %I.part_config_sub TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE
ON TABLE %I.custom_time_partitions TO %I WITH GRANT OPTION;', schemaname,
databaseowner);
    ELSIF r.object_identity = 'postgis_topology' THEN
        EXECUTE pg_catalog.format('GRANT SELECT, UPDATE, INSERT, DELETE ON ALL
TABLES IN SCHEMA topology TO %I WITH GRANT OPTION;', databaseowner);
        EXECUTE pg_catalog.format('GRANT USAGE, SELECT ON ALL SEQUENCES IN
SCHEMA topology TO %I WITH GRANT OPTION;', databaseowner);

```

```

EXECUTE pg_catalog.format('GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA
topology TO %I WITH GRANT OPTION;', databaseowner);
EXECUTE pg_catalog.format('GRANT USAGE ON SCHEMA topology TO %I WITH
GRANT OPTION;', databaseowner);
END IF;
END LOOP;
END IF;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;

CREATE EVENT TRIGGER log_create_ext ON ddl_command_end EXECUTE PROCEDURE
create_ext();

```

## Configuration used in Aurora delegated extension support for PostgreSQL

Config Name	Description	Default Value	Notes	Who can modify or grant permission
<code>rds.allowed_extensions</code>	This parameter limits the extension role can manage in a database. It must be a subset of <code>rds.allowed_extensions</code> .	empty string	<ul style="list-style-type: none"> <li>By default, this parameter is empty string, which means that no extensions have been delegated to users with <code>rds_extensions</code>.</li> <li>Any supported extension can be added if the user has permission to do so. To do this, set the <code>rds.allowed_extensions</code>.</li> </ul>	<code>rds_superuser</code>

Config tion Name	Description	Default Value	Notes	Who can modify or grant permission
			<p>ted_extensions parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter , you explicitly identify the extensions that the user with the rds_extensions role can install.</p> <ul style="list-style-type: none"> <li>• When set to *, it means that all extensions listed in rds_allowed_extensions are delegated to users with rds_extensions role.</li> </ul> <p>To learn more about setting up this parameter , see <a href="#">Turning on</a></p>	

Config Name	Description	Default Value	Notes	Who can modify or grant permission
			<a href="#">delegate extension support to a user.</a>	
rds.delegated_extensions	This parameter lets the customer limit the extensions that can be installed in the Aurora PostgreSQL DB instance. For more information, see <a href="#">Restricting installation of PostgreSQL extensions</a>	"*"	By default, this parameter is set to "*", which means that all extensions supported on RDS for PostgreSQL and Aurora PostgreSQL are allowed to be created by users with necessary privileges.  Empty means no extensions can be installed in the Aurora PostgreSQL DB instance.	administrator

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
<code>rds-delegated_extension_allow_drop_cascade</code>	This parameter controls the ability for users with <code>rds_extension</code> to drop the extension using a cascade option.	off	<p>By default, <code>rds-delegated_extension_allow_drop_cascade</code> is set to off. This means that users with <code>rds_extension</code> are not allowed to drop an extension using the cascade option.</p> <p>To grant that ability, the <code>rds.delegated_extension_allow_drop_cascade</code> parameter should be set to on.</p>	<code>rds_superuser</code>

## Turning off the support for the delegated extension

### Turning off partially

The delegated users can't create new extensions but can still update existing extensions.

- Reset `rds.allowed_delegated_extensions` to the default value in the DB cluster parameter group.
- Use the following command at the database level:

```
alter database database_name reset rds.allowed_delegated_extensions;
```

- Use the following command at the user level:

```
alter user user_name reset rds.allowed_delegated_extensions;
```

## Turning off fully

Revoking `rds_extension` role from a user will revert the user to standard permissions. The user can no longer create, update, or drop extensions.

```
postgres => revoke rds_extension from user_name;
```

## Benefits of using Amazon Aurora delegated extension support

By using Amazon Aurora delegated extension support for PostgreSQL, you securely delegate the extension management to users who do not have the `rds_superuser` role. This feature provides the following benefits:

- You can easily delegate extension management to users of your choice.
- This doesn't require `rds_superuser` role.
- Provides ability to support different set of extensions for different databases in the same DB cluster.

## Limitation of Aurora delegated extension support for PostgreSQL

- Objects created during the extension creation process may require additional privileges for the extension to function properly.

## Permissions required for certain extensions

In order to create, use, or update the following extensions, the delegated user should have the necessary privileges on the following functions, tables, and schema.

Extensions that need ownership or permissions	Function	Tables	Schema	Text Search Dictionary	Comment
address_standardizer_data_loader		us_gaz, us_lex, us_lex, l.us_rules			
amcheck	bt_index_check, bt_index_parent_check				
dict_int				intdict	
pg_partman		custom_time_partitions, part_config, part_config_sub			
pg_stat_statements					
PostGIS	st_tileenvelope	spatial_ref_sys			
postgis					
postgis_topology		topology, layer	topology		the delegated user Must be

Extensions that need ownership or permissions	Function	Tables	Schema	Text Search Dictionary	Comment
					the database owner
log_fdw	create_foreign_table_for_log_file				
rds_superuser	role_password_encryption_type				
postgis		geocode_settings_default, geocode_settings	tiger		
pg_freespace	pg_freespace				
pg_visibility	pg_visibility				

## Security Considerations

Keep in mind that a user with `rds_extension` role will be able to manage extensions on all databases they have the connect privilege on. If the intention is to have a delegated user manage extension on a single database, a good practice is to revoke all privileges from public on each database, then explicitly grant the connect privilege for that specific database to the delegate user.

There are several extensions that can allow a user to access information from multiple database. Ensure the users you grant `rds_extension` has cross database capabilities before adding these extensions to `rds.allowed_delegated_extensions`. For example, `postgres_fdw` and `dblink` provide functionality to query across databases on the same instance or remote instances. `log_fdw` reads the postgres engine log files, which are for all databases in the instance, potentially containing slow queries or error messages from multiple databases. `pg_cron` enables running scheduled background jobs on the DB instance and can configure jobs to run in a different database.

## Drop extension cascade disabled

The ability to drop the extension with cascade option by a user with the `rds_extension` role is controlled by `rds.delegated_extension_allow_drop_cascade` parameter. By default, `rds-delegated_extension_allow_drop_cascade` is set to `off`. This means that users with the `rds_extension` role are not allowed to drop an extension using the cascade option as shown in the below query.

```
DROP EXTENSION CASCADE;
```

As this will automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Attempting to use the cascade option will result in an error.

To grant that ability, the `rds.delegated_extension_allow_drop_cascade` parameter should be set to `on`.

Changing the `rds.delegated_extension_allow_drop_cascade` dynamic parameter doesn't require a database restart. You can do this at one of the following levels:

- In the cluster or the instance parameter group, through the Amazon Web Services Management Console or API.
- Using the following command at the database level:

```
alter database database_name set rds.delegated_extension_allow_drop_cascade = 'on';
```

- Using the following command at the user level:

```
alter role tenant_user set rds.delegated_extension_allow_drop_cascade = 'on';
```

## Example extensions that can be added using delegated extension support

- `rds_tools`

```
extension_test_db=> create extension rds_tools;
CREATE EXTENSION
extension_test_db=> SELECT * from rds_tools.role_password_encryption_type() where
  rolname = 'pg_read_server_files';
ERROR: permission denied for function role_password_encryption_type
```

- `amcheck`

```
extension_test_db=> CREATE TABLE amcheck_test (id int);
CREATE TABLE
extension_test_db=> INSERT INTO amcheck_test VALUES (generate_series(1,100000));
INSERT 0 100000
extension_test_db=> CREATE INDEX amcheck_test_btree_idx ON amcheck_test USING btree
  (id);
CREATE INDEX
extension_test_db=> create extension amcheck;
CREATE EXTENSION
extension_test_db=> SELECT bt_index_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_check
extension_test_db=> SELECT bt_index_parent_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_parent_check
```

- `pg_freespacemap`

```
extension_test_db=> create extension pg_freespacemap;
CREATE EXTENSION
extension_test_db=> SELECT * FROM pg_freespace('pg_authid');
ERROR: permission denied for function pg_freespace
extension_test_db=> SELECT * FROM pg_freespace('pg_authid',0);
ERROR: permission denied for function pg_freespace
```

- `pg_visibility`

```
extension_test_db=> create extension pg_visibility;
CREATE EXTENSION
extension_test_db=> select * from pg_visibility('pg_database'::regclass);
ERROR: permission denied for function pg_visibility
```

- `postgres_fdw`

```
extension_test_db=> create extension postgres_fdw;  
CREATE EXTENSION  
extension_test_db=> create server myserver foreign data wrapper postgres_fdw options  
  (host 'foo', dbname 'foodb', port '5432');  
ERROR: permission denied for foreign-data wrapper postgres_fdw
```

## Managing large objects with the lo module

The lo module (extension) is for database users and developers working with PostgreSQL databases through JDBC or ODBC drivers. Both JDBC and ODBC expect the database to handle deletion of large objects when references to them change. However, PostgreSQL doesn't work that way. PostgreSQL doesn't assume that an object should be deleted when its reference changes. The result is that objects remain on disk, unreferenced. The lo extension includes a function that you use to trigger on reference changes to delete objects if needed.

### Tip

To determine if your database can benefit from the lo extension, use the `vacuumlo` utility to check for orphaned large objects. To get counts of orphaned large objects without taking any action, run the utility with the `-n` option (no-op). To learn how, see [vacuumlo utility](#) following.

The lo module is available for Aurora PostgreSQL 13.7, 12.11, 11.16, 10.21 and higher minor versions.

To install the module (extension), you need `rds_superuser` privileges. Installing the lo extension adds the following to your database:

- `lo` – This is a large object (lo) data type that you can use for binary large objects (BLOBs) and other large objects. The lo data type is a domain of the oid data type. In other words, it's an object identifier with optional constraints. For more information, see [Object identifiers](#) in the PostgreSQL documentation. In simple terms, you can use the lo data type to distinguish your database columns that hold large object references from other object identifiers (OIDs).
- `lo_manage` – This is a function that you can use in triggers on table columns that contain large object references. Whenever you delete or modify a value that references a large object, the

trigger unlinks the object (`lo_unlink`) from its reference. Use the trigger on a column only if the column is the sole database reference to the large object.

For more information about the large objects module, see [lo](#) in the PostgreSQL documentation.

## Installing the lo extension

Before installing the lo extension, make sure that you have `rds_superuser` privileges.

### To install the lo extension

1. Use `psql` to connect to the primary DB instance of your Aurora PostgreSQL DB cluster.

```
psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. Install the extension as follows.

```
postgres=> CREATE EXTENSION lo;  
CREATE EXTENSION
```

You can now use the `lo` data type to define columns in your tables. For example, you can create a table (`images`) that contains raster image data. You can use the `lo` data type for a column `raster`, as shown in the following example, which creates a table.

```
postgres=> CREATE TABLE images (image_name text, raster lo);
```

## Using the lo\_manage trigger function to delete objects

You can use the `lo_manage` function in a trigger on a `lo` or other large object columns to clean up (and prevent orphaned objects) when the `lo` is updated or deleted.

### To set up triggers on columns that reference large objects

- Do one of the following:

- Create a BEFORE UPDATE OR DELETE trigger on each column to contain unique references to large objects, using the column name for the argument.

```
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON images
           FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

- Apply a trigger only when the column is being updated.

```
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OF images
           FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

The `lo_manage` trigger function works only in the context of inserting or deleting column data, depending on how you define the trigger. It has no effect when you perform a DROP or TRUNCATE operation on a database. That means that you should delete object columns from any tables before dropping, to prevent creating orphaned objects.

For example, suppose that you want to drop the database containing the `images` table. You delete the column as follows.

```
postgres=> DELETE FROM images COLUMN raster
```

Assuming that the `lo_manage` function is defined on that column to handle deletes, you can now safely drop the table.

## Removing orphaned large objects using `vacuumlo`

The `vacuumlo` utility identifies and removes orphaned large objects from databases. This utility has been available since PostgreSQL 9.1.24. If your database users routinely work with large objects, we recommend that you run `vacuumlo` occasionally to clean up orphaned large objects.

Before installing the `lo` extension, you can use `vacuumlo` to assess whether your Aurora PostgreSQL DB cluster can benefit. To do so, run `vacuumlo` with the `-n` option (`no-op`) to show what would be removed, as shown in the following:

```
$ vacuumlo -v -n -h your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com -
p 5433 -U postgres docs-lab-spatial-db
Password:*****
Connected to database "docs-lab-spatial-db"
```

```
Test run: no large objects will be removed!  
Would remove 0 large objects from database "docs-lab-spatial-db".
```

As the output shows, orphaned large objects aren't a problem for this particular database.

For more information about this utility, see [vacuumlo](#) in the PostgreSQL documentation.

## Understanding how vacuumlo works

The vacuumlo command removes orphaned large objects (LOs) from your PostgreSQL database without affecting or conflicting with your user tables.

The command works as follows:

1. vacuumlo starts by creating a temporary table containing all the Object IDs (OIDs) of the large objects in your database.
2. vacuumlo then scans through every column in the database that uses the data types oid or lo. If vacuumlo finds a matching OID in these columns, it removes the OID from the temporary table. vacuumlo checks only columns specifically named oid or lo, not domains based on these types.
3. The remaining entries in the temporary table represent orphaned LOs, which vacuumlo then safely removes.

## Improving vacuumlo performance

You can potentially improve the performance of vacuumlo by increasing the batch size using the `-l` option. This allows vacuumlo to process more LOs at once.

If your system has sufficient memory and you can accommodate the temporary table completely in memory, increasing the `temp_buffers` setting at the database level may improve performance. This allows the table to reside entirely in memory, which can enhance the overall performance.

Following query estimates the size of the temporary table:

```
SELECT  
    pg_size_pretty(SUM(pg_column_size(oid))) estimated_lo_temp_table_size  
FROM  
    pg_largeobject_metadata;
```

## Considerations for large objects

Following you can find some important considerations to note when working with large objects:

- `VacuumLo` is the only solution as there is currently no other method to remove orphaned LOs.
- Tools like `pglogical`, native logical replication, and Amazon DMS that use replication technologies do not support replicating large objects.
- When designing your database schema, avoid using large objects when possible and consider using alternative data types like `bytea` instead.
- Run `vacuumLo` regularly, at least weekly, to prevent issues with orphaned LOs.
- Use a trigger with the `lo_manage` function on tables that store large objects to help prevent orphaned LOs from being created.

## Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see [PostGIS.net](https://postgis.net).

Starting with version 10.5, PostgreSQL supports the `libprotobuf 1.3.0` library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

### Topics

- [Step 1: Create a user \(role\) to manage the PostGIS extension](#)
- [Step 2: Load the PostGIS extensions](#)
- [Step 3: Transfer ownership of the extension schemas](#)
- [Step 4: Transfer ownership of the PostGIS tables](#)
- [Step 5: Test the extensions](#)
- [Step 6: Upgrade the PostGIS extension](#)

- [PostGIS extension versions](#)
- [Upgrading PostGIS 2 to PostGIS 3](#)

## Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres  
--password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';  
CREATE ROLE
```

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;  
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;  
CREATE DATABASE
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;  
GRANT
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=gis_admin --password --dbname=lab_gis  
Password for user gis_admin:...
```

```
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

## Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION
CREATE EXTENSION postgis_raster;
CREATE EXTENSION
CREATE EXTENSION fuzzystmatch;
CREATE EXTENSION
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION
CREATE EXTENSION postgis_topology;
CREATE EXTENSION
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

Name	Owner
public	postgres
tiger	rdsadmin
tiger_data	rdsadmin
topology	rdsadmin

(4 rows)

### Step 3: Transfer ownership of the extension schemas

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the `gis_admin` role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA topology OWNER TO gis_admin;
ALTER SCHEMA
```

You can confirm the ownership change by running the following SQL query. Or you can use the `\dn` metacommand from the `psql` command line.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM   pg_catalog.pg_namespace n
WHERE  n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

```
          List of schemas
  Name      | Owner
-----+-----
 public     | postgres
 tiger      | gis_admin
 tiger_data | gis_admin
 topology   | gis_admin
(4 rows)
```

### Step 4: Transfer ownership of the PostGIS tables

#### Note

Do not change ownership of the PostGIS functions. Proper operation and future upgrades of PostGIS require these functions to retain original ownership. For more information about PostGIS permissions, see [PostgreSQL Security](#).

Use the following function to transfer ownership of the PostGIS tables to the `gis_admin` role. Run the following statement from the `psql` prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $$ BEGIN EXECUTE
  $1; RETURN $1; END; $$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname)
  || ' OWNER TO gis_admin;')
FROM (
  SELECT nspname, relname
  FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
  WHERE nspname in ('tiger','topology') AND
  relkind IN ('r','S','v') ORDER BY relkind = 'S')
s;
```

## Step 5: Test the extensions

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;
SET
```

Test the `tiger` schema by using the following `SELECT` statement.

```
SELECT address, streetname, streettypeabbrev, zip
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
address | streetname | streettypeabbrev | zip
-----+-----+-----+-----
      1 | Devonshire | Pl                | 02109
(1 row)
```

To learn more about this extension, see [Tiger Geocoder](#) in the PostGIS documentation.

Test access to the `topology` schema by using the following `SELECT` statement. This calls the `createtopology` function to register a new topology object (`my_new_topo`) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](#) in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
   createtopology
-----
                1
(1 row)
```

## Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see [PostGIS extension versions](#).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see [Testing an upgrade of your production DB cluster to a new major version](#).

You can check for available PostGIS extension version updates on your Aurora PostgreSQL DB cluster at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed.

For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see [Upgrading PostGIS 2 to PostGIS 3](#).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see [Testing an upgrade of your production DB cluster to a new major version](#).

## PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in [Extension versions for Aurora PostgreSQL-Compatible Edition](#) in the *Release Notes for Aurora PostgreSQL*. To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the *Release Notes for Aurora PostgreSQL*:

- [Extension versions for Aurora PostgreSQL 14](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 13](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 12](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 11](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 10](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 9.6](#)

## Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgis_raster` to the new version.

## To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your Aurora PostgreSQL DB cluster. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
  WHERE default_version > installed_version;
 name | default_version | installed_version | comment
-----+-----+-----
+-----+-----+-----
 postgis | 3.1.4          | 2.3.7           | PostGIS geometry and geography
 spatial types and functions
(1 row)
```

2. Identify the versions of PostGIS installed in each database on the writer instance of your Aurora PostgreSQL DB cluster. In other words, query each user database as follows.

```
SELECT
  e.extname AS "Name",
  e.extversion AS "Version",
  n.nspname AS "Schema",
  c.description AS "Description"
FROM
  pg_catalog.pg_extension e
  LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
  LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
  AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;
 Name | Version | Schema | Description
-----+-----+-----
+-----+-----+-----
 postgis | 2.3.7   | public | PostGIS geometry, geography, and raster spatial types
 and functions
(1 row)
```

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```
ALTER EXTENSION postgis UPDATE;
```

```
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged
```

3. Run the following query to verify that the raster functionality is now in its own package.

```
SELECT
    probin,
    count(*)
FROM
    pg_proc
WHERE
    probin LIKE '%postgis%'
GROUP BY
    probin;
```

probin	count
\$libdir/rtpostgis-2.3	107
\$libdir/postgis-3	487

(2 rows)

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
```

```

FROM
  pg_catalog.pg_extension e
  LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
  LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
      AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;

```

Name	Version	Schema	Description
postgis	3.1.5	public	PostGIS geometry, geography, and raster spatial types and functions
postgis_raster	3.1.5	public	PostGIS raster types and functions

(2 rows)

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```

## Managing PostgreSQL partitions with the `pg_partman` extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

## Topics

- [Overview of the PostgreSQL pg\\_partman extension](#)
- [Enabling the pg\\_partman extension](#)
- [Configuring partitions using the create\\_parent function](#)
- [Configuring partition maintenance using the run\\_maintenance\\_proc function](#)

## Overview of the PostgreSQL `pg_partman` extension

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see [PG Partition Manager](#) in the `pg_partman` documentation.

### Note

The `pg_partman` extension is supported on Aurora PostgreSQL versions 12.6 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

## Enabling the `pg_partman` extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```
CREATE SCHEMA partman;  
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

**Note**

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"  
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema `data_mart` contains a table named `events` with a column named `created_at`. The following settings are included in the `events` table:

- Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.
- A check constraint `ck_valid_operation` to enforce values for an `operation` table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```
CREATE SCHEMA data_mart;  
CREATE TABLE data_mart.organization (  
    org_id BIGSERIAL,  
    org_name TEXT,  
    CONSTRAINT pk_organization PRIMARY KEY (org_id)  
);
```

```

CREATE TABLE data_mart.events(
    event_id          BIGSERIAL,
    operation         CHAR(1),
    value            FLOAT(24),
    parent_event_id  BIGINT,
    event_type       VARCHAR(25),
    org_id           BIGSERIAL,
    created_at       timestamp,
    CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
    CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
    CONSTRAINT fk_orga_membership
        FOREIGN KEY(org_id)
        REFERENCES data_mart.organization (org_id),
    CONSTRAINT fk_parent_event_id
        FOREIGN KEY(parent_event_id, created_at)
        REFERENCES data_mart.events (event_id,created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id      ON data_mart.events(org_id);
CREATE INDEX idx_event_type ON data_mart.events(event_type);

```

## Configuring partitions using the create\_parent function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table example created in [Enabling the pg\\_partman extension](#). Call the `create_parent` function as follows.

```

SELECT partman.create_parent(
    p_parent_table => 'data_mart.events',
    p_control      => 'created_at',
    p_type         => 'range',
    p_interval     => '1 day',
    p_premake     => 30);

```

The parameters are as follows:

- `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.

- `p_type` – The type is either 'range' or 'list'.
- `p_interval` – The time interval or integer range for each partition. Example values include 1 day, 1 hour, and so on.
- `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see [Creation Functions](#) in the `pg_partman` documentation.

## Configuring partition maintenance using the `run_maintenance_proc` function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in [Enabling the `pg\_partman` extension](#) to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;

UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see [Scheduling maintenance with the PostgreSQL `pg\_cron` extension](#).

3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
  - a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
  - b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
  - c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see [Maintenance Functions](#) in the `pg_partman` documentation.

## Scheduling maintenance with the PostgreSQL `pg_cron` extension

You can use the PostgreSQL `pg_cron` extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see [What is pg\\_cron?](#) in the `pg_cron` documentation.

The `pg_cron` extension is supported on Aurora PostgreSQL engine versions 12.6 and higher version

To learn more about using `pg_cron`, see [Schedule jobs with pg\\_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.](#)

### Note

The `pg_cron` extension version is displayed as a two digit version, for example, 1.6, in the `pg_available_extensions` view. While you might see three digit versions, for example, 1.6.4 or 1.6.5, listed in some contexts, you must specify the two digit version when performing an extension upgrade.

## Topics

- [Setting up the pg\\_cron extension](#)
- [Granting database users permissions to use pg\\_cron](#)
- [Scheduling pg\\_cron jobs](#)
- [Reference for the pg\\_cron extension](#)

## Setting up the pg\_cron extension

Set up the pg\_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg\_cron to the shared\_preload\_libraries parameter value.

Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see [Amazon Aurora PostgreSQL parameters](#).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds\_superuser permissions. For example, if you used the default settings when you created your Aurora PostgreSQL DB cluster, connect as user postgres and create the extension.

```
CREATE EXTENSION pg_cron;
```

The pg\_cron scheduler is set in the default PostgreSQL database named postgres. The pg\_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

## Granting database users permissions to use pg\_cron

Installing the pg\_cron extension requires the rds\_superuser privileges. However, permissions to use the pg\_cron can be granted (by a member of the rds\_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.

To grant a database user permission in the `cron` schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives *db-user* permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@[30647]:ERROR: permission denied for table table-name  
2020-12-08 16:41:00 UTC::@[27071]:LOG: background worker "pg_cron" (PID 30647) exited  
with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see [Tables for scheduling jobs and capturing status](#).

## Scheduling `pg_cron` jobs

The following sections show how you can schedule various management tasks using `pg_cron` jobs.

### Note

When you create `pg_cron` jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A `pg_cron` job fails if it runs out of background worker processes. The default number of `pg_cron` jobs is 5. For more information, see [Parameters for managing the `pg\_cron` extension](#).

## Topics

- [Vacuuming a table](#)
- [Purging the `pg\_cron` history table](#)
- [Logging errors to the `postgresql.log` file only](#)
- [Scheduling a cron job for a database other than the default database](#)

## Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

Following is an example of using the `cron.schedule` function to set up a job to use `VACUUM FREEZE` on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
 schedule
-----
1
(1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
 jobid | runid | job_pid | database | username | command | status | return_message | start_time | end_time
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1      | 1     | 3395   | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded | VACUUM          | 2020-12-04 21:10:00.050386+00 | 2020-12-04
21:10:00.072028+00
(1 row)
```

Following is a query of the `cron.job_run_details` table to see the failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
 jobid | runid | job_pid | database | username | command | status | return_message | start_time | end_time
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
5      | 4     | 30339  | postgres | adminuser| vacuum freeze pgbench_account | failed | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see [Tables for scheduling jobs and capturing status](#).

## Purging the `pg_cron` history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the [`cron.schedule`](#) function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE
    FROM cron.job_run_details
    WHERE end_time < now() - interval '7 days'$$);
```

For more information, see [Tables for scheduling jobs and capturing status](#).

## Logging errors to the `postgresql.log` file only

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to `off`. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see [Parameters for managing the `pg\_cron` extension](#).

## Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

### Note

Only users with `rds_superuser` role or `rds_superuser` privileges can list all cron jobs in the database. Other users can view only their own jobs in the `cron.job` table.

1. In the cron database, schedule the job as you normally do using the [cron.schedule](#).

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum
freeze test_table');
```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the `cron.job` table.

```
postgres=> SELECT * FROM cron.job;
jobid | schedule      | command                                     | nodename | nodeport |
database | username      | active | jobname
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
106   | 29 03 * * * | vacuum freeze test_table                   | localhost | 8192     |
database1 | adminuser    | t      | database1 manual vacuum
1     | 59 23 * * * | vacuum freeze pgbench_accounts            | localhost | 8192     |
postgres | adminuser    | t      | manual vacuum
(2 rows)
```

### Note

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

## Reference for the `pg_cron` extension

You can use the following parameters, functions, and tables with the `pg_cron` extension. For more information, see [What is pg\\_cron?](#) in the `pg_cron` documentation.

### Topics

- [Parameters for managing the `pg\_cron` extension](#)
- [Function reference: `cron.schedule`](#)

- [Function reference: cron.unschedule](#)
- [Tables for scheduling jobs and capturing status](#)

## Parameters for managing the pg\_cron extension

Following is a list of parameters that control the pg\_cron extension behavior.

Parameter	Description
<code>cron.database_name</code>	The database in which pg_cron metadata is kept.
<code>cron.host</code>	The hostname to connect to PostgreSQL. You can't modify this value.
<code>cron.log_run</code>	Log every job that runs in the <code>job_run_details</code> table. Values are on or off. For more information, see <a href="#">Tables for scheduling jobs and capturing status</a> .
<code>cron.log_statement</code>	Log all cron statements before running them. Values are on or off.
<code>cron.max_running_jobs</code>	The maximum number of jobs that can run concurrently.
<code>cron.use_background_workers</code>	Use background workers instead of client sessions. You can't modify this value.

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%'
ORDER BY name;
```

## Function reference: cron.schedule

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in

other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

The function has two syntax formats.

## Syntax

```
cron.schedule (job_name,
              schedule,
              command
            );

cron.schedule (schedule,
              command
            );
```

## Parameters

Parameter	Description
job_name	The name of the cron job.
schedule	Text indicating the schedule for the cron job. The format is the standard cron format.
command	Text of the command to run.

## Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
 schedule
-----
        145
(1 row)

postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
 schedule
-----
        146
(1 row)
```

## Function reference: cron.unschedule

This function deletes a cron job. You can specify either the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

### Syntax

```
cron.unschedule (job_id);  
  
cron.unschedule (job_name);
```

### Parameters

Parameter	Description
<code>job_id</code>	A job identifier that was returned from the <code>cron.schedule</code> function when the cron job was scheduled.
<code>job_name</code>	The name of a cron job that was scheduled with the <code>cron.schedule</code> function.

### Examples

```
postgres=> SELECT cron.unschedule(108);  
unschedule  
-----  
t  
(1 row)  
  
postgres=> SELECT cron.unschedule('test');  
unschedule  
-----  
t  
(1 row)
```

## Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

Table	Description
<code>cron.job</code>	<p>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code> functions.</p> <div style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>⚠ Important</b></p> <p>We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code> .</p> </div>
<code>cron.job_run_details</code>	<p>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</p> <div style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>📘 Note</b></p> <p>To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see <a href="#">Purging the pg_cron history table</a>.</p> </div>

## Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep *audit logs* to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your Aurora PostgreSQL DB cluster, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see [Aurora PostgreSQL database log files](#).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your Aurora PostgreSQL DB cluster is configured to log data manipulation language (DML) statements as detailed in [Turning on query logging for your Aurora PostgreSQL DB cluster](#), you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see [Excluding users or databases from audit logging](#).

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available Aurora PostgreSQL versions. For a list of pgAudit versions supported by Aurora PostgreSQL version, see [Extension versions for Amazon Aurora PostgreSQL](#) in the *Release Notes for Aurora PostgreSQL*.

## Topics

- [Setting up the pgAudit extension](#)
- [Auditing database objects](#)
- [Excluding users or databases from audit logging](#)
- [Reference for the pgAudit extension](#)

## Setting up the pgAudit extension

To set up the pgAudit extension on your Aurora PostgreSQL DB cluster, you first add pgAudit to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. For information about creating a custom DB cluster parameter group, see [Parameter groups for Amazon Aurora](#). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the Amazon Web Services Management Console or the Amazon CLI.

You must have permissions as the `ids_superuser` role to perform all these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group.

## Console

### To set up the pgAudit extension

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance .
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pgaudit` to the list in the **Values** field. Use a comma to separate items in the list of values.

The screenshot shows the Amazon RDS console interface for a custom DB parameter group named 'docs-lab-rpg-14-custom-db-parameters'. The 'Parameters' section is active, with a search filter 'shared\_pre' applied. A table lists parameters, and the 'shared\_preload\_libraries' parameter is selected. The 'Values' field for this parameter contains 'pgaudit,pg\_stat\_statements', which is highlighted with a red box. The 'Allowed values' column lists various PostgreSQL extensions: auto\_explain, orafce, pgaudit, pglogical, pg\_bigm, pg\_cron, pg\_hint\_plan, pg\_prewarm, pg\_similarity, pg\_stat\_statements, pg\_transport, and plprofiler.

<input type="checkbox"/>	Name	Values	Allowed values
<input type="checkbox"/>	shared_preload_libraries	pgaudit,pg_stat_statements	auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_transport, plprofiler

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the `shared_preload_libraries` parameter takes effect.

9. When the instance is available, verify that pgAudit has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pgaudit
(1 row)
```

10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the `psql` session.

```
labdb=> \q
```

12. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

The screenshot shows the Amazon RDS console interface for configuring parameters. The breadcrumb navigation is "RDS > Parameter groups > docs-lab-rpg-14-custom-db-parameters". The main heading is "docs-lab-rpg-14-custom-db-parameters". Below this, there is a "Parameters" section with a search bar containing "pgau". A table lists the parameters, with the "pgaudit.log" parameter highlighted. The table has columns for Name, Values, Allowed values, and Modifiable.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable
<input type="checkbox"/>	pgaudit.log	write	ddl, function, misc, read, role, write, none, all, -ddl, -function, -misc, -read, -role, -write	true

You can also choose one of the following values for the `pgaudit.log` parameter.

- `none` – This is the default. No database changes are logged.
- `all` – Logs everything (read, write, function, role, ddl, misc).
- `ddl` – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- `function` – Logs function calls and D0 blocks.
- `misc` – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- `read` – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- `role` – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- `write` – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

14. Choose **Save changes**.

15. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

16. Choose your Aurora PostgreSQL DB cluster's writer instance from the Databases list.

## Amazon CLI

### To setup pgAudit

To setup pgAudit using the Amazon CLI, you call the [modify-db-parameter-group](#) operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following Amazon CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \  
  --region aws-region
```

2. Use the following Amazon CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the `pgaudit` library is initialized.

```
aws rds reboot-db-instance \  
  --db-instance-identifier writer-instance \  
  --region aws-region
```

3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;  
shared_preload_libraries  
-----  
rdsutils,pgaudit  
(1 row)
```

With `pgAudit` initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the Amazon CLI.

```
labdb=> \q
```

5. Use the following Amazon CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to `write`, which captures inserts, updates, and deletes to the log.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \  
  --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- `none` – This is the default. No database changes are logged.
- `all` – Logs everything (read, write, function, role, ddl, misc).

- `ddl` – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- `function` – Logs function calls and DO blocks.
- `misc` – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- `read` – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- `role` – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- `write` – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following Amazon CLI command.

```
aws rds reboot-db-instance \  
  --db-instance-identifier writer-instance \  
  --region aws-region
```

## Auditing database objects

With `pgAudit` set up on your Aurora PostgreSQL DB cluster and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in a database table, with the `pgAudit` extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that `pgaudit` has been initialized and that you have created the `pgaudit` extension by following the procedure in [Setting up the pgAudit extension](#).

```

2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: statement: SELECT feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: AUDIT: SESSION,2,1,READ,SELECT,TABLE,public.support,"SELECT
feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;",<none>
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: QUERY STATISTICS
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:DETAIL: ! system usage stats:
! 0.009494 s user, 0.007442 s system, 0.141985 s elapsed
! [0.022327 s user, 0.007442 s system total]

```

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

## To set up object auditing

1. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --
username=postgrespostgres --password --dbname=labdb
```

2. Create a database role named `rds_pgaudit` using the following command.

```
labdb=> CREATE ROLE rds_pgaudit;
CREATE ROLE
labdb=>
```

3. Close the `psql` session.

```
labdb=> \q
```

In the next few steps, use the Amazon CLI to modify the audit log parameters in your custom parameter group.

4. Use the following Amazon CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters
  "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot"
  \
  --region aws-region
```

5. Use the following Amazon CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes to the parameters take effect.

```
aws rds reboot-db-instance \
  --db-instance-identifier writer-instance \
  --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```
SHOW pgaudit.role;
pgaudit.role
-----
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
...
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...
```

For information on viewing the logs, see [Monitoring Amazon Aurora log files](#).

To learn more about the pgAudit extension, see [pgAudit](#) on GitHub.

## Excluding users or databases from audit logging

As discussed in [Aurora PostgreSQL database log files](#), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees,

depending on the changes that you track. You might not need to audit every user or database in your Aurora PostgreSQL DB cluster.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

**Note**

Parameter settings at the session level take precedence over the settings in the custom DB cluster parameter group for the Aurora PostgreSQL DB cluster's writer instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your Aurora PostgreSQL DB cluster is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```
SELECT
  username AS user_name,
  useconfig AS user_specific_settings
FROM
  pg_user
WHERE
  username = 'myuser';
```

You see output such as the following.

```
user_name | user_specific_settings
-----+-----
myuser    | {pgaudit.log=NONE}
(1 row)
```

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for `pgaudit.log` for a specific user and database combination.

```
SELECT
  username AS "user_name",
  datname AS "database_name",
  pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
  pg_catalog.pg_db_role_setting s
  LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
  LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
  username = 'myuser'
  AND datname = 'mydatabase'
ORDER BY
  1,
  2;
```

You see output similar to the following.

```
 user_name | database_name | settings
-----+-----+-----
 myuser   | mydatabase   | pgaudit.log=none
(1 row)
```

After turning off auditing for `myuser`, you decide that you don't want to track changes to `mydatabase`. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the `database_specific_settings` column to confirm that `pgaudit.log` is set to `NONE`.

```
SELECT
  a.datname AS database_name,
```

```
b.setconfig AS database_specific_settings
FROM
pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
a.datname = 'mydatabase';
```

You see output such as the following.

```
database_name | database_specific_settings
-----+-----
mydatabase   | {pgaudit.log=NONE}
(1 row)
```

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see [List of allowable settings for the pgaudit.log parameter](#).

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

## Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

## Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

Parameter	Description
<code>pgaudit.log</code>	Specifies the statement classes that will be logged by session audit logging. Allowable values include <code>ddl</code> , <code>function</code> , <code>misc</code> , <code>read</code> , <code>role</code> , <code>write</code> , <code>none</code> , <code>all</code> . For more information, see <a href="#">List of allowable settings for the <code>pgaudit.log</code> parameter</a> .
<code>pgaudit.log_catalog</code>	When turned on (set to 1), adds statements to audit trail if all relations in a statement are in <code>pg_catalog</code> .
<code>pgaudit.log_level</code>	Specifies the log level to use for log entries. Allowed values: <code>debug5</code> , <code>debug4</code> , <code>debug3</code> , <code>debug2</code> , <code>debug1</code> , <code>info</code> , <code>notice</code> , <code>warning</code> , <code>log</code>
<code>pgaudit.log_parameter</code>	When turned on (set to 1), parameters passed with the statement are captured in the audit log.
<code>pgaudit.log_relation</code>	When turned on (set to 1), the audit log for the session creates a separate log entry for each relation ( <code>TABLE</code> , <code>VIEW</code> , and so on) referenced in a <code>SELECT</code> or <code>DML</code> statement.
<code>pgaudit.log_statement_once</code>	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
<code>pgaudit.role</code>	Specifies the master role to use for object audit logging. The only allowable entry is <code>rds_pgaudit</code> .

### List of allowable settings for the `pgaudit.log` parameter

Value	Description
none	This is the default. No database changes are logged.
all	Logs everything (read, write, function, role, ddl, misc).
ddl	Logs all data definition language (DDL) statements that aren't included in the ROLE class.
function	Logs function calls and DO blocks.
misc	Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
read	Logs SELECT and COPY when the source is a relation (such as a table) or a query.
role	Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
write	Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to ALL. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.

## Using `pglogical` to synchronize data across instances

All currently available Aurora PostgreSQL versions support the `pglogical` extension. The `pglogical` extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see [Overview of PostgreSQL logical replication with Aurora](#).

The `pglogical` extension supports logical replication between two or more Aurora PostgreSQL DB clusters. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The

`pglogical` extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The *publisher node* is the Aurora PostgreSQL DB cluster that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The *subscriber node* is the Aurora PostgreSQL DB cluster that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the `pglogical` extension.

## Topics

- [Requirements and limitations for the `pglogical` extension](#)
- [Setting up the `pglogical` extension](#)
- [Setting up logical replication for Aurora PostgreSQL DB cluster](#)
- [Reestablishing logical replication after a major upgrade](#)
- [Managing logical replication slots for Aurora PostgreSQL](#)
- [Parameter reference for the `pglogical` extension](#)

## Requirements and limitations for the `pglogical` extension

All currently available releases of Aurora PostgreSQL support the `pglogical` extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from a publisher to a subscriber must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The `pglogical` extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see [PostgreSQL bi-directional replication using pglogical](#).

## Setting up the pglogical extension

To set up the `pglogical` extension on your Aurora PostgreSQL DB cluster, you add `pglogical` to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the Amazon Web Services Management Console or the Amazon CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group. For information about creating a custom DB cluster parameter group, see [Parameter groups for Amazon Aurora](#).

### Console

#### To set up the pglogical extension

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance .
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.

RDS > Parameter groups > docs-lab-rpg-12-parameter-group

## docs-lab-rpg-12-parameter-group

**Parameters**

Q shared\_pre X

<input type="checkbox"/>	Name	Values	Allowed values
<input type="checkbox"/>	shared_preload_libraries	pglogical,pg_stat_statements	auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_transport, plprofiler

8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.
9. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes take effect.
10. When the instance is available, you can use `psql` (or `pgAdmin`) to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

11. To verify that `pglogical` is initialized, run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pglogical
(1 row)
```

12. Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
-----
logical
(1 row)
```

### 13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;  
EXTENSION CREATED
```

### 14. Choose **Save changes**.

### 15. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

### 16. Choose your Aurora PostgreSQL DB cluster's writer instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

## Amazon CLI

### To setup the pglogical extension

To setup pglogical using the Amazon CLI, you call the [modify-db-parameter-group](#) operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following Amazon CLI command to add pglogical to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-  
reboot" \  
  --region aws-region
```

2. Use the following Amazon CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the writer instance of the Aurora PostgreSQL DB cluster.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-  
reboot" \  
  --region aws-region
```

3. Use the following Amazon CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the pglogical library is initialized.

```
aws rds reboot-db-instance \  
  --db-instance-identifier writer-instance \  
  --region aws-region
```

4. When the instance is available, use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```
CREATE EXTENSION pglogical;  
EXTENSION CREATED
```

6. Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following Amazon CLI command.

```
aws rds reboot-db-instance \  
  --db-instance-identifier writer-instance \  
  --region aws-region
```

## Setting up logical replication for Aurora PostgreSQL DB cluster

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in [Setting up the pglogical extension](#).

### Note

The `node_name` of a subscriber node can't start with `rds`.

### To create the publisher node and define the tables to replicate

These steps assume that your Aurora PostgreSQL DB cluster has a writer instance with a database that has one or more tables that you want to replicate to another node. You need to recreate the

table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do that by using the `psql` metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use `psql` to connect to the instance that has the table you want to use as a source for subscribers.

```
psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

If you don't have an existing table that you want to replicate, you can create a sample table as follows.

- a. Create an example table using the following SQL statement.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

- b. Populate the table with generated data by using the following SQL statement.

```
INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
INSERT 0 5000
```

- c. Verify that data exists in the table by using the following SQL statement.

```
SELECT count(*) FROM docs_lab_table;
```

2. Identify this Aurora PostgreSQL DB cluster as the publisher node, as follows.

```
SELECT pglogical.create_node(
  node_name := 'docs_lab_provider',
  dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
  dbname=labdb');
create_node
-----
 3410995529
(1 row)
```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see [Replication sets](#) in the pglogical documentation.

```
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true',
NULL, NULL);
replication_set_add_table
-----
t
(1 row)
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

### To set up the subscriber node and create a subscription to receive updates

These steps assume that the Aurora PostgreSQL DB cluster has been set up with the `pglogical` extension. For more information, see [Setting up the pglogical extension](#).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. On the subscriber Aurora PostgreSQL DB cluster, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

3. Verify that this table is empty.

```
SELECT count(*) FROM docs_lab_table;
count
-----
0
(1 row)
```

4. Identify this Aurora PostgreSQL DB cluster as the subscriber node, as follows.

```
SELECT pglogical.create_node(
node_name := 'docs_lab_target',
dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
sslmode=require dbname=labdb user=postgres password=*****');
create_node
```

```

-----
      2182738256
(1 row)

```

## 5. Create the subscription.

```

SELECT pglogical.create_subscription(
  subscription_name := 'docs_lab_subscription',
  provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
sslmode=require dbname=labdb user=postgres password=*****',
  replication_sets := ARRAY['default'],
  synchronize_data := true,
  forward_origins := '{}');
create_subscription
-----
1038357190
(1 row)

```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```

SELECT count(*) FROM docs_lab_table;
count
-----
   5000
(1 row)

```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

## Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an Aurora PostgreSQL DB cluster that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the Aurora PostgreSQL DB cluster, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The Aurora PostgreSQL subscriber node in a logical replication scenario has no slots to drop. The Aurora PostgreSQL major version

upgrade process supports upgrading the subscriber to a new major version of PostgreSQL independent of the publisher node. However, the upgrade process does disrupt the replication process and interferes with the synchronization of WAL data between publisher node and subscriber node. You need to re-establish logical replication between publisher and subscriber after upgrading the publisher, the subscriber, or both. The following procedure shows you how to determine that replication has been disrupted and how to resolve the issue.

## Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

### To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the `active` column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name,plugin,slot_type,active FROM pg_replication_slots;
      slot_name          |      plugin      | slot_type | active
-----+-----+-----+-----
pgl_labdb_docs_labcb4fa94_docs_lab3de412c | pglogical_output | logical   | f
(1 row)
```

### To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@[7361]:LOG: background worker "pglogical apply
16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@[7361]:LOG: background worker "pglogical apply
16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```
SELECT * FROM pg_replication_origin;
 roident | roname
-----+-----
(0 rows)
```

The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
 roident | roname
-----+-----
      1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

- Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
 subscription_name | status | slot_name
-----+-----+-----
 docs_lab_subscription | down | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as replicating.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

### To reestablish logical replication between publisher and subscriber nodes

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

```
psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

- Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

```
SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
alter_subscription_disable
-----
t
(1 row)
```

- Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```
SELECT * FROM pg_replication_origin;
roident |          roname
-----+-----
1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

- Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
pg_replication_origin_create
-----
1
(1 row)
```

- Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
alter_subscription_enable
-----
t
(1 row)
```

Check the status of the node. Its status should be `replicating` as shown in this example.

```
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();
subscription_name | status | slot_name
-----+-----+-----
```

```
docs_lab_subscription      | replicating |
pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's `active` column should return `t` (true), indicating that replication has been re-established.

```
SELECT slot_name,plugin,slot_type,active
FROM pg_replication_slots;
          slot_name          |      plugin      | slot_type | active
-----+-----+-----+-----
pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical   | t
(1 row)
```

## Managing logical replication slots for Aurora PostgreSQL

Before you can perform a major version upgrade on an Aurora PostgreSQL DB cluster's writer instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT * FROM pglogical.node;
node_id | node_name
-----+-----
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.

```
SELECT sub_name,sub_slot_name,sub_target
FROM pglogical.subscription;
sub_name | sub_slot_name          | sub_target
-----+-----+-----
docs_lab_subscription      | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
(1 row)
```

You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
 drop_subscription
-----
                1
(1 row)
```

After dropping the subscription, you can delete the node.

```
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
 drop_node
-----
t
(1 row)
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
 node_id | node_name
-----+-----
(0 rows)
```

## Parameter reference for the pglogical extension

In the table you can find parameters associated with the `pglogical` extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](#).

Parameter	Description
<code>pglogical.batch_inserts</code>	Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.
<code>pglogical.conflict_log_level</code>	Sets the log level to use for logging resolved conflicts. Supported string values are <code>debug5</code> , <code>debug4</code> , <code>debug3</code> , <code>debug2</code> , <code>debug1</code> , <code>info</code> , <code>notice</code> , <code>warning</code> , <code>error</code> , <code>log</code> , <code>fatal</code> , <code>panic</code> .

Parameter	Description
<code>pglogical.conflict_resolution</code>	Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are <code>error</code> , <code>apply_remote</code> , <code>keep_local</code> , <code>last_update_wins</code> , <code>first_update_wins</code> .
<code>pglogical.extra_connection_options</code>	Connection options to add to all peer node connections.
<code>pglogical.synchronous_commit</code>	pglogical specific synchronous commit value
<code>pglogical.use_spi</code>	Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="#">Server Programming Interface</a> in the PostgreSQL documentation.

## Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB instance to work with Oracle databases.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

### Topics

- [Using the `log\_fdw` extension to access the DB log using SQL](#)
- [Using the `postgres\_fdw` extension to access external data](#)
- [Working with MySQL databases by using the `mysql\_fdw` extension](#)
- [Working with Oracle databases by using the `oracle\_fdw` extension](#)
- [Working with SQL Server databases by using the `tds\_fdw` extension](#)

## Using the `log_fdw` extension to access the DB log using SQL

Aurora PostgreSQL DB cluster supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text)` – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

By default, the log files are generated by Amazon Aurora in `stderr` (standard error) format, as specified in `log_destination` parameter. There are only two options for this parameter, `stderr` and `csvlog` (comma-separated values, CSV). If you add the `csvlog` option to the parameter, Amazon Aurora generates both `stderr` and `csvlog` logs. This can affect the storage capacity on your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see [Setting the log destination \(stderr, csvlog\)](#).

One benefit of generating `csvlog` logs is that the `log_fdw` extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for `log_destination`. For more information about how to do so, see [Parameter groups for Amazon Aurora](#).

The following example assumes that the `log_destination` parameter includes `csvlog`.

### To use the `log_fdw` extension

1. Install the `log_fdw` extension.

```
postgres=> CREATE EXTENSION log_fdw;  
CREATE EXTENSION
```

2. Create the log server as a foreign data wrapper.

```
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;  
CREATE SERVER
```

### 3. Select all from a list of log files.

```
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

A sample response is as follows.

file_name	file_size_bytes
postgresql.log.2023-08-09-22.csv	1111
postgresql.log.2023-08-09-23.csv	1172
postgresql.log.2023-08-10-00.csv	1744
postgresql.log.2023-08-10-01.csv	1102

(4 rows)

### 4. Create a table with a single 'log\_entry' column for the selected file.

```
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
  'log_server', 'postgresql.log.2023-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
-----
(1 row)
```

### 5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

log_time	message
Tue Aug 09 15:45:18.172 2023 PDT	ending log output to stderr
Tue Aug 09 15:45:18.175 2023 PDT	database system was interrupted; last known up at 2023-08-09 22:43:34 UTC
Tue Aug 09 15:45:18.223 2023 PDT	checkpoint record is at 0/90002E0
Tue Aug 09 15:45:18.223 2023 PDT	redo record is at 0/90002A8; shutdown FALSE
Tue Aug 09 15:45:18.223 2023 PDT	next transaction ID: 0/1879; next OID: 24578
Tue Aug 09 15:45:18.223 2023 PDT	next MultiXactId: 1; next MultiXactOffset: 0

```
Tue Aug 09 15:45:18.223 2023 PDT | oldest unfrozen transaction ID: 1822, in
database 1
(7 rows)
```

## Using the `postgres_fdw` extension to access external data

You can access data in a table on a remote database server with the [postgres\\_fdw](#) extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

### To use `postgres_fdw` to access a remote database server

1. Install the `postgres_fdw` extension.

```
CREATE EXTENSION postgres_fdw;
```

2. Create a foreign data server using `CREATE SERVER`.

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

#### Important

To redact the password so that it doesn't appear in the logs, set `log_statement=none` at the session level. Setting at the parameter level doesn't redact the password.

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text)
```

```
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

## Working with MySQL databases by using the `mysql_fdw` extension

To access a MySQL-compatible database from your Aurora PostgreSQL DB cluster, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from Aurora PostgreSQL DB cluster to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see [Using encryption in transit with the extension](#).

The `mysql_fdw` extension is supported on Amazon Aurora PostgreSQL version 15.4, 14.9, 13.12, 12.16, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

### Topics

- [Setting up your Aurora PostgreSQL DB to use the `mysql\_fdw` extension](#)
- [Example: Working with an Aurora MySQL database from Aurora PostgreSQL](#)
- [Using encryption in transit with the extension](#)

## Setting up your Aurora PostgreSQL DB to use the `mysql_fdw` extension

Setting up the `mysql_fdw` extension on your Aurora PostgreSQL DB cluster involves loading the extension in your DB cluster and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an Aurora MySQL DB cluster, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the Aurora PostgreSQL DB cluster and the Aurora MySQL DB cluster need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the `rds_superuser` account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

## To use `mysql_fdw` to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role. If you accepted the defaults when you created your Aurora PostgreSQL DB cluster, the user name is `postgres`, and you can connect using the `psql` command line tool as follows:

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Install the `mysql_fdw` extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;  
CREATE EXTENSION
```

After the extension is installed on your Aurora PostgreSQL DB cluster, you set up the foreign server that provides the connection to a MySQL database.

## To create the foreign server

Perform these tasks on the Aurora PostgreSQL DB cluster. The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the Aurora PostgreSQL DB cluster:

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');  
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
```

## GRANT

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

### Example: Working with an Aurora MySQL database from Aurora PostgreSQL

Suppose that you have a simple table on an Aurora PostgreSQL DB instance . Your Aurora PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the `mysql_fdw` extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the Aurora PostgreSQL DB instance, create a foreign server:

```
test=> CREATE SERVER mysqlldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER mysqlldb TO user1;
GRANT
```

3. Connect as `user1`, and then create a mapping to the MySQL user:

```
test=> CREATE USER MAPPING FOR user1 SERVER mysqlldb OPTIONS (username 'myuser',
password 'mypassword');
CREATE USER MAPPING
```

4. Create a foreign table linked to the MySQL table:

```
test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqlldb OPTIONS (dbname
'test', table_name '');
CREATE FOREIGN TABLE
```

5. Run a simple query against the foreign table:

```
test=> SELECT * FROM mytab;
a | b
---+-----
```

```
1 | apple
(1 row)
```

6. You can add, change, and remove data from the MySQL table. For example:

```
test=> INSERT INTO mytab values (2, 'mango');
INSERT 0 1
```

Run the SELECT query again to see the results:

```
test=> SELECT * FROM mytab ORDER BY 1;
 a |  b
----+-----
 1 | apple
 2 | mango
(2 rows)
```

## Using encryption in transit with the extension

The connection to MySQL from Aurora PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the `REQUIRE SSL` option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to `REQUIRE SSL`, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the `ALTER USER` command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see [ALTER USER](#) in *MySQL Reference Manual*.

MySQL 5.7, MySQL 8.0	MySQL 5.6
<code>ALTER USER 'user'@'%' REQUIRE SSL;</code>	<code>GRANT USAGE ON *.* to 'user'@'%' REQUIRE SSL;</code>

For more information about the `mysql_fdw` extension, see the [mysql\\_fdw](#) documentation.

## Working with Oracle databases by using the `oracle_fdw` extension

To access an Oracle database from your Aurora PostgreSQL DB cluster you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the [oracle\\_fdw](#) documentation.

The `oracle_fdw` extension is supported on Aurora PostgreSQL 12.7 (Amazon Aurora release 4.2) and higher versions.

### Topics

- [Turning on the `oracle\_fdw` extension](#)
- [Example: Using a foreign server linked to an Amazon RDS for Oracle database](#)
- [Working with encryption in transit](#)
- [Understanding the `pg\_user\_mappings` view and permissions](#)

### Turning on the `oracle_fdw` extension

To use the `oracle_fdw` extension, perform the following procedure.

#### To turn on the `oracle_fdw` extension

- Run the following command using an account that has `rds_superuser` permissions.

```
CREATE EXTENSION oracle_fdw;
```

### Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

#### To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:

- Endpoint
- Port
- Database name

## 2. Create a foreign server.

```
test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver
'//endpoint:port/DB_name');
CREATE SERVER
```

## 3. Grant usage to a user who doesn't have rds\_superuser privileges, for example user1.

```
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

## 4. Connect as user1, and create a mapping to an Oracle user.

```
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser',
password 'mypassword');
CREATE USER MAPPING
```

## 5. Create a foreign table linked to an Oracle table.

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

## 6. Query the foreign table.

```
test=> SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

## Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see [About the Values for Negotiating](#)

[Encryption and Integrity](#) in the Oracle documentation. The client used for oracle\_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration and it uses Oracle Security Library (libnntz) for encryption.

If your database is on RDS for Oracle, see [Oracle native network encryption](#) to configure the encryption.

## Understanding the pg\_user\_mappings view and permissions

The PostgreSQL catalog pg\_user\_mapping stores the mapping from an Aurora PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the pg\_user\_mappings view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users rdssu1 and rdssu2 are members of the rds\_superuser role, and user1 isn't. The example uses the psql metacommand \du to list existing roles.

```
test=> \du
```

Role name	Member of	Attributes	List of roles
rdssu1	{rds_superuser}		
rdssu2	{rds_superuser}		
user1			{ }

All users, including users that have rds\_superuser privileges, are allowed to view their own user mappings (umoptions) in the pg\_user\_mappings table. As shown in the following example, when rdssu1 tries to obtain all user mappings, an error is raised even though rdssu1 has rds\_superuser privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```

test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
  umid | srvid | srvname | umuser | username |          umoptions
-----+-----+-----+-----+-----+-----
 16414 | 16411 | oradb  | 16412 | user1    |
 16423 | 16411 | oradb  | 16421 | rdssu1   | {user=oracleuser,password=mypwd}
 16424 | 16411 | oradb  | 16422 | rdssu2   |
(3 rows)

test=> SET SESSION AUTHORIZATION rdssu2;
SET
test=> SELECT * FROM pg_user_mappings;
  umid | srvid | srvname | umuser | username |          umoptions
-----+-----+-----+-----+-----+-----
 16414 | 16411 | oradb  | 16412 | user1    |
 16423 | 16411 | oradb  | 16421 | rdssu1   |
 16424 | 16411 | oradb  | 16422 | rdssu2   | {user=oracleuser,password=mypwd}
(3 rows)

test=> SET SESSION AUTHORIZATION user1;
SET
test=> SELECT * FROM pg_user_mappings;
  umid | srvid | srvname | umuser | username |          umoptions
-----+-----+-----+-----+-----+-----
 16414 | 16411 | oradb  | 16412 | user1    | {user=oracleuser,password=mypwd}
 16423 | 16411 | oradb  | 16421 | rdssu1   |
 16424 | 16411 | oradb  | 16422 | rdssu2   |
(3 rows)

```

Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the `USAGE` privilege on it.

- The current user is the server owner and the mapping is for PUBLIC.

## Working with SQL Server databases by using the tds\_fdw extension

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your Aurora PostgreSQL DB cluster to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see [tds-fdw/tds\\_fdw](#) documentation on GitHub.

The `tds_fdw` extension is supported on Amazon Aurora PostgreSQL version 13.6 and higher releases.

### Setting up your Aurora PostgreSQL DB to use the tds\_fdw extension

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an Aurora PostgreSQL DB cluster. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the Aurora PostgreSQL DB cluster and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:
Adaptive Server is unavailable or does not exist (mssql2019.aws-
region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

### To use tds\_fdw to connect to a SQL Server database

1. Connect to your Aurora PostgreSQL DB cluster's primary instance using an account that has the `rds_superuser` role:

```
psql --host=your-cluster-name-instance-1.aws-region.rds.amazonaws.com --port=5432
--username=test --password
```

## 2. Install the `tds_fdw` extension:

```
test=> CREATE EXTENSION tds_fdw;
CREATE EXTENSION
```

After the extension is installed on your Aurora PostgreSQL DB cluster, you set up the foreign server.

### To create the foreign server

Perform these tasks on the Aurora PostgreSQL DB cluster using an account that has `rds_superuser` privileges.

#### 1. Create a foreign server in the Aurora PostgreSQL DB cluster:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS
(servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database
'tds_fdw_testing');
CREATE SERVER
```

To access non-ASCII data on the SQLServer side, create a server link with the `character_set` option in the Aurora PostgreSQL DB cluster:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername
'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing',
character_set 'UTF-8');
CREATE SERVER
```

#### 2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

#### 3. Connect as `user1` and create a mapping to a SQL Server user:

```
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username
'sqlserveruser', password 'password');
CREATE USER MAPPING
```

4. Create a foreign table linked to a SQL Server table:

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table
'MYTABLE');
CREATE FOREIGN TABLE
```

5. Query the foreign table:

```
test=> SELECT * FROM mytab;
 a
---
 1
(1 row)
```

## Using encryption in transit for the connection

The connection from Aurora PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see [Forcing connections to your DB instance to use SSL](#). For more information about SSL/TLS configuration for RDS for SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#).

# Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see [Packaging Related Objects into an Extension](#) in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your Aurora PostgreSQL DB clusters.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on Aurora PostgreSQL version 14.5 and higher versions.

The Trusted Language Extensions development environment and runtime are packaged as the `pg_tle` PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the `pg_tle` extension in your Aurora PostgreSQL DB cluster in the same way that you install other PostgreSQL extensions. After the `pg_tle` is set up, developers can use it to create new PostgreSQL extensions, known as *TLE extensions*.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

## Topics

- [Terminology](#)
- [Requirements for using Trusted Language Extensions for PostgreSQL](#)
- [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#)
- [Overview of Trusted Language Extensions for PostgreSQL](#)

- [Creating TLE extensions for Aurora PostgreSQL](#)
- [Dropping your TLE extensions from a database](#)
- [Uninstalling Trusted Language Extensions for PostgreSQL](#)
- [Using PostgreSQL hooks with your TLE extensions](#)
- [Function reference for Trusted Language Extensions for PostgreSQL](#)
- [Hooks reference for Trusted Language Extensions for PostgreSQL](#)

## Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

### Trusted Language Extensions for PostgreSQL

*Trusted Language Extensions for PostgreSQL* is the official name of the open source development kit that's packaged as the `pg_tle` extension. It's available for use on any PostgreSQL system. For more information, see [aws/pg\\_tle](#) on GitHub.

### Trusted Language Extensions

*Trusted Language Extensions* is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

### trusted language

A *trusted language* is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see [Trusted and Untrusted PL/Perl](#) in the PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

### TLE extension

A *TLE extension* is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

## Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **Aurora PostgreSQL versions** – Trusted Language Extensions is supported on Aurora PostgreSQL version 14.5 and higher versions only.
  - If you need to upgrade your Aurora PostgreSQL DB cluster, see [Upgrading Amazon Aurora PostgreSQL DB clusters](#).
  - If you don't yet have an Aurora DB cluster running PostgreSQL, you can create one. For more information, see [Creating and connecting to an Aurora PostgreSQL DB cluster](#).
- **Requires `rds_superuser` privileges** – To set up and configure the `pg_tle` extension, your database user role must have the permissions of the `rds_superuser` role. By default, this role is granted to the `postgres` user that creates the Aurora PostgreSQL DB cluster.
- **Requires a custom DB parameter group** – Your Aurora PostgreSQL DB cluster must be configured with a custom DB parameter group. You use the custom DB parameter group for the writer instance of your Aurora PostgreSQL DB cluster.
  - If your Aurora PostgreSQL DB cluster isn't configured with a custom DB parameter group, you should create one and associate it with the writer instance of your Aurora PostgreSQL DB cluster. For a short summary of steps, see [Creating and applying a custom DB parameter group](#).
  - If your Aurora PostgreSQL DB cluster is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

### Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your Aurora PostgreSQL DB cluster to use it.

#### Console

#### To create a custom DB parameter group and use it with your Aurora PostgreSQL DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose Parameter groups from the Amazon RDS menu.

3. Choose **Create parameter group**.
4. In the **Parameter group details** page, enter the following information.
  - For **Parameter group family**, choose `aurora-postgresql14`.
  - For **Type**, choose **DB Parameter Group**.
  - For **Group name**, give your parameter group a meaningful name in the context of your operations.
  - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose **Create**. Your custom DB parameter group is created in your Amazon Web Services Region. You can now modify your Aurora PostgreSQL DB cluster to use it by following the next steps.
6. Choose **Databases** from the Amazon RDS menu.
7. Choose the Aurora PostgreSQL DB cluster that you want to use with TLE from among those listed, and then choose **Modify**.
8. In the Modify DB cluster settings page, find **Database options** and use the selector to choose your custom DB parameter group.
9. Choose **Continue** to save the change.
10. Choose **Apply immediately** so that you can continue setting up the Aurora PostgreSQL DB cluster to use TLE.

To continue setting up your system for Trusted Language Extensions, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

For more information working with DB cluster and DB parameter groups, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

## Amazon CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your Amazon CLI with your default Amazon Web Services Region. For more information, see [Configuration basics](#) in the *Amazon Command Line Interface User Guide*.

### To create a custom DB parameter group and use it with your Aurora PostgreSQL DB cluster

1. Use the [create-db-parameter-group](#) Amazon CLI command to create a custom DB parameter group based on `aurora-postgresql14` for your Amazon Web Services Region. Note that in

this step you create a DB parameter group to apply to the writer instance of your Aurora PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --region aws-region \  
  --db-parameter-group-name custom-params-for-pg-tle \  
  --db-parameter-group-family aurora-postgresql14 \  
  --description "My custom DB parameter group for Trusted Language Extensions"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --region aws-region ^  
  --db-parameter-group-name custom-params-for-pg-tle ^  
  --db-parameter-group-family aurora-postgresql14 ^  
  --description "My custom DB parameter group for Trusted Language Extensions"
```

Your custom DB parameter group is available in your Amazon Web Services Region, so you can modify the writer instance of your Aurora PostgreSQL DB cluster to use it.

2. Use the [modify-db-instance](#) Amazon CLI command to apply your custom DB parameter group to the writer instance of your Aurora PostgreSQL DB cluster. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --region aws-region \  
  --db-instance-identifier your-writer-instance-name \  
  --db-parameter-group-name custom-params-for-pg-tle \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --region aws-region ^  
  --db-instance-identifier your-writer-instance-name ^  
  --db-parameter-group-name custom-params-for-pg-tle ^
```

```
--apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

For more information, see [DB parameter groups for Amazon Aurora DB instances](#) .

## Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster

The following steps assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group. You can use the Amazon Web Services Management Console or the Amazon CLI for these steps.

When you set up Trusted Language Extensions in your Aurora PostgreSQL DB cluster , you install it in a specific database for use by the database users who have permissions on that database.

### Console

#### To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance .
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

## Parameters

Cancel editing

Preview changes

<input type="checkbox"/>	Name	Values	Allowed values
<input type="checkbox"/>	shared_preload_libraries	pg_tle	auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, <b>pg_tle</b> , pg_transport, plprofiler

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pg_tle
(1 row)
```

10. With the `pg_tle` extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following `psql` metacommand.

```
labdb=> \dx
                                     List of installed extensions
 Name | Version | Schema | Description
-----+-----+-----+-----
 pg_tle | 1.0.1 | pgtle | Trusted-Language Extensions for PostgreSQL
 plpgsql | 1.0 | pg_catalog | PL/pgSQL procedural language
```

- Grant the `pgtle_admin` role to the primary user name that you created for your Aurora PostgreSQL DB cluster when you set it up. If you accepted the default, it's `postgres`.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the `psql` metacommand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see [Understanding PostgreSQL roles and permissions](#).

```
labdb=> \du
                                List of roles
  Role name  |          Attributes          |          Member of
-----+-----
+-----+-----
pgtle_admin | Cannot login                 | {}
postgres   | Create role, Create DB      +| {rds_superuser,pgtle_admin}
            | Password valid until infinity |...
```

- Close the `psql` session using the `\q` metacommand.

```
\q
```

To get started creating TLE extensions, see [Example: Creating a trusted language extension using SQL](#).

## Amazon CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your Amazon CLI with your default Amazon Web Services Region. For more information, see [Configuration basics](#) in the *Amazon Command Line Interface User Guide*.

### To set up Trusted Language Extensions

- Use the [modify-db-parameter-group](#) Amazon CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
```

```
--parameters
"ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-
reboot" \
--region aws-region
```

2. Use the [reboot-db-instance](#) Amazon CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster and initialize the `pg_tle` library.

```
aws rds reboot-db-instance \
--db-instance-identifier writer-instance \
--region aws-region
```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pg_tle
(1 row)
```

With `pg_tle` initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

4. Grant the `pgtle_admin` role to the primary user name that you created for your Aurora PostgreSQL DB cluster when you set it up. If you accepted the default, it's `postgres`.

```
GRANT pgtle_admin TO postgres;
GRANT ROLE
```

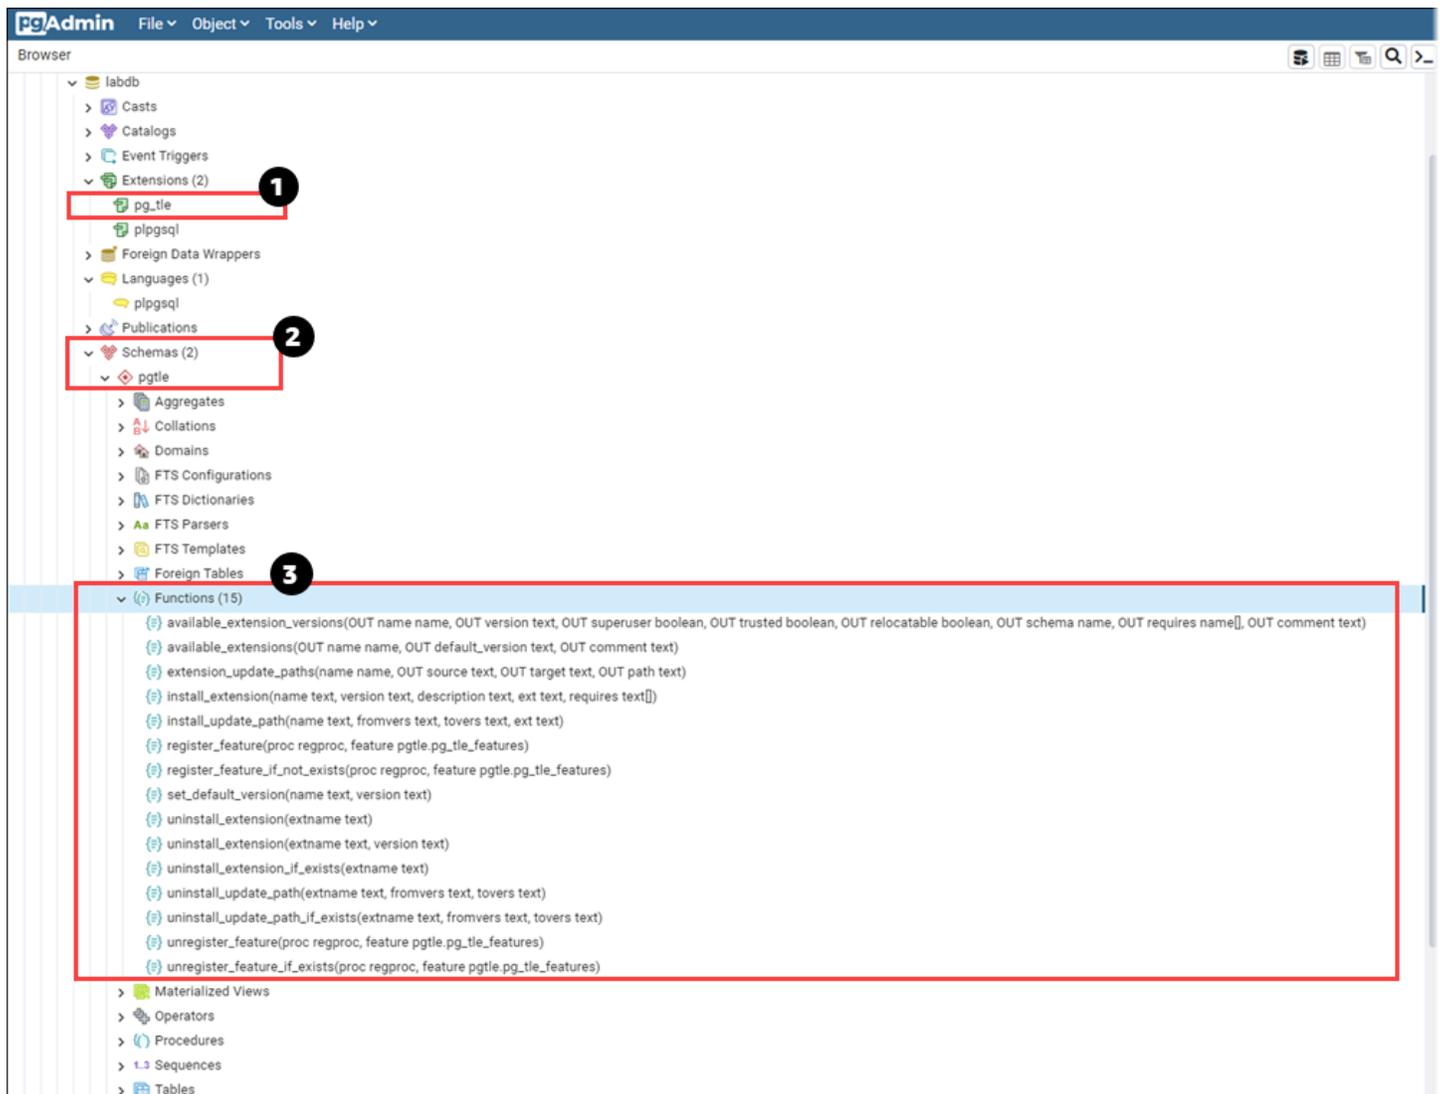

5. Close the `psql` session as follows.

```
labdb=> \q
```

To get started creating TLE extensions, see [Example: Creating a trusted language extension using SQL](#).

# Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your Aurora PostgreSQL DB cluster in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the `pg_tle` extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the `pg_tle` extension. As such, `pg_tle` is added to the available extensions for the database in which it's installed.
2. TLE has its own schema, `pgtle`. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see [Function reference for Trusted Language Extensions for PostgreSQL](#).

Other components of the `pg_tle` extension include the following:

- **The `pgtle_admin` role** – The `pgtle_admin` role is created when the `pg_tle` extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of *least privilege* when granting the `pgtle_admin` role to database users. In other words, grant the `pgtle_admin` role only to database users that are allowed to create, install, and manage new TLE extensions, such as `postgres`.
- **The `pgtle.feature_info` table** – The `pgtle.feature_info` table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have `pgtle_admin` privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - [pgtle.register\\_feature](#)
  - [pgtle.register\\_feature\\_if\\_not\\_exists](#)
  - [pgtle.unregister\\_feature](#)
  - [pgtle.unregister\\_feature\\_if\\_exists](#)

## Creating TLE extensions for Aurora PostgreSQL

You can install any extensions that you create with TLE in any Aurora PostgreSQL DB cluster that has the `pg_tle` extension installed. The `pg_tle` extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various `pgtle` functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the `pgtle_admin` role.

- [pgtle.install\\_extension](#)
- [pgtle.install\\_update\\_path](#)
- [pgtle.register\\_feature](#)
- [pgtle.register\\_feature\\_if\\_not\\_exists](#)
- [pgtle.set\\_default\\_version](#)
- [pgtle.uninstall\\_extension\(name\)](#)

- [pgtle.uninstall\\_extension\(name, version\)](#)
- [pgtle.uninstall\\_extension\\_if\\_exists](#)
- [pgtle.uninstall\\_update\\_path](#)
- [pgtle.uninstall\\_update\\_path\\_if\\_exists](#)
- [pgtle.unregister\\_feature](#)
- [pgtle.unregister\\_feature\\_if\\_exists](#)

## Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named `pg_distance` that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see [Taxicab geometry](#) and [Euclidean geometry](#) in Wikipedia.

You can use this example in your own Aurora PostgreSQL DB cluster if you have the `pg_tle` extension set up as detailed in [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

### Note

You need to have the privileges of the `pgtle_admin` role to follow this procedure.

## To create the example TLE extension

The following steps use an example database named `labdb`. This database is owned by the `postgres` primary user. The `postgres` role also has the permissions of the `pgtle_admin` role.

1. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Create a TLE extension named `pg_distance` by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_extension
```

```
(
  'pg_distance',
  '0.1',
  'Distance functions for two points',
  $_pg_tle_$
  CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
  RETURNS float8
  AS $$
    SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
  $$ LANGUAGE SQL;

  CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 1);
  $$ LANGUAGE SQL;

  CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 2);
  $$ LANGUAGE SQL;
  $_pg_tle_$
);
```

You see the output, such as the following.

```
install_extension
-----
 t
(1 row)
```

The artifacts that make up the `pg_distance` extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the `CREATE EXTENSION` command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the `CREATE EXTENSION` command as you do for any other extension. As with other extensions, the database user needs to have the `CREATE` permissions in the database.

```
CREATE EXTENSION pg_distance;
```

4. To test the `pg_distance` TLE extension, you can use it to calculate the [Manhattan distance](#) between four points.

```
labdb=> SELECT manhattan_dist(1, 1, 5, 5);  
8
```

To calculate the [Euclidean distance](#) between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);  
5.656854249492381
```

The `pg_distance` extension loads the functions in the database and makes them available to any users with permissions on the database.

## Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- **IMMUTABLE** – The **IMMUTABLE** attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see [Function Volatility Categories](#) in the PostgreSQL documentation.
- **PARALLEL SAFE** – The **PARALLEL SAFE** attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.

In the following example, you can see how the `pgtle.install_update_path` function is used to add these attributes to each function to create a version `0.2` of the `pg_distance` TLE extension. For more information about this function, see [pgtle.install\\_update\\_path](#). You need to have the `pgtle_admin` role to perform this task.

### To update an existing TLE extension and specify the default version

1. Connect to the writer instance of your Aurora PostgreSQL DB cluster using `psql` or another client tool, such as `pgAdmin`.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your psql session console.

```
SELECT pgtle.install_update_path
(
  'pg_distance',
  '0.1',
  '0.2',
  $_pg_tle_$
  CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8,
norm int)
  RETURNS float8
  AS $$
    SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

  CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2
float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 1);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

  CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2
float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 2);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
  $_pg_tle_$
);
```

You see a response similar to the following.

```
install_update_path
-----
 t
(1 row)
```

You can make this version of the extension the default version, so that database users don't have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see [pgtle.set\\_default\\_version](#).

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION ... UPDATE` command, as shown here:

```
ALTER EXTENSION pg_distance UPDATE;
```

## Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn't remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

### To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password --dbname=dbname
```

2. Drop the extension as you would any PostgreSQL extension.

```
DROP EXTENSION your-TLE-extension
```

For example, if you create the `pg_distance` extension as detailed in [Example: Creating a trusted language extension using SQL](#), you can drop the extension as follows.

```
DROP EXTENSION pg_distance;
```

You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
  - If you want to remove all files that make up the extension, continue to the next step.
3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
uninstall_extension
-----
t
(1 row)
```

## Uninstalling Trusted Language Extensions for PostgreSQL

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

### To drop the `pg_tle` extension and its schema from a database

1. Use `psql` or another client tool to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password --dbname=dbname
```

2. Drop the `pg_tle` extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the `CASCADE` keyword, as shown in the following.

```
DROP EXTENSION pg_tle CASCADE;
```

If the `pg_tle` extension isn't still active in the database, you don't need to use the `CASCADE` keyword.

3. Drop the `pgtle` schema. This action removes all the management functions from the database.

```
DROP SCHEMA pgtle CASCADE;
```

The command returns the following when the process completes.

```
DROP SCHEMA
```

The `pg_tle` extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

## Using PostgreSQL hooks with your TLE extensions

A *hook* is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the `pg_tle` extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with `pg_tle`. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to `on`, `off`, or `require`. For more information about specific requirements for available `pg_tle` hooks, see [Hooks reference for Trusted Language Extensions for PostgreSQL](#).

## Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the `password_check.bad_passwords` table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your Aurora PostgreSQL DB cluster, you must have already installed Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your Aurora PostgreSQL DB cluster](#).

### To set up the password-check hook example

1. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Copy the code from the [Password-check hook code listing](#) and paste it into your database.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
  $_pgtle_$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;

CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
  ('123456'),
  ('password'),
  ('12345678'),
```

```
('qwerty'),
('123456789'),
('12345'),
('1234'),
('111111'),
('1234567'),
('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestampz, valid_null boolean)
RETURNS void AS $$
DECLARE
    invalid bool := false;
BEGIN
    IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password
dictionary';
        END IF;
    ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password
dictionary';
        END IF;
    END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_
```

```
);
```

When the extension has been loaded into your database, you see the output such as the following.

```
install_extension
-----
 t
(1 row)
```

3. While still connected to the database, you can now create the extension.

```
CREATE EXTENSION my_password_check_rules;
```

4. You can confirm that the extension has been created in the database by using the following `psql` metacommand.

```
\dx
          List of installed extensions
  Name          | Version | Schema |
  Description
-----+-----+-----
my_password_check_rules | 1.0    | public | Prevent use of any of the top-ten
most common bad passwords
pg_tle          | 1.0.1  | pgtle  | Trusted-Language Extensions for
PostgreSQL
plpgsql         | 1.0    | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

5. Open another terminal session to work with the Amazon CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the [modify-db-parameter-group](#) CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the writer instance of the Aurora PostgreSQL DB cluster for the setting to take effect.

6. Open the `psql` session and query the database to verify that the `password_check` hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
-----
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(
    $1::pg_catalog.text,
    $2::pg_catalog.text,
    $3::pgtle.password_types,
    $4::pg_catalog.timestampz,
    $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `psql` interactive metacommand `\password` behavior is also affected by the `password_check` hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR:  Cannot use passwords from the common password dictionary
```

```
CONTEXT: PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
zone,boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text,
$2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestampz,
$5::pg_catalog.bool)"
```

You can drop this TLE extension and uninstall its source files if you want. For more information, see [Dropping your TLE extensions from a database](#).

### Password-check hook code listing

The example code shown here defines the specification for the `my_password_check_rules` TLE extension. When you copy this code and paste it into your database, the code for the `my_password_check_rules` extension is loaded into the database, and the `password_check` hook is registered for use by the extension.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
  $_pgtle_$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;

CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
  ('123456'),
  ('password'),
  ('12345678'),
  ('qwerty'),
  ('123456789'),
  ('12345'),
  ('1234'),
  ('111111'),
  ('1234567'),
  ('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestampz, valid_null boolean)
RETURNS void AS $$
```

```
DECLARE
  invalid bool := false;
BEGIN
  IF password_type = 'PASSWORD_TYPE_MD5' THEN
    SELECT EXISTS(
      SELECT 1
      FROM password_check.bad_passwords bp
      WHERE ('md5' || md5(bp.plaintext || username)) = password
    ) INTO invalid;
    IF invalid THEN
      RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
    END IF;
  ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
    SELECT EXISTS(
      SELECT 1
      FROM password_check.bad_passwords bp
      WHERE bp.plaintext = password
    ) INTO invalid;
    IF invalid THEN
      RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
    END IF;
  END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
_pgtle_$
);
```

## Function reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your *TLE extensions*, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

### Functions

- [pgtle.available\\_extensions](#)
- [pgtle.available\\_extension\\_versions](#)

- [pgtle.extension\\_update\\_paths](#)
- [pgtle.install\\_extension](#)
- [pgtle.install\\_update\\_path](#)
- [pgtle.register\\_feature](#)
- [pgtle.register\\_feature\\_if\\_not\\_exists](#)
- [pgtle.set\\_default\\_version](#)
- [pgtle.uninstall\\_extension\(name\)](#)
- [pgtle.uninstall\\_extension\(name, version\)](#)
- [pgtle.uninstall\\_extension\\_if\\_exists](#)
- [pgtle.uninstall\\_update\\_path](#)
- [pgtle.uninstall\\_update\\_path\\_if\\_exists](#)
- [pgtle.unregister\\_feature](#)
- [pgtle.unregister\\_feature\\_if\\_exists](#)

## pgtle.available\_extensions

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

### Function prototype

```
pgtle.available_extensions()
```

### Role

None.

### Arguments

None.

### Output

- `name` – The name of the TLE extension.

- `default_version` – The version of the TLE extension to use when `CREATE EXTENSION` is called without a version specified.
- `description` – A more detailed description about the TLE extension.

### Usage example

```
SELECT * FROM pgtle.available_extensions();
```

## `pgtle.available_extension_versions`

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

### Function prototype

```
pgtle.available_extension_versions()
```

### Role

None.

### Arguments

None.

### Output

- `name` – The name of the TLE extension.
- `version` – The version of the TLE extension.
- `superuser` – This value is always `false` for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- `trusted` – This value is always `false` for a TLE extension.
- `relocatable` – This value is always `false` for a TLE extension.
- `schema` – Specifies the name of the schema in which the TLE extension is installed.
- `requires` – An array containing the names of other extensions needed by this TLE extension.
- `description` – A detailed description of the TLE extension.

For more information about output values, see [Packaging Related Objects into an Extension > Extension Files](#) in the PostgreSQL documentation.

### Usage example

```
SELECT * FROM pgtle.available_extension_versions();
```

## pgtle.extension\_update\_paths

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

### Function prototype

```
pgtle.extension_update_paths(name)
```

### Role

None.

### Arguments

`name` – The name of the TLE extension from which to get upgrade paths.

### Output

- `source` – The source version for an update.
- `target` – The target version for an update.
- `path` – The upgrade path used to update a TLE extension from source version to target version, for example, `0.1--0.2`.

### Usage example

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

## pgtle.install\_extension

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

## Function prototype

```
pgtle.install_extension(name text, version text, description text, ext text, requires
text[] DEFAULT NULL::text[])
```

### Role

None.

### Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension.
- `description` – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
- `ext` – The contents of the TLE extension. This value contains objects such as functions.
- `requires` – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the [Extension Files](#) in [Packaging Related Objects into an Extension](#) in the PostgreSQL documentation.

### Output

This function returns OK on success and NULL on error.

- OK – The TLE extension has been successfully installed in the database.
- NULL – The TLE extension hasn't been successfully installed in the database.

### Usage example

```
SELECT pgtle.install_extension(
  'pg_tle_test',
  '0.1',
  'My first pg_tle extension',
  $_pgtle_$
```

```
CREATE FUNCTION my_test()  
RETURNS INT  
AS $$  
    SELECT 42;  
$$ LANGUAGE SQL IMMUTABLE;  
_pgtle_  
);
```

## pgtle.install\_update\_path

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.

### Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

### Role

`pgtle_admin`

### Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension for the upgrade.
- `tovers` – The destination version of the TLE extension for the upgrade.
- `ext` – The contents of the update. This value contains objects such as functions.

### Output

None.

### Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',  
    _pgtle_  
    CREATE OR REPLACE FUNCTION my_test()  
    RETURNS INT  
    AS $$  
        SELECT 21;
```

```
$$ LANGUAGE SQL IMMUTABLE;  
$_pgtle_$  
);
```

## pgtle.register\_feature

The `register_feature` function adds the specified internal PostgreSQL feature to the `pgtle.feature_info` table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- `passcheck` – Registers the password-check hook with your procedure or function that customizes PostgreSQL's password-check behavior.

### Function prototype

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

### Role

`pgtle_admin`

### Arguments

- `proc` – The name of a stored procedure or function to use for the feature.
- `feature` – The name of the `pg_tle` feature (such as `passcheck`) to register with the function.

### Output

None.

### Usage example

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

## pgtle.register\_feature\_if\_not\_exists

The `register_feature_if_not_exists` function adds the specified PostgreSQL feature to the `pgtle.feature_info` table and identifies the TLE extension or other procedure

or function that uses the feature. For more information about hooks and Trusted Language Extensions, see [Using PostgreSQL hooks with your TLE extensions](#).

## Function prototype

```
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

## Role

pgtle\_admin

## Arguments

- `proc` – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the `pw_hook` code.
- `feature` – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the `passcheck` hook. For more information, see [Password-check hook \(passcheck\)](#).

## Output

Returns `true` after registering the feature for the specified extension. Returns `false` if the feature is already registered.

## Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

## pgtle.set\_default\_version

The `set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION . . . UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns `true` on success. If the TLE extension specified in the `name` argument doesn't exist, the function returns an error. Similarly, if the `version` of the TLE extension doesn't exist, it returns an error.

## Function prototype

```
pgtle.set_default_version(name text, version text)
```

### Role

pgtle\_admin

### Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to set the default.

### Output

- `true` – When setting default version succeeds, the function returns `true`.
- `ERROR` – Returns an error message if a TLE extension with the specified name or version doesn't exist.

### Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

## **pgtle.uninstall\_extension(name)**

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

## Function prototype

```
pgtle.uninstall_extension(extname text)
```

## Role

pgtle\_admin

## Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

## Output

None.

## Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```

## pgtle.uninstall\_extension(name, version)

The `uninstall_extension(name, version)` function removes the specified version of the TLE extension from the database. This function prevents `CREATE EXTENSION` and `ALTER EXTENSION` from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call `DROP EXTENSION` to remove the TLE extension. To uninstall all versions of a TLE extension, see [pgtle.uninstall\\_extension\(name\)](#).

## Function prototype

```
pgtle.uninstall_extension(extname text, version text)
```

## Role

pgtle\_admin

## Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to uninstall from the database.

## Output

None.

## Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

## pgtle.uninstall\_extension\_if\_exists

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call `DROP EXTENSION` to remove the TLE extension before using this function to uninstall its artifacts.

## Function prototype

```
pgtle.uninstall_extension_if_exists(extname text)
```

## Role

`pgtle_admin`

## Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.

## Output

The `uninstall_extension_if_exists` function returns `true` after uninstalling the specified extension. If the specified extension doesn't exist, the function returns `false`.

- `true` – Returns `true` after uninstalling the TLE extension.
- `false` – Returns `false` when the TLE extension doesn't exist in the database.

## Usage example

```
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

## pgtle.uninstall\_update\_path

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents `ALTER EXTENSION ... UPDATE TO` from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

### Function prototype

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

### Role

`pgtle_admin`

### Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

### Output

None.

### Usage example

```
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

## pgtle.uninstall\_update\_path\_if\_exists

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

### Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

## Role

pgtle\_admin

## Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

## Output

- `true` – The function has successfully updated the path for the TLE extension.
- `false` – The function wasn't able to update the path for the TLE extension.

## Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

## pgtle.unregister\_feature

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see [pgtle.register\\_feature](#).

## Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

## Role

pgtle\_admin

## Arguments

- `proc` – The name of a stored function to register with a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see [Password-check hook \(passcheck\)](#).

## Output

None.

## Usage example

```
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

## pgtle.unregister\_feature\_if\_exists

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see [Using PostgreSQL hooks with your TLE extensions](#). Returns `true` after successfully unregistering the feature. Returns `false` if the feature wasn't registered.

For information about registering `pg_tle` features for your TLE extensions, see [pgtle.register\\_feature](#).

## Function prototype

```
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
```

## Role

`pgtle_admin`

## Arguments

- `proc` – The name of the stored function that was registered to include a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature that was registered with the trusted language extension.

## Output

Returns `true` or `false`, as follows.

- `true` – The function has successfully unregistered the feature from extension.
- `false` – The function wasn't able to unregister the feature from the TLE extension.

## Usage example

```
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
```

## Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A *hook* is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a passcheck hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the passcheck hook available for your TLE extensions. To learn more about the available hooks including the client authentication hook, see [Trusted Language Extensions hooks](#).

### Password-check hook (passcheck)

The passcheck hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and psql metacommand.

- CREATE ROLE *username* . . . PASSWORD – For more information, see [CREATE ROLE](#) in the PostgreSQL documentation.
- ALTER ROLE *username* . . . PASSWORD – For more information, see [ALTER ROLE](#) in the PostgreSQL documentation.
- \password *username* – This interactive psql metacommand securely changes the password for the specified user by hashing the password before transparently using the ALTER ROLE . . . PASSWORD syntax. The metacommand is a secure wrapper for the ALTER ROLE . . . PASSWORD command, thus the hook applies to the behavior of the psql metacommand.

For an example, see [Password-check hook code listing](#).

### Contents

- [Function prototype](#)
- [Arguments](#)

- [Configuration](#)
- [Usage notes](#)

## Function prototype

```
passcheck_hook(username text, password text, password_type pgtle.password_types,  
valid_until timestamptz, valid_null boolean)
```

## Arguments

A passcheck hook function takes the following arguments.

- `username` – The name (as text) of the role (username) that's setting a password.
- `password` – The plaintext or hashed password. The password entered should match the type specified in `password_type`.
- `password_type` – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.
  - `PASSWORD_TYPE_PLAINTEXT` – A plaintext password.
  - `PASSWORD_TYPE_MD5` – A password that's been hashed using MD5 (message digest 5) algorithm.
  - `PASSWORD_TYPE_SCRAM_SHA_256` – A password that's been hashed using SCRAM-SHA-256 algorithm.
- `valid_until` – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a `timestamptz` value.
- `valid_null` – If this Boolean is set to `true`, the `valid_until` option is set to `NULL`.

## Configuration

The function `pgtle.enable_password_check` controls whether the passcheck hook is active. The passcheck hook has three possible settings.

- `off` – Turns off the passcheck password-check hook. This is the default value.
- `on` – Turns on the passcode password-check hook so that passwords are checked against the table.
- `require` – Requires a password check hook to be defined.

## Usage notes

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for the writer instance of your Aurora PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --region aws-region \  
  --db-parameter-group-name your-custom-parameter-group \  
  --parameters  
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --region aws-region ^  
  --db-parameter-group-name your-custom-parameter-group ^  
  --parameters  
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

# Amazon Aurora PostgreSQL reference

In the following topics, you can find information about collations, functions, parameters, and wait events in Amazon Aurora PostgreSQL.

## Topics

- [Aurora PostgreSQL collations for EBCDIC and other mainframe migrations](#)
- [Collations supported in Aurora PostgreSQL](#)
- [Aurora PostgreSQL functions reference](#)
- [Amazon Aurora PostgreSQL parameters](#)
- [Amazon Aurora PostgreSQL wait events](#)

## Aurora PostgreSQL collations for EBCDIC and other mainframe migrations

Migrating mainframe applications to new platforms such as Amazon ideally preserves application behavior. To preserve application behavior on a new platform exactly as it was on the mainframe requires that migrated data be collated using the same collation and sorting rules. For example, many Db2 migration solutions shift null values to u0180 (Unicode position 0180), so these collations sort u0180 first. This is one example of how collations can vary from their mainframe source and why it's necessary to choose a collation that better maps to the original EBCDIC collation.

Aurora PostgreSQL 14.3 and higher versions provide many ICU and EBCDIC collations to support such migration to Amazon using the Amazon Mainframe Modernization service. To learn more about this service, see [What is Amazon Mainframe Modernization?](#)

In the following table, you can find Aurora PostgreSQL–provided collations. These collations follow EBCDIC rules and ensure that mainframe applications function the same on Amazon as they did in the mainframe environment. The collation name includes the relevant code page, (*cpnnnn*), so that you can choose the appropriate collation for your mainframe source. For example, use `en-US-cp037-x-icu` for to achieve the collation behavior for EBCDIC data that originated from a mainframe application that used code page 037.

EBCDIC collations	Amazon Blu Age collations	Amazon Micro Focus collations

To learn more about Amazon Blu Age, see [Tutorial: Managed Runtime for Amazon Blu Age](#) in the *Amazon Mainframe Modernization User Guide*.

For more information about working with Amazon Micro Focus, see [Tutorial: Managed Runtime for Micro Focus](#) in the *Amazon Mainframe Modernization User Guide*.

For more information about managing collations in PostgreSQL, see [Collation Support](#) in the PostgreSQL documentation.

## Collations supported in Aurora PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, Aurora PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

When you create a new Aurora PostgreSQL DB cluster, it checks the operating system for the available collation. The PostgreSQL parameters of the `CREATE DATABASE` command `LC_COLLATE` and `LC_CTYPE` are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the `LOCALE` parameter in `CREATE DATABASE` to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

Aurora PostgreSQL depends on the glibc library in the operating system for collation support. Aurora PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, Aurora PostgreSQL now includes an independent default collation library. This collation library is available in Aurora PostgreSQL 14.6, 13.9, 12.13, 11.18 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

## Aurora PostgreSQL functions reference

Following, you can find a list of Aurora PostgreSQL functions that are available for your Aurora DB clusters that run the Aurora PostgreSQL-Compatible Edition DB engine. These Aurora PostgreSQL functions are in addition to the standard PostgreSQL functions. For more information about standard PostgreSQL functions, see [PostgreSQL–Functions and Operators](#).

### Overview

You can use the following functions for Amazon RDS DB instances running Aurora PostgreSQL:

- [aurora\\_db\\_instance\\_identifier](#)
- [aurora\\_ccm\\_status](#)
- [aurora\\_global\\_db\\_instance\\_status](#)
- [aurora\\_global\\_db\\_status](#)
- [aurora\\_list\\_builtins](#)
- [aurora\\_replica\\_status](#)
- [aurora\\_stat\\_activity](#)
- [aurora\\_stat\\_backend\\_waits](#)
- [aurora\\_stat\\_bgwriter](#)
- [aurora\\_stat\\_database](#)
- [aurora\\_stat\\_dml\\_activity](#)
- [aurora\\_stat\\_get\\_db\\_commit\\_latency](#)
- [aurora\\_stat\\_logical\\_wal\\_cache](#)
- [aurora\\_stat\\_memctx\\_usage](#)
- [aurora\\_stat\\_optimized\\_reads\\_cache](#)
- [aurora\\_stat\\_plans](#)
- [aurora\\_stat\\_reset\\_wal\\_cache](#)
- [aurora\\_stat\\_statements](#)
- [aurora\\_stat\\_system\\_waits](#)
- [aurora\\_stat\\_wait\\_event](#)
- [aurora\\_stat\\_wait\\_type](#)
- [aurora\\_version](#)

- [aurora\\_volume\\_logical\\_start\\_lsn](#)
- [aurora\\_wait\\_report](#)

## aurora\_db\_instance\_identifier

Reports the name of the DB instance name to which you're connected.

### Syntax

```
aurora_db_instance_identifier()
```

### Arguments

None

### Return type

VARCHAR string

### Usage notes

This function displays the name of Aurora PostgreSQL-Compatible Edition cluster's DB instance for your database client or application connection.

This function is available starting with the release of Aurora PostgreSQL versions 13.7, 12.11, 11.16, 10.21 and for all other later versions.

### Examples

The following example shows results of calling the `aurora_db_instance_identifier` function.

```
=> SELECT aurora_db_instance_identifier();
aurora_db_instance_identifier
-----
test-my-instance-name
```

You can join the results of this function with the `aurora_replica_status` function to obtain details about the DB instance for your connection. The [aurora\\_replica\\_status](#) alone doesn't provide show you which DB instance you're using. The following example shows you how.

```
=> SELECT *
```

```

FROM aurora_replica_status() rt,
     aurora_db_instance_identifier() di
WHERE rt.server_id = di;
-[ RECORD 1 ]-----+-----
server_id          | test-my-instance-name
session_id         | MASTER_SESSION_ID
durable_lsn        | 88492069
highest_lsn_rcvd   |
current_read_lsn   |
cur_replay_latency_in_usec |
active_txns        |
is_current         | t
last_transport_error | 0
last_error_timestamp |
last_update_timestamp | 2022-06-03 11:18:25+00
feedback_xmin      |
feedback_epoch     |
replica_lag_in_msec |
log_stream_speed_in_kib_per_second | 0
log_buffer_sequence_number | 0
oldest_read_view_trx_id |
oldest_read_view_lsn |
pending_read_ios   | 819

```

## aurora\_ccm\_status

Displays the status of cluster cache manager.

### Syntax

```
aurora_ccm_status()
```

### Arguments

None.

### Return type

SETOF record with the following columns:

- `buffers_sent_last_minute` – The number of buffers sent to the designated reader in the past minute.

- `buffers_found_last_minute` – The number of frequently accessed buffers identified during the past minute.
- `buffers_sent_last_scan` – The number of buffers sent to the designated reader during the last complete scan of the buffer cache.
- `buffers_found_last_scan` – The number of frequently accessed buffers sent during the last complete scan of the buffer cache. Buffers that are already cached on the designated reader aren't sent.
- `buffers_sent_current_scan` – The number of buffers sent during the current scan.
- `buffers_found_current_scan` – The number of frequently accessed buffers that were identified in the current scan.
- `current_scan_progress` – The number of buffers visited so far during the current scan.

### Usage notes

You can use this function to check and monitor the cluster cache management (CCM) feature. This function works only if CCM is active on your Aurora PostgreSQL DB cluster. To use this function you connect to the Write DB instance on your Aurora PostgreSQL DB cluster.

You turn on CCM for an Aurora PostgreSQL DB cluster by setting the `apg_ccm_enabled` to 1 in the cluster's custom DB cluster parameter group. To learn how, see [Configuring cluster cache management](#).

Cluster cache management is active on an Aurora PostgreSQL DB cluster when the cluster has an Aurora Reader instance configured as follows:

- The Aurora Reader instance uses same DB instance class type and size as the cluster's Writer instance.
- The Aurora Reader instance is configured as Tier-0 for the cluster. If the cluster has more than one Reader, this is its only Tier-0 Reader.

Setting more than one Reader to Tier-0 disables CCM. When CCM is disabled, calling this function returns the following error message:

```
ERROR: Cluster Cache Manager is disabled
```

You can also use the PostgreSQL `pg_buffercache` extension to analyze the buffer cache. For more information, see [pg\\_buffercache](#) in the PostgreSQL documentation.

For more information, see [Introduction to Aurora PostgreSQL cluster cache management](#).

## Examples

The following example shows the results of calling the `aurora_ccm_status` function. This first example shows CCM statistics.

```
=> SELECT * FROM aurora_ccm_status();
 buffers_sent_last_minute | buffers_found_last_minute | buffers_sent_last_scan |
 buffers_found_last_scan | buffers_sent_current_scan | buffers_found_current_scan |
 current_scan_progress
-----+-----+-----
                2242000 |                2242003 |                17920442 |
                17923410 |                14098000 |                14100964 |
                15877443
```

For more complete detail, you can use expanded display, as shown following:

```
\x
Expanded display is on.
SELECT * FROM aurora_ccm_status();
[ RECORD 1 ]-----+-----
 buffers_sent_last_minute      | 2242000
 buffers_found_last_minute    | 2242003
 buffers_sent_last_scan       | 17920442
 buffers_found_last_scan     | 17923410
 buffers_sent_current_scan    | 14098000
 buffers_found_current_scan   | 14100964
 current_scan_progress        | 15877443
```

This example shows how to check warm rate and warm percentage.

```
=> SELECT buffers_sent_last_minute * 8/60 AS warm_rate_kbps,
 100 * (1.0-buffers_sent_last_scan/buffers_found_last_scan) AS warm_percent
FROM aurora_ccm_status ();
 warm_rate_kbps | warm_percent
-----+-----
            16523 |           100.0
```

## aurora\_global\_db\_instance\_status

Displays the status of all Aurora instances, including replicas in an Aurora global DB cluster.

### Syntax

```
aurora_global_db_instance_status()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- `server_id` – The identifier of the DB instance.
- `session_id` – A unique identifier for the current session. A value of `MASTER_SESSION_ID` identifies the Writer (primary) DB instance.
- `aws_region` – The Amazon Web Services Region in which this global DB instance runs. For a list of Regions, see [Region availability](#).
- `durable_lsn` – The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- `highest_lsn_rcvd` – The highest LSN received by the DB instance from the writer DB instance.
- `feedback_epoch` – The epoch that the DB instance uses when it generates hot standby information. A *hot standby* is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that's being used as a hot standby. For more information, see [Hot Standby](#) in the PostgreSQL documentation.
- `feedback_xmin` – The minimum (oldest) active transaction ID used by the DB instance.
- `oldest_read_view_lsn` – The oldest LSN used by the DB instance to read from storage.
- `visibility_lag_in_msec` – How far this DB instance is lagging behind the writer DB instance in milliseconds.

## Usage notes

This function shows replication statistics for an Aurora DB cluster. For each Aurora PostgreSQL DB instance in the cluster, the function shows a row of data that includes any cross-Region replicas in a global database configuration.

You can run this function from any instance in an Aurora PostgreSQL DB cluster or an Aurora PostgreSQL global database. The function returns details about lag for all replica instances.

To learn more about monitoring lag using this function (`aurora_global_db_instance_status`) or by using `aurora_global_db_status`, see [Monitoring Aurora PostgreSQL-based global databases](#).

For more information about Aurora global databases, see [Overview of Amazon Aurora Global Database](#).

To get started with Aurora global databases, see [Getting started with Amazon Aurora Global Database](#) or see [Amazon Aurora FAQs](#).

## Examples

This example shows cross-Region instance stats.

```
=> SELECT *
FROM aurora_global_db_instance_status();
      server_id          |          session_id          |
aws_region | durable_lsn | highest_lsn_rcvd | feedback_epoch | feedback_xmin |
oldest_read_view_lsn | visibility_lag_in_msec
-----+-----
+-----+-----+-----+-----+-----+
db-119-001-instance-01 | MASTER_SESSION_ID          | eu-

This example shows how to check min, max and average lag per Amazon Web Services Region from the global database configuration.

```
=> SELECT 'Secondary' global_role,
        aws_region,
        min(visibility_lag_in_msec) min_lag_in_msec,
        max(visibility_lag_in_msec) max_lag_in_msec,
        round(avg(visibility_lag_in_msec),0) avg_lag_in_msec
FROM aurora_global_db_instance_status()
WHERE aws_region NOT IN (SELECT  aws_region
                        FROM aurora_global_db_instance_status()
                        WHERE session_id='MASTER_SESSION_ID')
        GROUP BY aws_region

UNION ALL
SELECT 'Primary' global_role,
        aws_region,
        NULL,
        NULL,
        NULL
FROM aurora_global_db_instance_status()
WHERE session_id='MASTER_SESSION_ID'
ORDER BY 1, 5;
```

global_role	aws_region	min_lag_in_msec	max_lag_in_msec	avg_lag_in_msec
Primary	eu-west-1	[NULL]	[NULL]	[NULL]
Secondary	eu-central-1	133	133	133
Secondary	eu-west-2	0	495	248

## aurora\_global\_db\_status

Displays information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO).

### Syntax

```
aurora_global_db_status()
```

## Arguments

None.

## Return type

SETOF record with the following columns:

- `aws_region` – The Amazon Web Services Region that this DB cluster is in. For a complete listing of Amazon Web Services Regions by engine, see [Regions and Availability Zones](#).
- `highest_lsn_written` – The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.
- `durability_lag_in_msec` – The difference in the timestamp values between the `highest_lsn_written` on a secondary DB cluster and the `highest_lsn_written` on the primary DB cluster. A value of -1 identifies the primary DB cluster of the Aurora global database.
- `rpo_lag_in_msec` – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. A value of -1 denotes the primary DB cluster (and thus, lag isn't relevant).

In simple terms, this metric calculates the recovery point objective for each Aurora PostgreSQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.

- `last_lag_calculation_time` – The timestamp that specifies when values were last calculated for `durability_lag_in_msec` and `rpo_lag_in_msec`. A time value such as `1970-01-01 00:00:00+00` means this is the primary DB cluster.
- `feedback_epoch` – The epoch that the secondary DB cluster uses when it generates hot standby information. A *hot standby* is a DB instance that supports connections and queries while the primary DB is in recovery or standby mode. The hot standby information includes the epoch (point in time) and other details about the DB instance that's being used as a hot standby. For more information, see [Hot Standby](#) in the PostgreSQL documentation.
- `feedback_xmin` – The minimum (oldest) active transaction ID used by a secondary DB cluster.

## Usage notes

All currently available Aurora PostgreSQL versions support this function. This function shows replication statistics for an Aurora global database. It shows one row for each DB cluster in an Aurora PostgreSQL global database. You can run this function from any instance in your Aurora PostgreSQL global database.

To evaluate Aurora global database replication lag, which is the visible data lag, see [aurora\\_global\\_db\\_instance\\_status](#).

To learn more about using `aurora_global_db_status` and `aurora_global_db_instance_status` to monitor Aurora global database lag, see [Monitoring Aurora PostgreSQL-based global databases](#). For more information about Aurora global databases, see [Overview of Amazon Aurora Global Database](#).

## Examples

This example shows how to display cross-region storage statistics.

```
=> SELECT CASE
      WHEN '-1' = durability_lag_in_msec THEN 'Primary'
      ELSE 'Secondary'
    END AS global_role,
    *
  FROM aurora_global_db_status();
global_role | aws_region | highest_lsn_written | durability_lag_in_msec |
rpo_lag_in_msec | last_lag_calculation_time | feedback_epoch | feedback_xmin
-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
Primary    | eu-west-1 | 131031557 | -1 |
-1 | 1970-01-01 00:00:00+00 | 0 | 0
Secondary  | eu-west-2 | 131031554 | 410 |
0 | 2021-06-01 18:59:36.124+00 | 0 | 12640
Secondary  | eu-west-3 | 131031554 | 410 |
0 | 2021-06-01 18:59:36.124+00 | 0 | 12640
```

## aurora\_list\_builtins

Lists all available Aurora PostgreSQL built-in functions, along with brief descriptions and function details.

## Syntax

```
aurora_list_builtins()
```

## Arguments

None

## Return type

SETOF record

## Examples

The following example shows results from calling the `aurora_list_builtins` function.

```
=> SELECT *
FROM aurora_list_builtins();
```

Name	Result data type	Argument data
types	Type   Volatility   Parallel   Security	Description

```

## aurora\_replica\_status

Displays the status of all Aurora PostgreSQL reader nodes.

### Syntax

```
aurora_replica_status()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- `server_id` – The DB instance ID (identifier).
- `session_id` – A unique identifier for the current session, returned for primary instance and reader instances as follows:
  - For the primary instance, `session_id` is always `'MASTER_SESSION_ID'`.
  - For reader instances, `session_id` is always the UUID (universally unique identifier) of the reader instance.
- `durable_lsn` – The log sequence number (LSN) that's been saved in storage.
  - For the primary volume, the primary volume durable LSN (VDL) that's currently in effect.
  - For any secondary volumes, the VDL of the primary up to which the secondary has successfully been applied.

**Note**

A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a transaction that's occurred later in the sequence.

- `highest_lsn_rcvd` – The highest (most recent) LSN received by the DB instance from the writer DB instance.
- `current_read_lsn` – The LSN of the most recent snapshot that's been applied to all readers.
- `cur_replay_latency_in_usec` – The number of microseconds that it's expected to take to replay the log on the secondary.
- `active_txns` – The number of currently active transactions.
- `is_current` – Not used.
- `last_transport_error` – Last replication error code.
- `last_error_timestamp` – Timestamp of last replication error.
- `last_update_timestamp` – Timestamp of last update to replica status. From Aurora PostgreSQL 13.9, the `last_update_timestamp` value for the DB instance that you are connected to is set to NULL.
- `feedback_xmin` – The hot standby `feedback_xmin` of the replica. The minimum (oldest) active transaction ID used by the DB instance.
- `feedback_epoch` – The epoch the DB instance uses when it generates hot standby information.
- `replica_lag_in_msec` – Time that reader instance lags behind writer instance, in milliseconds.
- `log_stream_speed_in_kib_per_second` – The log stream throughput in kilobytes per second.
- `log_buffer_sequence_number` – The log buffer sequence number.
- `oldest_read_view_trx_id` – Not used.
- `oldest_read_view_lsn` – The oldest LSN used by the DB instance to read from storage.
- `pending_read_ios` – The outstanding page reads that are still pending on replica.
- `read_ios` – The total number of page reads on replica.
- `iops` – Not used.
- `cpu` – CPU usage of the Aurora Storage Daemon for each node in the cluster. For information about CPU usage by the instance, see [Instance-level metrics for Amazon Aurora](#).

## Usage notes

All currently available Aurora PostgreSQL versions support this function. The `aurora_replica_status` function returns values from an Aurora PostgreSQL DB cluster's replica status manager. You can use this function to obtain information about the status of replication on your Aurora PostgreSQL DB cluster, including metrics for all DB instances in your Aurora DB cluster. For example, you can do the following:

- **Get information about the type of instance (writer, reader) in the Aurora PostgreSQL DB cluster** – You can obtain this information by checking the values of the following columns:
  - `server_id` – Contains the name of the instance that you specified when you created the instance. In some cases, such as for the primary (writer) instance, the name is typically created for you by appending `-instance-1` to the name that you create for your Aurora PostgreSQL DB cluster.
  - `session_id` – The `session_id` field indicates whether the instance is a reader or a writer. For a writer instance, `session_id` is always set to "MASTER\_SESSION\_ID". For a reader instance, `session_id` is set to the UUID of the specific reader.
- **Diagnose common replication issues, such as replica lag** – Replica lag is the time in milliseconds that the page cache of a reader instance is behind that of the writer instance. This lag occurs because Aurora clusters use asynchronous replication, as described in [Replication with Amazon Aurora](#). It's shown in the `replica_lag_in_msec` column in the results returned by this function. Lag can also occur when a query is cancelled due to conflicts with recovery on a standby server. You can check `pg_stat_database_conflicts()` to verify that such a conflict is causing the replica lag (or not). For more information, see [The Statistics Collector](#) in the *PostgreSQL documentation*. To learn more about high availability and replication, see [Amazon Aurora FAQs](#).

Amazon CloudWatch stores `replica_lag_in_msec` results over time, as the `AuroraReplicaLag` metric. For information about using CloudWatch metrics for Aurora, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#)

To learn more about troubleshooting Aurora read replicas and restarts, see [Why did my Amazon Aurora read replica fall behind and restart?](#) in the [Amazon Web Services Support Center](#).

## Examples

The following example shows how to get the replication status of all instances in an Aurora PostgreSQL DB cluster:

```
=> SELECT *
FROM aurora_replica_status();
```

The following example shows the writer instance in the docs-lab-apg-main Aurora PostgreSQL DB cluster:

```
=> SELECT server_id,
CASE
    WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
    ELSE 'reader'
END AS instance_role
FROM aurora_replica_status()
WHERE session_id = 'MASTER_SESSION_ID';
server_id      | instance_role
-----+-----
db-119-001-instance-01 | writer
```

The following example lists all reader instances in a cluster:

```
=> SELECT server_id,
CASE
    WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
    ELSE 'reader'
END AS instance_role
FROM aurora_replica_status()
WHERE session_id <> 'MASTER_SESSION_ID';
server_id      | instance_role
-----+-----
db-119-001-instance-02 | reader
db-119-001-instance-03 | reader
db-119-001-instance-04 | reader
db-119-001-instance-05 | reader
(4 rows)
```

The following example lists all instances, how far each instance is lagging behind the writer, and how long since the last update:

```
=> SELECT server_id,
       CASE
         WHEN 'MASTER_SESSION_ID' = session_id THEN 'writer'
         ELSE 'reader'
       END AS instance_role,
       replica_lag_in_msec AS replica_lag_ms,
       round(extract (epoch FROM (SELECT age(clock_timestamp(), last_update_timestamp))) *
       1000) AS last_update_age_ms
FROM aurora_replica_status()
ORDER BY replica_lag_in_msec NULLS FIRST;
```

server_id	instance_role	replica_lag_ms	last_update_age_ms
db-124-001-instance-03	writer	[NULL]	1756
db-124-001-instance-01	reader	13	1756
db-124-001-instance-02	reader	13	1756

(3 rows)

## aurora\_stat\_activity

Returns one row per server process, showing information related to the current activity of that process.

### Syntax

```
aurora_stat_activity();
```

### Arguments

None

### Return type

Returns one row per server process. In addition to `pg_stat_activity` columns, the following field is added:

- `planid` – plan identifier

### Usage notes

A supplementary view to `pg_stat_activity` returning the same columns with an additional `plan_id` column which shows the current query execution plan.

`aurora_compute_plan_id` must be enabled for the view to return a `plan_id`.

This function is available from Aurora PostgreSQL versions 14.10, 15.5, and for all other later versions.

## Examples

The example query below aggregates the top load by `query_id` and `plan_id`.

```
db1=# select count(*), query_id, plan_id
db1-# from aurora_stat_activity() where state = 'active'
db1-# and pid <> pg_backend_pid()
db1-# group by query_id, plan_id
db1-# order by 1 desc;
```

count	query_id	plan_id
11	-5471422286312252535	-2054628807
3	-6907107586630739258	-815866029
1	5213711845501580017	300482084

(3 rows)

If the plan used for `query_id` changes, a new `plan_id` will be reported by `aurora_stat_activity`.

count	query_id	plan_id
10	-5471422286312252535	1602979607
1	-6907107586630739258	-1809935983
1	-2446282393000597155	-207532066

(3 rows)

## `aurora_stat_backend_waits`

Displays statistics for wait activity for a specific backend process.

## Syntax

```
aurora_stat_backend_waits(pid)
```

## Arguments

`pid` – The ID for the backend process. You can obtain process IDs by using the `pg_stat_activity` view.

## Return type

SETOF record with the following columns:

- `type_id` – A number that denotes the type of wait event, such as 1 for a lightweight lock (LWLock), 3 for a lock, or 6 for a client session, to name some examples. These values become meaningful when you join the results of this function with columns from `aurora_stat_wait_type` function, as shown in the [Examples](#).
- `event_id` – An identifying number for the wait event. Join this value with the columns from `aurora_stat_wait_event` to obtain meaningful event names.
- `waits` – A count of the number of waits accumulated for the specified process ID.
- `wait_time` – Wait time in milliseconds.

## Usage notes

You can use this function to analyze specific backend (session) wait events that occurred since a connection opened. To get more meaningful information about wait event names and types, you can combine this function `aurora_stat_wait_type` and `aurora_stat_wait_event`, by using JOIN as shown in the examples.

## Examples

This example shows all waits, types, and event names for a backend process ID 3027.

```
=> SELECT type_name, event_name, waits, wait_time
       FROM aurora_stat_backend_waits(3027)
       NATURAL JOIN aurora_stat_wait_type()
       NATURAL JOIN aurora_stat_wait_event();
type_name |          event_name          | waits | wait_time
-----+-----+-----+-----
```

```

```

## aurora\_stat\_bgwriter

`aurora_stat_bgwriter` is a statistics view showing information about Optimized Reads cache writes.

### Syntax

```
aurora_stat_bgwriter()
```

### Arguments

None

### Return type

SETOF record with all `pg_stat_bgwriter` columns and the following additional columns. For more information on `pg_stat_bgwriter` columns, see [pg\\_stat\\_bgwriter](#).

You can reset stats for this function using `pg_stat_reset_shared("bgwriter")`.

- `orcache_blks_written` – Total number of optimized reads cache data blocks written.
- `orcache_blk_write_time` – If `track_io_timing` is enabled, it tracks the total time spent writing optimized reads cache data file blocks, in milliseconds. For more information, see [track\\_io\\_timing](#).

## Usage notes

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

## Examples

```
=> select * from aurora_stat_bgwriter();
-[ RECORD 1 ]-----+-----
 orcache_blks_written          | 246522
 orcache_blk_write_time       | 339276.404
```

## aurora\_stat\_database

It carries all columns of `pg_stat_database` and adds new columns in the end.

## Syntax

```
aurora_stat_database()
```

## Arguments

None

## Return type

SETOF record with all `pg_stat_database` columns and the following additional columns. For more information on `pg_stat_database` columns, see [pg\\_stat\\_database](#).

- `storage_blks_read` – Total number of shared blocks read from aurora storage in this database.
- `ocache_blks_hit` – Total number of optimized reads cache hits in this database.
- `local_blks_read` – Total number of local blocks read in this database.
- `storage_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time spent reading data file blocks from aurora storage, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).

- `local_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time spent reading local data file blocks, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).
- `orcache_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time spent reading data file blocks from optimized reads cache, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).

### Note

The value of `blks_read` is the sum of `storage_blks_read`, `orcache_blks_hit`, and `local_blks_read`.

The value of `blk_read_time` is the sum of `storage_blk_read_time`, `orcache_blk_read_time`, and `local_blk_read_time`.

## Usage notes

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

## Examples

The following example shows how it carries all the `pg_stat_database` columns and appends 6 new columns in the end:

```
=> select * from aurora_stat_database() where datid=14717;
-[ RECORD 1 ]-----+-----
datid          | 14717
datname        | postgres
numbackends    | 1
xact_commit    | 223
xact_rollback  | 4
blks_read      | 1059
blks_hit       | 11456
tup_returned   | 27746
tup_fetched    | 5220
```

```

tup_inserted          | 165
tup_updated           | 42
tup_deleted           | 91
conflicts              | 0
temp_files            | 0
temp_bytes            | 0
deadlocks              | 0
checksum_failures     |
checksum_last_failure |
blk_read_time         | 3358.689
blk_write_time        | 0
session_time          | 1076007.997
active_time           | 3684.371
idle_in_transaction_time | 0
sessions              | 10
sessions_abandoned   | 0
sessions_fatal        | 0
sessions_killed       | 0
stats_reset           | 2023-01-12 20:15:17.370601+00
orcache_blks_hit      | 425
orcache_blk_read_time | 89.934
storage_blks_read     | 623
storage_blk_read_time | 3254.914
local_blks_read       | 0
local_blk_read_time   | 0

```

## aurora\_stat\_dml\_activity

Reports cumulative activity for each type of data manipulation language (DML) operation on a database in an Aurora PostgreSQL cluster.

### Syntax

```
aurora_stat_dml_activity(database_oid)
```

### Arguments

*database\_oid*

The object ID (OID) of the database in the Aurora PostgreSQL cluster.

## Return type

SETOF record

## Usage notes

The `aurora_stat_dml_activity` function is only available with Aurora PostgreSQL release 3.1 compatible with PostgreSQL engine 11.6 and later.

Use this function on Aurora PostgreSQL clusters with a large number of databases to identify which databases have more or slower DML activity, or both.

The `aurora_stat_dml_activity` function returns the number of times the operations ran and the cumulative latency in microseconds for SELECT, INSERT, UPDATE, and DELETE operations. The report includes only successful DML operations.

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see [The Statistics Collector](#) in the PostgreSQL documentation.

## Examples

The following example shows how to report DML activity statistics for the connected database.

```
--Define the oid variable from connected database by using \gset
=> SELECT oid,
        datname
        FROM pg_database
        WHERE datname=(select current_database()) \gset
=> SELECT *
        FROM aurora_stat_dml_activity(:oid);
select_count | select_latency_microsecs | insert_count | insert_latency_microsecs |
update_count | update_latency_microsecs | delete_count | delete_latency_microsecs
-----+-----+-----+-----+
+-----+-----+-----+-----+
          178957 |          66684115 |          171065 |          28876649 |
          519538 |          1454579206167 |              1 |              53027 |

-- Showing the same results with expanded display on
=> SELECT *
```

```

FROM aurora_stat_dml_activity(:oid);
-[ RECORD 1 ]-----+-----
select_count          | 178957
select_latency_microsecs | 66684115
insert_count          | 171065
insert_latency_microsecs | 28876649
update_count          | 519538
update_latency_microsecs | 1454579206167
delete_count          | 1
delete_latency_microsecs | 53027

```

The following example shows DML activity statistics for all databases in the Aurora PostgreSQL cluster. This cluster has two databases, postgres and mydb. The comma-separated list corresponds with the `select_count`, `select_latency_microsecs`, `insert_count`, `insert_latency_microsecs`, `update_count`, `update_latency_microsecs`, `delete_count`, and `delete_latency_microsecs` fields.

Aurora PostgreSQL creates and uses a system database named `rdsadmin` to support administrative operations such as backups, restores, health checks, replication, and so on. These DML operations have no impact on your Aurora PostgreSQL cluster.

```

=> SELECT oid,
    datname,
    aurora_stat_dml_activity(oid)
FROM pg_database;
oid | datname | aurora_stat_dml_activity
-----+-----
+-----+-----
14006 | template0 | (,,,,,,)
16384 | rdsadmin | (2346623,1211703821,4297518,817184554,0,0,0,0)
1 | template1 | (,,,,,,)
14007 | postgres |
(178961,66716329,171065,28876649,519538,1454579206167,1,53027)
16401 | mydb | (200246,64302436,200036,107101855,600000,83659417514,0,0)

```

The following example shows DML activity statistics for all databases, organized in columns for better readability.

```

SELECT db.datname,
    BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 1), '()') AS select_count,
    BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 2), '()') AS select_latency_microsecs,

```

```

BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 3), '()') AS insert_count,
BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 4), '()') AS insert_latency_microsecs,
BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 5), '()') AS update_count,
BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 6), '()') AS update_latency_microsecs,
BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 7), '()') AS delete_count,
BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 8), '()') AS delete_latency_microsecs
FROM (SELECT datname,
          aurora_stat_dml_activity(oid) AS asdmla
      FROM pg_database
      ) AS db;

```

datname	select_count	select_latency_microsecs	insert_count	insert_latency_microsecs	update_count	update_latency_microsecs	delete_count	delete_latency_microsecs
template0								
rdsadmin	4206523	2478812333	7009414	1338482258				
template1	0	0	0	0				
fault_test	66	452099	0	0				
db_access_test	1	5982	0	0				
postgres	42035	95179203	5752	2678832898				
mydb	21157	441883182488	2	1520				
	71	453514	0	0				
	1	190	1	152				

The following example shows the average cumulative latency (cumulative latency divided by count) for each DML operation for the database with the OID 16401.

```

=> SELECT select_count,
          select_latency_microsecs,
          select_latency_microsecs/NULLIF(select_count,0) select_latency_per_exec,
          insert_count,
          insert_latency_microsecs,
          insert_latency_microsecs/NULLIF(insert_count,0) insert_latency_per_exec,
          update_count,
          update_latency_microsecs,

```

```

        update_latency_microsecs/NULLIF(update_count,0) update_latency_per_exec,
        delete_count,
        delete_latency_microsecs,
        delete_latency_microsecs/NULLIF(delete_count,0) delete_latency_per_exec
    FROM aurora_stat_dml_activity(16401);
-[ RECORD 1 ]-----+-----
select_count          | 451312
select_latency_microsecs | 80205857
select_latency_per_exec | 177
insert_count         | 451001
insert_latency_microsecs | 123667646
insert_latency_per_exec | 274
update_count         | 1353067
update_latency_microsecs | 200900695615
update_latency_per_exec | 148478
delete_count         | 12
delete_latency_microsecs | 448
delete_latency_per_exec | 37

```

## aurora\_stat\_get\_db\_commit\_latency

Gets the cumulative commit latency in microseconds for Aurora PostgreSQL databases. *Commit latency* is measured as the time between when a client submits a commit request and when it receives the commit acknowledgement.

### Syntax

```
aurora_stat_get_db_commit_latency(database_oid)
```

### Arguments

*database\_oid*

The object ID (OID) of the Aurora PostgreSQL database.

### Return type

SETOF record

## Usage notes

Amazon CloudWatch uses this function to calculate the average commit latency. For more information about Amazon CloudWatch metrics and how to troubleshoot high commit latency, see [Viewing metrics in the Amazon RDS console](#) and [Making better decisions about Amazon RDS with Amazon CloudWatch metrics](#).

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see [The Statistics Collector](#) in the PostgreSQL documentation.

## Examples

The following example gets the cumulative commit latency for each database in the `pg_database` cluster.

```
=> SELECT oid,
       datname,
       aurora_stat_get_db_commit_latency(oid)
FROM pg_database;
```

oid	datname	aurora_stat_get_db_commit_latency
14006	template0	0
16384	rdsadmin	654387789
1	template1	0
16401	mydb	229556
69768	postgres	22011

The following example gets the cumulative commit latency for the currently connected database. Before calling the `aurora_stat_get_db_commit_latency` function, the example first uses `\gset` to define a variable for the `oid` argument and sets its value from the connected database.

```
--Get the oid value from the connected database before calling
aurora_stat_get_db_commit_latency
=> SELECT oid
      FROM pg_database
      WHERE datname=(SELECT current_database()) \gset
=> SELECT *
      FROM aurora_stat_get_db_commit_latency(:oid);
```

```
aurora_stat_get_db_commit_latency
```

```
-----  
1424279160
```

The following example gets the cumulative commit latency for the mydb database in the pg\_database cluster. Then, it resets this statistic by using the pg\_stat\_reset function and shows the results. Finally, it uses the pg\_stat\_get\_db\_stat\_reset\_time function to check the last time this statistic was reset.

```
=> SELECT oid,  
       datname,  
       aurora_stat_get_db_commit_latency(oid)  
FROM pg_database  
WHERE datname = 'mydb';
```

oid	datname	aurora_stat_get_db_commit_latency
16427	mydb	3320370

```
=> SELECT pg_stat_reset();  
pg_stat_reset  
-----
```

```
=> SELECT oid,  
       datname,  
       aurora_stat_get_db_commit_latency(oid)  
FROM pg_database  
WHERE datname = 'mydb';
```

oid	datname	aurora_stat_get_db_commit_latency
16427	mydb	6

```
=> SELECT *  
FROM pg_stat_get_db_stat_reset_time(16427);
```

pg_stat_get_db_stat_reset_time
2021-04-29 21:36:15.707399+00

## aurora\_stat\_logical\_wal\_cache

Shows logical write-ahead log (WAL) cache usage per slot.

### Syntax

```
SELECT * FROM aurora_stat_logical_wal_cache()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- name – The name of the replication slot.
- active\_pid – ID of the walsender process.
- cache\_hit – The total number of wal cache hits since last reset.
- cache\_miss – The total number of wal cache misses since last reset.
- blks\_read – The total number of wal cache read requests.
- hit\_rate – The WAL cache hit rate (cache\_hit / blks\_read).
- last\_reset\_timestamp – Last time that the counter was reset.

### Usage notes

This function is available for the following Aurora PostgreSQL versions.

- 15.2 and all higher versions
- 14.7 and higher versions
- 13.8 and higher versions
- 12.12 and higher versions
- 11.17 and higher versions

## Examples

The following example shows two replication slots with only one active.  
[aurora\\_stat\\_logical\\_wal\\_cache](#) function.

```
=> SELECT *
      FROM aurora_stat_logical_wal_cache();
 name      | active_pid | cache_hit | cache_miss | blks_read | hit_rate |
 last_reset_timestamp
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
 test_slot1 |      79183 |         24 |          0 |         24 | 100.00% | 2022-08-05
 17:39:56.830635+00
 test_slot2 |           |          1 |          0 |          1 | 100.00% | 2022-08-05
 17:34:04.036795+00
(2 rows)
```

## aurora\_stat\_memctx\_usage

Reports the memory context usage for each PostgreSQL process.

### Syntax

```
aurora_stat_memctx_usage()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- `pid` – The ID of the process.
- `name` – The name of the memory context.
- `allocated` – The number of bytes obtained from the underlying memory subsystem by the memory context.
- `used` – The number of bytes committed to clients of the memory context.
- `instances` – The count of currently existing contexts of this type.

## Usage notes

This function displays the memory context usage for each PostgreSQL process. Some processes are labeled anonymous. The processes aren't exposed because they contain restricted keywords.

This function is available starting with the following Aurora PostgreSQL versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
- 12.15 and higher 12 versions
- 11.20 and higher 11 versions

## Examples

The following example shows the results of calling the `aurora_stat_memctx_usage` function.

```
=> SELECT *
      FROM aurora_stat_memctx_usage();
```

pid	name	allocated	used	instances
123864	Miscellaneous	19520	15064	3
123864	Aurora File Context	8192	616	1
123864	Aurora WAL Context	8192	296	1
123864	CacheMemoryContext	524288	422600	1
123864	Catalog tuple context	16384	13736	1
123864	ExecutorState	32832	28304	1
123864	ExprContext	8192	1720	1
123864	GWAL record construction	1024	832	1
123864	MdSmgr	8192	296	1
123864	MessageContext	532480	353832	1
123864	PortalHeapMemory	1024	488	1
123864	PortalMemory	8192	576	1
123864	printtup	8192	296	1
123864	RelCache hash table entries	8192	8152	1
123864	RowDescriptionContext	8192	1344	1
123864	smgr relation context	8192	296	1
123864	Table function arguments	8192	352	1
123864	TopTransactionContext	8192	632	1
123864	TransactionAbortContext	32768	296	1

```

123864 | WAL record construction | 50216 | 43904 | 1
123864 | hash table | 65536 | 52744 | 6
123864 | Relation metadata | 191488 | 124240 | 87
104992 | Miscellaneous | 9280 | 7728 | 3
104992 | Aurora File Context | 8192 | 376 | 1
104992 | Aurora WAL Context | 8192 | 296 | 1
104992 | Autovacuum Launcher | 8192 | 296 | 1
104992 | Autovacuum database list | 16384 | 744 | 2
104992 | CacheMemoryContext | 262144 | 140288 | 1
104992 | Catalog tuple context | 8192 | 296 | 1
104992 | GWAL record construction | 1024 | 832 | 1
104992 | MdSmgr | 8192 | 296 | 1
104992 | PortalMemory | 8192 | 296 | 1
104992 | RelCache hash table entries | 8192 | 296 | 1
104992 | smgr relation context | 8192 | 296 | 1
104992 | Autovacuum start worker (tmp) | 8192 | 296 | 1
104992 | TopTransactionContext | 16384 | 592 | 2
104992 | TransactionAbortContext | 32768 | 296 | 1
104992 | WAL record construction | 50216 | 43904 | 1
104992 | hash table | 49152 | 34024 | 4
(39 rows)

```

Some restricted keywords will be hidden and the output will look as follows:

```

postgres=>SELECT *
FROM aurora_stat_memctx_usage();

 pid| name | allocated | used | instances
-----+-----+-----+-----+-----
 5482 | anonymous | 8192 | 456 | 1
 5482 | anonymous | 8192 | 296 | 1

```

## aurora\_stat\_optimized\_reads\_cache

This function shows tiered cache stats.

### Syntax

```
aurora_stat_optimized_reads_cache()
```

## Arguments

None

## Return type

SETOF record with the following columns:

- `total_size` – Total optimized reads cache size.
- `used_size` – Used page size in optimized reads cache.

## Usage notes

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions

## Examples

The following example shows the output on a r6gd.8xlarge instance :

```
=> select pg_size_pretty(total_size) as total_size, pg_size_pretty(used_size)
       as used_size from aurora_stat_optimized_reads_cache();
total_size | used_size
-----+-----
1054 GB   | 975 GB
```

## aurora\_stat\_plans

Returns a row for every tracked execution plan.

## Syntax

```
aurora_stat_plans(
  showtext
)
```

## Arguments

- `showtext` – Show the query and plan text. Valid values are `NULL`, `true` or `false`. `True` will show the query and plan text.

## Return type

Returns a row for each tracked plan that contains all the columns from `aurora_stat_statements` and the following additional columns.

- `planid` – plan identifier
- `explain_plan` – explain plan text
- `plan_type`:
  - `no plan` - no plan was captured
  - `estimate` - plan captured with estimated costs
  - `actual` - plan captured with `EXPLAIN ANALYZE`
- `plan_captured_time` – last time a plan was captured

## Usage notes

`aurora_compute_plan_id` must be enabled and `pg_stat_statements` must be in `shared_preload_libraries` for the plans to be tracked.

The number of plans available is controlled by the value set in the `pg_stat_statements.max` parameter. When `aurora_compute_plan_id` is enabled, you can track the plans up to this specified value in `aurora_stat_plans`.

This function is available from Aurora PostgreSQL versions 14.10, 15.5, and for all other later versions.

## Examples

In the example below, the two plans that are for the query identifier `-5471422286312252535` are captured and the statements statistics are tracked by the `planid`.

```
db1=# select calls, total_exec_time, planid, plan_captured_time, explain_plan
db1-# from aurora_stat_plans(true)
```

```
db1-# where queryid = '-5471422286312252535'
```

```
calls      | total_exec_time | planid    | plan_captured_time |
          explain_plan
-----+-----+-----+-----+
1532632 | 3209846.097107853 | 1602979607 | 2023-10-31 03:27:16.925497+00 | Update on

| | | | |
Index Cond: (bid = 17)
```

## aurora\_stat\_reset\_wal\_cache

Resets the counter for logical wal cache.

### Syntax

To reset a specific slot

```
SELECT * FROM aurora_stat_reset_wal_cache('slot_name')
```

To reset all slots

```
SELECT * FROM aurora_stat_reset_wal_cache(NULL)
```

### Arguments

NULL or slot\_name

## Return type

Status message, text string

- Reset the logical wal cache counter – Success message. This text is returned when the function succeeds.
- Replication slot not found. Please try again. – Failure message. This text is returned when the function doesn't succeed.

## Usage notes

This function is available for the following versions.

- Aurora PostgreSQL 14.5 and higher
- Aurora PostgreSQL version 13.8 and higher
- Aurora PostgreSQL version 12.12 and higher
- Aurora PostgreSQL version 11.17 and higher

## Examples

The following example uses the `aurora_stat_reset_wal_cache` function to reset a slot named `test_results`, and then tries to reset a slot that doesn't exist.

```
=> SELECT *
      FROM aurora_stat_reset_wal_cache('test_slot');
aurora_stat_reset_wal_cache
-----
Reset the logical wal cache counter.
(1 row)
=> SELECT *
      FROM aurora_stat_reset_wal_cache('slot-not-exist');
aurora_stat_reset_wal_cache
-----
Replication slot not found. Please try again.
(1 row)
```

## aurora\_stat\_resource\_usage

Reports the real-time resource utilization which consists of backend resource metrics and cpu usage for all Aurora PostgreSQL backend processes.

### Syntax

```
aurora_stat_resource_usage()
```

### Arguments

None

### Return type

SETOF record with columns:

- pid - Process identifier
- allocated\_memory - Total memory allocated by process in bytes
- used\_memory - Actually used memory by process in bytes
- cpu\_usage\_percent - CPU usage percentage of the process

### Usage notes

This function displays the backend resource usage for each Aurora PostgreSQL backend process.

This function is available starting with the following Aurora PostgreSQL versions:

- Aurora PostgreSQL 17.5 and higher 17 versions
- Aurora PostgreSQL 16.9 and higher 16 versions
- Aurora PostgreSQL 15.13 and higher 15 versions
- Aurora PostgreSQL 14.18 and higher 14 versions
- Aurora PostgreSQL 13.21 and higher 13 versions

### Examples

The following example shows the output of the `aurora_stat_resource_usage` function.

```
=> select * from aurora_stat_resource_usage();
 pid | allocated_memory | used_memory |  cpu_usage_percent
-----+-----+-----+-----
 666 |      1074032 |      333544 | 0.00729274882897963
 667 |       787312 |      287360 | 0.0029263928146372746
 668 |      3076776 |     1563488 | 0.006013116835953961
 684 |       803744 |      307480 | 0.002226855426881142
2401 |      1232992 |      943144 |
 647 |         8000 |         944 | 0.48853387812429855
 659 |      319344 |     243000 | 0.0004135602076683591
 663 |      262000 |     185736 | 0.008181301476644002
 664 |         9024 |         1216 | 0.10992313082653653
(9 rows)
```

## aurora\_stat\_statements

Displays all `pg_stat_statements` columns and adds more columns in the end.

### Syntax

```
aurora_stat_statements(showtext boolean)
```

### Arguments

*showtext boolean*

### Return type

SETOF record with all `pg_stat_statements` columns and the following additional columns. For more information on `pg_stat_statements` columns, see [pg\\_stat\\_statements](#).

You can reset stats for this function using `pg_stat_statements_reset()`.

- `storage_blks_read` – Total number of shared blocks read from aurora storage by this statement.
- `orcache_blks_hit` – Total number of optimized reads cache hits by this statement.
- `storage_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time the statement spent reading shared blocks from aurora storage, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).

- `local_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time the statement spent reading local blocks, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).
- `orcache_blk_read_time` – If `track_io_timing` is enabled, it tracks the total time the statement spent reading shared blocks from optimized reads cache, in milliseconds, otherwise the value is zero. For more information, see [track\\_io\\_timing](#).
- `total_plan_peakmem` – Total sum of peak memory values during planning phase for all calls to this statement. To see the average peak memory during planning for the statement, divide this value by the number of calls.
- `min_plan_peakmem` – Smallest peak memory value seen during planning across all calls to this statement.
- `max_plan_peakmem` – Largest peak memory value during planning seen across all calls to this statement.
- `total_exec_peakmem` – Total sum of peak memory values during execution phase for all calls to this statement. To see the average peak memory during execution for the statement, divide this value by the number of calls.
- `min_exec_peakmem` – Smallest peak memory value, in bytes, seen during execution across all calls to this statement.
- `max_exec_peakmem` – Largest peak memory value, in bytes, seen during execution across all calls to this statement.

**Note**

`total_plan_peakmem`, `min_plan_peakmem`, and `max_plan_peakmem` are only monitored when the setting `pg_stat_statements.track_planning` is turned on.

**Usage notes**

To use the `aurora_stat_statements()` function, you must include `pg_stat_statements` extension in the `shared_preload_libraries` parameter.

This function is available in the following Aurora PostgreSQL versions:

- 15.4 and higher 15 versions

```

```

## aurora\_stat\_system\_waits

Reports wait event information for the Aurora PostgreSQL DB instance.

### Syntax

```
aurora_stat_system_waits()
```

### Arguments

None

## Return type

SETOF record

## Usage notes

This function returns the cumulative number of waits and cumulative wait time for each wait event generated by the DB instance that you're currently connected to.

The returned recordset includes the following fields:

- `type_id` – The ID of the type of wait event.
- `event_id` – The ID of the wait event.
- `waits` – The number of times the wait event occurred.
- `wait_time` – The total amount of time in microseconds spent waiting for this event.

Statistics returned by this function are reset when a DB instance restarts.

## Examples

The following example shows results from calling the `aurora_stat_system_waits` function.

```
=> SELECT *
      FROM aurora_stat_system_waits();
type_id | event_id |   waits   |  wait_time
-----+-----+-----+-----
      1 | 16777219 |         11 |      12864
      1 | 16777220 |        501 |     174473
      1 | 16777270 |     53171 |    23641847
      1 | 16777271 |         23 |     319668
      1 | 16777274 |         60 |     12759
      .
      .
      .
     10 | 167772231 |    204596 |   790945212
     10 | 167772232 |          2 |      47729
     10 | 167772234 |          1 |       888
     10 | 167772235 |          2 |        64
```

The following example shows how you can use this function together with `aurora_stat_wait_event` and `aurora_stat_wait_type` to produce more readable results.

```
=> SELECT type_name,
        event_name,
        waits,
        wait_time
        FROM aurora_stat_system_waits()
NATURAL JOIN aurora_stat_wait_event()
NATURAL JOIN aurora_stat_wait_type();
```

type_name	event_name	waits	wait_time
LWLock	XidGenLock	11	12864
LWLock	ProcArrayLock	501	174473
LWLock	buffer_content	53171	23641847

## aurora\_stat\_wait\_event

Lists all supported wait events for Aurora PostgreSQL. For information about Aurora PostgreSQL wait events, see [Amazon Aurora PostgreSQL wait events](#).

### Syntax

```
aurora_stat_wait_event()
```

### Arguments

None

## Return type

SETOF record with the following columns:

- `type_id` – The ID of the type of wait event.
- `event_id` – The ID of the wait event.
- `type_name` – Wait type name
- `event_name` – Wait event name

## Usage notes

To see event names with event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_type` and `aurora_stat_system_waits`. Wait event names returned by this function are the same as those returned by the `aurora_wait_report` function.

## Examples

The following example shows results from calling the `aurora_stat_wait_event` function.

```
=> SELECT *
      FROM aurora_stat_wait_event();
```

type_id	event_id	event_name
1	16777216	<unassigned:0>
1	16777217	ShmemIndexLock
1	16777218	OidGenLock
1	16777219	XidGenLock
.		
.		
.		
9	150994945	PgSleep
9	150994946	RecoveryApplyDelay
10	167772160	BufFileRead
10	167772161	BufFileWrite
10	167772162	ControlFileRead
.		
.		
.		
10	167772226	WALInitWrite
10	167772227	WALRead

```

10 | 167772228 | WALSync
10 | 167772229 | WALSyncMethodAssign
10 | 167772230 | WALWrite
10 | 167772231 | XactSync
.
.
.
11 | 184549377 | LsnAllocate

```

The following example joins `aurora_stat_wait_type` and `aurora_stat_wait_event` to return type names and event names for improved readability.

```

=> SELECT *
    FROM aurora_stat_wait_type() t
   JOIN aurora_stat_wait_event() e
     ON t.type_id = e.type_id;

```

type_id	type_name	type_id	event_id	event_name
1	LWLock	1	16777216	<unassigned:0>
1	LWLock	1	16777217	ShmemIndexLock
1	LWLock	1	16777218	OidGenLock
1	LWLock	1	16777219	XidGenLock

## aurora\_stat\_wait\_type

Lists all supported wait types for Aurora PostgreSQL.

### Syntax

```
aurora_stat_wait_type()
```

### Arguments

None

### Return type

SETOF record with the following columns:

- `type_id` – The ID of the type of wait event.
- `type_name` – Wait type name.

### Usage notes

To see wait event names with wait event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_event` and `aurora_stat_system_waits`. Wait type names returned by this function are the same as those returned by the `aurora_wait_report` function.

### Examples

The following example shows results from calling the `aurora_stat_wait_type` function.

```
=> SELECT *
      FROM aurora_stat_wait_type();
 type_id | type_name
-----+-----
       1 | LWLock
       3 | Lock
       4 | BufferPin
       5 | Activity
       6 | Client
       7 | Extension
       8 | IPC
```

```
9 | Timeout
10 | IO
11 | LSN
```

## aurora\_version

Returns the string value of the Amazon Aurora PostgreSQL-Compatible Edition version number.

### Syntax

```
aurora_version()
```

### Arguments

None

### Return type

CHAR or VARCHAR string

### Usage notes

This function displays the version of the Amazon Aurora PostgreSQL-Compatible Edition database engine. The version number is returned as a string formatted as *major.minor.patch*. For more information about Aurora PostgreSQL version numbers, see [Aurora version number](#).

You can choose when to apply minor version upgrades by setting the maintenance window for your Aurora PostgreSQL DB cluster. To learn how, see [Maintaining an Amazon Aurora DB cluster](#).

Starting with the release of Aurora PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers follow PostgreSQL version numbers. For more information about all Aurora PostgreSQL releases, see [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

### Examples

The following example shows the results of calling the `aurora_version` function on an Aurora PostgreSQL DB cluster running [PostgreSQL 12.7, Aurora PostgreSQL release 4.2](#) and then running the same function on a cluster running [Aurora PostgreSQL version 13.3](#).

```
=> SELECT * FROM aurora_version();
```

```

aurora_version
-----
4.2.2
SELECT * FROM aurora_version();
aurora_version
-----
13.3.0

```

This example shows how to use the function with various options to get more detail about the Aurora PostgreSQL version. This example has an Aurora version number that's distinct from the PostgreSQL version number.

```

=> SHOW SERVER_VERSION;
server_version
-----
12.7
(1 row)

=> SELECT * FROM aurora_version();
aurora_version
-----
4.2.2
(1 row)

=> SELECT current_setting('server_version') AS "PostgreSQL Compatiblility";
PostgreSQL Compatiblility
-----
12.7
(1 row)

=> SELECT version() AS "PostgreSQL Compatiblility Full String";
PostgreSQL Compatiblility Full String
-----
PostgreSQL 12.7 on aarch64-unknown-linux-gnu, compiled by aarch64-unknown-linux-gnu-
gcc (GCC) 7.4.0, 64-bit
(1 row)

=> SELECT 'Aurora: '
|| aurora_version()
|| ' Compatible with PostgreSQL: '
|| current_setting('server_version') AS "Instance Version";
Instance Version

```

```
-----
Aurora: 4.2.2 Compatible with PostgreSQL: 12.7
(1 row)
```

This next example uses the function with the same options in the previous example. This example doesn't have an Aurora version number that's distinct from the PostgreSQL version number.

```
=> SHOW SERVER_VERSION;
server_version
-----
13.3

=> SELECT * FROM aurora_version();
aurora_version
-----
13.3.0

=> SELECT current_setting('server_version') AS "PostgreSQL Compatibility";
PostgreSQL Compatibility
-----
13.3

=> SELECT version() AS "PostgreSQL Compatibility Full String";
PostgreSQL Compatibility Full String
-----
PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC)
7.4.0, 64-bit

=> SELECT 'Aurora: '
        || aurora_version()
        || ' Compatible with PostgreSQL: '
        || current_setting('server_version') AS "Instance Version";
Instance Version
-----
Aurora: 13.3.0 Compatible with PostgreSQL: 13.3
```

## aurora\_volume\_logical\_start\_lsn

Returns the log sequence number (LSN) used for identifying the beginning of a record in the logical write-ahead log (WAL) stream of the Aurora cluster volume.

### Syntax

```
aurora_volume_logical_start_lsn()
```

## Arguments

None

## Return type

pg\_lsn

## Usage notes

This function identifies the beginning of the record in the logical WAL stream for a given Aurora cluster volume. You can use this function while performing major version upgrade using logical replication and Aurora fast cloning to determine the LSN at which a snapshot or database clone is taken. You can then use logical replication to continuously stream the newer data recorded after the LSN and synchronize the changes from publisher to subscriber.

For more information on using logical replication for a major version upgrade, see [Using logical replication to perform a major version upgrade for Aurora PostgreSQL](#).

This function is available on the following versions of Aurora PostgreSQL:

- 15.2 and higher 15 versions
- 14.3 and higher 14 versions
- 13.6 and higher 13 versions
- 12.10 and higher 12 versions
- 11.15 and higher 11 versions
- 10.20 and higher 10 versions

## Examples

You can obtain the log sequence number (LSN) using the following query:

```
postgres=> SELECT aurora_volume_logical_start_lsn();

aurora_volume_logical_start_lsn
-----
0/402E2F0
```

```
(1 row)
```

## aurora\_wait\_report

This function shows wait event activity over a period of time.

### Syntax

```
aurora_wait_report([time])
```

### Arguments

*time* (optional)

The time in seconds. Default is 10 seconds.

### Return type

SETOF record with the following columns:

- `type_name` – Wait type name
- `event_name` – Wait event name
- `wait` – Number of waits
- `wait_time` – Wait time in milliseconds
- `ms_per_wait` – Average milliseconds by the number of an wait
- `waits_per_xact` – Average waits by the number of one transaction
- `ms_per_xact` – Average milliseconds by the number of transactions

### Usage notes

This function is available as of Aurora PostgreSQL release 1.1 compatible with PostgreSQL 9.6.6 and higher versions.

To use this function, you need to first create the Aurora PostgreSQL `aurora_stat_utils` extension, as follows:

```
=> CREATE extension aurora_stat_utils;
```

## CREATE EXTENSION

For more information about available Aurora PostgreSQL extension versions, see [Extension versions for Amazon Aurora PostgreSQL](#) in *Release Notes for Aurora PostgreSQL*.

This function calculates the instance-level wait events by comparing two snapshots of statistics data from `aurora_stat_system_waits()` function and `pg_stat_database` PostgreSQL Statistics Views.

For more information about `aurora_stat_system_waits()` and `pg_stat_database`, see [The Statistics Collector](#) in the *PostgreSQL documentation*.

When run, this function takes an initial snapshot, waits the number of seconds specified, and then takes a second snapshot. The function compares the two snapshots and returns the difference. This difference represents the instance's activity for that time interval.

On the writer instance, the function also displays the number of committed transactions and TPS (transactions per second). This function returns information at the instance level and includes all databases on the instance.

## Examples

This example shows how to create `aurora_stat_utils` extension to be able to use `aurora_wait_report` function.

```
=> CREATE extension aurora_stat_utils;
CREATE EXTENSION
```

This example shows how to check wait report for 10 seconds.

```
=> SELECT *
      FROM aurora_wait_report();
NOTICE: committed 34 transactions in 10 seconds (tps 3)
 type_name | event_name | waits | wait_time | ms_per_wait | waits_per_xact |
ms_per_xact
-----+-----+-----+-----+-----+-----+
+-----+
Client    | ClientRead |    26 | 30003.00 | 1153.961 |          0.76 |

## Amazon Aurora PostgreSQL parameters

You manage your Amazon Aurora DB cluster in the same way that you manage Amazon RDS DB instances, by using parameters in a DB parameter group. However, Amazon Aurora differs from Amazon RDS in that an Aurora DB cluster has multiple DB instances. Some of the parameters that you use to manage your Amazon Aurora DB cluster apply to the entire cluster, while other parameters apply only to a given DB instance in the DB cluster, as follows:

- **DB cluster parameter group** – A DB cluster parameter group contains the set of engine configuration parameters that apply throughout the Aurora DB cluster. For example, cluster cache management is a feature of an Aurora DB cluster that's controlled by the `apg_ccm_enabled` parameter which is part of the DB cluster parameter group. The DB cluster parameter group also contains default settings for the DB parameter group for the DB instances that make up the cluster.
- **DB parameter group** – A DB parameter group is the set of engine configuration values that apply to a specific DB instance of that engine type. The DB parameter groups for the PostgreSQL DB engine are used by an RDS for PostgreSQL DB instance and Aurora PostgreSQL DB cluster.

These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

You manage cluster-level parameters in DB cluster parameter groups. You manage instance-level parameters in DB parameter groups. You can manage parameters using the Amazon RDS console, the Amazon CLI, or the Amazon RDS API. There are separate commands for managing cluster-level parameters and instance-level parameters.

- To manage cluster-level parameters in a DB cluster parameter group, use the [modify-db-cluster-parameter-group](#) Amazon CLI command.
- To manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster, use the [modify-db-parameter-group](#) Amazon CLI command.

To learn more about the Amazon CLI, see [Using the Amazon CLI](#) in the *Amazon Command Line Interface User Guide*.

For more information about parameter groups, see [Parameter groups for Amazon Aurora](#).

## Viewing Aurora PostgreSQL DB cluster and DB parameters

You can view all available default parameter groups for RDS for PostgreSQL DB instances and for Aurora PostgreSQL DB clusters in the Amazon Web Services Management Console. The default parameter groups for all DB engines and DB cluster types and versions are listed for each Amazon Region. Any custom parameter groups are also listed.

Rather than viewing in the Amazon Web Services Management Console, you can also list parameters contained in DB cluster parameter groups and DB parameter groups by using the Amazon CLI or the Amazon RDS API. For example, to list parameters in a DB cluster parameter group you use the [describe-db-cluster-parameters](#) Amazon CLI command as follows:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name
default.aurora-postgresql12
```

The command returns detailed JSON descriptions of each parameter. To reduce the amount of information returned, you can specify what you want by using the `--query` option. For example, you can get the parameter name, its description, and allowed values for the default Aurora PostgreSQL 12 DB cluster parameter group as follows:

## For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name
default.aurora-postgresql12 \
  --query 'Parameters[]'.
[{"ParameterName":ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:Allowed
```

## For Windows:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name
default.aurora-postgresql12 ^
  --query "Parameters[]".
[{"ParameterName":ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:Allowed
```

An Aurora DB cluster parameter group includes the DB instance parameter group and default values for a given Aurora DB engine. You can get the list of DB parameters from the same default Aurora PostgreSQL default parameter group by using the [describe-db-parameters](#) Amazon CLI command as shown following.

## For Linux, macOS, or Unix:

```
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 \
  --query 'Parameters[]'.
[{"ParameterName":ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:Allowed
```

## For Windows:

```
aws rds describe-db-parameters --db-parameter-group-name default.aurora-postgresql12 ^
  --query "Parameters[]".
[{"ParameterName":ParameterName,Description:Description,ApplyType:ApplyType,AllowedValues:Allowed
```

The preceding commands return lists of parameters from the DB cluster or DB parameter group with descriptions and other details specified in the query. Following is an example response.

```
[
  [
    {
      "ParameterName": "apg_enable_batch_mode_function_execution",
      "ApplyType": "dynamic",
      "Description": "Enables batch-mode functions to process sets of rows at a
time.",
```

```
        "AllowedValues": "0,1"
    }
],
[
    {
        "ParameterName": "apg_enable_correlated_any_transform",
        "ApplyType": "dynamic",
        "Description": "Enables the planner to transform correlated ANY Sublink
(IN/NOT IN subquery) to JOIN when possible.",
        "AllowedValues": "0,1"
    }
],...
```

Following are tables containing values for the default DB cluster parameter and DB parameter for Aurora PostgreSQL version 14.

## Aurora PostgreSQL cluster-level parameters

You can view the cluster-level parameters available for a specific Aurora PostgreSQL version using the Amazon Management console, the Amazon CLI, or the Amazon RDS API. For information about viewing the parameters in an Aurora PostgreSQL DB cluster parameter groups in the RDS console, see [Viewing parameter values for a DB cluster parameter group in Amazon Aurora](#).

Some cluster-level parameters aren't available in all versions and some are being deprecated. For information about viewing the parameters of a specific Aurora PostgreSQL version, see [Viewing Aurora PostgreSQL DB cluster and DB parameters](#).

For example, the following table lists the parameters available in the default DB cluster parameter group for Aurora PostgreSQL version 14. If you create an Aurora PostgreSQL DB cluster without specifying your own custom DB parameter group, your DB cluster is created using the default Aurora DB cluster parameter group for the version chosen, such as `default.aurora-postgresql14`, `default.aurora-postgresql13`, and so on.

For a listing of the DB instance parameters for this same default DB cluster parameter group, see [Aurora PostgreSQL instance-level parameters](#).

Parameter name	Description	Default
<code>ansi_constraint_trigger_ordering</code>	Change the firing order of constraint triggers to be compatible with the ANSI SQL standard.	–
<code>ansi_force_foreign_key_checks</code>	Ensure referential actions such as cascaded delete or cascaded update will always occur regardless of the various trigger contexts that exist for the action.	–
<code>ansi_qualified_update_set_target</code>	Support table and schema qualifiers in UPDATE ... SET statements.	–
<code>apg_ccm_enabled</code>	Enable or disable cluster cache management for the cluster.	–
<code>apg_enable_batch_mode_function_execution</code>	Enables batch-mode functions to process sets of rows at a time.	–

Parameter name	Description	Default
<code>apg_enable_correlated_any_transform</code>	Enables the planner to transform correlated ANY Sublink (IN/NOT IN subquery) to JOIN when possible.	–
<code>apg_enable_function_migration</code>	Enables the planner to migrate eligible scalar functions to the FROM clause.	–
<code>apg_enable_not_in_transform</code>	Enables the planner to transform NOT IN subquery to ANTI JOIN when possible.	–
<code>apg_enable_remove_redundant_inner_joins</code>	Enables the planner to remove redundant inner joins.	–
<code>apg_enable_semijoin_push_down</code>	Enables the use of semijoin filters for hash joins.	–
<code>apg_plan_mgmt.capture_plan_baselines</code>	Capture plan baseline mode. manual - enable plan capture for any SQL statement, off - disable plan capture, automatic - enable plan capture for for statements in <code>pg_stat_statements</code> that satisfy the eligibility criteria.	off
<code>apg_plan_mgmt.max_databases</code>	Sets the maximum number of databases that that may manage queries using <code>apg_plan_mgmt</code> .	10
<code>apg_plan_mgmt.max_plans</code>	Sets the maximum number of plans that may be cached by <code>apg_plan_mgmt</code> .	10000
<code>apg_plan_mgmt.plan_retention_period</code>	Maximum number of days since a plan was <code>last_used</code> before a plan will be automatically deleted.	32

Parameter name	Description	Default
apg_plan_mgmt.unapproved_plan_execution_threshold	Estimated total plan cost below which an Unapproved plan will be executed.	0
apg_plan_mgmt.use_plan_baselines	Use only approved or fixed plans for managed statements.	false
application_name	Sets the application name to be reported in statistics and logs.	–
array_nulls	Enable input of NULL elements in arrays.	–
aurora_compute_plan_id	Monitors query execution plans to detect the execution plans contributing to current database load and to track performance statistics of execution plans over time. For more information, see <a href="#">Monitoring query execution plans for Aurora PostgreSQL</a> .	on
authentication_timeout	(s) Sets the maximum allowed time to complete client authentication.	–
auto_explain.log_analyze	Use EXPLAIN ANALYZE for plan logging.	–
auto_explain.log_buffers	Log buffers usage.	–
auto_explain.log_format	EXPLAIN format to be used for plan logging.	–
auto_explain.log_min_duration	Sets the minimum execution time above which plans will be logged.	–
auto_explain.log_nested_statements	Log nested statements.	–

Parameter name	Description	Default
auto_explain.log_timing	Collect timing data, not just row counts.	–
auto_explain.log_triggers	Include trigger statistics in plans.	–
auto_explain.log_verbose	Use EXPLAIN VERBOSE for plan logging.	–
auto_explain.sample_rate	Fraction of queries to process.	–
autovacuum	Starts the autovacuum subprocess.	–
autovacuum_analyze_scale_factor	Number of tuple inserts, updates or deletes prior to analyze as a fraction of reltuples.	0.05
autovacuum_analyze_threshold	Minimum number of tuple inserts, updates or deletes prior to analyze.	–
autovacuum_freeze_max_age	Age at which to autovacuum a table to prevent transaction ID wraparound.	–
autovacuum_max_workers	Sets the maximum number of simultaneously running autovacuum worker processes.	GREATEST(DBInstanceClassMemory/64371566592,3)
autovacuum_multixact_freeze_max_age	Multixact age at which to autovacuum a table to prevent multixact wraparound.	–
autovacuum_naptime	(s) Time to sleep between autovacuum runs.	5
autovacuum_vacuum_cost_delay	(ms) Vacuum cost delay in milliseconds, for autovacuum.	5

Parameter name	Description	Default
autovacuum_vacuum_cost_limit	Vacuum cost amount available before napping, for autovacuum.	GREATEST(log(DBInstanceClassMemory/21474836480)*600,200)
autovacuum_vacuum_insert_scale_factor	Number of tuple inserts prior to vacuum as a fraction of reltuples.	–
autovacuum_vacuum_insert_threshold	Minimum number of tuple inserts prior to vacuum, or -1 to disable insert vacuums.	–
autovacuum_vacuum_scale_factor	Number of tuple updates or deletes prior to vacuum as a fraction of reltuples.	0.1
autovacuum_vacuum_threshold	Minimum number of tuple updates or deletes prior to vacuum.	–
autovacuum_work_mem	(kB) Sets the maximum memory to be used by each autovacuum worker process.	GREATEST(DBInstanceClassMemory/32768,131072)
babelfishpg_tds.default_server_name	Default Babelfish server name	Microsoft SQL Server
babelfishpg_tds.listen_addresses	Sets the host name or IP address(es) to listen TDS to.	*
babelfishpg_tds.port	Sets the TDS TCP port the server listens on.	1433
babelfishpg_tds.tds_debug_log_level	Sets logging level in TDS, 0 disables logging	1

Parameter name	Description	Default
<code>babelfishpg_tds.tds_default_numeric_precision</code>	Sets the default precision of numeric type to be sent in the TDS column metadata if the engine does not specify one.	38
<code>babelfishpg_tds.tds_default_numeric_scale</code>	Sets the default scale of numeric type to be sent in the TDS column metadata if the engine does not specify one.	8
<code>babelfishpg_tds.tds_default_packet_size</code>	Sets the default packet size for all the SQL Server clients being connected	4096
<code>babelfishpg_tds.tds_default_protocol_version</code>	Sets a default TDS protocol version for all the clients being connected	DEFAULT
<code>babelfishpg_tds.tds_ssl_encrypt</code>	Sets the SSL Encryption option	0
<code>babelfishpg_tds.tds_ssl_max_protocol_version</code>	Sets the maximum SSL/TLS protocol version to use for tds session.	TLSv1.2
<code>babelfishpg_tds.tds_ssl_min_protocol_version</code>	Sets the minimum SSL/TLS protocol version to use for tds session.	TLSv1.2 from Aurora PostgreSQL version 16, TLSv1 for versions older than Aurora PostgreSQL version 16
<code>babelfishpg_tsql.default_locale</code>	Default locale to be used for collations created by CREATE COLLATION.	en-US

Parameter name	Description	Default
<code>babelfishpg_tsql.migration_mode</code>	Defines if multiple user databases are supported	multi-db from Aurora PostgreSQL version 16, single-db for versions older than Aurora PostgreSQL version 16
<code>babelfishpg_tsql.server_collation_name</code>	Name of the default server collation	<code>sql_latin1_general_cp1_ci_as</code>
<code>babelfishpg_tsql.version</code>	Sets the output of @@VERSION variable	default
<code>backend_flush_after</code>	(8Kb) Number of pages after which previously performed writes are flushed to disk.	–
<code>backslash_quote</code>	Sets whether <code>\\</code> is allowed in string literals.	–
<code>backtrace_functions</code>	Log backtrace for errors in these functions.	–
<code>bytea_output</code>	Sets the output format for bytea.	–
<code>check_function_bodies</code>	Check function bodies during CREATE FUNCTION.	–
<code>client_connection_check_interval</code>	Sets the time interval between checks for disconnection while running queries.	–
<code>client_encoding</code>	Sets the clients character set encoding.	UTF8
<code>client_min_messages</code>	Sets the message levels that are sent to the client.	–
<code>compute_query_id</code>	Compute query identifiers.	auto
<code>config_file</code>	Sets the servers main configuration file.	<code>/rdsdbdata/config/postgresql.conf</code>

Parameter name	Description	Default
<code>constraint_exclusion</code>	Enables the planner to use constraints to optimize queries.	–
<code>cpu_index_tuple_cost</code>	Sets the planners estimate of the cost of processing each index entry during an index scan.	–
<code>cpu_operator_cost</code>	Sets the planners estimate of the cost of processing each operator or function call.	–
<code>cpu_tuple_cost</code>	Sets the planners estimate of the cost of processing each tuple (row).	–
<code>cron.database_name</code>	Sets the database to store <code>pg_cron</code> metadata tables	postgres
<code>cron.log_run</code>	Log all jobs runs into the <code>job_run_details</code> table	on
<code>cron.log_statement</code>	Log all cron statements prior to execution.	off
<code>cron.max_running_jobs</code>	Maximum number of jobs that can run concurrently.	5
<code>cron.use_background_workers</code>	Enables background workers for <code>pg_cron</code>	on
<code>cursor_tuple_fraction</code>	Sets the planners estimate of the fraction of a cursors rows that will be retrieved.	–
<code>data_directory</code>	Sets the servers data directory.	<code>/rdsdbdata/db</code>
<code>datestyle</code>	Sets the display format for date and time values.	–
<code>db_user_namespace</code>	Enables per-database user names.	–
<code>deadlock_timeout</code>	(ms) Sets the time to wait on a lock before checking for deadlock.	–

Parameter name	Description	Default
debug_pretty_print	Indents parse and plan tree displays.	–
debug_print_parse	Logs each query's parse tree.	–
debug_print_plan	Logs each query's execution plan.	–
debug_print_rewritten	Logs each query's rewritten parse tree.	–
default_statistics_target	Sets the default statistics target.	–
default_tablespace	Sets the default tablespace to create tables and indexes in.	–
default_toast_compression	Sets the default compression method for compressible values.	–
default_transaction_deferrable	Sets the default deferrable status of new transactions.	–
default_transaction_isolation	Sets the transaction isolation level of each new transaction.	–
default_transaction_read_only	Sets the default read-only status of new transactions.	–
effective_cache_size	(8kB) Sets the planner's assumption about the size of the disk cache.	SUM(DBInstanceClassMemory/12038,-50003)
effective_io_concurrency	Number of simultaneous requests that can be handled efficiently by the disk subsystem.	–
enable_async_append	Enables the planner's use of async append plans.	–

Parameter name	Description	Default
enable_bitmapscan	Enables the planners use of bitmap-scan plans.	–
enable_gathermerge	Enables the planners use of gather merge plans.	–
enable_hashagg	Enables the planners use of hashed aggregation plans.	–
enable_hashjoin	Enables the planners use of hash join plans.	–
enable_incremental_sort	Enables the planners use of incremental sort steps.	–
enable_indexonlyscan	Enables the planners use of index-only-scan plans.	–
enable_indexscan	Enables the planners use of index-scan plans.	–
enable_material	Enables the planners use of materialization.	–
enable_memoize	Enables the planners use of memoization	–
enable_mergejoin	Enables the planners use of merge join plans.	–
enable_nestloop	Enables the planners use of nested-loop join plans.	–
enable_parallel_append	Enables the planners use of parallel append plans.	–
enable_parallel_hash	Enables the planners user of parallel hash plans.	–
enable_partition_pruning	Enable plan-time and run-time partition pruning.	–

Parameter name	Description	Default
enable_partitionwise_aggregate	Enables partitionwise aggregation and grouping.	–
enable_partitionwise_join	Enables partitionwise join.	–
enable_seqscan	Enables the planners use of sequential-scan plans.	–
enable_sort	Enables the planners use of explicit sort steps.	–
enable_tidscan	Enables the planners use of TID scan plans.	–
escape_string_warning	Warn about backslash escapes in ordinary string literals.	–
exit_on_error	Terminate session on any error.	–
extra_float_digits	Sets the number of digits displayed for floating-point values.	–
force_parallel_mode	Forces use of parallel query facilities.	–
from_collapse_limit	Sets the FROM-list size beyond which subqueries are not collapsed.	–
geqo	Enables genetic query optimization.	–
geqo_effort	GEQO: effort is used to set the default for other GEQO parameters.	–
geqo_generations	GEQO: number of iterations of the algorithm.	–
geqo_pool_size	GEQO: number of individuals in the population.	–
geqo_seed	GEQO: seed for random path selection.	–

Parameter name	Description	Default
geqo_selection_bias	GEQO: selective pressure within the population.	–
geqo_threshold	Sets the threshold of FROM items beyond which GEQO is used.	–
gin_fuzzy_search_limit	Sets the maximum allowed result for exact search by GIN.	–
gin_pending_list_limit	(kB) Sets the maximum size of the pending list for GIN index.	–
hash_mem_multiplier	Multiple of work_mem to use for hash tables.	–
hba_file	Sets the servers hba configuration file.	/rdsdbdata/config/pg_hba.conf
hot_standby_feedback	Allows feedback from a hot standby to the primary that will avoid query conflicts.	on
huge_pages	Reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. It is turned on by default for all the DB instance classes other than t3.medium,db.t3.large,db.t4g.medium,db.t4g.large instance classes.	on
ident_file	Sets the servers ident configuration file.	/rdsdbdata/config/pg_ident.conf
idle_in_transaction_session_timeout	(ms) Sets the maximum allowed duration of any idling transaction.	86400000

Parameter name	Description	Default
idle_session_timeout	Terminate any session that has been idle (that is, waiting for a client query), but not within an open transaction, for longer than the specified amount of time	–
intervalstyle	Sets the display format for interval values.	–
join_collapse_limit	Sets the FROM-list size beyond which JOIN constructs are not flattened.	–
krb_caseins_users	Sets whether GSSAPI (Generic Security Service API) user names should be treated case-insensitively (true) or not. By default, this parameter is set to false, so Kerberos expects user names to be case sensitive. For more information, see <a href="#">GSSAPI Authentication</a> in the PostgreSQL documentation.	false
lc_messages	Sets the language in which messages are displayed.	–
lc_monetary	Sets the locale for formatting monetary amounts.	–
lc_numeric	Sets the locale for formatting numbers.	–
lc_time	Sets the locale for formatting date and time values.	–
listen_addresses	Sets the host name or IP address(es) to listen to.	*
lo_compat_privileges	Enables backward compatibility mode for privilege checks on large objects.	0
log_autovacuum_min_duration	(ms) Sets the minimum execution time above which autovacuum actions will be logged.	10000

Parameter name	Description	Default
log_connections	Logs each successful connection.	–
log_destination	Sets the destination for server log output.	stderr
log_directory	Sets the destination directory for log files.	/rdsdbdata/log/error
log_disconnections	Logs end of a session, including duration.	–
log_duration	Logs the duration of each completed SQL statement.	–
log_error_verbosity	Sets the verbosity of logged messages.	–
log_executor_stats	Writes executor performance statistics to the server log.	–
log_file_mode	Sets the file permissions for log files.	0644
log_filename	Sets the file name pattern for log files.	postgresql.log.%Y-%m-%d-%H%M
logging_collector	Start a subprocess to capture stderr output and/or csvlogs into log files.	1
log_hostname	Logs the host name in the connection logs.	0
logical_decoding_work_mem	(kB) This much memory can be used by each internal reorder buffer before spilling to disk.	–
log_line_prefix	Controls information prefixed to each log line.	%t:%r:%u@%d:%p]:
log_lock_waits	Logs long lock waits.	–
log_min_duration_sample	(ms) Sets the minimum execution time above which a sample of statements will be logged. Sampling is determined by log_statement_sample_rate.	–

Parameter name	Description	Default
log_min_duration_statement	(ms) Sets the minimum execution time above which statements will be logged.	–
log_min_error_statement	Causes all statements generating error at or above this level to be logged.	–
log_min_messages	Sets the message levels that are logged.	–
log_parameter_max_length	(B) When logging statements, limit logged parameter values to first N bytes.	–
log_parameter_max_length_on_error	(B) When reporting an error, limit logged parameter values to first N bytes.	–
log_parser_stats	Writes parser performance statistics to the server log.	–
log_planner_stats	Writes planner performance statistics to the server log.	–
log_replication_commands	Logs each replication command.	–
log_rotation_age	(min) Automatic log file rotation will occur after N minutes.	60
log_rotation_size	(kB) Automatic log file rotation will occur after N kilobytes.	100000
log_statement	Sets the type of statements logged.	–
log_statement_sample_rate	Fraction of statements exceeding log_min_duration_sample to be logged.	–
log_statement_stats	Writes cumulative performance statistics to the server log.	–

Parameter name	Description	Default
log_temp_files	(kB) Log the use of temporary files larger than this number of kilobytes.	–
log_timezone	Sets the time zone to use in log messages.	UTC
log_transaction_sample_rate	Set the fraction of transactions to log for new transactions.	–
log_truncate_on_rotation	Truncate existing log files of same name during log rotation.	0
maintenance_io_concurrency	A variant of effective_io_concurrency that is used for maintenance work.	1
maintenance_work_mem	(kB) Sets the maximum memory to be used for maintenance operations.	GREATEST(DBInstanceClassMemory/63963136*1024,65536)
max_connections	Sets the maximum number of concurrent connections.	LEAST(DBInstanceClassMemory/9531392,5000)
max_files_per_process	Sets the maximum number of simultaneously open files for each server process.	–
max_locks_per_transaction	Sets the maximum number of locks per transaction.	64
max_logical_replication_workers	Maximum number of logical replication worker processes.	–
max_parallel_maintenance_workers	Sets the maximum number of parallel processes per maintenance operation.	–
max_parallel_workers	Sets the maximum number of parallel workers than can be active at one time.	GREATEST(\$DBInstanceVCPU/2,8)

Parameter name	Description	Default
max_parallel_workers_per_gather	Sets the maximum number of parallel processes per executor node.	–
max_pred_locks_per_page	Sets the maximum number of predicate-locked tuples per page.	–
max_pred_locks_per_relation	Sets the maximum number of predicate-locked pages and tuples per relation.	–
max_pred_locks_per_transaction	Sets the maximum number of predicate locks per transaction.	–
max_prepared_transactions	Sets the maximum number of simultaneously prepared transactions.	0
max_replication_slots	Sets the maximum number of replication slots that the server can support.	20
max_slot_wal_keep_size	(MB) Replication slots will be marked as failed, and segments released for deletion or recycling, if this much space is occupied by WAL on disk.	–
max_stack_depth	(kB) Sets the maximum stack depth, in kilobytes.	6144
max_standby_streaming_delay	(ms) Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.	14000
max_sync_workers_per_subscription	Maximum number of synchronization workers per subscription	2
max_wal_senders	Sets the maximum number of simultaneously running WAL sender processes.	10

Parameter name	Description	Default
max_worker_processes	Sets the maximum number of concurrent worker processes.	GREATEST(\$DBInstanceVCPU*2,8)
min_dynamic_shared_memory	(MB) Amount of dynamic shared memory reserved at startup.	–
min_parallel_index_scan_size	(8kB) Sets the minimum amount of index data for a parallel scan.	–
min_parallel_table_scan_size	(8kB) Sets the minimum amount of table data for a parallel scan.	–
old_snapshot_threshold	(min) Time before a snapshot is too old to read pages changed after the snapshot was taken.	–
orafce.nls_date_format	Emulate oracles date output behaviour.	–
orafce.timezone	Specify timezone used for sysdate function.	–
parallel_leader_participation	Controls whether Gather and Gather Merge also run subplans.	–
parallel_setup_cost	Sets the planners estimate of the cost of starting up worker processes for parallel query.	–
parallel_tuple_cost	Sets the planners estimate of the cost of passing each tuple (row) from worker to master backend.	–
password_encryption	Encrypt passwords.	–
pgaudit.log	Specifies which classes of statements will be logged by session audit logging.	–

Parameter name	Description	Default
pgaudit.log_catalog	Specifies that session logging should be enabled in the case where all relations in a statement are in pg_catalog.	–
pgaudit.log_level	Specifies the log level that will be used for log entries.	–
pgaudit.log_parameter	Specifies that audit logging should include the parameters that were passed with the statement.	–
pgaudit.log_relation	Specifies whether session audit logging should create a separate log entry for each relation (TABLE, VIEW, etc.) referenced in a SELECT or DML statement.	–
pgaudit.log_statement_once	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.	–
pgaudit.role	Specifies the master role to use for object audit logging.	–
pg_bigm.enable_recheck	It specifies whether to perform Recheck which is an internal process of full text search.	on
pg_bigm.gin_key_limit	It specifies the maximum number of 2-grams of the search keyword to be used for full text search.	0
pg_bigm.last_update	It reports the last updated date of the pg_bigm module.	2013.11.22
pg_bigm.similarity_limit	It specifies the minimum threshold used by the similarity search.	0.3

Parameter name	Description	Default
pg_hint_plan.debug_print	Logs results of hint parsing.	–
pg_hint_plan.enable_hint	Force planner to use plans specified in the hint comment preceding to the query.	–
pg_hint_plan.enable_hint_table	Force planner to not get hint by using table lookups.	–
pg_hint_plan.message_level	Message level of debug messages.	–
pg_hint_plan.parse_messages	Message level of parse errors.	–
pglogical.batch_inserts	Batch inserts if possible	–
pglogical.conflict_log_level	Sets log level used for logging resolved conflicts.	–
pglogical.conflict_resolution	Sets method used for conflict resolution for resolvable conflicts.	–
pglogical.extra_connection_options	connection options to add to all peer node connections	–
pglogical.synchronous_commit	pglogical specific synchronous commit value	–
pglogical.use_spi	Use SPI instead of low-level API for applying changes	–
pgtle.clientauth_databases_to_skip	List of databases to skip for clientauth feature.	–
pgtle.clientauth_db_name	Controls which database is used for clientauth feature.	–

Parameter name	Description	Default
<code>pgtle.clientauth_num_parallel_workers</code>	Number of background workers used for clientauth feature.	–
<code>pgtle.clientauth_users_to_skip</code>	List of users to skip for clientauth feature.	–
<code>pgtle.enable_clientauth</code>	Enables the clientauth feature.	–
<code>pgtle.passcheck_db_name</code>	Sets which database is used for cluster-wide passcheck feature.	–
<code>pg_prewarm.autoprewarm</code>	Starts the autoprewarm worker.	–
<code>pg_prewarm.autoprewarm_interval</code>	Sets the interval between dumps of shared buffers	–
<code>pg_similarity.block_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.block_threshold</code>	Sets the threshold used by the Block similarity function.	–
<code>pg_similarity.block_tokenizer</code>	Sets the tokenizer for Block similarity function.	–
<code>pg_similarity.cosine_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.cosine_threshold</code>	Sets the threshold used by the Cosine similarity function.	–
<code>pg_similarity.cosine_tokenizer</code>	Sets the tokenizer for Cosine similarity function.	–
<code>pg_similarity.dice_is_normalized</code>	Sets if the result value is normalized or not.	–

Parameter name	Description	Default
<code>pg_similarity.dice_threshold</code>	Sets the threshold used by the Dice similarity measure.	–
<code>pg_similarity.dice_tokenizer</code>	Sets the tokenizer for Dice similarity measure.	–
<code>pg_similarity.euclidean_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.euclidean_threshold</code>	Sets the threshold used by the Euclidean similarity measure.	–
<code>pg_similarity.euclidean_tokenizer</code>	Sets the tokenizer for Euclidean similarity measure.	–
<code>pg_similarity.hamming_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.hamming_threshold</code>	Sets the threshold used by the Block similarity metric.	–
<code>pg_similarity.jaccard_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.jaccard_threshold</code>	Sets the threshold used by the Jaccard similarity measure.	–
<code>pg_similarity.jaccard_tokenizer</code>	Sets the tokenizer for Jaccard similarity measure.	–
<code>pg_similarity.jaro_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.jaro_threshold</code>	Sets the threshold used by the Jaro similarity measure.	–

Parameter name	Description	Default
<code>pg_similarity.jarowinkler_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.jarowinkler_threshold</code>	Sets the threshold used by the Jarowinkler similarity measure.	–
<code>pg_similarity.levenshtein_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.levenshtein_threshold</code>	Sets the threshold used by the Levenshtein similarity measure.	–
<code>pg_similarity.matching_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.matching_threshold</code>	Sets the threshold used by the Matching Coefficient similarity measure.	–
<code>pg_similarity.matching_tokenizer</code>	Sets the tokenizer for Matching Coefficient similarity measure.	–
<code>pg_similarity.mongeelkan_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.mongeelkan_threshold</code>	Sets the threshold used by the Monge-Elkan similarity measure.	–
<code>pg_similarity.mongeelkan_tokenizer</code>	Sets the tokenizer for Monge-Elkan similarity measure.	–
<code>pg_similarity.nw_gap_penalty</code>	Sets the gap penalty used by the Needleman-Wunsch similarity measure.	–
<code>pg_similarity.nw_is_normalized</code>	Sets if the result value is normalized or not.	–

Parameter name	Description	Default
<code>pg_similarity.nw_threshold</code>	Sets the threshold used by the Needleman-Wunsch similarity measure.	–
<code>pg_similarity.overlap_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.overlap_threshold</code>	Sets the threshold used by the Overlap Coefficient similarity measure.	–
<code>pg_similarity.overlap_tokenizer</code>	Sets the tokenizer for Overlap Coefficient similarity measure.	–
<code>pg_similarity.qgram_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.qgram_threshold</code>	Sets the threshold used by the Q-Gram similarity measure.	–
<code>pg_similarity.qgram_tokenizer</code>	Sets the tokenizer for Q-Gram measure.	–
<code>pg_similarity.swg_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.swg_threshold</code>	Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.	–
<code>pg_similarity.sw_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.sw_threshold</code>	Sets the threshold used by the Smith-Waterman similarity measure.	–
<code>pg_stat_statements.max</code>	Sets the maximum number of statements tracked by <code>pg_stat_statements</code> .	–
<code>pg_stat_statements.save</code>	Save <code>pg_stat_statements</code> statistics across server shutdowns.	–

Parameter name	Description	Default
pg_stat_statements.track	Selects which statements are tracked by pg_stat_statements.	–
pg_stat_statements.track_planning	Selects whether planning duration is tracked by pg_stat_statements.	–
pg_stat_statements.track_utility	Selects whether utility commands are tracked by pg_stat_statements.	–
plan_cache_mode	Controls the planner selection of custom or generic plan.	–
port	Sets the TCP port the server listens on.	EndPointPort
postgis.gdal_enabled_drivers	Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.	ENABLE_ALL
quote_all_identifiers	When generating SQL fragments, quote all identifiers.	–
random_page_cost	Sets the planners estimate of the cost of a nonsequentially fetched disk page.	–
rdkit.dice_threshold	Lower threshold of Dice similarity. Molecules with similarity lower than threshold are not similar by # operation.	–
rdkit.do_chiral_sss	Should stereochemistry be taken into account in substructure matching. If false, no stereochemistry information is used in substructure matches.	–
rdkit.tanimoto_threshold	Lower threshold of Tanimoto similarity. Molecules with similarity lower than threshold are not similar by % operation.	–

Parameter name	Description	Default
rds.accepted_password_auth_method	Force authentication for connections with password stored locally.	md5+scram
rds.adaptive_autovacuum	RDS parameter to enable/disable adaptive autovacuum.	1
rds.babelfish_status	RDS parameter to enable/disable Babelfish for Aurora PostgreSQL.	off
rds.enable_plan_management	Enable or disable the <code>apg_plan_mgmt</code> extension.	0

Parameter name	Description	Default
rds.extensions	List of extensions provided by RDS	address_standardizer, address_standardizer_data_us, apg_plan_mgmt, aurora_stat_utils, amcheck, autoinc, aws_commons, aws_ml, aws_s3, aws_lambda, bool_plperl, bloom, btree_gin, btree_gist, citext, cube, dblink, dict_int, dict_xsyn, earthdistance, fuzzystrmatch, hll, hstore, hstore_plperl, insert_username, intagg, intarray, ip4r, isn, jsonb_plperl, lo, log_fdw, ltree, moddatetime, old_snapshots, oracle_fdw, orafce, pgaudit, pgcrypto, pglogical, pgrouting, pgrowlocks, pgstattuple, pgtap, pg_bigm, pg_buffercache, pg_cron, pg_freemap, pg_hint_plan, pg_partman, pg_prewarm, pg_proctab,

Parameter name	Description	Default
		pg_repack, pg_similarity, pg_stat_statements, pg_trgm, pg_visibility, plcoffee, plls, plperl, plpgsql, plprofiler, pltcl, plv8, postgis, postgis_tiger_geocoder, postgis_raster, postgis_topology, postgres_fdw, prefix, rdkit, rds_tools, refint, sslinfo, tablefunc, tds_fdw, test_parser, tsm_system_rows, tsm_system_time, unaccent, uuid-oss
rds.force_admin_logging_level	See log messages for RDS admin user actions in customer databases.	–
rds.force_autovacuum_logging_level	See log messages related to autovacuum operations.	WARNING
rds.force_ssl	Force SSL connections.	0

Parameter name	Description	Default
rds.global_db_rpo	<p>(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated.</p> <div style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>⚠ Important</b></p> <p>This parameter is meant for Aurora PostgreSQL-based global databases. For a nonglobal database, leave it at the default value. For more information about using this parameter, see <a href="#">the section called “Managing RPOs (Aurora PostgreSQL)”</a>.</p> </div>	–
rds.logical_replication	Enables logical decoding.	0
rds.logically_replicate_unlogged_tables	Unlogged tables are logically replicated.	1
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.	4320
rds.pg_stat_ramdisk_size	Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk. This parameter is only available in Aurora PostgreSQL 14 and lower versions.	0
rds.rds_superuser_reserved_connections	Sets the number of connection slots reserved for rds_superuser. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation <a href="#">reserved connections</a> .	2
rds.restrict_password_commands	restricts password-related commands to members of rds_password	–

Parameter name	Description	Default
rds_superuser_variables	List of superuser-only variables for which we elevate rds_superuser modification statements.	session_replication_role
recovery_init_sync_method	Sets the method for synchronizing the data directory before crash recovery.	syncfs
remove_temp_files_after_crash	Remove temporary files after backend crash.	0
restart_after_crash	Reinitialize server after backend crash.	–
row_security	Enable row security.	–
search_path	Sets the schema search order for names that are not schema-qualified.	–
seq_page_cost	Sets the planner's estimate of the cost of a sequentially fetched disk page.	–
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.	–
shared_buffers	(8kB) Sets the number of shared memory buffers used by the server.	SUM(DBInstanceClassMemory/1024, -50003)
shared_preload_libraries	Lists shared libraries to preload into server.	pg_stat_statements
ssl	Enables SSL connections.	1
ssl_ca_file	Location of the SSL server authority file.	/rdsdbdata/rds-metadata/ca-cert.pem
ssl_cert_file	Location of the SSL server certificate file.	/rdsdbdata/rds-metadata/server-cert.pem

Parameter name	Description	Default
ssl_ciphers	Sets the list of allowed TLS ciphers to be used on secure connections.	–
ssl_crl_dir	Location of the SSL certificate revocation list directory.	/rdsdbdata/rds-met adata/ssl_crl_dir/
ssl_key_file	Location of the SSL server private key file	/rdsdbdata/rds-met adata/server-key.pem
ssl_max_protocol_version	Sets the maximum SSL/TLS protocol version allowed	–
ssl_min_protocol_version	Sets the minimum SSL/TLS protocol version allowed	TLSv1.2
standard_conforming_strings	Causes ... strings to treat backslashes literally.	–
statement_timeout	(ms) Sets the maximum allowed duration of any statement.	–
stats_temp_directory	Writes temporary statistics files to the specified directory.	/rdsdbdata/db/pg_s tat_tmp
superuser_reserved_connections	Sets the number of connection slots reserved for superusers.	3
synchronize_seqscans	Enable synchronized sequential scans.	–
synchronous_commit	Sets the current transactions synchronization level.	on
tcp_keepalives_count	Maximum number of TCP keepalive retransmits.	–
tcp_keepalives_idle	(s) Time between issuing TCP keepalives.	–

Parameter name	Description	Default
tcp_keepalives_interval	(s) Time between TCP keepalive retransmits.	–
temp_buffers	(8kB) Sets the maximum number of temporary buffers used by each session.	–
temp_file_limit	Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables	-1
temp_tablespaces	Sets the tablespace(s) to use for temporary tables and sort files.	–
timezone	Sets the time zone for displaying and interpreting time stamps.	UTC
track_activities	Collects information about executing commands.	–
track_activity_query_size	Sets the size reserved for pg_stat_activity.current_query, in bytes.	4096
track_commit_timestamp	Collects transaction commit time.	–
track_counts	Collects statistics on database activity.	–
track_functions	Collects function-level statistics on database activity.	pl
track_io_timing	Collects timing statistics on database IO activity.	1
track_wal_io_timing	Collects timing statistics for WAL I/O activity.	–
transform_null_equals	Treats expr=NULL as expr IS NULL.	–

Parameter name	Description	Default
update_process_title	Updates the process title to show the active SQL command.	–
vacuum_cost_delay	(ms) Vacuum cost delay in milliseconds.	–
vacuum_cost_limit	Vacuum cost amount available before napping.	–
vacuum_cost_page_dirty	Vacuum cost for a page dirtied by vacuum.	–
vacuum_cost_page_hit	Vacuum cost for a page found in the buffer cache.	–
vacuum_cost_page_miss	Vacuum cost for a page not found in the buffer cache.	0
vacuum_defer_cleanup_age	Number of transactions by which VACUUM and HOT cleanup should be deferred, if any.	–
vacuum_failsafe_age	Age at which VACUUM should trigger failsafe to avoid a wraparound outage.	1200000000
vacuum_freeze_min_age	Minimum age at which VACUUM should freeze a table row.	–
vacuum_freeze_table_age	Age at which VACUUM should scan whole table to freeze tuples.	–
vacuum_multixact_failsafe_age	Multixact age at which VACUUM should trigger failsafe to avoid a wraparound outage.	1200000000
vacuum_multixact_freeze_min_age	Minimum age at which VACUUM should freeze a MultiXactId in a table row.	–
vacuum_multixact_freeze_table_age	Multixact age at which VACUUM should scan whole table to freeze tuples.	–

Parameter name	Description	Default
wal_buffers	(8kB) Sets the number of disk-page buffers in shared memory for WAL.	–
wal_receiver_create_temp_slot	Sets whether a WAL receiver should create a temporary replication slot if no permanent slot is configured.	0
wal_receiver_status_interval	(s) Sets the maximum interval between WAL receiver status reports to the primary.	–
wal_receiver_timeout	(ms) Sets the maximum wait time to receive data from the primary.	30000
wal_sender_timeout	(ms) Sets the maximum time to wait for WAL replication.	–
work_mem	(kB) Sets the maximum memory to be used for query workspaces.	–
xmlbinary	Sets how binary values are to be encoded in XML.	–
xmloption	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.	–

## Aurora PostgreSQL instance-level parameters

You can view the instance-level parameters available for a specific Aurora PostgreSQL version using the Amazon Management console, the Amazon CLI, or the Amazon RDS API. For information about viewing the parameters in an Aurora PostgreSQL DB parameter groups in the RDS console, see [Viewing parameter values for a DB parameter group in Amazon Aurora](#).

Some instance-level parameters aren't available in all versions and some are being deprecated. For information about viewing the parameters of a specific Aurora PostgreSQL version, see [Viewing Aurora PostgreSQL DB cluster and DB parameters](#).

For example, the following table lists the parameters that apply to a specific DB instance in an Aurora PostgreSQL DB cluster. This list was generated by running the [describe-db-parameters](#) Amazon CLI command with `default.aurora-postgresql14` for the `--db-parameter-group-name` value.

For a listing of the DB cluster parameters for this same default DB parameter group, see [Aurora PostgreSQL cluster-level parameters](#).

Parameter name	Description	Default
<code>apg_enable_batch_mode_function_execution</code>	Enables batch-mode functions to process sets of rows at a time.	–
<code>apg_enable_correlated_any_transform</code>	Enables the planner to transform correlated ANY Sublink (IN/NOT IN subquery to JOIN when possible).	–
<code>apg_enable_function_migration</code>	Enables the planner to migrate eligible scalar functions to the FROM clause.	–
<code>apg_enable_not_in_transform</code>	Enables the planner to transform NOT IN subquery to ANTI JOIN when possible.	–
<code>apg_enable_remove_redundant_inner_joins</code>	Enables the planner to remove redundant inner joins.	–

Parameter name	Description	Default
apg_enable_semijoin_push_down	Enables the use of semijoin filters for hash joins.	–
apg_plan_mgmt.capture_plan_baselines	Capture plan baseline mode. manual - enable plan capture for any SQL statement, off - disable plan capture, automatic - enable plan capture for for statements in pg_stat_statements that satisfy the eligibility criteria.	off
apg_plan_mgmt.max_databases	Sets the maximum number of databases that that may manage queries using apg_plan_mgmt.	10
apg_plan_mgmt.max_plans	Sets the maximum number of plans that may be cached by apg_plan_mgmt.	10000
apg_plan_mgmt.plan_retention_period	Maximum number of days since a plan was last_used before a plan will be automatically deleted.	32
apg_plan_mgmt.unapproved_plan_execution_threshold	Estimated total plan cost below which an Unapproved plan will be executed.	0
apg_plan_mgmt.use_plan_baselines	Use only approved or fixed plans for managed statements.	false
application_name	Sets the application name to be reported in statistics and logs.	–
aurora_compute_planner_id	Monitors query execution plans to detect the execution plans contributing to current database load and to track performance statistics of execution plans over time. For more information, see <a href="#">Monitoring query execution plans for Aurora PostgreSQL</a> .	on

Parameter name	Description	Default
aurora_temp_space_size	(MB) Sets size of the allocated space for Optimized Reads-enabled temporary objects on Aurora I/O-Optimized clusters with supported instance classes.	DBInstanceClassMemory/524288
authentication_timeout	(s) Sets the maximum allowed time to complete client authentication.	–
auto_explain.log_analyze	Use EXPLAIN ANALYZE for plan logging.	–
auto_explain.log_buffers	Log buffers usage.	–
auto_explain.log_format	EXPLAIN format to be used for plan logging.	–
auto_explain.log_min_duration	Sets the minimum execution time above which plans will be logged.	–
auto_explain.log_nested_statements	Log nested statements.	–
auto_explain.log_timing	Collect timing data, not just row counts.	–
auto_explain.log_triggers	Include trigger statistics in plans.	–
auto_explain.log_verbose	Use EXPLAIN VERBOSE for plan logging.	–
auto_explain.sample_rate	Fraction of queries to process.	–
babelfishpg_tds_listen_addresses	Sets the host name or IP address(es) to listen TDS to.	*

Parameter name	Description	Default
<code>babelfishpg_tds.tds_debug_log_level</code>	Sets logging level in TDS, 0 disables logging	1
<code>backend_flush_after</code>	(8Kb Number of pages after which previously performed writes are flushed to disk.	–
<code>bytea_output</code>	Sets the output format for bytea.	–
<code>check_function_bodies</code>	Check function bodies during CREATE FUNCTION.	–
<code>client_connection_check_interval</code>	Sets the time interval between checks for disconnection while running queries.	–
<code>client_min_messages</code>	Sets the message levels that are sent to the client.	–
<code>config_file</code>	Sets the servers main configuration file.	<code>/rdsdbdata/config/postgresql.conf</code>
<code>constraint_exclusion</code>	Enables the planner to use constraints to optimize queries.	–
<code>cpu_index_tuple_cost</code>	Sets the planners estimate of the cost of processing each index entry during an index scan.	–
<code>cpu_operator_cost</code>	Sets the planners estimate of the cost of processing each operator or function call.	–
<code>cpu_tuple_cost</code>	Sets the planners estimate of the cost of processing each tuple (row.	–
<code>cron.database_name</code>	Sets the database to store pg_cron metadata tables	postgres
<code>cron.log_run</code>	Log all jobs runs into the job_run_details table	on

Parameter name	Description	Default
<code>cron.log_statement</code>	Log all cron statements prior to execution.	off
<code>cron.max_running_jobs</code>	Maximum number of jobs that can run concurrently.	5
<code>cron.use_background_workers</code>	Enables background workers for <code>pg_cron</code>	on
<code>cursor_tuple_fraction</code>	Sets the planners estimate of the fraction of a cursors rows that will be retrieved.	–
<code>db_user_namespace</code>	Enables per-database user names.	–
<code>deadlock_timeout</code>	(ms) Sets the time to wait on a lock before checking for deadlock.	–
<code>debug_pretty_print</code>	Indents parse and plan tree displays.	–
<code>debug_print_parse</code>	Logs each querys parse tree.	–
<code>debug_print_plan</code>	Logs each querys execution plan.	–
<code>debug_print_rewritten</code>	Logs each querys rewritten parse tree.	–
<code>default_statistics_target</code>	Sets the default statistics target.	–
<code>default_transaction_deferrable</code>	Sets the default deferrable status of new transactions.	–
<code>default_transaction_isolation</code>	Sets the transaction isolation level of each new transaction.	–
<code>default_transaction_read_only</code>	Sets the default read-only status of new transactions.	–

Parameter name	Description	Default
effective_cache_size	(8kB Sets the planners assumption about the size of the disk cache.	SUM(DBInstanceClassMemory/12038,-50003
effective_io_concurrency	Number of simultaneous requests that can be handled efficiently by the disk subsystem.	–
enable_async_append	Enables the planners use of async append plans.	–
enable_bitmapscan	Enables the planners use of bitmap-scan plans.	–
enable_gathermerge	Enables the planners use of gather merge plans.	–
enable_hashagg	Enables the planners use of hashed aggregation plans.	–
enable_hashjoin	Enables the planners use of hash join plans.	–
enable_incremental_sort	Enables the planners use of incremental sort steps.	–
enable_indexonlyscan	Enables the planners use of index-only-scan plans.	–
enable_indexscan	Enables the planners use of index-scan plans.	–
enable_material	Enables the planners use of materialization.	–
enable_memoize	Enables the planners use of memoization	–
enable_mergejoin	Enables the planners use of merge join plans.	–
enable_nestloop	Enables the planners use of nested-loop join plans.	–

Parameter name	Description	Default
enable_parallel_append	Enables the planners use of parallel append plans.	–
enable_parallel_hash	Enables the planners user of parallel hash plans.	–
enable_partition_pruning	Enable plan-time and run-time partition pruning.	–
enable_partitionwise_aggregate	Enables partitionwise aggregation and grouping.	–
enable_partitionwise_join	Enables partitionwise join.	–
enable_seqscan	Enables the planners use of sequential-scan plans.	–
enable_sort	Enables the planners use of explicit sort steps.	–
enable_tidscan	Enables the planners use of TID scan plans.	–
escape_string_warning	Warn about backslash escapes in ordinary string literals.	–
exit_on_error	Terminate session on any error.	–
force_parallel_mode	Forces use of parallel query facilities.	–
from_collapse_limit	Sets the FROM-list size beyond which subqueries are not collapsed.	–
geqo	Enables genetic query optimization.	–
geqo_effort	GEQO: effort is used to set the default for other GEQO parameters.	–
geqo_generations	GEQO: number of iterations of the algorithm.	–

Parameter name	Description	Default
geqo_pool_size	GEQO: number of individuals in the population.	–
geqo_seed	GEQO: seed for random path selection.	–
geqo_selection_bias	GEQO: selective pressure within the population.	–
geqo_threshold	Sets the threshold of FROM items beyond which GEQO is used.	–
gin_fuzzy_search_limit	Sets the maximum allowed result for exact search by GIN.	–
gin_pending_list_limit	(kB Sets the maximum size of the pending list for GIN index.	–
hash_mem_multiplier	Multiple of work_mem to use for hash tables.	–
hba_file	Sets the servers hba configuration file.	/rdsdbdata/config/pg_hba.conf
hot_standby_feedback	Allows feedback from a hot standby to the primary that will avoid query conflicts.	on
ident_file	Sets the servers ident configuration file.	/rdsdbdata/config/pg_ident.conf
idle_in_transaction_session_timeout	(ms Sets the maximum allowed duration of any idling transaction.	86400000
idle_session_timeout	Terminate any session that has been idle (that is, waiting for a client query, but not within an open transaction, for longer than the specified amount of time	–
join_collapse_limit	Sets the FROM-list size beyond which JOIN constructs are not flattened.	–

Parameter name	Description	Default
lc_messages	Sets the language in which messages are displayed.	–
listen_addresses	Sets the host name or IP address(es to listen to.	*
lo_compat_privileges	Enables backward compatibility mode for privilege checks on large objects.	0
log_connections	Logs each successful connection.	–
log_destination	Sets the destination for server log output.	stderr
log_directory	Sets the destination directory for log files.	/rdsdbdata/log/error
log_disconnections	Logs end of a session, including duration.	–
log_duration	Logs the duration of each completed SQL statement.	–
log_error_verbosity	Sets the verbosity of logged messages.	–
log_executor_stats	Writes executor performance statistics to the server log.	–
log_file_mode	Sets the file permissions for log files.	0644
log_filename	Sets the file name pattern for log files.	postgresql.log.%Y-%m-%d-%H%M
logging_collector	Start a subprocess to capture stderr output and/or csvlogs into log files.	1
log_hostname	Logs the host name in the connection logs.	0
logical_decoding_work_mem	(kB This much memory can be used by each internal reorder buffer before spilling to disk.	–
log_line_prefix	Controls information prefixed to each log line.	%t:%r:%u@%d:%p]:

Parameter name	Description	Default
log_lock_waits	Logs long lock waits.	–
log_min_duration_sample	(ms Sets the minimum execution time above which a sample of statements will be logged. Sampling is determined by log_statement_sample_rate.	–
log_min_duration_statement	(ms Sets the minimum execution time above which statements will be logged.	–
log_min_error_statement	Causes all statements generating error at or above this level to be logged.	–
log_min_messages	Sets the message levels that are logged.	–
log_parameter_max_length	(B When logging statements, limit logged parameter values to first N bytes.	–
log_parameter_max_length_on_error	(B When reporting an error, limit logged parameter values to first N bytes.	–
log_parser_stats	Writes parser performance statistics to the server log.	–
log_planner_stats	Writes planner performance statistics to the server log.	–
log_replication_commands	Logs each replication command.	–
log_rotation_age	(min Automatic log file rotation will occur after N minutes.	60
log_rotation_size	(kB Automatic log file rotation will occur after N kilobytes.	100000
log_statement	Sets the type of statements logged.	–

Parameter name	Description	Default
log_statement_sample_rate	Fraction of statements exceeding log_min_duration_sample to be logged.	–
log_statement_stats	Writes cumulative performance statistics to the server log.	–
log_temp_files	(kB Log the use of temporary files larger than this number of kilobytes.	–
log_timezone	Sets the time zone to use in log messages.	UTC
log_truncate_on_rotation	Truncate existing log files of same name during log rotation.	0
maintenance_io_concurrency	A variant of effective_io_concurrency that is used for maintenance work.	1
maintenance_work_mem	(kB Sets the maximum memory to be used for maintenance operations.	GREATEST(DBInstanceClassMemory/63963136*1024,65536
max_connections	Sets the maximum number of concurrent connections.	LEAST(DBInstanceClassMemory/9531392,5000
max_files_per_process	Sets the maximum number of simultaneously open files for each server process.	–
max_locks_per_transaction	Sets the maximum number of locks per transaction.	64
max_parallel_maintenance_workers	Sets the maximum number of parallel processes per maintenance operation.	–
max_parallel_workers	Sets the maximum number of parallel workers than can be active at one time.	GREATEST(\$DBInstanceVCPU/2,8

Parameter name	Description	Default
max_parallel_workers_per_gather	Sets the maximum number of parallel processes per executor node.	–
max_pred_locks_per_page	Sets the maximum number of predicate-locked tuples per page.	–
max_pred_locks_per_relation	Sets the maximum number of predicate-locked pages and tuples per relation.	–
max_pred_locks_per_transaction	Sets the maximum number of predicate locks per transaction.	–
max_slot_wal_keep_size	(MB Replication slots will be marked as failed, and segments released for deletion or recycling, if this much space is occupied by WAL on disk.	–
max_stack_depth	(kB Sets the maximum stack depth, in kilobytes.	6144
max_standby_streaming_delay	(ms Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.	14000
max_worker_processes	Sets the maximum number of concurrent worker processes.	GREATEST(\$DBInstanceVCPU*2,8
min_dynamic_shared_memory	(MB Amount of dynamic shared memory reserved at startup.	–
min_parallel_index_scan_size	(8kB Sets the minimum amount of index data for a parallel scan.	–
min_parallel_table_scan_size	(8kB Sets the minimum amount of table data for a parallel scan.	–

Parameter name	Description	Default
old_snapshot_threshold	(min Time before a snapshot is too old to read pages changed after the snapshot was taken.	–
parallel_leader_participation	Controls whether Gather and Gather Merge also run subplans.	–
parallel_setup_cost	Sets the planners estimate of the cost of starting up worker processes for parallel query.	–
parallel_tuple_cost	Sets the planners estimate of the cost of passing each tuple (row from worker to master backend.	–
pgaudit.log	Specifies which classes of statements will be logged by session audit logging.	–
pgaudit.log_catalog	Specifies that session logging should be enabled in the case where all relations in a statement are in pg_catalog.	–
pgaudit.log_level	Specifies the log level that will be used for log entries.	–
pgaudit.log_parameter	Specifies that audit logging should include the parameters that were passed with the statement.	–
pgaudit.log_relation	Specifies whether session audit logging should create a separate log entry for each relation (TABLE, VIEW, etc. referenced in a SELECT or DML statement.	–
pgaudit.log_statement_once	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.	–

Parameter name	Description	Default
pgaudit.role	Specifies the master role to use for object audit logging.	–
pg_bigm.enable_recheck	It specifies whether to perform Recheck which is an internal process of full text search.	on
pg_bigm.gin_key_limit	It specifies the maximum number of 2-grams of the search keyword to be used for full text search.	0
pg_bigm.last_update	It reports the last updated date of the pg_bigm module.	2013.11.22
pg_bigm.similarity_limit	It specifies the minimum threshold used by the similarity search.	0.3
pg_hint_plan.debug_print	Logs results of hint parsing.	–
pg_hint_plan.enable_hint	Force planner to use plans specified in the hint comment preceding to the query.	–
pg_hint_plan.enable_hint_table	Force planner to not get hint by using table lookups.	–
pg_hint_plan.message_level	Message level of debug messages.	–
pg_hint_plan.parse_messages	Message level of parse errors.	–
pglogical.batch_inserts	Batch inserts if possible	–
pglogical.conflict_log_level	Sets log level used for logging resolved conflicts.	–

Parameter name	Description	Default
pglogical.conflict_resolution	Sets method used for conflict resolution for resolvable conflicts.	–
pglogical.extra_connection_options	connection options to add to all peer node connections	–
pglogical.synchronous_commit	pglogical specific synchronous commit value	–
pglogical.use_spi	Use SPI instead of low-level API for applying changes	–
pg_similarity.block_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.block_threshold	Sets the threshold used by the Block similarity function.	–
pg_similarity.block_tokenizer	Sets the tokenizer for Block similarity function.	–
pg_similarity.cosine_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.cosine_threshold	Sets the threshold used by the Cosine similarity function.	–
pg_similarity.cosine_tokenizer	Sets the tokenizer for Cosine similarity function.	–
pg_similarity.dice_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.dice_threshold	Sets the threshold used by the Dice similarity measure.	–
pg_similarity.dice_tokenizer	Sets the tokenizer for Dice similarity measure.	–

Parameter name	Description	Default
pg_similarity.euclidean_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.euclidean_threshold	Sets the threshold used by the Euclidean similarity measure.	–
pg_similarity.euclidean_tokenizer	Sets the tokenizer for Euclidean similarity measure.	–
pg_similarity.hamming_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.hamming_threshold	Sets the threshold used by the Block similarity metric.	–
pg_similarity.jaccard_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jaccard_threshold	Sets the threshold used by the Jaccard similarity measure.	–
pg_similarity.jaccard_tokenizer	Sets the tokenizer for Jaccard similarity measure.	–
pg_similarity.jaro_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jaro_threshold	Sets the threshold used by the Jaro similarity measure.	–
pg_similarity.jaro_winkler_is_normalized	Sets if the result value is normalized or not.	–
pg_similarity.jaro_winkler_threshold	Sets the threshold used by the Jarowinkler similarity measure.	–

Parameter name	Description	Default
<code>pg_similarity.levenshtein_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.levenshtein_threshold</code>	Sets the threshold used by the Levenshtein similarity measure.	–
<code>pg_similarity.matching_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.matching_threshold</code>	Sets the threshold used by the Matching Coefficient similarity measure.	–
<code>pg_similarity.matching_tokenizer</code>	Sets the tokenizer for Matching Coefficient similarity measure.	–
<code>pg_similarity.mongeeelkan_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.mongeeelkan_threshold</code>	Sets the threshold used by the Monge-Elkan similarity measure.	–
<code>pg_similarity.mongeeelkan_tokenizer</code>	Sets the tokenizer for Monge-Elkan similarity measure.	–
<code>pg_similarity.nw_gap_penalty</code>	Sets the gap penalty used by the Needleman-Wunsch similarity measure.	–
<code>pg_similarity.nw_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.nw_threshold</code>	Sets the threshold used by the Needleman-Wunsch similarity measure.	–
<code>pg_similarity.overlap_is_normalized</code>	Sets if the result value is normalized or not.	–

Parameter name	Description	Default
<code>pg_similarity.overlap_threshold</code>	Sets the threshold used by the Overlap Coefficient similarity measure.	–
<code>pg_similarity.overlap_tokenizer</code>	Sets the tokenizer for Overlap Coefficient similarity measure.	–
<code>pg_similarity.qgram_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.qgram_threshold</code>	Sets the threshold used by the Q-Gram similarity measure.	–
<code>pg_similarity.qgram_tokenizer</code>	Sets the tokenizer for Q-Gram measure.	–
<code>pg_similarity.swg_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.swg_threshold</code>	Sets the threshold used by the Smith-Waterman-Gotoh similarity measure.	–
<code>pg_similarity.sw_is_normalized</code>	Sets if the result value is normalized or not.	–
<code>pg_similarity.sw_threshold</code>	Sets the threshold used by the Smith-Waterman similarity measure.	–
<code>pg_stat_statements.max</code>	Sets the maximum number of statements tracked by <code>pg_stat_statements</code> .	–
<code>pg_stat_statements.save</code>	Save <code>pg_stat_statements</code> statistics across server shutdowns.	–
<code>pg_stat_statements.track</code>	Selects which statements are tracked by <code>pg_stat_statements</code> .	–
<code>pg_stat_statements.track_planning</code>	Selects whether planning duration is tracked by <code>pg_stat_statements</code> .	–

Parameter name	Description	Default
pg_stat_statements.track_utility	Selects whether utility commands are tracked by pg_stat_statements.	–
postgis.gdal_enabled_drivers	Enable or disable GDAL drivers used with PostGIS in Postgres 9.3.5 and above.	ENABLE_ALL
quote_all_identifiers	When generating SQL fragments, quote all identifiers.	–
random_page_cost	Sets the planners estimate of the cost of a nonsequentially fetched disk page.	–
rds.enable_memory_management	Improves memory management capabilities in Aurora PostgreSQL 12.17, 13.13, 14.10, 15.5, and higher versions that prevents stability issues and database restarts caused by insufficient free memory. For more information, see <a href="#">Improved memory management in Aurora PostgreSQL</a> .	True
rds.force_admin_logging_level	See log messages for RDS admin user actions in customer databases.	–
rds.log_retention_period	Amazon RDS will delete PostgreSQL log that are older than N minutes.	4320
rds.memory_allocation_guard	Improves memory management capabilities in Aurora PostgreSQL 11.21, 12.16, 13.12, 14.9, 15.4, and older versions that prevents stability issues and database restarts caused by insufficient free memory. For more information, see <a href="#">Improved memory management in Aurora PostgreSQL</a> .	False
rds.pg_stat_ramdisk_size	Size of the stats ramdisk in MB. A nonzero value will setup the ramdisk.	0

Parameter name	Description	Default
rds.rds_superuser_reserved_connections	Sets the number of connection slots reserved for rds_superuser. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation <a href="#">reserved connections</a> .	2
rds.superuser_variables	List of superuser-only variables for which we elevate rds_superuser modification statements.	session_replication_role
remove_temp_files_after_crash	Remove temporary files after backend crash.	0
restart_after_crash	Reinitialize server after backend crash.	–
row_security	Enable row security.	–
search_path	Sets the schema search order for names that are not schema-qualified.	–
seq_page_cost	Sets the planner's estimate of the cost of a sequentially fetched disk page.	–
session_replication_role	Sets the sessions behavior for triggers and rewrite rules.	–
shared_buffers	(8kB) Sets the number of shared memory buffers used by the server.	SUM(DBInstanceClassMemory/12038,-50003)
shared_preload_libraries	Lists shared libraries to preload into server.	pg_stat_statements
ssl_ca_file	Location of the SSL server authority file.	/rdsdbdata/rds-metadata/ca-cert.pem

Parameter name	Description	Default
ssl_cert_file	Location of the SSL server certificate file.	/rdsdbdata/rds-met adata/server-cert. pem
ssl_crl_dir	Location of the SSL certificate revocation list directory.	/rdsdbdata/rds-met adata/ssl_crl_dir/
ssl_key_file	Location of the SSL server private key file	/rdsdbdata/rds-met adata/server-key.pem
standard_conforming_strings	Causes ... strings to treat backslashes literally.	–
statement_timeout	(ms Sets the maximum allowed duration of any statement.	–
stats_temp_directory	Writes temporary statistics files to the specified directory.	/rdsdbdata/db/pg_s tat_tmp
superuser_reserved_connections	Sets the number of connection slots reserved for superusers.	3
synchronize_seqscans	Enable synchronized sequential scans.	–
tcp_keepalives_count	Maximum number of TCP keepalive retransmits.	–
tcp_keepalives_idle	(s Time between issuing TCP keepalives.	–
tcp_keepalives_interval	(s Time between TCP keepalive retransmits.	–
temp_buffers	(8kB Sets the maximum number of temporary buffers used by each session.	–

Parameter name	Description	Default
temp_file_limit	Constrains the total amount disk space in kilobytes that a given PostgreSQL process can use for temporary files, excluding space used for explicit temporary tables	-1
temp_tablespaces	Sets the tablespace(s to use for temporary tables and sort files.	–
track_activities	Collects information about executing commands.	–
track_activity_query_size	Sets the size reserved for pg_stat_activity.current_query, in bytes.	4096
track_counts	Collects statistics on database activity.	–
track_functions	Collects function-level statistics on database activity.	pl
track_io_timing	Collects timing statistics on database IO activity.	1
transform_null_equals	Treats expr= as expr IS .	–
update_process_title	Updates the process title to show the active SQL command.	–
wal_receiver_status_interval	(s Sets the maximum interval between WAL receiver status reports to the primary.	–
work_mem	(kB Sets the maximum memory to be used for query workspaces.	–
xmlbinary	Sets how binary values are to be encoded in XML.	–

Parameter name	Description	Default
xmloption	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.	–

## Amazon Aurora PostgreSQL wait events

The following are common wait events for Aurora PostgreSQL. To learn more about wait events and tuning your Aurora PostgreSQL DB cluster, see [Tuning with wait events for Aurora PostgreSQL](#).

### Activity:ArchiverMain

The archiver process is waiting for activity.

### Activity:AutoVacuumMain

The autovacuum launcher process is waiting for activity.

### Activity:BgWriterHibernate

The background writer process is hibernating while waiting for activity.

### Activity:BgWriterMain

The background writer process is waiting for activity.

### Activity:CheckpointMain

The checkpoint process is waiting for activity.

### Activity:LogicalApplyMain

The logical replication apply process is waiting for activity.

### Activity:LogicalLauncherMain

The logical replication launcher process is waiting for activity.

### Activity:PgStatMain

The statistics collector process is waiting for activity.

### Activity:RecoveryWalAll

A process is waiting for the write-ahead log (WAL) from a stream at recovery.

**Activity:RecoveryWalStream**

The startup process is waiting for the write-ahead log (WAL) to arrive during streaming recovery.

**Activity:SysLoggerMain**

The sysloger process is waiting for activity.

**Activity:WalReceiverMain**

The write-ahead log (WAL) receiver process is waiting for activity.

**Activity:WalSenderMain**

The write-ahead log (WAL) sender process is waiting for activity.

**Activity:WalWriterMain**

The write-ahead log (WAL) writer process is waiting for activity.

**BufferPin:BufferPin**

A process is waiting to acquire an exclusive pin on a buffer.

**Client:GSSOpenServer**

A process is waiting to read data from the client while establishing a Generic Security Service Application Program Interface (GSSAPI) session.

**Client:ClientRead**

A backend process is waiting to receive data from a PostgreSQL client. For more information, see [Client:ClientRead](#).

**Client:ClientWrite**

A backend process is waiting to send more data to a PostgreSQL client. For more information, see [Client:ClientWrite](#).

**Client:LibPQWalReceiverConnect**

A process is waiting in the write-ahead log (WAL) receiver to establish connection to remote server.

**Client:LibPQWalReceiverReceive**

A process is waiting in the write-ahead log (WAL) receiver to receive data from remote server.

**Client:SSLOpenServer**

A process is waiting for Secure Sockets Layer (SSL) while attempting connection.

**Client:WalReceiverWaitStart**

A process is waiting for startup process to send initial data for streaming replication.

**Client:WalSenderWaitForWAL**

A process is waiting for the write-ahead log (WAL) to be flushed in the WAL sender process.

**Client:WalSenderWriteData**

A process is waiting for any activity when processing replies from the write-ahead log (WAL) receiver in the WAL sender process.

**CPU**

A backend process is active in or is waiting for CPU. For more information, see [CPU](#).

**Extension:extension**

A backend process is waiting for a condition defined by an extension or module.

**IO:AuroraEnhancedLogicalWALRead**

A backend process is fetching log records from the change data capture (CDC) volume.

**IO:AuroraOptimizedReadsCacheRead**

A process is waiting for a read from Optimized Reads tiered cache because the page isn't available in shared memory.

**IO:AuroraOptimizedReadsCacheSegmentTruncate**

A process is waiting for an Optimized Reads tiered cache segment file to be truncated.

**IO:AuroraOptimizedReadsCacheWrite**

The background writer process is waiting to write in Optimized Reads tiered cache.

**IO:AuroraStorageLogAllocate**

A session is allocating metadata and preparing for a transaction log write.

**IO:BufFileRead**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations read from the temporary files. For more information, see [IO:BufFileRead and IO:BufFileWrite](#).

**IO:BufFileWrite**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations write to the temporary files. For more information, see [IO:BufFileRead and IO:BufFileWrite](#).

**IO:ControlFileRead**

A process is waiting for a read from the `pg_control` file.

**IO:ControlFileSync**

A process is waiting for the `pg_control` file to reach durable storage.

**IO:ControlFileSyncUpdate**

A process is waiting for an update to the `pg_control` file to reach durable storage.

**IO:ControlFileWrite**

A process is waiting for a write to the `pg_control` file.

**IO:ControlFileWriteUpdate**

A process is waiting for a write to update the `pg_control` file.

**IO:CopyFileRead**

A process is waiting for a read during a file copy operation.

**IO:CopyFileWrite**

A process is waiting for a write during a file copy operation.

**IO:DataFileExtend**

A process is waiting for a relation data file to be extended.

**IO:DataFileFlush**

A process is waiting for a relation data file to reach durable storage.

**IO:DataFileImmediateSync**

A process is waiting for an immediate synchronization of a relation data file to durable storage.

**IO:DataFilePrefetch**

A process is waiting for an asynchronous prefetch from a relation data file.

**IO:DataFileSync**

A process is waiting for changes to a relation data file to reach durable storage.

**IO:DataFileRead**

A backend process tried to find a page in the shared buffers, didn't find it, and so read it from storage. For more information, see [IO:DataFileRead](#).

**IO:DataFileTruncate**

A process is waiting for a relation data file to be truncated.

**IO:DataFileWrite**

A process is waiting for a write to a relation data file.

**IO:DSMFillZeroWrite**

A process is waiting to write zero bytes to a dynamic shared memory backing file.

**IO:LockFileAddToDataDirRead**

A process is waiting for a read while adding a line to the data directory lock file.

**IO:LockFileAddToDataDirSync**

A process is waiting for data to reach durable storage while adding a line to the data directory lock file.

**IO:LockFileAddToDataDirWrite**

A process is waiting for a write while adding a line to the data directory lock file.

**IO:LockFileCreateRead**

A process is waiting to read while creating the data directory lock file.

**IO:LockFileCreateSync**

A process is waiting for data to reach durable storage while creating the data directory lock file.

**IO:LockFileCreateWrite**

A process is waiting for a write while creating the data directory lock file.

**IO:LockFileReCheckDataDirRead**

A process is waiting for a read during recheck of the data directory lock file.

**IO:LogicalRewriteCheckpointSync**

A process is waiting for logical rewrite mappings to reach durable storage during a checkpoint.

**IO:LogicalRewriteMappingSync**

A process is waiting for mapping data to reach durable storage during a logical rewrite.

**IO:LogicalRewriteMappingWrite**

A process is waiting for a write of mapping data during a logical rewrite.

**IO:LogicalRewriteSync**

A process is waiting for logical rewrite mappings to reach durable storage.

**IO:LogicalRewriteTruncate**

A process is waiting for the truncation of mapping data during a logical rewrite.

**IO:LogicalRewriteWrite**

A process is waiting for a write of logical rewrite mappings.

**IO:RelationMapRead**

A process is waiting for a read of the relation map file.

**IO:RelationMapSync**

A process is waiting for the relation map file to reach durable storage.

**IO:RelationMapWrite**

A process is waiting for a write to the relation map file.

**IO:ReorderBufferRead**

A process is waiting for a read during reorder buffer management.

**IO:ReorderBufferWrite**

A process is waiting for a write during reorder buffer management.

**IO:ReorderLogicalMappingRead**

A process is waiting for a read of a logical mapping during reorder buffer management.

**IO:ReplicationSlotRead**

A process is waiting for a read from a replication slot control file.

**IO:ReplicationSlotRestoreSync**

A process is waiting for a replication slot control file to reach durable storage while restoring it to memory.

**IO:ReplicationSlotSync**

A process is waiting for a replication slot control file to reach durable storage.

**IO:ReplicationSlotWrite**

A process is waiting for a write to a replication slot control file.

**IO:SLRUFlushSync**

A process is waiting for simple least-recently used (SLRU) data to reach durable storage during a checkpoint or database shutdown.

**IO:SLRURead**

A process is waiting for a read of a simple least-recently used (SLRU) page.

**IO:SLRUSync**

A process is waiting for simple least-recently used (SLRU) data to reach durable storage following a page write.

**IO:SLRUWrite**

A process is waiting for a write of a simple least-recently used (SLRU) page.

**IO:SnapbuildRead**

A process is waiting for a read of a serialized historical catalog snapshot.

**IO:SnapbuildSync**

A process is waiting for a serialized historical catalog snapshot to reach durable storage.

**IO:SnapbuildWrite**

A process is waiting for a write of a serialized historical catalog snapshot.

**IO:TimelineHistoryFileSync**

A process is waiting for a timeline history file received through streaming replication to reach durable storage.

**IO:TimelineHistoryFileWrite**

A process is waiting for a write of a timeline history file received through streaming replication.

**IO:TimelineHistoryRead**

A process is waiting for a read of a timeline history file.

**IO:TimelineHistorySync**

A process is waiting for a newly created timeline history file to reach durable storage.

**IO:TimelineHistoryWrite**

A process is waiting for a write of a newly created timeline history file.

**IO:TwophaseFileRead**

A process is waiting for a read of a two phase state file.

**IO:TwophaseFileSync**

A process is waiting for a two phase state file to reach durable storage.

**IO:TwophaseFileWrite**

A process is waiting for a write of a two phase state file.

**IO:WALBootstrapSync**

A process is waiting for the write-ahead log (WAL) to reach durable storage during bootstrapping.

**IO:WALBootstrapWrite**

A process is waiting for a write of a write-ahead log (WAL) page during bootstrapping.

**IO:WALCopyRead**

A process is waiting for a read when creating a new write-ahead log (WAL) segment by copying an existing one.

**IO:WALCopySync**

A process is waiting for a new write-ahead log (WAL) segment created by copying an existing one to reach durable storage.

**IO:WALCopyWrite**

A process is waiting for a write when creating a new write-ahead log (WAL) segment by copying an existing one.

**IO:WALInitSync**

A process is waiting for a newly initialized write-ahead log (WAL) file to reach durable storage.

**IO:WALInitWrite**

A process is waiting for a write while initializing a new write-ahead log (WAL) file.

**IO:WALRead**

A process is waiting for a read from a write-ahead log (WAL) file.

**IO:WALSenderTimelineHistoryRead**

A process is waiting for a read from a timeline history file during a WAL sender timeline command.

**IO:WALSync**

A process is waiting for a write-ahead log (WAL) file to reach durable storage.

**IO:WALSyncMethodAssign**

A process is waiting for data to reach durable storage while assigning a new write-ahead log (WAL) sync method.

**IO:WALWrite**

A process is waiting for a write to a write-ahead log (WAL) file.

**IO:XactSync**

A backend process is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. For more information, see [IO:XactSync](#).

**IPC:AuroraLogicalSchemaUpdate**

Two backend processes are attempting to insert the same entry into the schema cache. One process will continue while the other waits for it to complete.

**IPC:AuroraOptimizedReadsCacheWriteStop**

A process is waiting for the background writer to stop writing into Optimized Reads tiered cache.

**IPC:BackupWaitWalArchive**

A process is waiting for write-ahead log (WAL) files required for a backup to be successfully archived.

**IPC:BgWorkerShutdown**

A process is waiting for a background worker to shut down.

**IPC:BgWorkerStartup**

A process is waiting for a background worker to start.

**IPC:BtreePage**

A process is waiting for the page number needed to continue a parallel B-tree scan to become available.

**IPC:CheckpointDone**

A process is waiting for a checkpoint to complete.

**IPC:CheckpointStart**

A process is waiting for a checkpoint to start.

**IPC:ClogGroupUpdate**

A process is waiting for the group leader to update the transaction status at a transaction's end.

**IPC:DamRecordTxAck**

A backend process has generated a database activity streams event and is waiting for the event to become durable. For more information, see [IPC:DamRecordTxAck](#).

**IPC:ExecuteGather**

A process is waiting for activity from a child process while executing a Gather plan node.

**IPC:Hash/Batch/Allocating**

A process is waiting for an elected parallel hash participant to allocate a hash table.

**IPC:Hash/Batch/Electing**

A process is electing a parallel hash participant to allocate a hash table.

**IPC:Hash/Batch/Loading**

A process is waiting for other parallel hash participants to finish loading a hash table.

**IPC:Hash/Build/Allocating**

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

**IPC:Hash/Build/Electing**

A process is electing a parallel hash participant to allocate the initial hash table.

**IPC:Hash/Build/HashingInner**

A process is waiting for other parallel hash participants to finish hashing the inner relation.

**IPC:Hash/Build/HashingOuter**

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

**IPC:Hash/GrowBatches/Allocating**

A process is waiting for an elected parallel hash participant to allocate more batches.

**IPC:Hash/GrowBatches/Deciding**

A process is electing a parallel hash participant to decide on future batch growth.

**IPC:Hash/GrowBatches/Electing**

A process is electing a parallel hash participant to allocate more batches.

**IPC:Hash/GrowBatches/Finishing**

A process is waiting for an elected parallel hash participant to decide on future batch growth.

**IPC:Hash/GrowBatches/Repartitioning**

A process is waiting for other parallel hash participants to finishing repartitioning.

**IPC:Hash/GrowBuckets/Allocating**

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

**IPC:Hash/GrowBuckets/Electing**

A process is electing a parallel hash participant to allocate more buckets.

**IPC:Hash/GrowBuckets/Reinserting**

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

**IPC:HashBatchAllocate**

A process is waiting for an elected parallel hash participant to allocate a hash table.

**IPC:HashBatchElect**

A process is waiting to elect a parallel hash participant to allocate a hash table.

**IPC:HashBatchLoad**

A process is waiting for other parallel hash participants to finish loading a hash table.

**IPC:HashBuildAllocate**

A process is waiting for an elected parallel hash participant to allocate the initial hash table.

**IPC:HashBuildElect**

A process is waiting to elect a parallel hash participant to allocate the initial hash table.

**IPC:HashBuildHashInner**

A process is waiting for other parallel hash participants to finish hashing the inner relation.

**IPC:HashBuildHashOuter**

A process is waiting for other parallel hash participants to finish partitioning the outer relation.

**IPC:HashGrowBatchesAllocate**

A process is waiting for an elected parallel hash participant to allocate more batches.

**IPC:HashGrowBatchesDecide**

A process is waiting to elect a parallel hash participant to decide on future batch growth.

**IPC:HashGrowBatchesElect**

A process is waiting to elect a parallel hash participant to allocate more batches.

**IPC:HashGrowBatchesFinish**

A process is waiting for an elected parallel hash participant to decide on future batch growth.

**IPC:HashGrowBatchesRepartition**

A process is waiting for other parallel hash participants to finish repartitioning.

**IPC:HashGrowBucketsAllocate**

A process is waiting for an elected parallel hash participant to finish allocating more buckets.

**IPC:HashGrowBucketsElect**

A process is waiting to elect a parallel hash participant to allocate more buckets.

**IPC:HashGrowBucketsReinsert**

A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

**IPC:LogicalSyncData**

A process is waiting for a logical replication remote server to send data for initial table synchronization.

**IPC:LogicalSyncStateChange**

A process is waiting for a logical replication remote server to change state.

**IPC:MessageQueueInternal**

A process is waiting for another process to be attached to a shared message queue.

**IPC:MessageQueuePutMessage**

A process is waiting to write a protocol message to a shared message queue.

**IPC:MessageQueueReceive**

A process is waiting to receive bytes from a shared message queue.

**IPC:MessageQueueSend**

A process is waiting to send bytes to a shared message queue.

**IPC:ParallelBitmapScan**

A process is waiting for a parallel bitmap scan to become initialized.

**IPC:ParallelCreateIndexScan**

A process is waiting for parallel CREATE INDEX workers to finish a heap scan.

**IPC:ParallelFinish**

A process is waiting for parallel workers to finish computing.

**IPC:ProcArrayGroupUpdate**

A process is waiting for the group leader to clear the transaction ID at transaction end.

**IPC:ProcSignalBarrier**

A process is waiting for a barrier event to be processed by all backends.

**IPC:Promote**

A process is waiting for standby promotion.

**IPC:RecoveryConflictSnapshot**

A process is waiting for recovery conflict resolution for a vacuum cleanup.

**IPC:RecoveryConflictTablespace**

A process is waiting for recovery conflict resolution for dropping a tablespace.

**IPC:RecoveryPause**

A process is waiting for recovery to be resumed.

**IPC:ReplicationOriginDrop**

A process is waiting for a replication origin to become inactive so it can be dropped.

**IPC:ReplicationSlotDrop**

A process is waiting for a replication slot to become inactive so it can be dropped.

**IPC:SafeSnapshot**

A process is waiting to obtain a valid snapshot for a READ ONLY DEFERRABLE transaction.

**IPC:SyncRep**

A process is waiting for confirmation from a remote server during synchronous replication.

**IPC:XactGroupUpdate**

A process is waiting for the group leader to update the transaction status at transaction end.

**Lock:advisory**

A backend process requested an advisory lock and is waiting for it. For more information, see [Lock:advisory](#).

**Lock:extend**

A backend process is waiting for a lock to be released so that it can extend a relation. This lock is needed because only one backend process can extend a relation at a time. For more information, see [Lock:extend](#).

**Lock:frozenid**

A process is waiting to update `pg_database.datfrozenxid` and `pg_database.datminmxid`.

**Lock:object**

A process is waiting to get a lock on a nonrelation database object.

**Lock:page**

A process is waiting to get a lock on a page of a relation.

**Lock:Relation**

A backend process is waiting to acquire a lock on a relation that is locked by another transaction. For more information, see [Lock:Relation](#).

**Lock:spectoken**

A process is waiting to get a speculative insertion lock.

**Lock:speculative token**

A process is waiting to acquire a speculative insertion lock.

**Lock:transactionid**

A transaction is waiting for a row-level lock. For more information, see [Lock:transactionid](#).

**Lock:tuple**

A backend process is waiting to acquire a lock on a tuple while another backend process holds a conflicting lock on the same tuple. For more information, see [Lock:tuple](#).

**Lock:userlock**

A process is waiting to get a user lock.

**Lock:virtualxid**

A process is waiting to get a virtual transaction ID lock.

**LWLock:AddinShmemInit**

A process is waiting to manage an extension's space allocation in shared memory.

**LWLock:AddinShmemInitLock**

A process is waiting to manage space allocation in shared memory.

**LWLock:async**

A process is waiting for I/O on an async (notify) buffer.

**LWLock:AsyncCtlLock**

A process is waiting to read or update a shared notification state.

**LWLock:AsyncQueueLock**

A process is waiting to read or update notification messages.

**LWLock:AuroraOptimizedReadsCacheMapping**

A process is waiting to associate a data block with a page in the Optimized Reads tiered cache.

**LWLock:AutoFile**

A process is waiting to update the `postgresql.auto.conf` file.

**LWLock:AutoFileLock**

A process is waiting to update the `postgresql.auto.conf` file.

**LWLock:Autovacuum**

A process is waiting to read or update the current state of autovacuum workers.

**LWLock:AutovacuumLock**

An autovacuum worker or launcher is waiting to update or read the current state of autovacuum workers.

**LWLock:AutovacuumSchedule**

A process is waiting to ensure that a table selected for autovacuum still needs vacuuming.

**LWLock:AutovacuumScheduleLock**

A process is waiting to ensure that the table it has selected for a vacuum still needs vacuuming.

**LWLock:BackendRandomLock**

A process is waiting to generate a random number.

**LWLock:BackgroundWorker**

A process is waiting to read or update background worker state.

**LWLock:BackgroundWorkerLock**

A process is waiting to read or update the background worker state.

**LWLock:BtreeVacuum**

A process is waiting to read or update vacuum-related information for a B-tree index.

**LWLock:BtreeVacuumLock**

A process is waiting to read or update vacuum-related information for a B-tree index.

**LWLock:buffer\_content**

A backend process is waiting to acquire a lightweight lock on the contents of a shared memory buffer. For more information, see [LWLock:buffer\\_content \(BufferContent\)](#).

**LWLock:buffer\_mapping**

A backend process is waiting to associate a data block with a buffer in the shared buffer pool. For more information, see [LWLock:buffer\\_mapping](#).

**LWLock:BufferIO**

A backend process wants to read a page into shared memory. The process is waiting for other processes to finish their I/O for the page. For more information, see [LWLock:BufferIO \(IPC:BufferIO\)](#).

**LWLock:Checkpoint**

A process is waiting to begin a checkpoint.

**LWLock:CheckpointLock**

A process is waiting to perform checkpoint.

**LWLock:CheckpointerComm**

A process is waiting to manage fsync requests.

**LWLock:CheckpointerCommLock**

A process is waiting to manage fsync requests.

**LWLock:clog**

A process is waiting for I/O on a clog (transaction status) buffer.

**LWLock:CLogControlLock**

A process is waiting to read or update transaction status.

**LWLock:CLogTruncationLock**

A process is waiting to run `txid_status` or update the oldest transaction ID available to it.

**LWLock:commit\_timestamp**

A process is waiting for I/O on a commit timestamp buffer.

**LWLock:CommitTs**

A process is waiting to read or update the last value set for a transaction commit timestamp.

**LWLock:CommitTsBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a commit timestamp.

**LWLock:CommitTsControlLock**

A process is waiting to read or update transaction commit timestamps.

**LWLock:CommitTsLock**

A process is waiting to read or update the last value set for the transaction timestamp.

**LWLock:CommitTsSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a commit timestamp.

**LWLock:ControlFile**

A process is waiting to read or update the `pg_control` file or create a new write-ahead log (WAL) file.

**LWLock:ControlFileLock**

A process is waiting to read or update the control file or creation of a new write-ahead log (WAL) file.

**LWLock:DynamicSharedMemoryControl**

A process is waiting to read or update dynamic shared memory allocation information.

**LWLock:DynamicSharedMemoryControlLock**

A process is waiting to read or update the dynamic shared memory state.

**LWLock:lock\_manager**

A backend process is waiting to add or examine locks for backend processes. Or it's waiting to join or exit a locking group that is used by parallel query. For more information, see [LWLock:lock\\_manager](#).

**LWLock:LockFastPath**

A process is waiting to read or update a process's fast-path lock information.

**LWLock:LogicalRepWorker**

A process is waiting to read or update the state of logical replication workers.

**LWLock:LogicalRepWorkerLock**

A process is waiting for an action on a logical replication worker to finish.

**LWLock:LogicalSchemaCache**

A process modified the schema cache.

**LWLock:multixact\_member**

A process is waiting for I/O on a multixact\_member buffer.

**LWLock:multixact\_offset**

A process is waiting for I/O on a multixact offset buffer.

**LWLock:MultiXactGen**

A process is waiting to read or update shared multixact state.

**LWLock:MultiXactGenLock**

A process is waiting to read or update a shared multixact state.

**LWLock:MultiXactMemberBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member. For more information, see [LWLock:MultiXact](#).

**LWLock:MultiXactMemberControlLock**

A process is waiting to read or update multixact member mappings.

**LWLock:MultiXactMemberSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member. For more information, see [LWLock:MultiXact](#).

**LWLock:MultiXactOffsetBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset. For more information, see [LWLock:MultiXact](#).

**LWLock:MultiXactOffsetControlLock**

A process is waiting to read or update multixact offset mappings.

**LWLock:MultiXactOffsetSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset.

For more information, see [LWLock:MultiXact](#).

**LWLock:MultiXactTruncation**

A process is waiting to read or truncate multixact information.

**LWLock:MultiXactTruncationLock**

A process is waiting to read or truncate multixact information.

**LWLock:NotifyBuffer**

A process is waiting for I/O on the simple least-recently used (SLRU) buffer for a NOTIFY message.

**LWLock:NotifyQueue**

A process is waiting to read or update NOTIFY messages.

**LWLock:NotifyQueueTail**

A process is waiting to update a limit on NOTIFY message storage.

**LWLock:NotifyQueueTailLock**

A process is waiting to update limit on notification message storage.

**LWLock:NotifySLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a NOTIFY message.

**LWLock:OidGen**

A process is waiting to allocate a new object ID (OID).

**LWLock:OidGenLock**

A process is waiting to allocate or assign an object ID (OID).

**LWLock:oldserxid**

A process is waiting for I/O on an oldserxid buffer.

**LWLock:OldSerXidLock**

A process is waiting to read or record conflicting serializable transactions.

**LWLock:OldSnapshotTimeMap**

A process is waiting to read or update old snapshot control information.

**LWLock:OldSnapshotTimeMapLock**

A process is waiting to read or update old snapshot control information.

**LWLock:parallel\_append**

A process is waiting to choose the next subplan during parallel append plan execution.

**LWLock:parallel\_hash\_join**

A process is waiting to allocate or exchange a chunk of memory or update counters during a parallel hash plan execution.

**LWLock:parallel\_query\_dsa**

A process is waiting for a lock on dynamic shared memory allocation for a parallel query.

**LWLock:ParallelAppend**

A process is waiting to choose the next subplan during parallel append plan execution.

**LWLock:ParallelHashJoin**

A process is waiting to synchronize workers during plan execution for a parallel hash join.

**Lwlock:ParallelQueryDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionDSA**

A process is waiting for dynamic shared memory allocation for a parallel query.

**Lwlock:PerSessionRecordType**

A process is waiting to access a parallel query's information about composite types.

**Lwlock:PerSessionRecordTypmod**

A process is waiting to access a parallel query's information about type modifiers that identify anonymous record types.

**LWlock:PerXactPredicateList**

A process is waiting to access the list of predicate locks held by the current serializable transaction during a parallel query.

**LWlock:predicate\_lock\_manager**

A process is waiting to add or examine predicate lock information.

**LWlock:PredicateLockManager**

A process is waiting to access predicate lock information used by serializable transactions.

**LWlock:proc**

A process is waiting to read or update the fast-path lock information.

**LWLock:ProcArray**

A process is waiting to access the shared per-process data structures (typically, to get a snapshot or report a session's transaction ID).

**LWLock:ProcArrayLock**

A process is waiting to get a snapshot or clearing a transaction ID at a transaction's end.

**LWLock:RelationMapping**

A process is waiting to read or update a `pg_filenode.map` file (used to track the file-node assignments of certain system catalogs).

**LWLock:RelationMappingLock**

A process is waiting to update the relation map file used to store catalog-to-file-node mapping.

**LWLock:RelCacheInit**

A process is waiting to read or update a `pg_internal.init` file (a relation cache initialization file).

**LWLock:RelCacheInitLock**

A process is waiting to read or write a relation cache initialization file.

**LWLock:replication\_origin**

A process is waiting to read or update the replication progress.

**LWLock:replication\_slot\_io**

A process is waiting for I/O on a replication slot.

**LWLock:ReplicationOrigin**

A process is waiting to create, drop, or use a replication origin.

**LWLock:ReplicationOriginLock**

A process is waiting to set up, drop, or use a replication origin.

**LWLock:ReplicationOriginState**

A process is waiting to read or update the progress of one replication origin.

**LWLock:ReplicationSlotAllocation**

A process is waiting to allocate or free a replication slot.

**LWLock:ReplicationSlotAllocationLock**

A process is waiting to allocate or free a replication slot.

**LWLock:ReplicationSlotControl**

A process is waiting to read or update a replication slot state.

**LWLock:ReplicationSlotControlLock**

A process is waiting to read or update the replication slot state.

**LWLock:ReplicationSlotIO**

A process is waiting for I/O on a replication slot.

**LWLock:SerialBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a serializable transaction conflict.

**LWLock:SerializableFinishedList**

A process is waiting to access the list of finished serializable transactions.

**LWLock:SerializableFinishedListLock**

A process is waiting to access the list of finished serializable transactions.

**LWLock:SerializablePredicateList**

A process is waiting to access the list of predicate locks held by serializable transactions.

**LWLock:SerializablePredicateLockListLock**

A process is waiting to perform an operation on a list of locks held by serializable transactions.

**LWLock:SerializableXactHash**

A process is waiting to read or update information about serializable transactions.

**LWLock:SerializableXactHashLock**

A process is waiting to retrieve or store information about serializable transactions.

**LWLock:SerialSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a serializable transaction conflict.

**LWLock:SharedTidBitmap**

A process is waiting to access a shared tuple identifier (TID) bitmap during a parallel bitmap index scan.

**LWLock:SharedTupleStore**

A process is waiting to access a shared tuple store during a parallel query.

**LWLock:ShmemIndex**

A process is waiting to find or allocate space in shared memory.

**LWLock:ShmemIndexLock**

A process is waiting to find or allocate space in shared memory.

**LWLock:SInvalRead**

A process is waiting to retrieve messages from the shared catalog invalidation queue.

**LWLock:SInvalReadLock**

A process is waiting to retrieve or remove messages from a shared invalidation queue.

**LWLock:SInvalWrite**

A process is waiting to add a message to the shared catalog invalidation queue.

**LWLock:InvalWriteLock**

A process is waiting to add a message in a shared invalidation queue.

**LWLock:SyncRep**

A process is waiting to read or update information about the state of synchronous replication.

**LWLock:SyncRepLock**

A process is waiting to read or update information about synchronous replicas.

**LWLock:SyncScan**

A process is waiting to select the starting location of a synchronized table scan.

**LWLock:SyncScanLock**

A process is waiting to get the start location of a scan on a table for synchronized scans.

**LWLock:TablespaceCreate**

A process is waiting to create or drop a tablespace.

**LWLock:TablespaceCreateLock**

A process is waiting to create or drop the tablespace.

**LWLock:tbm**

A process is waiting for a shared iterator lock on a tree bitmap (TBM).

**LWLock:TwoPhaseState**

A process is waiting to read or update the state of prepared transactions.

**LWLock:TwoPhaseStateLock**

A process is waiting to read or update the state of prepared transactions.

**LWLock:wal\_insert**

A process is waiting to insert the write-ahead log (WAL) into a memory buffer.

**LWLock:WALBufMapping**

A process is waiting to replace a page in write-ahead log (WAL) buffers.

**LWLock:WALBufMappingLock**

A process is waiting to replace a page in write-ahead log (WAL) buffers.

**LWLock:WALInsert**

A process is waiting to insert write-ahead log (WAL) data into a memory buffer.

**LWLock:WALWrite**

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

**LWLock:WALWriteLock**

A process is waiting for write-ahead log (WAL) buffers to be written to disk.

**LWLock:WrapLimitsVacuum**

A process is waiting to update limits on transaction ID and multixact consumption.

**LWLock:WrapLimitsVacuumLock**

A process is waiting to update limits on transaction ID and multixact consumption.

**LWLock:XactBuffer**

A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a transaction status.

**LWLock:XactSLRU**

A process is waiting to access the simple least-recently used (SLRU) cache for a transaction status.

**LWLock:XactTruncation**

A process is waiting to run `pg_xact_status` or update the oldest transaction ID available to it.

**LWLock:XidGen**

A process is waiting to allocate a new transaction ID.

**LWLock:XidGenLock**

A process is waiting to allocate or assign a transaction ID.

**Timeout:BaseBackupThrottle**

A process is waiting during base backup when throttling activity.

**Timeout:PgSleep**

A backend process has called the `pg_sleep` function and is waiting for the sleep timeout to expire. For more information, see [Timeout:PgSleep](#).

**Timeout:RecoveryApplyDelay**

A process is waiting to apply write-ahead log (WAL) during recovery because of a delay setting.

**Timeout:RecoveryRetrieveRetryInterval**

A process is waiting during recovery when write-ahead log (WAL) data is not available from any source (pg\_wal, archive, or stream).

**Timeout:VacuumDelay**

A process is waiting in a cost-based vacuum delay point.

For a complete list of PostgreSQL wait events, see [The Statistics Collector > Wait Event tables](#) in the PostgreSQL documentation.

# Database engine updates for Amazon Aurora PostgreSQL

Following, you can find information about Amazon Aurora PostgreSQL engine version releases and updates. You can also find information about how to upgrade your Aurora PostgreSQL engine. For more information about Aurora releases in general, see [Amazon Aurora versions](#).

## Tip

You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see [Using Blue/Green Deployments for database updates](#).

## Topics

- [Identifying versions of Amazon Aurora PostgreSQL](#)
- [Amazon Aurora PostgreSQL releases and engine versions](#)
- [Extension versions for Amazon Aurora PostgreSQL](#)
- [Upgrading Amazon Aurora PostgreSQL DB clusters](#)
- [Using an Aurora PostgreSQL long-term support \(LTS\) release](#)

## Identifying versions of Amazon Aurora PostgreSQL

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora database release typically has two version numbers, the database engine version number and the Aurora version number. If an Aurora PostgreSQL release has an Aurora version number, it's included after the engine version number in the [Amazon Aurora PostgreSQL releases and engine versions](#) listing.

## Topics

- [Aurora version number](#)
- [PostgreSQL engine version numbers](#)

## Aurora version number

Aurora version numbers use the *major.minor.patch* naming scheme. An Aurora patch version includes important bug fixes added to a minor version after its release. To learn more about Amazon Aurora major, minor, and patch releases, see [Amazon Aurora major versions](#), [Amazon Aurora minor versions](#), and [Amazon Aurora patch versions](#).

You can find out the Aurora version number of your Aurora PostgreSQL DB instance with the following SQL query:

```
postgres=> SELECT aurora_version();
```

Starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers align more closely to the PostgreSQL engine version. For example, querying an Aurora PostgreSQL 13.3 DB cluster returns the following:

```
aurora_version
-----
 13.3.1
(1 row)
```

Prior releases, such as Aurora PostgreSQL 10.14 DB cluster, return version numbers similar to the following:

```
aurora_version
-----
 2.7.3
(1 row)
```

## PostgreSQL engine version numbers

Starting with PostgreSQL 10, PostgreSQL database engine versions use a *major.minor* numbering scheme for all releases. Some examples include PostgreSQL 10.18, PostgreSQL 12.7, and PostgreSQL 13.3.

Releases prior to PostgreSQL 10 used a *major.major.minor* numbering scheme in which the first two digits make up the major version number and a third digit denotes a minor version. For example, PostgreSQL 9.6 was a major version, with minor versions 9.6.21 or 9.6.22 indicated by the third digit.

**Note**

The PostgreSQL engine version 9.6 is no longer supported. To upgrade, see [Upgrading Amazon Aurora PostgreSQL DB clusters](#). For version policies and release timelines, see [How long Amazon Aurora major versions remain available](#).

You can find out the PostgreSQL database engine version number with the following SQL query:

```
postgres=> SELECT version();
```

For an Aurora PostgreSQL 13.3 DB cluster, the results are as follows:

```
version
-----
PostgreSQL 13.3 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC)
7.4.0, 64-bit
(1 row)
```

## Amazon Aurora PostgreSQL releases and engine versions

Amazon Aurora PostgreSQL-Compatible Edition releases are updated regularly. Updates are applied to Aurora PostgreSQL DB clusters during system maintenance windows. When updates are applied depends on the type of update, the Amazon Web Services Region, and maintenance window setting for the DB cluster. Many of the listed releases include both a PostgreSQL version number and an Amazon Aurora version number. However, starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers aren't used. To identify the version numbers of your Aurora PostgreSQL database, see [Identifying versions of Amazon Aurora PostgreSQL](#).

For information about extensions and modules, see [Extension versions for Amazon Aurora PostgreSQL](#).

**Note**

For information about Amazon Aurora version policies and release timelines, see [How long Amazon Aurora major versions remain available](#).

For information about support for Amazon Aurora see [Amazon RDS FAQs](#).

To determine which Aurora PostgreSQL DB engine versions are available in an Amazon Web Services Region, use the [describe-db-engine-versions](#) Amazon CLI command. For example:

```
aws rds describe-db-engine-versions --engine aurora-postgresql --query '*[].[EngineVersion]' --output text --region aws-region
```

For a list of Amazon Web Services Regions, see [Aurora PostgreSQL Region availability](#).

For details about the PostgreSQL versions that are available on Aurora PostgreSQL, see the [Release Notes for Aurora PostgreSQL](#).

## Extension versions for Amazon Aurora PostgreSQL

You can install and configure various PostgreSQL extensions for use with Aurora PostgreSQL DB clusters. For example, you can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. To learn more about this and other extensions available for Aurora PostgreSQL, see [Working with extensions and foreign data wrappers](#).

For details about the PostgreSQL extensions that are supported on Aurora PostgreSQL, see [Extension versions for Amazon Aurora PostgreSQL](#) in *Release Notes for Aurora PostgreSQL*.

## Upgrading Amazon Aurora PostgreSQL DB clusters

Amazon Aurora makes new versions of the PostgreSQL database engine available in Amazon Web Services Regions only after extensive testing. You can upgrade your Aurora PostgreSQL DB clusters to the new version when it's available in your Region.

Depending on the version of Aurora PostgreSQL that your DB cluster is currently running, an upgrade to the new release is either a minor upgrade or a major upgrade. For example, upgrading an Aurora PostgreSQL 11.15 DB cluster to Aurora PostgreSQL 13.6 is a *major version upgrade*. Upgrading an Aurora PostgreSQL 13.3 DB cluster to Aurora PostgreSQL 13.7 is a *minor version upgrade*. In the following topics, you can find information about how to perform both types of upgrades.

- [Alternative blue/green upgrade technique](#)

## Overview of the Aurora PostgreSQL upgrade processes

The differences between major and minor version upgrades are as follows:

### Minor version upgrades and patches

Minor version upgrades and patches include only those changes that are backward-compatible with existing applications. Minor version upgrades and patches become available to you only after Aurora PostgreSQL tests and approves them.

Aurora can apply minor version upgrades for you automatically. When you create a new Aurora PostgreSQL DB cluster, the **Enable minor version upgrade** option is enabled by default. Unless you manually turn off this option, Aurora periodically applies automatic minor version upgrades during your scheduled maintenance window. For more information about the automatic minor version upgrade (AmVU) option and how to modify your Aurora DB cluster to use it, see [Automatic minor version upgrades for Aurora DB clusters](#).

If automatic minor version upgrade isn't enabled for your Aurora PostgreSQL DB cluster, your Aurora PostgreSQL isn't automatically upgraded to a new minor version. Instead, when a new minor version is released in your Amazon Web Services Region and your Aurora PostgreSQL DB

cluster is running an older minor version, Aurora prompts you to upgrade. It does so by adding a recommendation to the maintenance tasks for your cluster.

Patches aren't considered an upgrade, and they aren't applied automatically. Aurora PostgreSQL prompts you to apply any patches by adding a recommendation to maintenance tasks for your Aurora PostgreSQL DB cluster. For more information, see [How to perform minor version upgrades and apply patches](#).

**Note**

Patches that resolve security or other critical issues are also added as maintenance tasks. However, these patches are required. Make sure to apply security patches to your Aurora PostgreSQL DB cluster when they become available in your pending maintenance tasks.

Auto minor version upgrades are performed to the default minor version.

The upgrade process involves the possibility of brief outages as each instance in the cluster is upgraded to the new version. However, after Aurora PostgreSQL versions 14.3.3, 13.7.3, 12.11.3, 11.16.3, 10.21.3 and other higher releases of these minor versions and newer major versions, the upgrade process uses the zero-downtime patching (ZDP) feature. This feature minimizes outages, and in most cases completely eliminates them. For more information, see [Minor release upgrades and zero-downtime patching](#). For more information on the supported features and limitations of ZDP, see [Limitations of zero-downtime patching](#).

## Major version upgrades

Unlike for minor version upgrades and patches, Aurora PostgreSQL doesn't have an automatic major version upgrade option. New major PostgreSQL versions might contain database changes that aren't backward-compatible with existing applications. The new functionality can cause your existing applications to stop working correctly.

To prevent any issues, we strongly recommend that you follow the process outlined in [Testing an upgrade of your production DB cluster to a new major version](#) before upgrading the DB instances in your Aurora PostgreSQL DB clusters. First ensure that your applications can run on the new version by following that procedure. Then you can manually upgrade your Aurora PostgreSQL DB cluster to the new version.

The upgrade process involves the possibility of brief outage when all the instances in the cluster are upgraded to the new version. The preliminary planning process also takes time.

We recommend that you always perform upgrade tasks during your cluster's maintenance window or when operations are minimal. For more information, see [Performing a major version upgrade](#).

### Note

Both minor version upgrades and major version upgrades might involve brief outages. For that reason, we recommend strongly that you perform or schedule upgrades during your maintenance window or during other periods of low utilization.

Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in [Collations supported in Aurora PostgreSQL](#).

## Getting a list of available versions in your Amazon Web Services Region

You can get a list of all engine versions available as upgrade targets for your Aurora PostgreSQL DB cluster by querying your Amazon Web Services Region using the [describe-db-engine-versions](#) Amazon CLI command, as follows.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
  --engine aurora-postgresql \  
  --engine-version version-number \  
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \  
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^  
  --engine aurora-postgresql ^  
  --engine-version version-number ^  
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^  
  --output text
```

For example, to identify the valid upgrade targets for an Aurora PostgreSQL version 12.10 DB cluster, run the following Amazon CLI command:

## For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version 12.10 \
  --query 'DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}' \
  --output text
```

## For Windows:

```
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version 12.10 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
  --output text
```

In the following table, you can find both major and minor version upgrade targets for different Aurora PostgreSQL DB versions. To maintain compatibility, not all versions are offered as upgrade targets. Aurora PostgreSQL introduces new features and bug fixes with each quarterly minor version release. For information about Aurora PostgreSQL minor releases, see the [Release Notes for Aurora PostgreSQL](#).

Current source version	Upgrade targets
17.7	None
17.6	<a href="#">17.7</a>
17.5	<a href="#">17.7</a> , <a href="#">17.6</a>
17.4	<a href="#">17.7</a> , <a href="#">17.6</a> , <a href="#">17.5</a>
16.11	None
16.10	<a href="#">17.7</a> <a href="#">16.11</a>
16.9	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a>

Current source version	Upgrade targets
16.8	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a>
16.6	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a> , <a href="#">16.8</a>
16.4	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a> , <a href="#">16.8</a> , <a href="#">16.6</a>
16.3	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a> , <a href="#">16.8</a> , <a href="#">16.6</a> , <a href="#">16.4</a>
16.2	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a> , <a href="#">16.8</a> , <a href="#">16.6</a> , <a href="#">16.4</a> , <a href="#">16.3</a>
16.1	<a href="#">17.7</a> <a href="#">16.11</a> , <a href="#">17.6</a> , <a href="#">16.10</a> , <a href="#">17.5</a> , <a href="#">17.4</a> , <a href="#">16.9</a> , <a href="#">16.8</a> , <a href="#">16.6</a> , <a href="#">16.4</a> , <a href="#">16.3</a> , <a href="#">16.2</a>
15.15	None
15.14	<a href="#">17.7</a> <a href="#">16.11</a> <a href="#">15.15</a>

14.20	None

For any version that you're considering, always check the availability of your cluster's DB instance class. For example, `db.r4` isn't supported for Aurora PostgreSQL 13. If your Aurora PostgreSQL DB cluster currently uses a `db.r4` instance class, you need to modify it to use a supported DB instance class before you can upgrade to Aurora PostgreSQL 13. For more information about the available Aurora PostgreSQL DB instance classes, including which ones are Graviton2-based and which ones are Intel-based, see [Amazon Aurora DB instance classes](#).

## Performing a major version upgrade

Major version upgrades might contain database changes that are not backward-compatible with previous versions of the database. New functionality in a new version can cause your existing applications to stop working correctly. To avoid issues, Amazon Aurora doesn't apply major version upgrades automatically. Rather, we recommend that you carefully plan for a major version upgrade by following these steps:

1. Choose the major version that you want from the list of available targets from those listed for your version in the table. You can get a precise list of versions available in your Amazon Web Services Region for your current version by using the Amazon CLI. For details, see [Getting a list of available versions in your Amazon Web Services Region](#).
2. Verify that your applications work as expected on a trial deployment of the new version. For information about the complete process, see [Testing an upgrade of your production DB cluster to a new major version](#).
3. After verifying that your applications work as expected on the trial deployment, you can upgrade your cluster. For details, see [Upgrading the Aurora PostgreSQL engine to a new major version](#).

**Note**

You can perform a major version upgrade from Babelfish for Aurora PostgreSQL 13-based versions starting from 13.6 to Aurora PostgreSQL 14-based versions starting from 14.6. Babelfish for Aurora PostgreSQL 13.4 and 13.5 don't support major version upgrade.

You can get a list of engine versions available as major version upgrade targets for your Aurora PostgreSQL DB cluster by querying your Amazon Web Services Region using the [describe-db-engine-versions](#) Amazon CLI command, as follows.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version version-number \
  --query 'DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
{EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version version-number ^
  --query "DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
{EngineVersion:EngineVersion}" ^
  --output text
```

In some cases, the version that you want to upgrade to isn't a target for your current version. In such cases, use the information in the [versions table](#) to perform minor version upgrades until your cluster is at a version that has your chosen target in its row of targets.

### Testing an upgrade of your production DB cluster to a new major version

Each new major version includes enhancements to the query optimizer that are designed to improve performance. However, your workload might include queries that result in a worse performing plan in the new version. That's why we recommend that you test and review performance before upgrading in production. You can manage query plan stability across versions

by using the Query Plan Management (QPM) extension, as detailed in [Ensuring plan stability after a major version upgrade](#).

Before upgrading your production Aurora PostgreSQL DB clusters to a new major version, we strongly recommend that you test the upgrade to verify that all your applications work correctly:

1. Have a version-compatible parameter group ready.

If you are using a custom DB instance or DB cluster parameter group, you can choose from two options:

- a. Specify the default DB instance, DB cluster parameter group, or both for the new DB engine version.
  - b. Create your own custom parameter group for the new DB engine version.
2. Check for invalid databases and drop any that exist.

The `datconnlimit` column in the `pg_database` catalog includes a value of `-2` to mark as invalid any databases that were interrupted during a `DROP DATABASE` operation. Use the following query to check whether invalid databases exist.

```
SELECT
    datname
FROM
    pg_database
WHERE
    datconnlimit = - 2;
```

If the query returns database names, these databases are invalid. Use the `DROP DATABASE invalid_db_name` statement to drop invalid databases. You can use the following dynamic statement to drop all invalid databases.

```
SELECT
    'DROP DATABASE ' || quote_ident(datname) || ';'
FROM
    pg_database
WHERE
    datconnlimit = -2 \gexec
```

3. Check for unsupported usage:

- Commit or roll back all open prepared transactions before attempting an upgrade. You can use the following query to verify that there are no open prepared transactions on your instance.

```
SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
```

- Remove all uses of the *reg\** data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the *reg\** data types. The `pg_upgrade` utility (used by Amazon Aurora to do the upgrade) can't persist this data type. To learn more about this utility, see [pg\\_upgrade](#) in the PostgreSQL documentation.

To verify that there are no uses of unsupported *reg\** data types, use the following query for each database.

```
SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
pg_catalog.pg_attribute a
WHERE c.oid = a.attrelid
      AND NOT a.attisdropped
      AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                        'pg_catalog.regprocedure'::pg_catalog.regtype,
                        'pg_catalog.regoper'::pg_catalog.regtype,
                        'pg_catalog.regoperator'::pg_catalog.regtype,
                        'pg_catalog.regconfig'::pg_catalog.regtype,
                        'pg_catalog.regdictionary'::pg_catalog.regtype)
      AND c.relnamespace = n.oid
      AND n.nspname NOT IN ('pg_catalog', 'information_schema');
```

- If you are upgrading an Aurora PostgreSQL version 10.18 or higher DB cluster that has the `pgRouting` extension installed, drop the extension before upgrading to version 12.4 or higher.

If you are upgrading an Aurora PostgreSQL 10.x version that has the extension `pg_repack` version 1.4.3 installed, drop the extension before upgrading to any higher version.

#### 4. Check for `template1` and `template0` databases.

For a successful upgrade, `template 1` and `template 0` databases must exist and should be listed as a template. To check on this, use the following command:

```
SELECT datname, datistemplate FROM pg_database;
```

```
datname      | datistemplate
-----+-----
template0   | t
rdsadmin     | f
template1   | t
postgres    | f
```

In the command output, the `datistemplate` value for `template1` and `template0` databases should be `t`.

## 5. Drop logical replication slots.

The upgrade process can't proceed if the Aurora PostgreSQL DB cluster is using any logical replication slots. Logical replication slots are typically used for short-term data migration tasks, such as migrating data using Amazon DMS or for replicating tables from the database to data lakes, BI tools, or other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that exist, and confirm that it's okay to delete them. You can check for logical replication slots using the following query:

```
SELECT * FROM pg_replication_slots;
```

If logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade. However, if the logical replication slots aren't needed, you can delete them using the following SQL:

```
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication scenarios that use the `pglogical` extension also need to have slots dropped from the publisher node for a successful major version upgrade on that node. However, you can restart the replication process from the subscriber node after the upgrade. For more information, see [Reestablishing logical replication after a major upgrade](#).

## 6. Perform a backup.

The upgrade process creates a DB cluster snapshot of your DB cluster during upgrading. If you also want to do a manual backup before the upgrade process, see [Creating a DB cluster snapshot](#) for more information.

## 7. Upgrade certain extensions to the latest available version before performing the major version upgrade. The extensions to update include the following:

- pgRouting
- postgis\_raster
- postgis\_tiger\_geocoder
- postgis\_topology
- address\_standardizer
- address\_standardizer\_data\_us

Run the following command for each extension that's currently installed.

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see [Upgrading PostgreSQL extensions](#). To learn more about upgrading PostGIS, see [Step 6: Upgrade the PostGIS extension](#).

8. If you're upgrading to version 11.x, drop the extensions that it doesn't support before performing the major version upgrade. The extensions to drop include:
  - chkpass
  - tsearch2
9. Drop unknown data types, depending on your target version.

PostgreSQL version 10 doesn't support the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to version 10 shows an error message such as the following.

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:  
The instance could not be upgraded because the 'unknown' data type is used in user  
tables.  
Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so that you can remove such columns or change them to supported data types, use the following SQL code for each database.

```
SELECT n.nspname, c.relname, a.attname  
FROM pg_catalog.pg_class c,  
pg_catalog.pg_namespace n,  
pg_catalog.pg_attribute a  
WHERE c.oid = a.attrelid AND NOT a.attisdropped AND  
a.atttypid = 'pg_catalog.unknown'::pg_catalog.regtype AND  
c.relkind IN ('r','m','c') AND
```

```
c.relnamespace = n.oid AND  
n.nspname !~ '^pg_temp_' AND  
n.nspname !~ '^pg_toast_temp_' AND n.nspname NOT IN ('pg_catalog',  
'information_schema');
```

## 10 Perform a dry-run upgrade.

We highly recommend testing a major version upgrade on a duplicate of your production database before trying the upgrade on your production database. You can monitor the execution plans on the duplicate test instance for any possible execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or clone your database. For more information, see [Restoring from a snapshot](#) or [Cloning a volume for an Amazon Aurora DB cluster](#).

For more information, see [Upgrading the Aurora PostgreSQL engine to a new major version](#).

## 11 Upgrade your production instance.

When your dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see [Upgrading the Aurora PostgreSQL engine to a new major version](#).

### Note

During the upgrade process, Aurora PostgreSQL takes a DB cluster snapshot. You can't do a point-in-time restore of your cluster during this process. Later, you can perform a point-in-time restore to times before the upgrade began and after the automatic snapshot of your instance has completed. However, you can't perform a point-in-time restore to a previous minor version.

For information about an upgrade in progress, you can use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon Aurora appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see [Monitoring Amazon Aurora log files](#).

## 12 Upgrade PostgreSQL extensions. The PostgreSQL upgrade process doesn't upgrade any PostgreSQL extensions. For more information, see [Upgrading PostgreSQL extensions](#).

## Post-upgrade recommendations

After you complete a major version upgrade, we recommend the following:

- Run the ANALYZE operation to refresh the `pg_statistic` table. You should do this for every database on all your PostgreSQL DB instances. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE;
```

The VERBOSE flag is optional, but using it shows you the progress. For more information, see [ANALYZE](#) in the PostgreSQL documentation.

When analyzing specific tables instead of using ANALYZE VERBOSE, run the ANALYZE command for each table as follows:

```
ANALYZE table_name;
```

For partitioned tables, always analyze the parent table. This process:

- Automatically samples rows across all partitions
- Updates statistics for each partition recursively
- Maintains essential planning statistics at the parent level

While parent tables store no actual data, analyzing them is vital for query optimization. Running ANALYZE only on individual partitions can lead to poor query performance since the optimizer won't have the comprehensive statistics needed for efficient cross-partition planning.

### Note

Run ANALYZE on your system after the upgrade to avoid performance issues.

- If you upgraded to PostgreSQL version 10, run REINDEX on any hash indexes you have. Hash indexes were changed in version 10 and must be rebuilt. To locate invalid hash indexes, run the following SQL for each database that contains hash indexes.

```
SELECT idx.indrelid::regclass AS table_name,
```

```
idx.indexrelid::regclass AS index_name
FROM pg_catalog.pg_index idx
JOIN pg_catalog.pg_class cls ON cls.oid = idx.indexrelid
JOIN pg_catalog.pg_am am ON am.oid = cls.relam
WHERE am.amname = 'hash'
AND NOT idx.indisvalid;
```

- We recommend that you test your application on the upgraded database with a similar workload to verify that everything works as expected. After the upgrade is verified, you can delete this test instance.

## Upgrading the Aurora PostgreSQL engine to a new major version

When you initiate the upgrade process to a new major version, Aurora PostgreSQL takes a snapshot of the Aurora DB cluster before it makes any changes to your cluster. This snapshot is created for major version upgrades only, not minor version upgrades. When the upgrade process completes, you can find this snapshot among the manual snapshots listed under **Snapshots** in the RDS console. The snapshot name includes `preupgrade` as its prefix, the name of your Aurora PostgreSQL DB cluster, the source version, the target version, and the date and timestamp, as shown in the following example.

```
preupgrade-docs-lab-apg-global-db-12-8-to-13-6-2022-05-19-00-19
```

After the upgrade completes, you can use the snapshot that Aurora created and stored in your manual snapshot list to restore the DB cluster to its previous version, if necessary.

### Tip

In general, snapshots provide many ways to restore your Aurora DB cluster to various points in time. To learn more, see [Restoring from a DB cluster snapshot](#) and [Restoring a DB cluster to a specified time](#). However, Aurora PostgreSQL doesn't support using a snapshot to restore to a previous minor version.

During the major version upgrade process, Aurora allocates a volume and clones the source Aurora PostgreSQL DB cluster. If the upgrade fails for any reason, Aurora PostgreSQL uses the clone to roll back the upgrade. After more than 15 clones of a source volume are allocated, subsequent clones become full copies and take longer. This can cause the upgrade process also to take longer. If Aurora PostgreSQL rolls back the upgrade, be aware of the following:

- You might see billing entries and metrics for both the original volume and the cloned volume allocated during the upgrade. Aurora PostgreSQL cleans up the extra volume after the cluster backup retention window is beyond the time of the upgrade.
- The next cross-Region snapshot copy from this cluster will be a full copy instead of an incremental copy.

To safely upgrade the DB instances that make up your cluster, Aurora PostgreSQL uses the `pg_upgrade` utility. After the writer upgrade completes, each reader instance experiences a brief outage while it's upgraded to the new major version. To learn more about this PostgreSQL utility, see [pg\\_upgrade](#) in the PostgreSQL documentation.

You can upgrade your Aurora PostgreSQL DB cluster to a new version by using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

### To upgrade the engine version of a DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon Aurora DB cluster](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## Amazon CLI

To upgrade the engine version of a DB cluster, use the [modify-db-cluster](#) Amazon CLI command. Specify the following parameters:

- `--db-cluster-identifier` – The name of the DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the Amazon CLI [describe-db-engine-versions](#) command.
- `--allow-major-version-upgrade` – A required flag when the `--engine-version` parameter is a different major version than the DB cluster's current major version.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --engine-version new_version \  
  --allow-major-version-upgrade \  
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --engine-version new_version ^  
  --allow-major-version-upgrade ^  
  --no-apply-immediately
```

## RDS API

To upgrade the engine version of a DB cluster, use the [ModifyDBCluster](#) operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example *mydbcluster*.
- `EngineVersion` – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- `AllowMajorVersionUpgrade` – A required flag when the `EngineVersion` parameter is a different major version than the DB cluster's current major version.

- `ApplyImmediately` – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Major upgrades for global databases

For an Aurora global database cluster, the upgrade process upgrades all DB clusters that make up your Aurora global database at the same time. It does so to ensure that each runs the same Aurora PostgreSQL version. It also ensures that any changes to system tables, data file formats, and so on, are automatically replicated to all secondary clusters.

To upgrade a global database cluster to a new major version of Aurora PostgreSQL, we recommend that you test your applications on the upgraded version, as detailed in [Testing an upgrade of your production DB cluster to a new major version](#). Be sure to prepare your DB cluster parameter group and DB parameter group settings for each Amazon Web Services Region in your Aurora global database before the upgrade as detailed in [step 1.](#) of [Testing an upgrade of your production DB cluster to a new major version](#).

If your Aurora PostgreSQL global database cluster has a recovery point objective (RPO) set for its `rds.global_db_rpo` parameter, make sure to reset the parameter before upgrading. The major version upgrade process doesn't work if the RPO is turned on. By default, this parameter is turned off. For more information about Aurora PostgreSQL global databases and RPO, see [Managing RPOs for Aurora PostgreSQL-based global databases](#).

If you verify that your applications can run as expected on the trial deployment of the new version, you can start the upgrade process. To do so, see [Upgrading the Aurora PostgreSQL engine to a new major version](#). Be sure to choose the top-level item from the **Databases** list in the RDS console, **Global database**, as shown in the following image.

DB identifier	Role	Engine	Region & AZ	Size
<input type="radio"/> docs-lab-apg-aiml	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
<input checked="" type="radio"/> docs-lab-apg-global-db	Global database	Aurora PostgreSQL	2 regions	2 clusters
<input type="radio"/> docs-lab-apg-global-12-7	Primary cluster	Aurora PostgreSQL	us-west-1	2 instances
<input type="radio"/> docs-lab-apg-global-12-7-instance-1	Writer instance	Aurora PostgreSQL	us-west-1c	db.r6g.large
<input type="radio"/> docs-lab-apg-global-12-7-instance-1-us-west-1a	Reader instance	Aurora PostgreSQL	us-west-1a	db.r6g.large
<input type="radio"/> docs-lab-apg-global-db-cluster-northwest	Secondary cluster	Aurora PostgreSQL	us-west-2	2 instances
<input type="radio"/> docs-lab-apg-global-db-instance-north	Reader instance	Aurora PostgreSQL	us-west-2c	db.r6g.large
<input type="radio"/> docs-lab-apg-global-db-instance-north-us-west-2b	Reader instance	Aurora PostgreSQL	us-west-2b	db.r6g.large
<input type="radio"/> docs-lab-apg-main	Regional cluster	Aurora PostgreSQL	us-west-1	2 instances
<input type="radio"/> docs-lab-apg-sless-test-aws-s3	Serverless	Aurora PostgreSQL	us-west-1	0 capacity units

As with any modification, you can confirm that you want the process to proceed when prompted.

RDS > Databases > Modify global database

## Modify global database: docs-lab-apg-global-db

### Summary of modifications

You are about to submit the following modifications. Only values that will change are displayed. Carefully verify your changes and click **Modify global database**.

Attribute	Current value	New value
DB engine version	12.8	13.6
DB cluster parameter group	default.aurora-postgresql12	default.aurora-postgresql13
DB parameter group	default.aurora-postgresql12	default.aurora-postgresql13

 **Potential unexpected downtime**  
 This upgrade is applied immediately in an asynchronous fashion. If any pending modifications require rebooting your cluster, this upgrade can cause unexpected downtime.

**Note:**  
 To schedule modifications in the next maintenance window, modify the DB cluster or DB instance individually.

Rather than using the console, you can start the upgrade process by using the Amazon CLI or the RDS API. As with the console, you operate on the Aurora global database cluster rather than any of its constituents, as follows:

- Use the [modify-global-cluster](#) Amazon CLI command to start the upgrade for your Aurora global database by using the Amazon CLI.
- Use the [ModifyGlobalCluster](#) API to start the upgrade.

## Performing a minor version upgrade

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:

### Topics

- [Before performing a minor version upgrade](#)
- [How to perform minor version upgrades and apply patches](#)
- [Minor release upgrades and zero-downtime patching](#)
- [Limitations of zero-downtime patching](#)
- [Upgrading the Aurora PostgreSQL engine to a new minor version](#)

### Before performing a minor version upgrade

We recommend that you perform the following actions to reduce the downtime during a minor version upgrade:

- The Aurora DB cluster maintenance should be performed during a period of low traffic. Use Performance Insights to identify these time periods in order to configure the maintenance windows correctly. For more information on Performance Insights, see [Monitoring DB load with Performance Insights on Amazon RDS](#). For more information on DB cluster maintenance window, [Adjusting the preferred DB cluster maintenance window](#).
- Use Amazon SDKs that support exponential backoff and jitter as a best practice. For more information, see [Exponential Backoff And Jitter](#).

### How to perform minor version upgrades and apply patches

Minor version upgrades and patches become available in Amazon Web Services Regions only after rigorous testing. Before releasing upgrades and patches, Aurora PostgreSQL tests to ensure that known security issues, bugs, and other issues that emerge after the release of the minor community version don't disrupt Aurora PostgreSQL fleet stability.

If you turn on **Enable auto minor version upgrade**, Aurora PostgreSQL periodically upgrades your DB cluster during your specified maintenance window. Make sure that the **Enable auto minor version upgrade** option is turned on for all instances in your Aurora PostgreSQL DB cluster. For information on how to set **Auto minor version upgrade**, and how the setting works when applied at the cluster and instance levels, see [Automatic minor version upgrades for Aurora DB clusters](#).

Check the value of the **Enable auto minor version upgrade** option for all your Aurora PostgreSQL DB clusters by using the [describe-db-instances](#) Amazon CLI command as follows.

```
aws rds describe-db-instances \
  --query '*[*].
  {DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVer
```

This query returns a list of all Aurora DB clusters and their instances with a `true` or `false` value for the status of the `AutoMinorVersionUpgrade` setting. The command assumes that you have your Amazon CLI configured to target your default Amazon Web Services Region.

For more information about the AmVU option and how to modify your Aurora DB cluster to use it, see [Automatic minor version upgrades for Aurora DB clusters](#).

You can upgrade your Aurora PostgreSQL DB clusters to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

You can identify any available upgrades or patches for your Aurora PostgreSQL DB clusters by using the RDS console and opening the **Recommendations** menu. There, you can find a list of various maintenance issues such as **Old minor versions**. Depending on your production environment, you can choose to **Schedule** the upgrade or take immediate action, by choosing **Apply now**, as shown following.

The screenshot shows the 'Recommendations' page in the AWS RDS console. At the top, there are tabs for 'Active (6)', 'Dismissed (0)', 'Scheduled (0)', and 'Applied (0)'. Below this, a section titled 'Old minor versions (2)' contains a message: 'Databases are not running the latest minor DB engine version. The most current minor version contains the latest security fixes and other improvements. Info'. Underneath, there is a table of recommendations. The table has columns for 'DB clusters' and 'Recommendation'. A single recommendation is visible for the cluster 'docs-lab-appg-133-test', with the text 'Your DB cluster is running aurora-postgresql version 13.3. Upgrade to version 13.6.' To the right of the table, there are buttons for 'Dismiss', 'Schedule', and 'Apply now'. The 'Apply now' button is highlighted with a mouse cursor.

To learn more about how to maintain an Aurora DB cluster, including how to manually apply patches and minor version upgrades, see [Maintaining an Amazon Aurora DB cluster](#).

## Minor release upgrades and zero-downtime patching

Upgrading an Aurora PostgreSQL DB cluster involves the possibility of an outage. During the upgrade process, the database is shut down as it's being upgraded. If you start the upgrade while the database is busy, you lose all connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature improves the upgrading process. With ZDP, both minor version upgrades and patches can be applied with minimal impact to your Aurora PostgreSQL DB cluster. ZDP is used when applying patches or newer minor version upgrades to Aurora PostgreSQL versions and other higher releases of these minor versions and newer major versions. That is, upgrading to new minor versions from any of these releases onward uses ZDP.

The following table shows the Aurora PostgreSQL versions and DB instance classes where ZDP is available:

Version	db.r* instance classes	db.t* instance classes	db.x* instance classes	db.serverless instance class
10.21 and higher versions	Yes	Yes	Yes	N/A
11.16 and higher versions	Yes	Yes	Yes	N/A
11.17 and higher versions	Yes	Yes	Yes	N/A
12.11 and higher versions	Yes	Yes	Yes	N/A
12.12 and higher versions	Yes	Yes	Yes	N/A
13.7 and higher versions	Yes	Yes	Yes	N/A
13.8 and higher versions	Yes	Yes	Yes	Yes

Version	db.r* instance classes	db.t* instance classes	db.x* instance classes	db.serverless instance class
14.3 and higher versions	Yes	Yes	Yes	N/A
14.4 and higher versions	Yes	Yes	Yes	N/A
14.5 and higher versions	Yes	Yes	Yes	Yes
15.3 and higher versions	Yes	Yes	Yes	Yes
16.1 and higher versions	Yes	Yes	Yes	Yes

During the upgrade process using ZDP, the database engine looks for a quiet point to pause all new transactions. This action safeguards the database during patches and upgrades. To make sure that your applications run smoothly with paused transactions, we recommend integrating retry logic into your code. This approach ensures that the system can manage any brief downtime without failing and can retry the new transactions after the upgrade.

When ZDP completes successfully, application sessions are maintained except for those with dropped connections, and the database engine restarts while the upgrade is still in progress. Although the database engine restart can cause a temporary drop in throughput, this typically lasts only for a few seconds or at most, approximately one minute.

In some cases, zero-downtime patching (ZDP) might not succeed. For example, parameter changes that are in a pending state on your Aurora PostgreSQL DB cluster or its instances interfere with ZDP.

You can find metrics and events for ZDP operations in **Events** page in the console. The events include the start of the ZDP upgrade and completion of the upgrade. In this event you can find how long the process took, and the numbers of preserved and dropped connections that occurred during the restart. You can find details in your database error log.

## Limitations of zero-downtime patching

The following limitations apply to zero-downtime patching:

- ZDP tries to preserve current client connections to your Aurora PostgreSQL writer instance throughout the Aurora PostgreSQL upgrade process. However, in the following cases, connections will be dropped for ZDP to complete:
  - Long running query or transactions are in progress.
  - Data definition language (DDL) statements are running.
  - Temporary tables or table locks are in use.
  - All sessions are listening on notification channels.
  - A cursor in 'WITH HOLD' status is in use.
  - TLSv1.1 connections are in use. Starting with Aurora PostgreSQL versions later than 16.1, 15.3, 14.8, 13.11, 12.15, and 11.20, ZDP is supported with TLSv1.3 connections.
- ZDP isn't supported in the following cases:
  - When Aurora PostgreSQL DB clusters are configured as Aurora Serverless v1.
  - During the upgrade of any Aurora reader instances.
  - During the upgrade of any Aurora reader instances that are part of an Aurora Global Database cluster in a secondary Region.
  - During OS patches and OS upgrades.

## Upgrading the Aurora PostgreSQL engine to a new minor version

You can upgrade your Aurora PostgreSQL DB cluster to a new minor version by using the console, the Amazon CLI, or the RDS API. Before performing the upgrade, we recommend that you follow the same best practice that we recommend for major version upgrades. As with new major versions, new minor versions can also have optimizer improvements, such as fixes, that can cause query plan regressions. To ensure plan stability, we recommend that you use the Query Plan Management (QPM) extension as detailed in [Ensuring plan stability after a major version upgrade](#).

### Console

#### To upgrade the engine version of your Aurora PostgreSQL DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

2. In the navigation pane, choose **Databases**, and then choose the DB cluster that you want to upgrade.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. For **Engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon Aurora DB cluster](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify Cluster** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## Amazon CLI

To upgrade the engine version of a DB cluster, use the [modify-db-cluster](#) Amazon CLI command with the following parameters:

- `--db-cluster-identifier` – The name of your Aurora PostgreSQL DB cluster.
- `--engine-version` – The version number of the database engine to upgrade to. For information about valid engine versions, use the Amazon CLI [describe-db-engine-versions](#) command.
- `--no-apply-immediately` – Apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately` instead.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --engine-version new_version \  
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --engine-version new_version ^
```

```
--no-apply-immediately
```

## RDS API

To upgrade the engine version of a DB cluster, use the [ModifyDBCluster](#) operation. Specify the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster, for example *mydbcluster*.
- `EngineVersion` – The version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- `ApplyImmediately` – Whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Upgrading PostgreSQL extensions

Upgrading your Aurora PostgreSQL DB cluster to a new major or minor version doesn't upgrade the PostgreSQL extensions at the same time. For most extensions, you upgrade the extension after the major or minor version upgrade completes. However, in some cases, you upgrade the extension before you upgrade the Aurora PostgreSQL DB engine. For more information, see the [list of extensions to update](#) in [Testing an upgrade of your production DB cluster to a new major version](#).

Installing PostgreSQL extensions requires `rds_superuser` privileges. Typically, an `rds_superuser` delegates permissions over specific extensions to relevant users (roles), to facilitate the management of a given extension. That means that the task of upgrading all the extensions in your Aurora PostgreSQL DB cluster might involve many different users (roles). Keep this in mind especially if you want to automate the upgrade process by using scripts. For more information about PostgreSQL privileges and roles, see [Security with Amazon Aurora PostgreSQL](#).

### Note

For information about updating the PostGIS extension, see [Managing spatial data with the PostGIS extension \(Step 6: Upgrade the PostGIS extension\)](#).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded DB instance. For more information, see [pg\\_repack installation](#) in the `pg_repack` documentation.

To update an extension after an engine upgrade, use the `ALTER EXTENSION UPDATE` command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

To list your currently installed extensions, use the PostgreSQL [pg\\_extension](#) catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL [pg\\_available\\_extension\\_versions](#) view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

## Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see [Using Blue/Green Deployments for database updates](#).

## Using an Aurora PostgreSQL long-term support (LTS) release

Each new Aurora PostgreSQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora PostgreSQL version is no longer supported.

Aurora designates certain Aurora PostgreSQL versions as long-term support (LTS) releases. Database clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. LTS minor versions include only bug fixes (through patch versions) for critical stability and security issues; an LTS version doesn't include new features released after its introduction.

Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

**Note**

If you want to remain on an LTS minor version for the duration of its lifecycle, make sure to disable automatic minor version upgrade for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, clear the **Enable auto minor version upgrade** check box on any DB instance in your Aurora cluster.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora PostgreSQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora PostgreSQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora PostgreSQL database engine.
- The database version for your Aurora PostgreSQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora PostgreSQL are as follows:

- PostgreSQL 16.8. It was released on April 07, 2025. For more information, see [PostgreSQL 16.8](#) in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 15.10. It was released on December 27, 2024. For more information, see [PostgreSQL 15.10](#) in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 14.6. It was released on January 20, 2023. For more information, see [PostgreSQL 14.6](#) in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 13.9. It was released on January 20, 2023. For more information, see [PostgreSQL 13.9](#) in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 12.9. It was released on February 25, 2022. For more information, see [PostgreSQL 12.9](#) in the *Release Notes for Aurora PostgreSQL*.
- PostgreSQL 11.9 (Aurora PostgreSQL release 3.4). It was released on December 11, 2020. For more information about this version, see [PostgreSQL 11.9, Aurora PostgreSQL release 3.4](#) in the *Release Notes for Aurora PostgreSQL*.

---

For details about support timelines and release cycles for the LTS versions, see [Release calendars for Aurora PostgreSQL](#).

For information about how to identify Aurora and database engine versions, see [Identifying versions of Amazon Aurora PostgreSQL](#).

# Using Amazon Aurora PostgreSQL Limitless Database

Amazon Aurora PostgreSQL Limitless Database provides automated horizontal scaling to process millions of write transactions per second and manages petabytes of data while maintaining the simplicity of operating inside a single database. With Aurora PostgreSQL Limitless Database, you can focus on building high-scale applications without having to build and maintain complex solutions for scaling your data across multiple DB instances to support your workloads.

## Topics

- [Aurora PostgreSQL Limitless Database architecture](#)
- [Getting started with Aurora PostgreSQL Limitless Database](#)

## Aurora PostgreSQL Limitless Database architecture

Limitless Database achieves scale with a two-layer architecture consisting of multiple database nodes. Nodes are either routers or shards.

- Shards are Aurora PostgreSQL DB instances that each store a subset of the data for your database, allowing for simultaneous processing to achieve higher write throughput.
- Routers manage the distributed nature of the database and present a single database image to database clients. Routers maintain metadata about where data is stored, parse incoming SQL commands and send those commands to shards. Then they aggregate data from shards to return a single result to the client, and manage distributed transactions to maintain consistency across the entire distributed database.

Aurora PostgreSQL Limitless Database differs from standard [Aurora DB clusters](#) by having a DB shard group instead of a writer DB instance and reader DB instances. All of the nodes that make up your Limitless Database architecture are contained in the DB shard group. The individual shards and routers in the DB shard group aren't visible in your Amazon Web Services account. You use the DB cluster endpoint to access Limitless Database.

The following figure shows the high-level architecture of Aurora PostgreSQL Limitless Database.

For more information on the architecture of Aurora PostgreSQL Limitless Database and how you can use it, see [Achieving scale with Amazon Aurora PostgreSQL Limitless Database](#) on the Amazon Events channel on YouTube.

For more information on the architecture of a standard Aurora DB cluster, see [Amazon Aurora DB clusters](#).

# Key terms for Aurora PostgreSQL Limitless Database

## DB shard group

A container for Limitless Database nodes (shards and routers).

## Router

A node that accepts SQL connections from clients, sends SQL commands to shards, maintains system-wide consistency, and returns results to clients.

## Shard

A node that stores a subset of sharded tables, full copies of reference tables, and standard tables. Accepts queries from routers, but can't be connected to directly by the clients.

## Sharded table

A table with its data partitioned across shards.

## Shard key

A column or set of columns in a sharded table that's used to determine partitioning across shards.

## Collocated tables

Two sharded tables that share the same shard key and are explicitly declared as collocated. All data for the same shard key value is sent to the same shard.

## Reference table

A table with its data copied in full on every shard.

## Standard table

The default table type in Limitless Database. You can convert standard tables into sharded and reference tables.

All standard tables are stored on the same shard selected by the system, enabling joins between standard tables to be performed within a single shard. However, standard tables are limited by the shard's maximum capacity (128 TiB). This shard also stores data from sharded and reference tables, so the effective limit for standard tables is lower than 128 TiB.

## Table types for Aurora PostgreSQL Limitless Database

Aurora PostgreSQL Limitless Database supports three types of table: *sharded*, *reference*, and *standard*.

Sharded tables have their data distributed across all of the shards in the DB shard group. Limitless Database does this automatically by using a *shard key*, which is a column or set of columns that you specify when partitioning the table. All of the data with the same value for the shard key is sent to the same shard. Sharding is hash-based, not range- or list-based.

The following are good use cases for sharded tables:

- The application works with a distinct subset of data.
- The table is very large.
- The table potentially grows faster than other tables.

Sharded tables can be *collocated*, meaning that they share the same shard key, and that all of the data from both tables with the same shard key value is sent to the same shard. If you collocate tables and join them using the shard key, the join can be performed on a single shard because all of the necessary data is present on that shard.

Reference tables have a full copy of all their data on every shard in the DB shard group. Reference tables are commonly used for smaller tables with a lower write volume, but that still need to be joined frequently and don't lend themselves to sharding. Examples of reference tables include date tables, and tables of geographic data such as state, city, and postal code.

Standard tables are the default table type in Aurora PostgreSQL Limitless Database. They aren't distributed tables. Aurora PostgreSQL Limitless Database supports joins between standard tables and standard, sharded, and reference tables.

## Billing for Aurora PostgreSQL Limitless Database

For information on how you're charged for Aurora PostgreSQL Limitless Database, see [DB instance billing for Aurora](#).

For Aurora pricing information, see the [Aurora pricing page](#).

# Getting started with Aurora PostgreSQL Limitless Database

You perform the following actions to get started with Aurora PostgreSQL Limitless Database:

1. Create an Aurora PostgreSQL DB cluster and a DB shard group for Limitless Database. For more information, see [Creating a DB cluster that uses Aurora PostgreSQL Limitless Database](#).
2. Create sharded and reference tables in the DB shard group. For more information, see [Creating Aurora PostgreSQL Limitless Database tables](#).
3. Change the capacity for your DB shard group, split shards, and add routers. For more information, see [Working with DB shard groups](#).
4. Load data into the DB shard group. For more information, see [Loading data into Aurora PostgreSQL Limitless Database](#).
5. Run queries and other SQL statements on the DB shard group. For more information, see [Querying Aurora PostgreSQL Limitless Database](#).
6. Monitor the performance of Limitless Database. For more information, see [Monitoring Aurora PostgreSQL Limitless Database](#).

# Aurora PostgreSQL Limitless Database requirements and considerations

Aurora PostgreSQL Limitless Database has the following requirements and considerations.

## Topics

- [Requirements for Aurora PostgreSQL Limitless Database](#)
- [Considerations for Aurora PostgreSQL Limitless Database](#)
- [Features not supported in Aurora PostgreSQL Limitless Database](#)

## Requirements for Aurora PostgreSQL Limitless Database

Make sure to follow these requirements for Aurora PostgreSQL Limitless Database.

- Aurora PostgreSQL Limitless Database is available in all Amazon Web Services Regions except Asia Pacific (Taipei).

### Note

If you create your Aurora PostgreSQL Limitless Database DB cluster in US East (N. Virginia), don't include the us-east-1e Availability Zone (AZ) in your DB subnet group. Because of resource limitations, Aurora Serverless v2 (and therefore Aurora PostgreSQL Limitless Database) isn't supported in the us-east-1e AZ.

- Aurora PostgreSQL Limitless Database supports only the Aurora I/O-Optimized DB cluster storage configuration. For more information, see [Storage configurations for Amazon Aurora DB clusters](#).
- Aurora PostgreSQL Limitless Database uses special Aurora PostgreSQL DB engine versions for Aurora PostgreSQL Limitless Database:
  - 16.6.8-limitless
  - 16.6-limitless
  - 16.4-limitless
- Your DB cluster can't have any writer or reader DB instances.
- You must use Enhanced Monitoring and Performance Insights. The Performance Insights retention time must be at least 1 month (31 days).

- You must export the PostgreSQL log to Amazon CloudWatch Logs.

**Note**

Some required features, such as Enhanced Monitoring, Performance Insights, and CloudWatch Logs, incur extra charges. For Aurora pricing information, see the [Aurora pricing page](#).

## Considerations for Aurora PostgreSQL Limitless Database

The following considerations apply to DB shard groups in Aurora PostgreSQL Limitless Database:

- You can have only one DB shard group per DB cluster.
- You can have up to five DB shard groups per Amazon Web Services Region.

Therefore, you can have up to five Aurora PostgreSQL Limitless Database DB clusters per Amazon Web Services Region. For more information, see [Quotas in Amazon Aurora](#).

- You can set the maximum capacity of a DB shard group to 16–6144 ACUs. For capacity limits higher than 6144 ACUs, contact Amazon.

The initial number of routers and shards is determined by the maximum capacity that you set when you create a DB shard group. For more information, see [Correlating DB shard group maximum capacity with the number of routers and shards created](#).

- The number of routers and shards doesn't change when you modify the maximum capacity of a DB shard group.
- Make sure that the DB subnet where you create the DB shard group has enough free IP addresses for connecting with the DB shard group. You need one IP address for each router and up to three IP addresses for each shard in the DB shard group.

For more information on the number of routers created when you create a DB shard group, see [Correlating DB shard group maximum capacity with the number of routers and shards created](#).

- If you make your DB shard group publicly accessible, make sure to set up an internet gateway in your VPC.
- You use SQL functions to [split shards](#) and [add routers](#).
- Merging shards isn't supported.

- You can't delete individual shards and routers.
- You can't modify (perform UPDATE operations on) shard keys in any way, including changing their values in table rows.

To change a shard key, delete and then re-create it.

- The repeatable read, read committed, and read uncommitted isolation levels are supported. You can't set the isolation level to serializable.
- Some SQL commands aren't supported. For more information, see [Aurora PostgreSQL Limitless Database reference](#).
- Not all PostgreSQL extensions are supported. For more information, see [Extensions](#).
- When creating a shard group, or when adding new shard group nodes (shards or routers), those nodes are created in one of the Availability Zones (AZs) available to the DB cluster. You can't choose a specific AZ for individual nodes.
- If you use a compute redundancy of 2 (two compute standbys for the DB shard group), make sure that your DB subnet group has at least three AZs.
- Aurora PostgreSQL Limitless Database supports up to 54 characters for sharded table names.

The following considerations apply to the Aurora PostgreSQL Limitless Database DB cluster:

- We recommend that you use Amazon managed policies to limit permissions for your database and applications to those that customers need for their use cases. For more information, see [Policy best practices](#).
- When you create your Aurora PostgreSQL Limitless Database DB cluster, you only set scaling parameters for the DB shard group.
- If you need to delete your DB cluster, you must delete the DB shard group first.
- Aurora PostgreSQL Limitless Database can't be a replication source.

## Features not supported in Aurora PostgreSQL Limitless Database

The following Aurora PostgreSQL features aren't supported in Aurora PostgreSQL Limitless Database:

- Active Directory (Kerberos) authentication
- Amazon DevOps Guru
- Amazon ElastiCache
- Amazon RDS Blue/Green Deployments
- Amazon RDS Proxy
- Aurora Auto Scaling (adding reader instances to the DB cluster automatically)
- Aurora Global Database
- Aurora machine learning
- Aurora recommendations
- Aurora Serverless v1
- Aurora zero-ETL integrations
- Amazon Backup
- Amazon Lambda integration
- Amazon Secrets Manager
- Babelfish for Aurora PostgreSQL
- Cloning DB clusters
- Custom endpoints
- Database activity streams
- Read replicas
- RDS Data API

# Prerequisites for using Aurora PostgreSQL Limitless Database

To use Aurora PostgreSQL Limitless Database, you must first perform the following tasks.

## Topics

- [Enabling DB shard group operations](#)

## Enabling DB shard group operations

Before you can create a DB shard group, you must enable DB shard group operations.

- Add the following section to the IAM policy of the IAM role of the user that accesses Aurora PostgreSQL Limitless Database:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDBShardGroup",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBShardGroup",
        "rds:DescribeDBShardGroups",
        "rds>DeleteDBShardGroup",
        "rds:ModifyDBShardGroup",
        "rds:RebootDBShardGroup"
      ],
      "Resource": [
        "arn:aws:rds:*:*:shard-group:*",
        "arn:aws:rds:*:*:cluster:*"
      ]
    }
  ]
}
```

# Creating a DB cluster that uses Aurora PostgreSQL Limitless Database

You create a new Aurora DB cluster using the Limitless Database version of Aurora PostgreSQL, and add a DB shard group to the cluster. When adding a DB shard group, you specify the maximum compute capacity for the entire DB shard group (sum of the capacities for all routers and shards) in Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. Scaling increases or decreases capacity for your DB shard group, depending on your application workload, similar to how [Aurora Serverless v2](#) works.

## Topics

- [Correlating DB shard group maximum capacity with the number of routers and shards created](#)
- [Creating your DB cluster](#)

## Correlating DB shard group maximum capacity with the number of routers and shards created

The initial number of routers and shards in a DB shard group is determined by the maximum capacity that you set when you create the DB shard group. The higher the maximum capacity, the greater the number of routers and shards that are created in the DB shard group.

Each node (shard or router) has its own current capacity value, also measured in ACUs.

- Limitless Database scales a node up to a higher capacity when its current capacity is too low to handle the load. However, nodes won't scale up when the total capacity is at the maximum.
- Limitless Database scales the node down to a lower capacity when its current capacity is higher than needed. However, nodes won't scale down when the total capacity is at the minimum.

The following table shows the correlation between the DB shard group maximum capacity in Aurora capacity units (ACUs) and the number of nodes (routers and shards) created.

### Note

These values are subject to change.

If you set the compute redundancy to a nonzero value, the total number of shards will be doubled or tripled. This will incur extra costs.

The nodes in compute standbys are scaled up and down to the same capacity as the writer. You don't set the capacity range separately for the standbys.

Total nodes	Routers	Shards	Default minimum capacity (ACUs)	Maximum capacity range (ACUs)
4	2	2	16	16–400
5	2	3	20	401–500
6	2	4	24	501–600
7	3	4	28	601–700
8	3	5	32	701–800
9	3	6	36	801–900
10	4	6	40	901–1000
11	4	7	44	1001–1100
12	4	8	48	1101–1200
13	5	8	52	1201–1300
14	5	9	56	1301–1400
15	5	10	60	1401–1500
16	6	10	64	1501–1600
17	6	11	68	1601–1700
18	6	12	72	1701–1800
19	7	12	76	1801–1900
20	7	13	80	1901–2000

Total nodes	Routers	Shards	Default minimum capacity (ACUs)	Maximum capacity range (ACUs)
21	7	14	84	2001–2100
22	8	14	88	2101–2200
23	8	15	92	2201–2300
24	8	16	96	2301–6144

Maximum capacity–based dynamic configuration for the DB shard group is available only during creation. The number of routers and shards remains the same when the maximum capacity is modified. For more information, see [Changing the capacity of a DB shard group](#).

You can use SQL commands to add shards and routers to a DB shard group. For more information, see the following:

- [Splitting a shard in a DB shard group](#)
- [Adding a router to a DB shard group](#)

 **Note**

You can't delete shards or routers.

## Creating your DB cluster

Use the following procedures to create an Aurora PostgreSQL DB cluster that uses Aurora PostgreSQL Limitless Database.

You can use either the Amazon Web Services Management Console or the Amazon CLI to create your DB cluster that uses Aurora PostgreSQL Limitless Database. You create the primary DB cluster and the DB shard group.

### Console

When you use the Amazon Web Services Management Console to create the primary DB cluster, the DB shard group is also created in the same procedure.

#### To create the DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Create database**.

The **Create database** page displays.

3. For **Engine type**, choose **Aurora (PostgreSQL Compatible)**.
4. For **Version**, choose one of the following:
  - **Aurora PostgreSQL with Limitless Database (Compatible with PostgreSQL 16.4)**
  - **Aurora PostgreSQL with Limitless Database (Compatible with PostgreSQL 16.6)**
5. For **Aurora PostgreSQL Limitless Database**:

**Aurora Limitless Database - new** [Info](#)

With Limitless Database, Aurora can automatically scale write throughput and data storage capacity beyond the limits of a single DB cluster.

**DB shard group identifier**  
Type a name for your DB shard group. The name must be unique across all DB shard groups owned by your  account in the current  Region.

Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

**DB shard group capacity range** | [Info](#)  
Enter the minimum and maximum capacity for Limitless Database. The capacity is measured in Aurora capacity units (ACUs) across all routers and shards.

**Minimum capacity (ACUs)**  (48 GiB)      **Maximum capacity (ACUs)**  (768 GiB)

Enter a value greater than or equal to 16 ACUs      Enter a value less than or equal to 6144 ACUs

**DB shard group deployment**  
The number of additional cross Availability Zone standby shards. Adding compute redundancy will have a significant impact on cost. [Learn more](#) [↗](#)

**No compute redundancy**  
Creates a DB shard group without standbys for each shard.

**Compute redundancy with a single failover target**  
Each shard is created with one compute standby in a different Availability Zone.

**Compute redundancy with two failover targets**  
Each shard is created with two compute standbys in different Availability Zones.

**Public access** [Info](#)

**Yes**  
RDS assigns a public IP address to the DB shard group. Amazon EC2 instances and other resources outside of the VPC can connect to your DB shard group. Resources inside the VPC can also connect to the DB shard group. Choose one or more VPC security groups that specify which resources can connect to the DB shard group.

**No**  
RDS doesn't assign a public IP address to the DB shard group. Only Amazon EC2 instances and other resources inside the VPC can connect to your DB shard group. Choose one or more VPC security groups that specify which resources can connect to the DB shard group.

a. Enter a **DB shard group identifier**.

 **Important**

After you create the DB shard group, you can't change the DB cluster identifier or the DB shard group identifier.

b. For **DB shard group capacity range**:

i. Enter the **Minimum capacity (ACUs)**. Use a value of at least 16 ACUs.

For a development environment, the default value is 16 ACUs. For a production environment, the default value is 24 ACUs.

ii. Enter the **Maximum capacity (ACUs)**. Use a value of at least 16 ACUs or at most 6144 ACUs.

For a development environment, the default value is 64 ACUs. For a production environment, the default value is 384 ACUs.

For more information, see [Correlating DB shard group maximum capacity with the number of routers and shards created](#).

- c. For **DB shard group deployment**, choose whether to create standbys for the DB shard group:
- **No compute redundancy** – Creates a DB shard group without standbys for each shard. This is the default value.
  - **Compute redundancy with a single failover target** – Creates a DB shard group with one compute standby in a different Availability Zone (AZ).
  - **Compute redundancy with two failover targets** – Creates a DB shard group with two compute standbys in two different AZs.

 **Note**

If you set the compute redundancy to a nonzero value, the total number of shards DB instances will be doubled or tripled. These extra DB instances are compute standbys, scaled up and down to the same capacity as the writer instance. You don't set the capacity range separately for the standbys. Therefore, ACU usage and bill correspondingly doubles and triples. To know the exact ACU usage incurred from compute redundancy, refer to the `DBShardGroupComputeRedundancyCapacity` metric in [DBShardGroup metrics](#).

- d. Choose whether to make the DB shard group publicly accessible.

 **Note**

You can't modify this setting after you create the DB shard group.

6. For **Connectivity**:

- a. (Optional) Select **Connect to an EC2 compute resource**, then choose an existing EC2 instance or create a new one.

 **Note**

If you connect to an EC2 instance, you can't make the DB shard group publicly accessible.

- b. For **Network type**, choose either **IPv4** or **Dual-stack mode**.

- c. Choose the **Virtual private cloud (VPC)** and **DB subnet group**, or use the default settings.

**Note**

If you create your Limitless Database DB cluster in the US East (N. Virginia) Region, don't include the `us-east-1e` Availability Zone (AZ) in your DB subnet group. Because of resource limitations, Aurora Serverless v2—and therefore Limitless Database— isn't supported in the `us-east-1e` AZ.

- d. Choose the **VPC security group (firewall)**, or use the default setting.
7. For **Database authentication**, choose either **Password authentication** or **Password and IAM database authentication**.
8. For **Monitoring**, make sure that the **Turn on Performance Insights** and **Enable Enhanced Monitoring** check boxes are selected.

For Performance Insights, choose a retention time of at least 1 month.

9. Expand the last **Additional configuration** on the page.
10. For **Log exports**, make sure that the **PostgreSQL log** check box is selected.
11. Specify other settings as needed. For more information, see [Settings for Aurora DB clusters](#).
12. Choose **Create database**.

After the primary DB cluster and DB shard group are created, they're displayed on the **Databases** page.

The screenshot shows the Amazon RDS Databases page. At the top, there is a breadcrumb 'RDS > Databases' and a title 'Databases (2)'. Below the title is a search bar with the placeholder text 'Filter by databases'. A table lists the databases with columns for DB identifier, Status, DB cluster identifier, Role, Engine, Engine version, Region & AZ, and Size. Two databases are listed: 'my-limitless-cluster' and 'my-db-shard-group', both with a status of 'Available'.

DB identifier	Status	DB cluster identifier	Role	Engine	Engine version	Region & AZ	Size
<a href="#">my-limitless-cluster</a>	Available	my-limitless-cluster	Limitless cluster	Aurora PostgreSQL	16.4-limitless	us-east-1	1 DB shard group
<a href="#">my-db-shard-group</a>	Available	my-limitless-cluster	DB shard group	Aurora PostgreSQL	16.4-limitless	us-east-1	Limitless DB (16 - 96 ACUs)

## CLI

When you use the Amazon CLI to create a DB cluster that uses Aurora PostgreSQL Limitless Database, you perform the following tasks:

1. [Create the primary DB cluster.](#)
2. [Create the DB shard group.](#)

### Create the primary DB cluster

The following parameters are required to create the DB cluster:

- `--db-cluster-identifier` – The name of your DB cluster.
- `--engine` – The DB cluster must use the `aurora-postgresql` DB engine.
- `--engine-version` – The DB cluster must use one of the DB engine versions:
  - `16.4-limitless`
  - `16.6-limitless`
- `--storage-type` – The DB cluster must use the `aurora-iopt1` DB cluster storage configuration.
- `--cluster-scalability-type` – Specifies the scalability mode of the Aurora DB cluster. When set to `limitless`, the cluster operates as an Aurora PostgreSQL Limitless Database. When set to `standard` (the default), the cluster uses normal DB instance creation.

#### Note

You can't modify this setting after you create the DB cluster.

- `--master-username` – The name of the master user for the DB cluster.
- `--master-user-password` – The password for the master user.
- `--enable-performance-insights` – You must enable Performance Insights.
- `--performance-insights-retention-period` – The Performance Insights retention period must be at least 31 days.
- `--monitoring-interval` – The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB cluster. This value can't be 0.
- `--monitoring-role-arn` – The Amazon Resource Name (ARN) for the IAM role that permits RDS to send Enhanced Monitoring metrics to Amazon CloudWatch Logs.

- `--enable-cloudwatch-logs-exports` – You must export postgresql logs to CloudWatch Logs.

The following parameters are optional:

- `--db-subnet-group-name` – The DB subnet group to associate with the DB cluster. This also determines the VPC associated with the DB cluster.

#### Note

If you create your Limitless Database DB cluster in the US East (N. Virginia) Region, don't include the `us-east-1e` Availability Zone (AZ) in your DB subnet group. Because of resource limitations, Aurora Serverless v2—and therefore Limitless Database—isn't supported in the `us-east-1e` AZ.

- `--vpc-security-group-ids` – A list of VPC security groups to associate with the DB cluster.
- `--performance-insights-kms-key-id` – The Amazon KMS key identifier for encryption of Performance Insights data. If you don't specify a KMS key, the default key for your Amazon Web Services account is used.
- `--region` – The Amazon Web Services Region where you create the DB cluster. It must be one that supports Aurora PostgreSQL Limitless Database.

To use the default VPC and VPC security group, omit the `--db-subnet-group-name` and `--vpc-security-group-ids` options.

### To create the primary DB cluster

- ```
aws rds create-db-cluster \
  --db-cluster-identifier my-limitless-cluster \
  --engine aurora-postgresql \
  --engine-version 16.6-limitless \
  --storage-type aurora-iopt1 \
  --cluster-scalability-type limitless \
  --master-username myuser \
  --master-user-password mypassword \
  --db-subnet-group-name mysubnetgroup \
  --vpc-security-group-ids sg-c7e5b0d2 \
  --enable-performance-insights \
```

```
--performance-insights-retention-period 31 \  
--monitoring-interval 5 \  
--monitoring-role-arn arn:aws-cn:iam::123456789012:role/EMrole \  
--enable-cloudwatch-logs-exports postgresql
```

For more information, see [create-db-cluster](#).

## Create the DB shard group

Next you create the DB shard group in the DB cluster that you just created. The following parameters are required:

- `--db-shard-group-identifier` – The name of your DB shard group.

The DB shard group identifier has the following constraints:

- It must be unique in the Amazon Web Services account and Amazon Web Services Region where you create it.
- It must contain 1–63 letters, numbers, or hyphens.
- The first character must be a letter.
- It can't end with a hyphen or contain two consecutive hyphens.

• ** Important**

After you create the DB shard group, you can't change the DB cluster identifier or the DB shard group identifier.

- `--db-cluster-identifier` – The name of the DB cluster in which you're creating the DB shard group.
- `--max-acu` – The maximum capacity of your DB shard group. It must be from 16–6144 ACUs. For capacity limits higher than 6144 ACUs, contact Amazon.

The initial number of routers and shards is determined by the maximum capacity that you set when you create the DB shard group. The higher the maximum capacity, the greater the number of routers and shards that are created in the DB shard group. For more information, see [Correlating DB shard group maximum capacity with the number of routers and shards created](#).

The following parameters are optional:

- `--compute-redundancy` – Whether to create standbys for the DB shard group. This parameter can have the following values:
  - 0 – Creates a DB shard group without standbys for each shard. This is the default value.
  - 1 – Creates a DB shard group with one compute standby in a different Availability Zone (AZ).
  - 2 – Creates a DB shard group with two compute standbys in two different AZs.

**Note**

If you set the compute redundancy to a nonzero value, the total number of shards will be doubled or tripled. This will incur extra costs.

The nodes in compute standbys are scaled up and down to the same capacity as the writer. You don't set the capacity range separately for the standbys.

- `--min-acu` – The minimum capacity of your DB shard group. It must be at least 16 ACUs, which is the default value.
- `--publicly-accessible` | `--no-publicly-accessible` – Whether to assign publicly accessible IP addresses to the DB shard group. Access to the DB shard group is controlled by the security groups used by the cluster.

The default is `--no-publicly-accessible`.

**Note**

You can't modify this setting after you create the DB shard group.

**To create the DB shard group**

- ```
aws rds create-db-shard-group \  
  --db-shard-group-identifier my-db-shard-group \  
  --db-cluster-identifier my-limitless-cluster \  
  --max-acu 1000
```

# Working with DB shard groups

You perform the following tasks to add and manage a DB shard group for Aurora PostgreSQL Limitless Database.

## Topics

- [Connecting to your Aurora PostgreSQL Limitless Database DB cluster](#)
- [Finding the number of routers and shards in a DB shard group](#)
- [Describing DB shard groups](#)
- [Rebooting a DB shard group](#)
- [Changing the capacity of a DB shard group](#)
- [Splitting a shard in a DB shard group](#)
- [Adding a router to a DB shard group](#)
- [Deleting a DB shard group](#)
- [Adding a DB shard group to an existing Aurora PostgreSQL Limitless Database DB cluster](#)

## Connecting to your Aurora PostgreSQL Limitless Database DB cluster

To work with Aurora PostgreSQL Limitless Database, you connect to the cluster writer or reader endpoint. You can use `psql` or any other connection utility that works with PostgreSQL:

```
$ psql -h DB_cluster_endpoint -p port_number -U database_username -d postgres_limitless
```

The following example uses the endpoint for the DB cluster that you created in [CLI](#).

```
$ psql -h my-limitless-cluster.cluster-ckifpdyyyxxx.us-east-1.rds.amazonaws.com -p 5432  
-U postgres -d postgres_limitless
```

### Note

The default database for the DB shard group in Aurora PostgreSQL Limitless Database is `postgres_limitless`.

## Using the Limitless Connection Plugin

When connecting to Aurora PostgreSQL Limitless Database, clients connect using the cluster endpoint, and are routed to a transaction router by Amazon Route 53. However, Route 53 is limited in its ability to load balance, and can allow uneven workloads on transaction routers. The [Limitless Connection Plugin](#) for the [Amazon JDBC Driver](#) addresses this by performing client-side load balancing with load awareness. For more information on the [Amazon JDBC Driver](#), see [Connecting to Aurora PostgreSQL with the Amazon Web Services \(Amazon\) JDBC Driver](#).

## Finding the number of routers and shards in a DB shard group

You can use the following query to find the number of routers and shards:

```
SELECT * FROM rds_aurora.limitless_subclusters;
```

subcluster_id	subcluster_type
1	router
2	router
3	shard
4	shard
5	shard
6	shard

## Describing DB shard groups

Use the `describe-db-shard-groups` Amazon CLI command to describe your DB shard groups. The following parameter is optional:

- `--db-shard-group-identifier` – The name of a DB shard group.

The following example describes a specific DB shard group.

```
aws rds describe-db-shard-groups --db-shard-group-identifier my-db-shard-group
```

The output resembles the following example.

```
{
  "DBShardGroups": [
    {
      "DBShardGroupResourceId": "shardgroup-8986d309a93c4da1b1455add17abcdef",
      "DBShardGroupIdentifier": "my-shard-group",
      "DBClusterIdentifier": "my-limitless-cluster",
      "MaxACU": 1000.0,
      "ComputeRedundancy": 0,
      "Status": "available",
      "PubliclyAccessible": false,
      "Endpoint": "my-limitless-cluster.limitless-ccetp2abcdef.us-east-1.rds.amazonaws.com"
    }
  ]
}
```

```
]
}
```

## Rebooting a DB shard group

Sometimes you have to reboot your DB shard group, for example when the `max_connections` parameter changes because of a maximum capacity change.

You can use the Amazon Web Services Management Console or Amazon CLI to change the capacity of a DB shard group.

### Console

Use the following procedure.

Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

1. Navigate to the **Databases** page.
2. Select the DB shard group that you want to reboot.
3. For **Actions**, choose **Reboot**.
4. Choose **Confirm**.

### CLI

To reboot a DB shard group, use the `reboot-db-shard-group` Amazon CLI command with the following parameter:

- `--db-shard-group-identifier` – The name of a DB shard group.

The following example reboots a DB shard group.

```
aws rds reboot-db-shard-group --db-shard-group-identifier my-db-shard-group
```

## Changing the capacity of a DB shard group

You can use the Amazon Web Services Management Console or Amazon CLI to change the capacity of a DB shard group.

### Console

Use the following procedure.

Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

1. Navigate to the **Databases** page.
2. Select the DB shard group that you want to modify.
3. For **Actions**, choose **Modify**.

The **Modify DB shard group** page displays.

The screenshot shows the 'Modify DB shard group: my-shard-group' page in the AWS Management Console. The page is titled 'Modify DB shard group: my-shard-group' and contains the following sections:

- DB shard group configuration**
  - DB shard group identifier:** my-shard-group
  - DB shard group capacity range:** Enter the minimum and maximum capacity for Limitless Database. The capacity is measured in Aurora capacity units (ACUs) across all routers and shards.
  - Minimum capacity (ACUs):** 16 (32 GiB). Below the input field, it says 'Enter a value greater than or equal to 16 ACUs'.
  - Maximum capacity (ACUs):** 64 (128 GiB). Below the input field, it says 'Enter a value less than or equal to 6144 ACUs'.
- DB shard group deployment**
  - The number of additional cross Availability Zone standby shards. Adding compute redundancy will have a significant impact on cost. [Learn more](#)
  - No compute redundancy**  
Creates a DB shard group without standbys for each shard.
  - Compute redundancy with a single failover target**  
Each shard is created with one compute standby in a different Availability Zone.
  - Compute redundancy with two failover targets**  
Each shard is created with two compute standbys in different Availability Zones.

At the bottom right of the form, there are two buttons: 'Cancel' and 'Continue'.

4. Enter a new **Minimum capacity (ACUs)** value, for example **100**.
5. Enter a new **Maximum capacity (ACUs)** value, for example **1000**.
6. Choose **Continue**.

The confirmation page displays, with a summary of your changes.

## 7. Review your changes, then choose **Modify DB shard group**.

### CLI

Use the `modify-db-shard-group` Amazon CLI command with the following parameters:

- `--db-shard-group-identifier` – The name of the DB shard group.
- `--max-acu` – The new maximum capacity of the DB shard group. You can set the maximum capacity of the DB shard group to 16–6144 ACUs. For capacity limits higher than 6144 ACUs, contact Amazon.

The number of routers and shards doesn't change.

- `--min-acu` – The new minimum capacity of your DB shard group. It must be at least 16 ACUs, which is the default value.

The following CLI example changes the capacity range of a DB shard group to 100–1000 ACUs.

```
aws rds modify-db-shard-group \  
  --db-shard-group-identifier my-db-shard-group \  
  --min-acu 100 \  
  --max-acu 1000
```

## Splitting a shard in a DB shard group

You can split a shard in a DB shard group manually into two smaller shards. This is called a *user-initiated* shard split.

Aurora PostgreSQL Limitless Database can also split shards when they have very large amounts of data or very high usage. This is called a *system-initiated* shard split.

### Topics

- [Prerequisites](#)
- [Splitting a shard](#)
- [Tracking shard splits](#)
- [Finalizing shard splits](#)
- [Canceling a shard split](#)

### Prerequisites

User-initiated shard splits have the following prerequisites:

- You must have a DB shard group.
- The DB shard group can't be empty: it must contain at least one sharded table.
- A user must have the `rds_aurora_limitless_cluster_admin` privilege. The `rds_superuser` has this privilege; therefore the master user also has it. The `rds_superuser` can grant the privilege to other users:

```
/* Logged in as the master user or a user with rds_superuser privileges */  
CREATE USER username;  
GRANT rds_aurora_limitless_cluster_admin to username;
```

- You must know the subcluster (node) ID of the shard that you want to split. You can obtain the ID by using the following query:

```
SELECT * FROM rds_aurora.limitless_subclusters;  
  
subcluster_id | subcluster_type  
-----+-----  
1             | router  
2             | router
```

```

3          | shard
4          | shard
5          | shard
6          | shard

```

To enable system-initiated shard splits, set the following DB cluster parameters in a custom DB cluster parameter group associated with your DB cluster:

Parameter	Value
<code>rds_aurora.limitless_enable_auto_scale</code>	on
<code>rds_aurora.limitless_auto_scale_options</code>	Either <code>split_shard</code> or <code>add_router,split_shard</code>
<code>rds_aurora.limitless_finalize_split_shard_mode</code>	<p>This parameter determines how <i>system-initiated</i> shard splits are finalized. The value can be one of the following:</p> <ul style="list-style-type: none"> <li><code>user_initiated</code> – You decide when to finalize the shard split. This is the default value.</li> <li><code>immediate</code> – Shard splits are finalized immediately.</li> </ul> <p>For more information, see <a href="#">Finalizing shard splits</a>.</p> <div data-bbox="829 1493 1508 1713" style="border: 1px solid #00a0e3; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p><b>Note</b></p> <p>This parameter applies only to system-initiated shard splits.</p> </div>

For more information, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

## Splitting a shard

To split a shard in a DB shard group, use the `rds_aurora.limitless_split_shard` function. This function starts a shard-split job that runs asynchronously.

```
SELECT rds_aurora.limitless_split_shard('subcluster_id');
```

Wait for the return of a job ID upon successful submission of the job, for example:

```
SELECT rds_aurora.limitless_split_shard('3');
```

```

  job_id
-----
1691300000000
(1 row)

```

### Note

Concurrent shard split operations are not supported. Execute each operation sequentially and complete each operation before initiating another addition operation.

## Tracking shard splits

You can use the job ID to track a shard-split job. To describe a particular job and get more details about it, run the following query:

```
SELECT * FROM rds_aurora.limitless_list_shard_scale_jobs(job_id);
```

For example:

```
SELECT * FROM rds_aurora.limitless_list_shard_scale_jobs(1691300000000);
```

```

  job_id      | action      | job_details          | status  | submission_time
|             | message
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
1691300000000 | SPLIT_SHARD | Split Shard 3 by User | SUCCESS | 2023-08-06 05:33:20+00
| Scaling job succeeded.          |

```

```
|
|
|
|
| New shard instance with ID 7 was created.
(1 row)
```

The query returns an error when you pass a nonexistent job as the input.

```
SELECT * from rds_aurora.limitless_list_shard_scale_jobs(1691300000001);

ERROR: no job found with the job ID provided
```

You can track the status of all shard-split jobs by using the same query without a job ID, for example:

```
SELECT * FROM rds_aurora.limitless_list_shard_scale_jobs();

   job_id      | action | job_details           | status      | submission_time
   |              | message
-----+-----+-----+-----+-----
+-----+
+-----+
1691200000000 | SPLIT_SHARD | Split Shard 3 by User | IN_PROGRESS | 2023-08-05
01:46:40+00 |
1691300000000 | SPLIT_SHARD | Split Shard 4 by User | SUCCESS      | 2023-08-06
05:33:20+00 | Scaling job succeeded. +
              |         |
              |         |
              |         |
1691400000000 | SPLIT_SHARD | Split Shard 5 by User | FAILED      | 2023-08-07
09:20:00+00 | Error occurred for the add shard job 1691400000000.
              |         |
              |         |
              |         |
              |         |
1691500000000 | SPLIT_SHARD | Split Shard 5 by User | CANCELED    | 2023-08-07
09:20:00+00 | Scaling job was cancelled.
(4 rows)
```

The job status can be one of the following:

- **IN\_PROGRESS** – The shard-split job has been submitted and is in progress. You can have only one job in progress at a time.
- **PENDING** – The shard-split job is waiting for you to finalize it. For more information, see [Finalizing shard splits](#).
- **CANCELLATION\_IN\_PROGRESS** – The shard-split job is being canceled by the user.

- CANCELED – The shard-split job has been successfully canceled by the user or by the system.
- SUCCESS – The shard-split job completed successfully. The message field contains the instance ID of the new shard.
- FAILED – The shard-split job failed. The message field contains the details of the failure and any actions that can be taken as a followup to the failed job.

## Finalizing shard splits

Finalizing is the last step of the shard-split process. It causes some downtime. If you start a shard-split job, then finalizing happens immediately after the job completes successfully.

Sometimes the system splits shards based on workload, when you've enabled system-initiated shard splits by using the `rds_aurora.limitless_enable_auto_scale` parameter.

In this case, you can choose whether finalizing happens immediately, or at a time that you choose. You use the `rds_aurora.limitless_finalize_split_shard_mode` DB cluster parameter to choose when it happens:

- If you set the value to `immediate`, it happens immediately.
- If you set the value to `user_initiated`, you have to finalize the shard-split job manually.

An RDS event is sent to you, and the status of the shard-split job is set to PENDING.

When set to `user_initiated`, you use the `rds_aurora.limitless_finalize_split_shard` function to finalize the shard-split job:

```
SELECT * FROM rds_aurora.limitless_finalize_split_shard(job_id);
```

### Note

This function applies only to shard splits that are initiated by the system, not by you.

## Canceling a shard split

You can cancel a user-initiated or system-initiated shard split that's IN\_PROGRESS or PENDING. You need the job ID to cancel it.

```
SELECT * from rds_aurora.limitless_cancel_shard_scale_jobs(job_id);
```

No output is returned unless there's an error. You can track the cancellation using a job-tracking query.

## Adding a router to a DB shard group

You can add a router to a DB shard group.

### Topics

- [Prerequisites](#)
- [Adding a router](#)
- [Tracking router additions](#)
- [Canceling a router addition](#)

### Prerequisites

Adding a router has the following prerequisites:

- You must have a DB shard group.
- A user must have the `rds_aurora_limitless_cluster_admin` privilege. The `rds_superuser` has this privilege; therefore the master user also has it. The `rds_superuser` can grant the privilege to other users:

```
/* Logged in as the master user or a user with rds_superuser privileges */  
CREATE USER username;  
GRANT rds_aurora_limitless_cluster_admin to username;
```

#### Note

If you change your Amazon Web Services account's default CA certificate after the DB shard group is created, the new router will use the new CA certificate, which is different from the existing router's CA certificate. Depending on your trust store, some connections might fail.

- To enable system-initiated router addition, set the following DB cluster parameters in a custom DB cluster parameter group associated with your DB cluster:

Parameter	Value
<code>rds_aurora.limitless_enable_auto_scale</code>	on
<code>rds_aurora.limitless_auto_scale_options</code>	Either <code>add_router</code> or <code>add_router,split_shard</code>

For more information, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

## Adding a router

To add a router, use the `rds_aurora.limitless_add_router` function. This function starts a router-addition job that runs asynchronously.

```
SELECT rds_aurora.limitless_add_router();
```

Wait for the return of a job ID upon successful submission of the job, for example:

```

  job_id
-----
1691300000000
(1 row)
```

### Note

Concurrent router addition operations are not supported. Execute operations sequentially and complete each operation before initiating another addition operation.

## Tracking router additions

You can use the job ID to track a router-addition job. To describe a particular job and get more details about it, run the following query:

```
SELECT * FROM rds_aurora.limitless_list_router_scale_jobs(job_id);
```

## For example:

```
SELECT * FROM rds_aurora.limitless_list_router_scale_jobs(1691300000000);
```

job_id	action	job_details	status	submission_time
		message		
1691300000000	ADD_ROUTER	Add 1 new Router by User	SUCCESS	2023-08-06
05:33:20+00		Scaling job succeeded.		
		New router instance with ID 7 was created.		

(1 row)

The query returns an error when you pass a nonexistent job as the input.

```
SELECT * from rds_aurora.limitless_list_router_scale_jobs(1691300000001);
```

ERROR: no job found with the job ID provided

You can track the status of all router-addition jobs by using the same query without a job ID, for example:

```
SELECT * FROM rds_aurora.limitless_list_router_scale_jobs();
```

job_id	action	job_details	status	submission_time
		message		
1691200000000	ADD_ROUTER	Add 1 new Router by User	IN_PROGRESS	2023-08-05
01:46:40+00				
1691300000000	ADD_ROUTER	Add 1 new Router by User	SUCCESS	2023-08-06
05:33:20+00		Scaling job succeeded.		
		New router instance with ID 7 was created.		
1691400000000	ADD_ROUTER	Add 1 new Router by User	FAILED	2023-08-07
09:20:00+00		Error occurred for the add router job 1691400000000.		
		Retry the command. If the issue persists, contact AWS Support.		
1691500000000	ADD_ROUTER	Add 1 new Router by User	CANCELED	2023-08-07
09:20:00+00		Scaling job was cancelled.		

(4 rows)

The job status can be one of the following:

- **IN\_PROGRESS** – The router-addition job has been submitted and is in progress. You can have only one job in progress at a time.
- **CANCELLATION\_IN\_PROGRESS** – The router-addition job is being canceled by the user.
- **CANCELED** – The router-addition job has been successfully canceled by the user or by the system.
- **SUCCESS** – The router-addition job completed successfully. The message field contains the instance ID of the new router.
- **FAILED** – The router-addition job failed. The message field contains the details of the failure and any actions that can be taken as a followup to the failed job.

 **Note**

There's no PENDING status because router additions don't need to be finalized. They incur no downtime.

## Canceling a router addition

You can cancel a router addition that's IN\_PROGRESS. You need the job ID to cancel it.

```
SELECT * from rds_aurora.limitless_cancel_router_scale_jobs(job_id);
```

No output is returned unless there's an error. You can track the cancellation using a job-tracking query.

## Deleting a DB shard group

You can delete a DB shard group if necessary. Deleting the DB shard group deletes the compute nodes (shards and routers), but not the storage.

### Console

Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

1. Navigate to the **Databases** page.
2. Select the DB shard group that you want to delete.
3. For **Actions**, choose **Delete**.
4. Enter **delete me** in the box, then choose **Delete**.

The DB shard group is deleted.

### Amazon CLI

To delete your DB shard group, use the `delete-db-shard-group` Amazon CLI command with the following parameter:

- `--db-shard-group-identifier` – The name of the DB shard group.

The following example deletes a DB shard group in the Aurora PostgreSQL DB cluster that you created previously.

```
aws rds delete-db-shard-group --db-shard-group-identifier my-db-shard-group
```

## Adding a DB shard group to an existing Aurora PostgreSQL Limitless Database DB cluster

You can create a DB shard group in an existing DB cluster, for example if you're restoring a DB cluster or you had deleted the DB shard group.

For more information on primary DB cluster and DB shard group requirements, see [Aurora PostgreSQL Limitless Database requirements and considerations](#).

### Note

You can have only one DB shard group per cluster.  
The Limitless Database DB cluster must be in the available state before you can create a DB shard group.

### Console

You can use the Amazon Web Services Management Console to add a DB shard group to an existing DB cluster.

#### To add a DB shard group

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Navigate to the **Databases** page.
3. Select the Limitless Database DB cluster to which you want to add a DB shard group.
4. For **Actions**, choose **Add a DB shard group**.

RDS > Databases > Add a Limitless Database instance group

## Add a DB shard group

**Aurora Limitless Database** [Info](#)  
 Aurora Limitless Database is a new, automated horizontal scaling (sharding) capability of Amazon Aurora. Limitless Database lets you scale beyond the existing Aurora limits for write throughput and storage by distributing a database workload over multiple Aurora writer instances, while maintaining the ability to use it as a single database.

**DB shard group identifier**  
 Type a name for your DB shard group. The name must be unique across all DB shard groups owned by your  account in the current  Region.

Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

**DB Shard group capacity range**  
 Enter the minimum and maximum capacity for Limitless Database. The capacity is measured in Aurora capacity units (ACUs) across all routers and shards.

**Minimum capacity (ACUs)**  (0 GiB)  
 Enter a value greater than or equal to 16 ACUs

**Maximum capacity (ACUs)**  (0 GiB)  
 Enter a value less than or equal to 6144 ACUs

**DB shard group deployment**  
 The number of additional standby DB shard groups. Adding compute redundancy will have a significant impact on cost. [Learn more](#)

**No compute redundancy**  
 Creates a DB shard group without a standby DB shard group.

**Compute redundancy with a single failover target**  
 Creates a DB shard group with a standby DB shard group in a different Availability Zone.

**Compute redundancy with two failover targets**  
 Creates a DB shard group with two standby DB shard groups in two different Availability Zones.

**Public access** [Info](#)

**Yes**  
 RDS assigns a public IP address to the DB shard group. Amazon EC2 instances and other resources outside of the VPC can connect to your DB shard group. Resources inside the VPC can also connect to the DB shard group. Choose one or more VPC security groups that specify which resources can connect to the DB shard group.

**No**  
 RDS doesn't assign a public IP address to the DB shard group. Only Amazon EC2 instances and other resources inside the VPC can connect to your DB shard group. Choose one or more VPC security groups that specify which resources can connect to the DB shard group.

---

**Monitoring**

**Performance Insights**

Configuration management	Status	Retention period
Cluster level	Turned on	31 days

**AWS KMS key**  [Info](#)

**Enhanced Monitoring**

Configuration management	Status	Granularity
Cluster level	Turned on	5 seconds

**Monitoring role**  
 arn:aws:iam:::role/rds-monitoring-role

[Cancel](#) [Add a DB shard group](#)

5. Enter a **DB shard group identifier**.

**⚠ Important**

After you create the DB shard group, you can't change the DB cluster identifier or the DB shard group identifier.

6. Enter the **Minimum capacity (ACUs)**. Use a value of at least 16 ACUs.

7. Enter the **Maximum capacity (ACUs)**. Use a value from 16–6144 ACUs.

For more information, see [Correlating DB shard group maximum capacity with the number of routers and shards created](#).

8. For **DB shard group deployment**, choose whether to create standbys for the DB shard group:
  - **No compute redundancy** – Creates a DB shard group without standbys for each shard. This is the default value.
  - **Compute redundancy with a single failover target** – Creates a DB shard group with one compute standby in a different Availability Zone (AZ).
  - **Compute redundancy with two failover targets** – Creates a DB shard group with two compute standbys in two different AZs.
9. Choose whether to make the DB shard group publicly accessible.

 **Note**

You can't modify this setting after you create the DB shard group.

10. Choose **Add a DB shard group**.

## Amazon CLI

Use the `create-db-shard-group` Amazon CLI command to create a DB shard group.

The following parameters are required:

- `--db-cluster-identifier` – The DB cluster to which the DB shard group belongs.
- `--db-shard-group-identifier` – The name of the DB shard group.

The DB shard group identifier has the following constraints:

- It must be unique in the Amazon Web Services account and Amazon Web Services Region where you create it.
- It must contain 1–63 letters, numbers, or hyphens.
- The first character must be a letter.
- It can't end with a hyphen or contain two consecutive hyphens.

### Important

After you create the DB shard group, you can't change the DB cluster identifier or the DB shard group identifier.

- `--max-acu` – The maximum capacity of the DB shard group. Use a value from 16–6144 ACUs.

The following parameters are optional:

- `--compute-redundancy` – Whether to create standbys for the DB shard group. This parameter can have the following values:
  - `0` – Creates a DB shard group without standbys for each shard. This is the default value.
  - `1` – Creates a DB shard group with one compute standby in a different Availability Zone (AZ).
  - `2` – Creates a DB shard group with two compute standbys in two different AZs.

### Note

If you set the compute redundancy to a nonzero value, the total number of nodes will be doubled or tripled. This will incur extra costs.

- `--min-acu` – The minimum capacity of your DB shard group. It must be at least 16 ACUs, which is the default value.
- `--publicly-accessible` | `--no-publicly-accessible` – Whether to assign publicly accessible IP addresses to the DB shard group. Access to the DB shard group is controlled by the security groups used by the cluster.

The default is `--no-publicly-accessible`.

**Note**

You can't modify this setting after you create the DB shard group.

The following example creates a DB shard group in an Aurora PostgreSQL DB cluster.

```
aws rds create-db-shard-group \  
  --db-cluster-identifier my-db-cluster \  
  --db-shard-group-identifier my-new-shard-group \  
  --max-acu 1000
```

The output resembles the following example.

```
{  
  "Status": "CREATING",  
  "Endpoint": "my-db-cluster.limitless-ckifpdyyyxxx.us-east-1.rds.amazonaws.com",  
  "PubliclyAccessible": false,  
  "DBClusterIdentifier": "my-db-cluster",  
  "MaxACU": 1000.0,  
  "DBShardGroupIdentifier": "my-new-shard-group",  
  "DBShardGroupResourceId": "shardgroup-8986d309a93c4da1b1455add17abcdef",  
  "ComputeRedundancy": 0  
}
```

# Creating Aurora PostgreSQL Limitless Database tables

There are three types of tables that contain your data in Aurora PostgreSQL Limitless Database:

- **Standard** – This is the default table type in Aurora PostgreSQL Limitless Database. You create standard tables using the [CREATE TABLE](#) command, and can run Data Description Language (DDL) and Data Manipulation Language (DML) operations on them.

Standard tables aren't distributed tables. They're stored on one of the shards chosen internally by the system.

- **Sharded** – These tables are distributed across multiple shards. Data is split among the shards based on the values of designated columns in the table. This set of columns is called a shard key.
- **Reference** – These tables are replicated on all shards. They're used for infrequently modified reference data, such as product catalogs and zip codes.

Join queries between reference and sharded tables can be run on shards, eliminating unnecessary data movement between shards and routers.

There are two ways to create limitless tables:

- [Creating limitless tables by using variables](#) – Use this method when you want to create new sharded and reference tables.
- [Converting standard tables to limitless tables](#) – Use this method when you want to convert existing standard tables into sharded and reference tables.

We also provide [sample schemas](#) for Aurora PostgreSQL Limitless Database.

## Creating limitless tables by using variables

You can use variables to create sharded and reference tables by setting the table creation mode. Then the tables that you create will use this mode until you set a different mode.

Use the following variables to create sharded and reference tables:

- `rds_aurora.limitless_create_table_mode` – Set this session variable to sharded or reference. The default value of this variable is standard.
- `rds_aurora.limitless_create_table_shard_key` – Set this session variable to an array of column names to use as shard keys. This variable is ignored when `rds_aurora.limitless_create_table_mode` isn't sharded.

Format the value as untyped `array literal`, similar to when you insert literals into an array column. For more information, see [Arrays](#) in the PostgreSQL documentation.

- `rds_aurora.limitless_create_table_collocate_with` – Set this session variable to a specific table name to collocate newly created tables with that table.

If two or more tables are sharded using the same shard key, you can explicitly align (collocate) those tables. When two or more tables are collocated, rows from those tables with the same shard key values are placed on the same shard. Collocation helps to restrict some operations to a single shard, which results in better performance.

### Note

All primary and unique keys must include the shard key. This means that the shard key is a subset of the primary or unique key.

Limitless tables have some limitations. For more information, see [DDL limitations and other information for Aurora PostgreSQL Limitless Database](#).

### Topics

- [Examples using variables to create limitless tables](#)
- [Aurora PostgreSQL Limitless Database table views](#)

## Examples using variables to create limitless tables

The following examples show how to use these variables to create sharded and reference tables.

Create a sharded table named `items`, with the shard key `id`.

```
BEGIN;
SET LOCAL rds_aurora.limitless_create_table_mode='sharded';
SET LOCAL rds_aurora.limitless_create_table_shard_key='{\"id\"}';
CREATE TABLE items(id int, val int, item text);
COMMIT;
```

Create a sharded table named `items`, with a shard key composed of the `item_id` and `item_cat` columns.

```
BEGIN;
SET LOCAL rds_aurora.limitless_create_table_mode='sharded';
SET LOCAL rds_aurora.limitless_create_table_shard_key='{\"item_id\", \"item_cat\"}';
CREATE TABLE items(item_id int, item_cat varchar, val int, item text);
COMMIT;
```

Create a sharded table named `item_description`, with a shard key composed of the `item_id` and `item_cat` columns, and collocate it with the `items` table from the previous example.

```
BEGIN;
SET LOCAL rds_aurora.limitless_create_table_mode='sharded';
SET LOCAL rds_aurora.limitless_create_table_shard_key='{\"item_id\", \"item_cat\"}';
SET LOCAL rds_aurora.limitless_create_table_collocate_with='items';
CREATE TABLE item_description(item_id int, item_cat varchar, color_id int);
COMMIT;
```

Create a reference table named `colors`.

```
BEGIN;
SET LOCAL rds_aurora.limitless_create_table_mode='reference';
CREATE TABLE colors(color_id int primary key, color varchar);
COMMIT;
```

To reset the `rds_aurora.limitless_create_table_mode` session variable to standard, use the following statement:

```
RESET rds_aurora.limitless_create_table_mode;
```

After you reset this variable, tables are created as standard tables, which is the default. For more information on standard tables, see [Converting standard tables to limitless tables](#).

## Aurora PostgreSQL Limitless Database table views

You can find information about Limitless Database tables by using the following views.

### `rds_aurora.limitless_tables`

The `rds_aurora.limitless_tables` view contains information about limitless tables and their types.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_tables;
```

table_gid	local_oid	schema_name	table_name	table_status	table_type	distribution_key
5	18635	public	standard	active	standard	
6	18641	public	ref	active	reference	
7	18797	public	orders	active	sharded	
HASH (order_id)						
2	18579	public	customer	active	sharded	
HASH (cust_id)						

(4 rows)

### `rds_aurora.limitless_table_collocations`

The `rds_aurora.limitless_table_collocations` view contains information about collocated sharded tables. For example, the `orders` and `customers` tables are collocated, and have the same `collocation_id`. The `users` and `followers` tables are collocated, and have the same `collocation_id`.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_table_collocations ORDER BY collocation_id;
```

collocation_id	schema_name	table_name
16002	public	orders
16002	public	customers
16005	public	users
16005	public	followers

(4 rows)

## rds\_aurora.limitless\_table\_collocation\_distributions

The `rds_aurora.limitless_table_collocation_distributions` shows the key distribution for each collocation.

```
postgres_limitless=> SELECT * FROM
rds_aurora.limitless_table_collocation_distributions ORDER BY collocation_id,
lower_bound;
```

collocation_id	subcluster_id	lower_bound	upper_bound
16002	6	-9223372036854775808	-4611686018427387904
16002	5	-4611686018427387904	0
16002	4	0	4611686018427387904
16002	3	4611686018427387904	9223372036854775807
16005	6	-9223372036854775808	-4611686018427387904
16005	5	-4611686018427387904	0
16005	4	0	4611686018427387904
16005	3	4611686018427387904	9223372036854775807

(8 rows)

## Converting standard tables to limitless tables

You can convert standard tables into sharded or reference tables. During the conversion, data is moved from the standard table to the distributed table, then the source standard table is deleted. Data is moved using the `INSERT INTO SELECT FROM` command.

### Contents

- [Creating sharded tables](#)
- [Creating colocated tables](#)
- [Creating reference tables](#)

### Creating sharded tables

You create sharded tables by running the `rds_aurora.limitless_alter_table_type_sharded` procedure on standard tables. This procedure takes a standard table and a list of columns, then distributes the given table using the list of columns as the shard key. The procedure runs synchronously, and acquires an `ACCESS EXCLUSIVE` lock on the table.

After the procedure finishes successfully, the source standard table is deleted, and a sharded table with the same name becomes available.

The `rds_aurora.limitless_alter_table_type_sharded` procedure uses the following syntax:

```
postgres=> CALL rds_aurora.limitless_alter_table_type_sharded('schema.table',
ARRAY['shard_key1', 'shard_key2', ... 'shard_keyn']);
```

The procedure requires the following parameters:

- `schema` – The database schema that contains the table to be sharded. If the schema isn't specified, the procedure uses the `search_path`.
- `table` – The table to be sharded.
- `shard_keyn` – An array of table columns to use as the shard key.

Shard key values are string literals, and are therefore case sensitive. If a shard key contains a single quote (`'`), use another single quote to escape it. For example, if a table column is named

`customer's id`, use `customer's id` as the shard key. Backslashes (`\`) and double quotes (`"`) don't need to be escaped.

### Note

All primary and unique keys must include the shard key. This means that the shard key is a subset of the primary or unique key.

In sharded tables, the CHECK constraint doesn't support expressions.

For more information, see [Constraints](#).

## To create a sharded table

The following example shows how to create the `customer` sharded table with the shard key `customer_id`.

1. Create the standard table.

```
CREATE TABLE customer (customer_id INT PRIMARY KEY NOT NULL, zipcode INT, email VARCHAR);
```

2. Convert the standard table to a sharded table.

```
postgres=> CALL rds_aurora.limitless_alter_table_type_sharded('public.customer',
ARRAY['customer_id']);
```

```
postgres=> \d
```

```

                                List of relations
 Schema | Name          | Type              | Owner
-----+-----+-----+-----
 public | customer      | partitioned table | postgres_limitless
 public | customer_fs1  | foreign table     | postgres_limitless
 public | customer_fs2  | foreign table     | postgres_limitless
 public | customer_fs3  | foreign table     | postgres_limitless
 public | customer_fs4  | foreign table     | postgres_limitless
 public | customer_fs5  | foreign table     | postgres_limitless
(6 rows)
```

## Creating collocated tables

If two or more tables are sharded using the same shard key, you can explicitly align (collocate) those tables. When two or more tables are collocated, rows from those tables with the same shard key values are placed on the same shard. Collocation helps to restrict some operations to a single shard, which results in better performance.

You use the `rds_aurora.limitless_alter_table_type_sharded` procedure with the following syntax:

```
postgres=> CALL
  rds_aurora.limitless_alter_table_type_sharded('schema.collocated_table',
  ARRAY['shard_key1', 'shard_key2', ... 'shard_keyn'], 'schema.sharded_table');
```

The procedure requires the following parameters:

- `schema` – The database schema that contains the tables to be collocated. If the schema isn't specified, the procedure uses the `search_path`.
- `collocated_table` – The table to be collocated.
- `shard_keyn` – An array of table columns to use as the shard key.

You must use the same shard key as for the original sharded table, including the same column names and column types.

- `sharded_table` – The sharded table with which you're collocating the `collocated_table`.

### To create a collocated table

1. Create the first sharded table by following the procedure in [Creating sharded tables](#).
2. Create the standard table for the collocated table.

```
CREATE TABLE mytable2 (customer_id INT PRIMARY KEY NOT NULL, column1 INT, column2
  VARCHAR);
```

3. Convert the standard table to a collocated table.

```
postgres=> CALL rds_aurora.limitless_alter_table_type_sharded('public.mytable2',
  ARRAY['customer_id'], 'public.customer');
```

```
postgres=> \d
```

```

                List of relations
 Schema |      Name      |      Type      |      Owner
-----+-----+-----+-----
 public | customer       | partitioned table | postgres_limitless
 public | customer_fs1   | foreign table    | postgres_limitless
 public | customer_fs2   | foreign table    | postgres_limitless
 public | customer_fs3   | foreign table    | postgres_limitless
 public | customer_fs4   | foreign table    | postgres_limitless
 public | customer_fs5   | foreign table    | postgres_limitless
 public | mytable2       | partitioned table | postgres_limitless
 public | mytable2_fs1   | foreign table    | postgres_limitless
 public | mytable2_fs2   | foreign table    | postgres_limitless
 public | mytable2_fs3   | foreign table    | postgres_limitless
 public | mytable2_fs4   | foreign table    | postgres_limitless
 public | mytable2_fs5   | foreign table    | postgres_limitless
(12 rows)

```

## Creating reference tables

You create reference tables by running the `rds_aurora.limitless_alter_table_type_reference` procedure on standard tables. This procedure replicates a given table to all shards in the DB shard group, and changes the table type to reference. The procedure runs synchronously, and acquires an `ACCESS EXCLUSIVE` lock on the table.

After the procedure finishes successfully, the source standard table is deleted, and a reference table with the same name becomes available.

The `rds_aurora.limitless_alter_table_type_reference` procedure uses the following syntax:

```
postgres=> CALL rds_aurora.limitless_alter_table_type_reference('schema.table');
```

The stored procedure requires the following parameters:

- `schema` – The database schema that contains the table to be replicated. If the schema isn't specified, the procedure uses the `search_path`.
- `table` – The table to be replicated.

**Note**

The standard table from which you create the reference table must have a primary key. In reference tables, the CHECK constraint doesn't support expressions. The previous function, `limitless_table_alter_type_reference`, is deprecated.

**To create a reference table**

The following example shows how to create the zipcodes reference table.

1. Create the standard table.

```
CREATE TABLE zipcodes (zipcode INT PRIMARY KEY, details VARCHAR);
```

2. Convert the standard table to a reference table.

```
CALL rds_aurora.limitless_alter_table_type_reference('public.zipcodes');
```

```
postgres=> \d
```

```

                List of relations
 Schema |      Name      |      Type      |      Owner
-----+-----+-----+-----
 public | customer       | partitioned table | postgres_limitless
 public | customer_fs1   | foreign table   | postgres_limitless
 public | customer_fs2   | foreign table   | postgres_limitless
 public | customer_fs3   | foreign table   | postgres_limitless
 public | customer_fs4   | foreign table   | postgres_limitless
 public | customer_fs5   | foreign table   | postgres_limitless
 public | zipcodes       | foreign table   | postgres_limitless
(7 rows)
```

The output shows the customer sharded table and the zipcodes reference table.

**Aurora PostgreSQL Limitless Database sample schemas**

We provide the following sample schemas for Aurora PostgreSQL Limitless Database:

- [Limitless E-Commerce sample schema](#)

- [Limitless pgbench](#)

You can use these schemas to quickly create a sample database and load data into Aurora PostgreSQL Limitless Database tables. For more information, see the [GitHub repository](#).

# Loading data into Aurora PostgreSQL Limitless Database

You can load data into Aurora PostgreSQL Limitless Database tables by using the COPY command or by using the data loading utility.

## Note

You can load data into standard, sharded, and reference tables.

## Using the COPY command with Aurora PostgreSQL Limitless Database

You can use the [\copy](#) functionality in the `psql` utility for importing data into and exporting data from Aurora PostgreSQL Limitless Database

### Using the COPY command to load data into Aurora PostgreSQL Limitless Database

Aurora PostgreSQL Limitless Database is compatible with the [\copy](#) functionality in the `psql` utility for importing data.

In Limitless Database as in Aurora PostgreSQL, the following aren't supported:

- Direct SSH access to DB instances – You can't copy a data file (such as in .csv format) to the DB instance host and run COPY from the file.
- Using local files on the DB instance – Use COPY ... FROM STDIN and COPY ... TO STDOUT.

The COPY command in PostgreSQL has options for working with local files (FROM/TO) and transmitting data using a connection between the client and the server (STDIN/STDOUT). For more information, see [COPY](#) in the PostgreSQL documentation.

The `\copy` command in the PostgreSQL `psql` utility works with local files on the computer where you run the `psql` client. It invokes the respective COPY ... FROM STDIN or COPY ... FROM STDOUT command on the remote (for example, Limitless Database) server to which you connect. It reads data from the local file to STDIN or writes to it from STDOUT.

### Splitting data into multiple files

Data is stored on multiple shards in Aurora PostgreSQL Limitless Database. To speed up data loading using `\copy`, you can split your data into multiple files. Then import independently for each data file by running separate `\copy` commands in parallel.

For example, you have an input data file in CSV format with 3 million rows to import. You can split the file into chunks each holding 200,000 rows (15 chunks):

```
split -l200000 data.csv data_ --additional-suffix=.csv -d
```

This results in files `data_00.csv` through `data_14.csv`. You can then import data using 15 parallel `\copy` commands, for example:

```
psql -h dbcluster.limitless-111122223333.aws-region.rds.amazonaws.com -U username -c
"\copy test_table from '/tmp/data_00.csv';" postgres_limitless &
psql -h dbcluster.limitless-111122223333.aws-region.rds.amazonaws.com -U username -c
"\copy test_table FROM '/tmp/data_01.csv';" postgres_limitless &
...
psql -h dbcluster.limitless-111122223333.aws-region.rds.amazonaws.com -U username -c
"\copy test_table FROM '/tmp/data_13.csv';" postgres_limitless &
psql -h dbcluster.limitless-111122223333.aws-region.rds.amazonaws.com -U username -c
"\copy test_table FROM '/tmp/data_14.csv';" postgres_limitless
```

Using this technique, the same amount of data is imported approximately 10 times faster than using a single `\copy` command.

## Using the COPY command to copy Limitless Database data to a file

You can use the [\copy](#) command to copy data from a limitless table to a file, as shown in the following example:

```
postgres_limitless=> \copy test_table TO '/tmp/test_table.csv' DELIMITER ',' CSV
HEADER;
```

## Using the Aurora PostgreSQL Limitless Database data loading utility

Aurora provides a utility for loading data directly into Limitless Database from an Aurora PostgreSQL DB cluster or RDS for PostgreSQL DB instance.

You perform the following steps to use the data loading utility:

1. [Prerequisites](#)
2. [Preparing the source database](#)
3. [Preparing the destination database](#)
4. [Creating database credentials](#)
5. One of the following:
  - [Setting up database authentication and resource access using a script](#) (recommended)
  - [Setting up database authentication and resource access manually](#)
6. [Loading data from an Aurora PostgreSQL DB cluster or RDS for PostgreSQL DB instance](#)

### Limitations

The data loading utility has the following limitations:

- The following data types aren't supported: enum, ARRAY, BOX, CIRCLE, LINE, LSEG, PATH, PG\_LSN, PG\_SNAPSHOT, POLYGON, TSQUERY, TSVECTOR, and TXID\_SNAPSHOT.
- Leading zeroes (0) are stripped from the VARBIT data type during loading.
- Data migration fails when there are foreign keys on the destination tables.
- Loading data from RDS for PostgreSQL Multi-AZ DB clusters isn't supported.

### Prerequisites

The data loading utility has the following prerequisites:

- The source database uses Aurora PostgreSQL or RDS for PostgreSQL version 11.x and higher.
- The source database is in the same Amazon Web Services account and Amazon Web Services Region as the destination DB shard group.
- The source DB cluster or DB instance is in the available state.

- Tables on the source database and limitless database have the same table names, column names, and column data types.
- The source and destination tables have primary keys that use the same columns and column orders.
- You must have an environment for connecting to a limitless database to run data loading commands. Available commands are the following:
  - `rds_aurora.limitless_data_load_start`
  - `rds_aurora.limitless_data_load_cancel`
- For CDC:
  - Both the source database and the destination DB shard group must use the same DB subnet group, VPC security group, and database port. These setups are for network connections to both the source database and the routers in the DB shard group.
  - You must enable logical replication on the source database. The source database user must have privileges to read logical replication.

## Preparing the source database

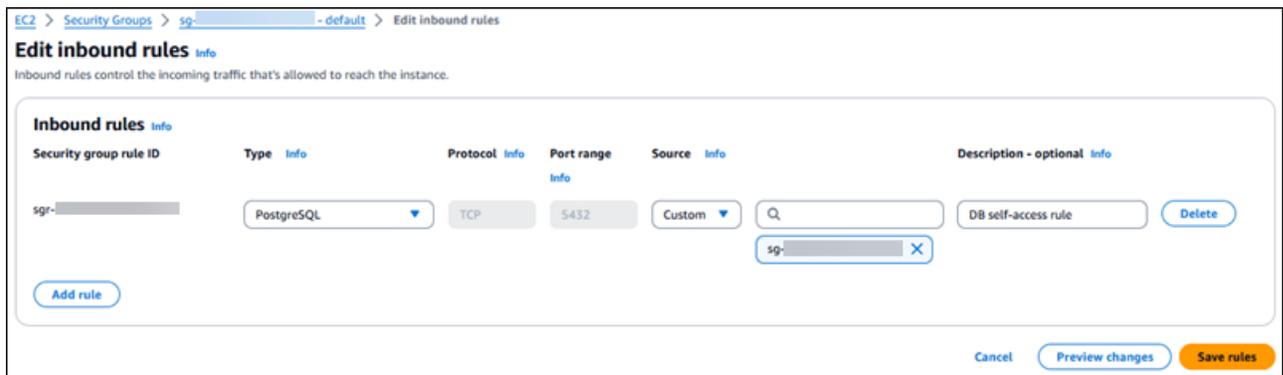

To access the source database for data loading, you must allow incoming network traffic to it. Perform the following steps.

### To allow network traffic to the source database

1. Sign in to the Amazon Web Services Management Console and open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
2. Navigate to the **Security groups** page.
3. Choose the **Security group ID** for the security group used by the source DB cluster or instance.

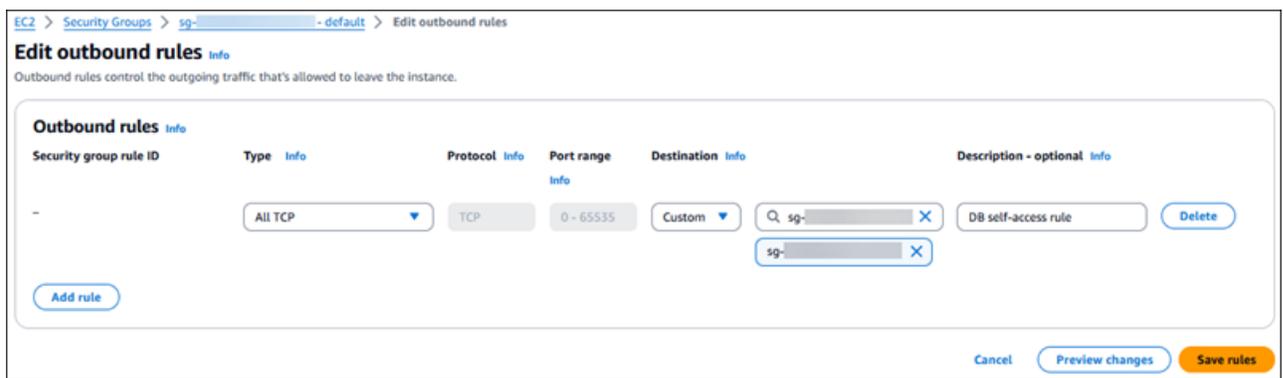

For example, its security group ID is `sg-056a84f1712b77926`.

4. On the **Inbound rules** tab:
  - a. Choose **Edit inbound rules**.
  - b. Add a new inbound rule for the source DB cluster or instance:
    - Port range – Database port for the source database, usually 5432
    - Security group ID – `sg-056a84f1712b77926` in this example

5. On the **Outbound rules** tab:

- a. Choose **Edit outbound rules**.
- b. Add a new outbound rule for the source DB cluster or instance:
  - Database port – All traffic (includes ports 0-65535)
  - Security group ID – sg-056a84f1712b77926 in this example

6. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
7. Navigate to the **Network ACLs** page.
8. Add the default network ACL configuration as outlined in [Default network ACL](#).

## Preparing the destination database

Follow the procedures in [Creating Aurora PostgreSQL Limitless Database tables](#) to create the destination tables in the DB shard group.

Your destination tables must have the same schemas, table names, and primary keys as the source tables.

## Creating database credentials

You must create database users in the source and destination databases, and grant necessary privileges to the users. For more information, see [CREATE USER](#) and [GRANT](#) in the PostgreSQL documentation.

### Create the source database credentials

The source database user is passed in the command to start loading. This user must have privileges to perform replication from the source database.

1. Use the database master user (or another user with the `rds_superuser` role) to create a source database user with LOGIN privileges.

```
CREATE USER source_db_username WITH PASSWORD 'source_db_user_password' ;
```

2. Grant the `rds_superuser` role to your source database user.

```
GRANT rds_superuser to source_db_username ;
```

3. If you're using `full_load_and_cdc` mode, grant the `rds_replication` role to your source database user. The `rds_replication` role grants permissions to manage logical slots and to stream data using logical slots.

```
GRANT rds_replication to source_db_username ;
```

### Create the destination database credentials

The destination database user must have permission to write to the destination tables in the DB shard group.

1. Use the database master user (or another user with the `rds_superuser` role) to create a destination database user with LOGIN privileges.

```
CREATE USER destination_db_username WITH PASSWORD 'destination_db_user_password' ;
```

2. Grant the `rds_superuser` role to your destination database user.

```
GRANT rds_superuser to destination_db_username;
```

## Setting up database authentication and resource access using a script

The setup script creates one customer-managed Amazon KMS key, one Amazon Identity and Access Management (IAM) role, and two Amazon Secrets Manager secrets.

Perform the following steps to use the setup script:

1. Make sure that you have the Amazon CLI installed and configured with your Amazon Web Services account credentials.
2. Install the `jq` command-line JSON processor. For more information, see [jq](#).
3. Copy the [data\\_loading\\_script.zip](#) file to your computer, and extract the `data_load_aws_setup_script.sh` file from it.
4. Edit the script to replace the placeholder variables with the appropriate values for the following:
  - Your Amazon Web Services account
  - The Amazon Web Services Region
  - Source database credentials
  - Destination database credentials
5. Open a new terminal on your computer and run the following command:

```
bash ./data_load_aws_setup_script.sh
```

### Setup script for the data loading utility

We provide the text of the `data_load_aws_setup_script.sh` file here for reference.

```
#!/bin/bash
# Aurora Limitless data loading - AWS resources setup script #
# Set up the account credentials in advance. #
# Update the following script variables. #

#####
#### Start of variable section ####

ACCOUNT_ID="12-digit_AWS_account_ID"

```

## Cleaning up failed resources

If you want to clean up failed resources manually, remove them in the following order:

### 1. IAM role, for example:

```
aws iam delete-role-policy \  
--role-name Test-Role \  
--policy-name ExamplePolicy  
  
aws iam delete-role \  
--role-name Test-Role
```

### 2. Source and destination secrets, for example:

```
aws secretsmanager delete-secret \  
--secret-id MyTestSecret \  
--force-delete-without-recovery
```

### 3. KMS key, for example:

```
aws kms schedule-key-deletion \  
--key-id arn:aws-cn:kms:us-  
west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab \  
--pending-window-in-days 7
```

Then you can retry the script.

## Setting up database authentication and resource access manually

The manual process for setting up database authentication and resource access has the following steps:

1. [Creating the customer-managed Amazon KMS key](#)
2. [Adding the IAM role permission policies](#)
3. [Creating the database secrets](#)
4. [Creating the IAM role](#)
5. [Updating the customer-managed Amazon KMS key](#)

This process is optional, and performs the same tasks as in [Setting up database authentication and resource access using a script](#). We recommend using the script.

### Creating the customer-managed Amazon KMS key

Follow the procedures in [Creating symmetric encryption keys](#) to create a customer-managed KMS key. You can also use an existing key if it meets these requirements.

#### To create a customer-managed KMS key

1. Sign in to the Amazon Web Services Management Console and open the Amazon KMS console at <https://console.amazonaws.cn/kms>.
2. Navigate to the **Customer managed keys** page.
3. Choose **Create key**.
4. On the **Configure key** page:
  - a. For **Key type**, select **Symmetric**.
  - b. For **Key usage**, select **Encrypt and decrypt**.
  - c. Choose **Next**.
5. On the **Add labels** page, enter an **Alias** such as **limitless**, then choose **Next**.
6. On the **Define key administrative permissions** page, make sure that the **Allow key administrators to delete this key** check box is selected, then choose **Next**.
7. On the **Define key usage permissions** page, choose **Next**.
8. On the **Review** page, choose **Finish**.

You update the key policy later.

Record the Amazon Resource Names (ARN) of the KMS key to use in [Adding the IAM role permission policies](#).

For information on using the Amazon CLI to create the customer-managed KMS key, see [create-key](#) and [create-alias](#).

## Creating the database secrets

To allow the data loading utility to access the source and destination database tables, you create two secrets in Amazon Secrets Manager: one for the source database and one for the destination database. These secrets store the usernames and passwords for accessing the source and destination databases.

Follow the procedures in [Create an Amazon Secrets Manager secret](#) to create the key-value pair secrets.

### To create the database secrets

1. Open the Secrets Manager console at <https://console.amazonaws.cn/secretsmanager/>.
2. Choose **Store a new secret**.
3. On the **Choose secret type** page:
  - a. For **Secret type**, select **Other type of secret**.
  - b. For **Key/value pairs**, choose the **Plaintext** tab.
  - c. Enter the following JSON code, where *sourcedbreader* and *sourcedbpassword* are the credentials for the source database user from [Create the source database credentials](#).

```
{
  "username": "sourcedbreader",
  "password": "sourcedbpassword"
}
```

- d. For **Encryption key**, choose the KMS key that you created in [Creating the customer-managed Amazon KMS key](#), for example *limitless*.
- e. Choose **Next**.

4. On the **Configure secret** page, enter a **Secret name**, such as `source_DB_secret`, then choose **Next**.
5. On the **Configure rotation - optional** page, choose **Next**.
6. On the **Review** page, choose **Store**.
7. Repeat the procedure for the destination database secret:
  - a. Enter the following JSON code, where `destinationdbwriter` and `destinationdbpassword` are the credentials for the destination database user from [Create the destination database credentials](#).

```
{
  "username": "destinationdbwriter",
  "password": "destinationdbpassword"
}
```

- b. Enter a **Secret name**, such as `destination_DB_secret`.

Record the ARNs of the secrets to use in [Adding the IAM role permission policies](#).

## Creating the IAM role

Data loading requires you to provide access to Amazon resources. To provide access, you create the `aurora-data-loader` IAM role by following the procedures in [Creating a role to delegate permissions to an IAM user](#).

### To create the IAM role

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Navigate to the **Roles** page.
3. Choose **Create role**.
4. On the **Select trusted entity** page:
  - a. For **Trusted entity type**, select **Custom trust policy**.
  - b. Enter the following JSON code for the custom trust policy:

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- c. Choose **Next**.
5. On the **Add permissions** page, choose **Next**.
6. On the **Name, review, and create** page:
  - a. For **Role name**, enter **aurora-data-loader** or another name that you prefer.
  - b. Choose **Add tag**, and enter the following tag:
    - **Key:** **assumer**
    - **Value:** **aurora\_limitless\_table\_data\_load**

**⚠ Important**

The Aurora PostgreSQL Limitless Database can only assume an IAM role that has this tag.

- c. Choose **Create role**.

**Updating the customer-managed Amazon KMS key**

Follow the procedures in [Changing a key policy](#) to add the IAM role `aurora-data-loader` to the default key policy.

## To add the IAM role to the key policy

1. Sign in to the Amazon Web Services Management Console and open the Amazon KMS console at <https://console.amazonaws.cn/kms>.
2. Navigate to the **Customer managed keys** page.
3. Choose the KMS key that you created in [Creating the customer-managed Amazon KMS key](#), for example `limitless`.
4. On the **Key policy** tab, for **Key users**, choose **Add**.
5. In the **Add key users** window, select the name of the IAM role that you created in [Creating the IAM role](#), for example `aurora-data-loader`.
6. Choose **Add**.

## Adding the IAM role permission policies

You must add permission policies to the IAM role that you created. This allows the Aurora PostgreSQL Limitless Database data loading utility to access related Amazon resources for building network connections and retrieving the source and destination DB credential secrets.

For more information, see [Modifying a role](#).

## To add the permission policies

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Navigate to the **Roles** page.
3. Choose the IAM role that you created in [Creating the IAM role](#), for example `aurora-data-loader`.
4. On the **Permissions** tab, for **Permissions policies** choose **Add permissions**, then **Create inline policy**.
5. On the **Specify permissions** page, choose the **JSON** editor.
6. Copy and paste the following template into the JSON editor, replacing the placeholders with the ARNs for your database secrets and KMS key.

JSON

8. Choose **Next**.
9. On the **Review and create** page, enter a **Policy name** such as **data\_loading\_policy**, then choose **Create policy**.

## Loading data from an Aurora PostgreSQL DB cluster or RDS for PostgreSQL DB instance

After you complete the resource and authentication setup, connect to the cluster endpoint and call the `rds_aurora.limitless_data_load_start` stored procedure from a limitless database, such as `postgres_limitless`. The limitless database is a database on the DB shard group into which you want to migrate data.

This function connects asynchronously in the background to the source database specified in the command, reads the data from the source, and loads the data onto the shards. For better performance, the data is loaded using parallel threads. The function retrieves a point-in-time table snapshot by running a `SELECT` command to read the data of the table(s) provided in the command.

You can load data into sharded, reference, and standard tables.

You can load data at the database, schema, or table level in `rds_aurora.limitless_data_load_start` calls.

- Database – You can load one database at a time in each call, with no limit on the schema or table count within the database.
- Schema – You can load a maximum of 15 schemas in each call, with no limit on the table count within each schema.
- Table – You can load a maximum of 15 tables in each call.

### Note

This feature doesn't use Amazon RDS snapshots or point-in-time isolation of the database. For consistency across tables, we recommend cloning the source database and pointing to that cloned database as the source.

The stored procedure uses the following syntax:

```
CALL rds_aurora.limitless_data_load_start('source_type',
    'source_DB_cluster_or_instance_ID',
    'source_database_name',
    'streaming_mode',
    'data_loading_IAM_role_arn',
    'source_DB_secret_arn',
    'destination_DB_secret_arn',
    'ignore_primary_key_conflict_boolean_flag',
    'is_dry_run',
    (optional parameter) schemas/tables => ARRAY['name1', 'name2', ...]);
```

The input parameters are the following:

- `source_type` – The source type: `aurora_postgresql` or `rds_postgresql`
- `source_DB_cluster_or_instance_ID` – The source Aurora PostgreSQL DB cluster identifier or RDS for PostgreSQL DB instance identifier
- `source_database_name` – The source database name, such as *postgres*
- `streaming_mode` – Whether to include change data capture (CDC): `full_load` or `full_load_and_cdc`
- `data_loading_IAM_role_arn` – The IAM role Amazon Resource Name (ARN) for `aurora-data-loader`
- `source_DB_secret_arn` – The source DB secret ARN
- `destination_DB_secret_arn` – The destination DB secret ARN
- `ignore_primary_key_conflict_boolean_flag` – Whether to continue if a primary key conflict occurs:
  - If set to `true`, data loading ignores new changes for rows with a primary key conflict.
  - If set to `false`, data loading overwrites the existing rows on destination tables when it encounters a primary key conflict.
- `is_dry_run` – Whether to test that the data loading job can connect to the source and destination databases:
  - If set to `true`, tests the connections without loading data
  - If set to `false`, loads the data
- (optional) `schemas` or `tables` – An array of schemas or tables to load. You can specify either of the following:

- A list of tables in the format `tables => ARRAY['schema1.table1', 'schema1.table2', 'schema2.table1', ...]`
- A list of schemas in the format `schemas => ARRAY['schema1', 'schema2', ...]`

If you don't include this parameter, the entire specified source database is migrated.

The output parameter is the job ID with a message.

The following example shows how to use the `rds_aurora.limitless_data_load_start` stored procedure to load data from an Aurora PostgreSQL DB cluster.

```
CALL rds_aurora.limitless_data_load_start('aurora_postgresql',
    'my-db-cluster',
    'postgres',
    'full_load_and_cdc',
    'arn:aws-cn:iam::123456789012:role/aurora-data-loader-8f2c66',
    'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:secret-source-8f2c66-
EWrr0V',
    'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:secret-destination-8f2c66-
d04fbD',
    'true',
    'false',
    tables => ARRAY['public.customer', 'public.order', 'public.orderdetails']);

INFO: limitless data load job id 1688761223647 is starting.
```

## Monitoring data loading

Aurora PostgreSQL Limitless Database provides several ways to monitor data loading jobs:

- [Listing data loading jobs](#)
- [Viewing details of data loading jobs using the job ID](#)
- [Monitoring the Amazon CloudWatch log group](#)
- [Monitoring RDS events](#)

### Listing data loading jobs

You can connect to the cluster endpoint and use the `rds_aurora.limitless_data_load_jobs` view to list data loading jobs.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_data_load_jobs LIMIT 6;
```

job_id	status	message	source_db_identifier	source_db_name	full_load_complete_time	progress_details	start_time	last_updated_time	streaming_mode	source_engine_type	ignore_primary_key_conflict	is_dryrun
1725697520693	COMPLETED		persistent-kdm-auto-source-01	postgres	2024-09-07 08:48:15+00	{"FULL_LOAD": {"STATUS": "COMPLETED", "DETAILS": "9 of 9 tables loaded", "COMPLETED_AT": "2024/09/07 08:48:15+00", "RECORDS_MIGRATED": 600003}}	2024-09-07 08:47:13+00	2024-09-07 08:48:15+00	full_load	aurora_postgresql	t	f

aurora_postgresql | t          | f
(6 rows)

```

Job records are deleted after 90 days.

## Viewing details of data loading jobs using the job ID

If you know a job ID, you can connect to the cluster endpoint and use the `rds_aurora.limitless_data_load_job_details` view to see the details of that data loading job, including the table name, job status, and number of rows loaded. You can get the job ID in the responses to the data loading start functions, or from the `rds_aurora.limitless_data_load_jobs` view.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_data_load_job_details WHERE
job_id='1725696114225';
```

```

job_id          | destination_table_name | destination_schema_name | start_time
| status        | full_load_rows | full_load_total_rows | full_load_complete_time |
cdc_insert | cdc_update | cdc_delete

Job records are deleted after 90 days.

## Monitoring the Amazon CloudWatch log group

After the data loading job status changes to RUNNING, you can check the runtime progress using Amazon CloudWatch Logs.

### To monitor CloudWatch log streams

Sign in to the Amazon Web Services Management Console and open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.

1. Navigate to **Logs**, then **Log groups**.
2. Choose the `/aws/rds/aurora-limitless-database` log group.
3. Search for the log stream of your data loading job by `job_id`.

The log stream has the pattern **Data-Load-Job-*job\_id***.

4. Choose the log stream to see the log events.

Each log stream shows events containing the job status and the number of rows loaded to the Aurora PostgreSQL Limitless Database destination tables. If a data loading job fails, an error log is also created that shows the failure status and the reason.

Job records are deleted after 90 days.

## Monitoring RDS events

The data loading job also publishes RDS events, for example when a job succeeds, fails, or is canceled. You can view the events from the destination database.

For more information, see [DB shard group events](#).

## Canceling data loading

To cancel a data loading job, call the `rds_aurora.limitless_data_load_cancel` stored procedure, with the job ID as the input parameter. You call this stored procedure from the same database in the DB shard group where the specific data loading job was started. For example:

```
CALL rds_aurora.limitless_data_load_cancel(12345);
```

```
INFO: limitless data load job with id 12345 is canceling without rollback.
```

You can't cancel a data loading job that doesn't exist or isn't running in the same DB shard group.

The Aurora PostgreSQL Limitless Database data loading utility leaves loaded data in the destination tables without rollback, as the response shows. If you don't want to keep the loaded data, we recommend truncating the destination tables.

# Querying Aurora PostgreSQL Limitless Database

Aurora PostgreSQL Limitless Database is compatible with PostgreSQL syntax for queries. You can query your Limitless Database using `psql` or any other connection utility that works with PostgreSQL. To run queries, you connect to the limitless endpoint as shown in [Connecting to your Aurora PostgreSQL Limitless Database DB cluster](#).

All PostgreSQL `SELECT` queries are supported in Aurora PostgreSQL Limitless Database. However, queries are performed on two layers:

1. Router to which the client sends the query
2. Shards where the data is located

Performance depends on querying the database in a way that allows it to achieve a high degree of simultaneous processing of different queries on different shards. Queries are first parsed in the distributed transaction layer (router). Before planning the query execution, there's an analysis phase to identify the location for all relations participating in the query. If all relations are sharded tables with a filtered shard key on the same shard, or reference tables, then query planning is skipped on the router layer and completely pushed down to the shard for planning and execution. This process reduces the number of round trips between different nodes (router and shard) and results in better performance in most cases. For more information, see [Single-shard queries in Aurora PostgreSQL Limitless Database](#).

## Note

There can be specific cases, such as a [Cartesian product](#) (cross join), where the query performs better by retrieving data separately from the shard.

For more information on query execution plans, see [EXPLAIN](#) in the [Aurora PostgreSQL Limitless Database reference](#). For general information on queries, see [Queries](#) in the PostgreSQL documentation.

## Topics

- [Distributed queries in Aurora PostgreSQL Limitless Database](#)
- [Distributed query tracing in PostgreSQL logs in Aurora PostgreSQL Limitless Database](#)

- [Distributed deadlocks in Aurora PostgreSQL Limitless Database](#)

## Single-shard queries in Aurora PostgreSQL Limitless Database

A *single-shard query* is a query that can be run directly on a shard while maintaining SQL [ACID](#) semantics. When such a query is encountered by the query planner on the router, the planner detects it and proceeds to push down the entire SQL query to the corresponding shard.

This optimization reduces the number of network round trips from the router to the shard, improving the performance. Currently this optimization is performed for INSERT, SELECT, UPDATE, and DELETE queries.

### Topics

- [Single-shard query examples](#)
- [Restrictions for single-shard queries](#)
- [Fully qualified \(explicit\) joins](#)
- [Setting an active shard key](#)

### Single-shard query examples

In the following examples, we have the sharded table `customers`, with the shard key `customer_id`, and the reference table `zipcodes`.

#### SELECT

```
postgres_limitless=> EXPLAIN (VERBOSE, COSTS OFF) SELECT * FROM customers WHERE
customer_id = 100;
```

#### QUERY PLAN

```
-----
Foreign Scan
  Output: customer_id, other_id, customer_name, balance
  Remote SQL:  SELECT customer_id,
                other_id,
                customer_name,
                balance
  FROM public.customers
  WHERE (customer_id = 100)
```

Single Shard Optimized  
(9 rows)

```
postgres_limitless=> EXPLAIN (VERBOSE, COSTS OFF) SELECT * FROM orders
  LEFT JOIN zipcodes ON orders.zipcode_id = zipcodes.zipcode_id
  WHERE customer_id = 11;
```

#### QUERY PLAN

#### Foreign Scan

Output: customer\_id, order\_id, zipcode\_id, customer\_name, balance,  
zipcodes.zipcode\_id, zipcodes.city

```
Remote SQL:  SELECT orders.customer_id,
  orders.order_id,
  orders.zipcode_id,
  orders.customer_name,
  orders.balance,
  zipcodes.zipcode_id,
  zipcodes.city
```

```
FROM (public.orders
  LEFT JOIN public.zipcodes ON ((orders.zipcode_id = zipcodes.zipcode_id)))
WHERE (orders.customer_id = 11)
```

Single Shard Optimized  
(13 rows)

## INSERT

```
postgres_limitless=> EXPLAIN (VERBOSE, COSTS OFF) INSERT INTO customers
  (customer_id, other_id, customer_name, balance)
  VALUES (1, 10, 'saikiran', 1000);
```

#### QUERY PLAN

Insert on public.customers

-> Result

Output: 1, 10, 'saikiran'::text, '1000'::real

Single Shard Optimized  
(4 rows)

## UPDATE

```
postgres_limitless=> EXPLAIN (VERBOSE, COSTS OFF) UPDATE orders SET balance = balance +
100
WHERE customer_id = 100;
```

### QUERY PLAN

```
-----
Update on public.orders
Foreign Update on public.orders_fs00002 orders_1
-> Foreign Update
Remote SQL: UPDATE public.orders SET balance = (balance + (100)::double
precision)
WHERE (customer_id = 100)
Single Shard Optimized
(6 rows)
```

## DELETE

```
postgres_limitless=> EXPLAIN (VERBOSE, COSTS OFF) DELETE FROM orders
WHERE customer_id = 100 and balance = 0;
```

### QUERY PLAN

```
-----
Delete on public.orders
Foreign Delete on public.orders_fs00002 orders_1
-> Foreign Delete
Remote SQL: DELETE FROM public.orders
WHERE ((customer_id = 100) AND (balance = (0)::double precision))
Single Shard Optimized
(6 rows)
```

## Restrictions for single-shard queries

Single-shard queries have the following restrictions:

### Functions

If a single-shard query contains a function, the query qualifies for single-shard optimization only if one of the following conditions applies:

- The function is immutable. For more information, see [Function volatility](#).
- The function is mutable, but is registered in the `rds_aurora.limitless_distributed_functions` view. For more information, see [Function distribution](#).

## Views

If a query contains one or more views, single-shard optimization is disabled for the query if it has one of the following conditions:

- Any view has the `security_barrier` attribute.
- Objects used in the query require multiple user privileges. For example, a query contains two views, and the views are run under two different users.

```
CREATE VIEW v1 AS SELECT customer_name FROM customers c WHERE c.customer_id = 1;
CREATE VIEW v2 WITH (security_barrier) AS SELECT customer_name FROM customers c
WHERE c.customer_id = 1;

postgres_limitless=> EXPLAIN VERBOSE SELECT * FROM v1;
                        QUERY PLAN
-----
Foreign Scan (cost=100.00..101.00 rows=100 width=0)
  Output: customer_name
  Remote Plans from Shard postgres_s3:
    Seq Scan on public.customers_ts00001 c (cost=0.00..24.12 rows=6 width=32)
      Output: c.customer_name
      Filter: (c.customer_id = 1)
      Query Identifier: -6005737533846718506
  Remote SQL: SELECT customer_name
  FROM ( SELECT c.customer_name
        FROM public.customers c
        WHERE (c.customer_id = 1)) v1
  Query Identifier: -5754424854414896228
(12 rows)

postgres_limitless=> EXPLAIN VERBOSE SELECT * FROM v2;
                        QUERY PLAN
-----
Foreign Scan on public.customers_fs00001 c (cost=100.00..128.41 rows=7 width=32)
  Output: c.customer_name
  Remote Plans from Shard postgres_s3:
```

```
Seq Scan on public.customers_ts00001 customers (cost=0.00..24.12 rows=6
width=32)
  Output: customers.customer_name
  Filter: (customers.customer_id = 1)
  Query Identifier: 4136563775490008117
  Remote SQL: SELECT customer_name FROM public.customers WHERE ((customer_id = 1))
  Query Identifier: 5056054318010163757
(9 rows)
```

## PREPARE and EXECUTE statements

Aurora PostgreSQL Limitless Database supports single-shard optimization for prepared SELECT, UPDATE, and DELETE statements.

However, if you use prepared statements for PREPARE and EXECUTE with `plan_cache_mode` set to `'force_generic_plan'`, the query planner rejects single-shard optimization for that query.

## PL/pgSQL

Queries with PL/pgSQL variables are run as implicitly prepared statements. If a query contains any PL/pgSQL variables, the query planner rejects single-shard optimization.

Optimization is supported in the PL/pgSQL block if the statement doesn't contain any PL/pgSQL variables.

## Fully qualified (explicit) joins

Single-shard optimization is based on partition eliminations. The PostgreSQL optimizer eliminates partitions based on constant conditions. If Aurora PostgreSQL Limitless Database finds that all of the remaining partitions and tables are on the same shard, it marks the query eligible for single-shard optimization. All filter conditions must be explicit for partition elimination to work. Aurora PostgreSQL Limitless Database can't eliminate partitions without one or more join predicates or filter predicates on the shard keys of every sharded table in the statement.

Assume that we've partitioned the `customers`, `orders`, and `order_details` tables based on the `customer_id` column. In this schema, the application tries to keep all of the data for a customer on a single shard.

Consider the following query:

```
SELECT * FROM
  customers c, orders o, order_details od
WHERE c.customer_id = o.customer_id
      AND od.order_id = o.order_id
      AND c.customer_id = 1;
```

This query retrieves all of the data for a customer (`c.customer_id = 1`). Data for this customer is on a single shard, but Aurora PostgreSQL Limitless Database doesn't qualify this query as a single-shard query. The optimizer process for the query is as follows:

1. The optimizer can eliminate partitions for `customers` and `orders` based on the following condition:

```
c.customer_id = 1
c.customer_id = o.customer_id
o.customer_id = 1 (transitive implicit condition)
```

2. The optimizer can't eliminate any partitions for `order_details`, because there's no constant condition on the table.
3. The optimizer concludes that it has read all of the partitions from `order_details`. Therefore, the query can't be qualified for single-shard optimization.

To make this a single-shard query, we add the following explicit join condition:

```
o.customer_id = od.customer_id
```

The changed query looks like this:

```
SELECT * FROM
  customers c, orders o, order_details od
WHERE c.customer_id = o.customer_id
      AND o.customer_id = od.customer_id
      AND od.order_id = o.order_id
      AND c.customer_id = 1;
```

Now the optimizer can eliminate partitions for `order_details`. The new query becomes a single-shard query and qualifies for optimization.

## Setting an active shard key

This feature allows you to set a single shard key while querying the database, causing all SELECT and DML queries to be appended with the shard key as a constant predicate. This feature is useful if you've migrated to Aurora PostgreSQL Limitless Database and have denormalized the schema by adding shard keys to tables.

You can append a shard key predicate automatically to the existing SQL logic, without changing the semantics of the queries. Appending an active shard key predicate is done only for [compatible tables](#).

The active shard key feature uses the `rds_aurora.limitless_active_shard_key` variable, which has the following syntax:

```
SET [session | local] rds_aurora.limitless_active_shard_key = '{"col1_value",  
"col2_value", ...}';
```

Some considerations about active shard keys and foreign keys:

- A sharded table can have a foreign key constraint if the parent and child tables are colocated and the foreign key is a superset of the shard key.
- A sharded table can have a foreign key constraint to a reference table.
- A reference table can have a foreign key constraint to another reference table.

Assume that we have a `customers` table that is sharded on the `customer_id` column.

```
BEGIN;  
SET local rds_aurora.limitless_create_table_mode='sharded';  
SET local rds_aurora.limitless_create_table_shard_key='{"customer_id}';  
CREATE TABLE customers(customer_id int PRIMARY KEY, name text , email text);  
COMMIT;
```

With an active shard key set, queries have the following transformations.

### SELECT

```
SET rds_aurora.limitless_active_shard_key = '{"123}';  
SELECT * FROM customers;
```

```
-- This statement is changed to:  
SELECT * FROM customers WHERE customer_id = '123'::int;
```

## INSERT

```
SET rds_aurora.limitless_active_shard_key = '{"123"}';  
INSERT INTO customers(name, email) VALUES('Alex', 'alex@example.com');  
  
-- This statement is changed to:  
INSERT INTO customers(customer_id, name, email) VALUES('123'::int, 'Alex',  
'alex@example.com');
```

## UPDATE

```
SET rds_aurora.limitless_active_shard_key = '{"123"}';  
UPDATE customers SET email = 'alex_new_email@example.com';  
  
-- This statement is changed to:  
UPDATE customers SET email = 'alex_new_email@example.com' WHERE customer_id =  
'123'::int;
```

## DELETE

```
SET rds_aurora.limitless_active_shard_key = '{"123"}';  
DELETE FROM customers;  
  
-- This statement is changed to:  
DELETE FROM customers WHERE customer_id = '123'::int;
```

## Joins

When performing join operations on tables with an active shard key, the shard key predicate is automatically added to all tables involved in the join. This automatic addition of the shard key predicate occurs only when all tables in the query belong to the same collocation group. If the query involves tables from different collocation groups, an error is raised instead.

Assume that we also have `orders` and `order_details` tables that are collocated with the `customers` table.

```
SET local rds_aurora.limitless_create_table_mode='sharded';  
SET local rds_aurora.limitless_create_table_collocate_with='customers';
```

```
SET local rds_aurora.limitless_create_table_shard_key='{"customer_id"}';
CREATE TABLE orders (id int , customer_id int, total_amount int, date date);
CREATE TABLE order_details (id int , order_id int, customer_id int, product_name
  VARCHAR(100), price int);
COMMIT;
```

Retrieve the last 10 order invoices for a customer whose customer ID is 10.

```
SET rds_aurora.limitless_active_shard_key = '{"10"}';
SELECT * FROM customers, orders, order_details WHERE
  orders.customer_id = customers.customer_id AND
  order_details.order_id = orders.order_id AND
  customers.customer_id = 10
  order by order_date limit 10;
```

This query is transformed into the following:

```
SELECT * FROM customers, orders, order_details WHERE
  orders.customer_id = customers.customer_id AND
  orders.order_id = order_details.order_id AND
  customers.customer_id = 10 AND
  order_details.customer_id = 10 AND
  orders.customer_id = 10 AND
  ORDER BY "order_date" LIMIT 10;
```

## Active shard key compatible tables

The shard key predicate is added only to tables that are compatible with the active shard key. A table is considered compatible if it has the same number of columns in its shard key as specified in the `rds_aurora.limitless_active_shard_key` variable. If the query involves tables that are incompatible with the active shard key, the system raises an error instead of proceeding with the query.

For example:

```
-- Compatible table
SET rds_aurora.limitless_active_shard_key = '{"10"}';

-- The following query works because the customers table is sharded on one column.
SELECT * FROM customers;
```

```
-- Incompatible table
SET rds_aurora.limitless_active_shard_key = '{"10","20"}';

-- The following query raises a error because the customers table isn't sharded on
two columns.
SELECT * FROM customers;
```

## Distributed queries in Aurora PostgreSQL Limitless Database

Distributed queries run on a router and more than one shard. The query is received by one of the routers. The router creates and manages the distributed transaction, which is sent to the participating shards. The shards create a local transaction with the context provided by the router, and the query is run.

When the transaction is committed, the router uses an optimized two-phase commit protocol if needed, and time-based Multi Version Concurrency Control (MVCC) to provide [ACID](#) semantics in a distributed database system.

Time-based MVCC records the commit time for each transaction and uses the transaction start time to generate the data snapshot time. To identify whether a transaction is committed (visible) given a reader's snapshot, the database compares its commit time with the snapshot time. If its commit time is less than the reader's snapshot time, it is visible; otherwise, invisible. Under this protocol, you will always expect to see strongly consistent data on Aurora PostgreSQL Limitless Database.

# Distributed query tracing in PostgreSQL logs in Aurora PostgreSQL Limitless Database

Distributed query tracing is a tool to trace and correlate queries in PostgreSQL logs across Aurora PostgreSQL Limitless Database. In Aurora PostgreSQL, you use the transaction ID to identify a transaction. But in Aurora PostgreSQL Limitless Database, the transaction ID can repeat across various routers. Therefore, we recommend that you use the tracing ID instead in Limitless Database.

The key use cases are the following:

- Use the `rds_aurora.limitless_get_last_trace_id()` function to find the unique tracing ID of the last query run in the current session. Then search the DB cluster log group in Amazon CloudWatch Logs using that tracing ID to find all the related logs.

You can use the `log_min_messages` and `log_min_error_statement` parameters together to control the volume of logs printed and print a statement that contains the tracing ID.

- Use the `log_min_duration_statement` parameter to determine the run time above which all of the queries print their run duration and tracing ID. This run time can then be searched in the DB cluster log group in CloudWatch Logs to help determine the bottleneck nodes and planner optimization efforts.

The `log_min_duration_statement` parameter enables the tracing ID for all nodes regardless of the values of `log_min_messages` and `log_min_error_statement` parameters.

## Topics

- [Tracing ID](#)
- [Using query tracing](#)
- [Log examples](#)

## Tracing ID

Central to this feature is a unique identifier known as the *tracing ID*. The tracing ID is a 31-digit string appended to the STATEMENT log lines of PostgreSQL logs, acting as a precise identifier for correlating logs related to a specific query execution. Examples are 1126253375719408504000000000011 and 1126253375719408495000000000090.

The tracing ID is composed of the following:

- Transaction identifier – The first 20 digits, uniquely identifying the transaction.
- Command identifier – The first 30 digits, indicating an individual query within a transaction.

If more than 4,294,967,294 queries are run inside an explicit transaction block, the command Identifier wraps around to 1. When this happens, you're notified by the following LOG message in the PostgreSQL log:

```
wrapping around the tracing ID back to 1 after running 4294967294 (4.2 billion or 2^32-2) queries inside of an explicit transaction block
```

- Node type identifier – The last digit, indicating whether the node is functioning as a coordinator router (1) or a participant node (0).

The following examples illustrate the components of the tracing ID:

- 1126253375719408504000000000011:
  - Transaction identifier – 1126253375719408504
  - Command identifier – 112625337571940850400000000001 indicates the first command in the transaction block
  - Node type identifier – 1 indicates a coordinator router
- 1126253375719408495000000000090:
  - Transaction identifier – 1126253375719408495
  - Command identifier – 112625337571940849500000000009 indicates the ninth command in the transaction block
  - Node type identifier – 0 indicates a participant node

## Using query tracing

Perform the following tasks to use query tracing:

1. Make sure that tracing is enabled.

You can check using the following command:

```
SHOW rds_aurora.limitless_log_distributed_trace_id;
```

It's enabled by default (on). If it's not enabled, set it using the following command:

```
SET rds_aurora.limitless_log_distributed_trace_id = on;
```

## 2. Control the volume of logs printed by configuring the log severity level.

The log volume is controlled by the `log_min_messages` parameter. The `log_min_error_statement` parameter is used to print the STATEMENT line with the tracing ID. Both are set to ERROR by default. You can check using the following commands:

```
SHOW log_min_messages;  
SHOW log_min_error_statement;
```

To update the severity level and print the STATEMENT line for the current session, use the following commands with one of these severity levels:

```
SET log_min_messages = 'DEBUG5 | DEBUG4 | DEBUG3 | DEBUG2 | DEBUG1 | INFO | NOTICE  
| WARNING | ERROR | LOG | FATAL | PANIC';  
SET log_min_error_statement = 'DEBUG5 | DEBUG4 | DEBUG3 | DEBUG2 | DEBUG1 | INFO  
| NOTICE | WARNING | ERROR | LOG | FATAL | PANIC';
```

For example:

```
SET log_min_messages = 'WARNING';  
SET log_min_error_statement = 'WARNING';
```

## 3. Enable printing the tracing ID in the logs above a specific run time.

The `log_min_duration_statement` parameter can be changed to the minimum query run time above which the query prints a log line with the run duration, along with the tracing IDs across the DB cluster. This parameter is set to -1 by default, which means it's disabled. You can check using the following command:

```
SHOW log_min_duration_statement;
```

Changing it to 0 prints the duration and tracing ID in the logs for every query across the DB cluster. You can set it to 0 for the current session by using the following command:

```
SET log_min_duration_statement = 0;
```

#### 4. Obtain the tracing ID.

After running a query (even inside an explicit transaction block), call the `rds_aurora.limitless_get_last_trace_id` function to obtain the tracing ID of the last query run:

```
SELECT * FROM rds_aurora.limitless_get_last_trace_id();
```

This function returns the transaction identifier and the command identifier. It doesn't return the node type identifier.

```
=> SELECT * FROM customers;
 customer_id | fname | lname
-----+-----+-----
(0 rows)

=> SELECT * FROM rds_aurora.limitless_get_last_trace_id();
 transaction_identifier |      command_identifier
-----+-----
 10104661421959001813  | 101046614219590018130000000001
(1 row)
```

The function returns a blank line for nondistributed queries, as they don't have a tracing ID.

```
=> SET search_path = public;
SET

=> SELECT * FROM rds_aurora.limitless_get_last_trace_id();
 transaction_identifier | command_identifier
-----+-----
                                |
(1 row)
```

**Note**

For VACUUM and ANALYZE queries, the duration statement isn't logged with the tracing ID. Therefore, `limitless_get_last_trace_id()` doesn't return the tracing ID. If VACUUM or ANALYZE is a long-running operation, you can use the following query to obtain the tracing ID for that operation:

```
SELECT * FROM rds_aurora.limitless_stat_activity
WHERE distributed_tracing_id IS NOT NULL;
```

If the server stops before you can find the last tracing ID, you will have to search the PostgreSQL logs manually to find the tracing IDs in the logs from right before the failure.

## 5. Search for the tracing ID across the DB cluster logs using CloudWatch.

Use [CloudWatch Insights](#) to query the DB cluster's log group, as shown in the following examples.

- Query for a particular transaction identifier and all of the commands run inside it:

```
fields @timestamp, @message
| filter @message like /10104661421959001813/
| sort @timestamp desc
```

- Query for a particular command identifier:

```
fields @timestamp, @message
| filter @message like /101046614219590018130000000001/
| sort @timestamp desc
```

## 6. Examine all of the logs across the DB cluster produced by the distributed query.

## Log examples

The following examples show the use of query tracing.

### Correlating logs for error-prone queries

In this example the TRUNCATE command is run on the customers table when that table doesn't exist.

#### Without query tracing

PostgreSQL log file on the coordinator router:

```
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[27503]:ERROR: failed to
execute remote query
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[27503]:DETAIL: relation
"public.customers" does not exist
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[27503]:CONTEXT: remote
SQL command: truncate public.customers;
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[27503]:STATEMENT:
truncate customers;
```

PostgreSQL log file on a participant shard:

```
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[ 27503]:ERROR: failed to
execute remote query
2023-09-26 04:03:19 UTC:[local]: postgres@postgres_limitless:[ 27503]:STATEMENT:
truncate customers;
```

These logs are typical. They lack the precise identifiers needed to easily correlate queries across the DB cluster.

#### With query tracing

PostgreSQL log file on the coordinator router:

```
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:ERROR: failed to
execute remote query
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:DETAIL: relation
"public.customers" does not exist
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:CONTEXT: remote SQL
command: truncate public.customers;
```

```
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:STATEMENT: /* tid =
1126253375719408502700000000011 */ truncate customers;
```

### PostgreSQL log file on a participant shard:

```
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:ERROR: failed to
execute remote query
2023-09-26 04:03:19 UTC:[local]:postgres@postgres_limitless:[27503]:STATEMENT: /* tid
= 1126253375719408502700000000010 */ truncate customers;
```

In the presence of query tracing, each log line is appended with a 31-digit unique identifier. Here, 1126253375719408502700000000011 and 1126253375719408502700000000010 represent the tracing IDs for the coordinator and participant nodes, respectively.

- Transaction identifier – 11262533757194085027
- Command identifier: –112625337571940850270000000001
- Node type identifier – The last digit, 1 or 0, indicates a coordinator router and participant node, respectively.

## Correlating logs to find the query run time on various nodes

In this example, the `log_min_duration_statement` parameter has been updated to 0 to print the duration for all queries.

### Without query tracing

```
2024-01-15 07:28:46 UTC:[local]:postgres@postgres_limitless:[178322]:LOG: duration:
12.779 ms statement: select * from customers;
```

### With query tracing

#### PostgreSQL log file on the coordinator router:

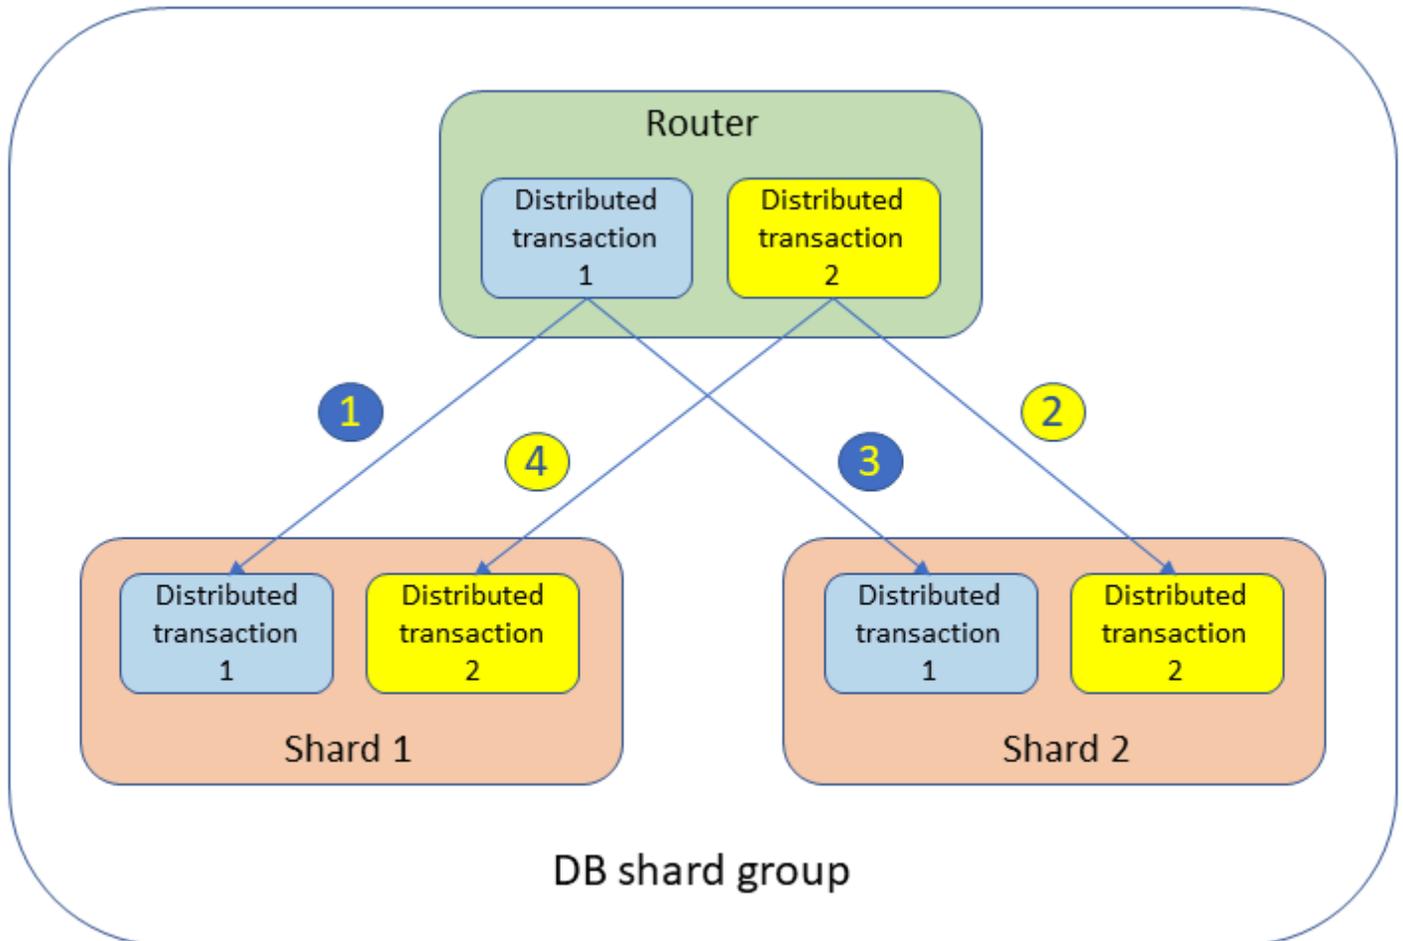

```
2024-01-15 07:32:08 UTC:[local]:postgres@postgres_limitless:[183877]:LOG: duration:
12.618 ms statement: /* tid = 0457669566240497088400000000011 */ select * from
customers;
```

#### PostgreSQL log file on a participant shard:

```
2024-01-15 07:32:08 UTC:localhost(46358):postgres@postgres_limitless:[183944]:LOG:
duration: 0.279 ms statement: /* tid = 0457669566240497088400000000010 */ START
TRANSACTION ISOLATION LEVEL READ COMMITTED
2024-01-15 07:32:08 UTC:localhost(46358):postgres@postgres_limitless:[183944]:LOG:
duration: 0.249 ms parse <unnamed>: SELECT customer_id, fname, lname FROM
public.customers
2024-01-15 07:32:08 UTC:localhost(46358):postgres@postgres_limitless:[183944]:LOG:
duration: 0.398 ms bind <unnamed>/c1: SELECT customer_id, fname, lname FROM
public.customers
2024-01-15 07:32:08 UTC:localhost(46358):postgres@postgres_limitless:[183944]:LOG:
duration: 0.019 ms execute <unnamed>/c1: SELECT customer_id, fname, lname FROM
public.customers
2024-01-15 07:32:08 UTC:localhost(46358):postgres@postgres_limitless:[183944]:LOG:
duration: 0.073 ms statement: /* tid = 0457669566240497088400000000010 */ COMMIT
TRANSACTION
```

## Distributed deadlocks in Aurora PostgreSQL Limitless Database

In a DB shard group, deadlocks can occur between transactions that are distributed among different routers and shards. For example, two concurrent distributed transactions that span two shards are run, as shown in the following figure.

The transactions lock tables and create wait events in the two shards as follows:

### 1. Distributed transaction 1:

```
UPDATE table SET value = 1 WHERE key = 'shard1_key';
```

This holds a lock on shard 1.

### 2. Distributed transaction 2:

```
UPDATE table SET value = 2 WHERE key = 'shard2_key';
```

This holds a lock on shard 2.

### 3. Distributed transaction 1:

```
UPDATE table SET value = 3 WHERE key = 'shard2_key';
```

Distributed transaction 1 is waiting on shard 2.

### 4. Distributed transaction 2:

```
UPDATE table SET value = 4 WHERE key = 'shard1_key';
```

Distributed transaction 2 is waiting on shard 1.

In this scenario, neither shard 1 nor shard 2 sees the problem: transaction 1 is waiting for transaction 2 on shard 2, and transaction 2 is waiting for transaction 1 on shard 1. From a global view, transaction 1 is waiting for transaction 2, and transaction 2 is waiting for transaction 1. This situation where two transactions on two different shards are waiting for each other is called a distributed deadlock.

Aurora PostgreSQL Limitless Database can detect and resolve distributed deadlocks automatically. A router in the DB shard group is notified when a transaction is waiting too long to acquire a resource. The router receiving the notification starts to collect the necessary information from all of the routers and shards within the DB shard group. The router then proceeds to end transactions that are participating in a distributed deadlock, until the rest of the transactions in the DB shard group can proceed without being blocked by each other.

You receive the following error when your transaction was part of a distributed deadlock, and was then ended by the router:

```
ERROR: aborting transaction participating in a distributed deadlock
```

The `rds_aurora.limitless_distributed_deadlock_timeout` DB cluster parameter sets the time for each transaction to wait on a resource before notifying the router to check for a distributed deadlock. You can increase the parameter value if your workload is less prone to deadlock situations. The default is 1000 milliseconds (1 second).

The distributed deadlock cycle is published to the PostgreSQL logs when a cross-node deadlock is found and resolved. The information about each process that's part of the deadlock includes the following:

- Coordinator node that started the transaction
- Virtual transaction ID (xid) of the transaction on the coordinator node, in the format *backend\_id/backend\_local\_xid*
- Distributed session ID of the transaction

# Managing Aurora PostgreSQL Limitless Database

The following topics describe how to manage your Aurora PostgreSQL Limitless Database DB clusters.

## Topics

- [Database and table size considerations](#)
- [Reclaiming storage space by vacuuming](#)

## Database and table size considerations

For Aurora PostgreSQL Limitless Database, on each shard a sharded table is divided into a number of table slices that varies depending on how many shards are available in the DB shard group. Each table slice can grow up to 32 TiB, but each shard has a maximum capacity of 128 TiB. Reference tables have a size limit of 32 TiB for the entire DB shard group.

### Note

The maximum capacity of each node (router or shard) is 128 TiB, as this is the maximum capacity for an Aurora PostgreSQL DB cluster.

The maximum number of relations per database (including tables, views, and indexes) in both Aurora PostgreSQL and Aurora PostgreSQL Limitless Database is 1,431,650,303.

For more information, see [Appendix K. PostgreSQL limits](#) in the PostgreSQL documentation and [Amazon Aurora size limits](#).

## Reclaiming storage space by vacuuming

PostgreSQL Multiversion Concurrency Control (MVCC) helps to preserve data integrity by saving an internal copy of updated or deleted rows until a transaction is either committed or rolled back. These copies, also called *tuples*, can cause table bloat if they aren't cleaned up regularly. PostgreSQL instances order transactions by their transaction IDs, and PostgreSQL uses transaction ID-based MVCC to control tuple visibility and provide transaction isolation. Each transaction establishes a snapshot of data, and each tuple has a version. Both the snapshot and version are transaction ID-based.

To clean up data, the VACUUM utility performs four key functions in PostgreSQL:

- VACUUM – Removes expired row versions, making the space available for reuse.
- VACUUM FULL – Provides complete defragmentation by removing dead row versions and compacting the tables, reducing the size and increasing efficiency.
- VACUUM FREEZE – Protects against transaction ID wraparound issues by marking older row versions as frozen.
- VACUUM ANALYZE – Removes dead row versions and updates the database's query planning statistics. It's a combination of the VACUUM and ANALYZE functions. For more information on how ANALYZE works in Aurora PostgreSQL Limitless Database, see [ANALYZE](#).

As with MVCC, vacuuming in Aurora PostgreSQL is transaction ID-based. If there's an ongoing transaction when vacuuming starts, rows that are still visible to that transaction aren't removed.

For more information on the VACUUM utility, see [VACUUM](#) in the PostgreSQL documentation. For more information about VACUUM support in Aurora PostgreSQL Limitless Database, see [VACUUM](#).

### Topics

- [AUTOVACUUM](#)
- [Time-based vacuuming in Aurora PostgreSQL Limitless Database](#)
- [Using database statistics for vacuuming](#)
- [Differences in vacuuming behavior between Aurora PostgreSQL and Aurora PostgreSQL Limitless Database](#)

## AUTOVACUUM

Aurora PostgreSQL uses the VACUUM and AUTOVACUUM utilities to remove unneeded tuples. The underlying mechanism for AUTOVACUUM and manual VACUUM is the same; the only difference is the automation.

AUTOVACUUM in Aurora PostgreSQL and Aurora PostgreSQL Limitless Database is a combination of the VACUUM and ANALYZE utilities. AUTOVACUUM determines which databases and tables to clean up, according to a predefined rule, such as the percentage of dead tuples and the number of inserts.

For example, AUTOVACUUM "wakes up" periodically to perform cleanup. The interval is controlled by the `autovacuum_naptime` parameter. The default value is 1 minute. The default values for AUTOVACUUM and VACUUM configuration parameters are the same for Aurora PostgreSQL Limitless Database as for Aurora PostgreSQL.

The AUTOVACUUM daemon, if enabled, automatically issues ANALYZE commands whenever the content of a table has changed sufficiently. In Aurora PostgreSQL Limitless Database, AUTOVACUUM issues ANALYZE on both routers and shards.

For more information about the AUTOVACUUM daemon and table storage parameters associated with AUTOVACUUM, see [The autovacuum daemon](#) and [Storage parameters](#) in the PostgreSQL documentation.

### Time-based vacuuming in Aurora PostgreSQL Limitless Database

Aurora PostgreSQL Limitless Database is a distributed system, meaning that multiple instances can be involved in a transaction. Therefore, transaction ID–based visibility doesn't apply. Instead, Aurora PostgreSQL Limitless Database uses *time-based* visibility, because transaction IDs aren't "unified" across instances, but time can be "unified" across instances. Each transaction snapshot and each tuple version obeys the time instead of the transaction ID. To be more specific, a transaction snapshot has a snapshot start time, and a tuple has a creation time (when an INSERT or UPDATE happens) and a deletion time (when a DELETE happens).

To maintain data consistency across the instances in the DB shard group, Aurora PostgreSQL Limitless Database has to make sure that vacuuming doesn't remove any tuples that are still visible to any active transaction in the DB shard group. Therefore, vacuuming in Aurora PostgreSQL Limitless Database is also time-based. Other aspects of VACUUM remain the same, including that to run VACUUM on a particular table, a user must have access to that table.

**Note**

We strongly recommend that you don't leave transactions open for long periods of time. Time-based vacuuming consumes more memory than transaction ID–based vacuuming.

The following example illustrates how time-based vacuuming works.

1. A customer table is distributed across four shards.
2. Transaction 1 starts with a repeatable read, and targets only one shard (shard 1). This transaction remains open.

Transaction 1 is older than any other transaction started after it.

3. Transaction 2 starts later, and deletes all tuples from a table, then commits.
4. If AUTOVACUUM or manual VACUUM tries to clean up dead tuples (dead due to transaction 2), it doesn't remove anything.

This is true not only for shard 1, but also for shards 2–4, because transaction 1 might still need to access these tuples. They're still visible to transaction 1 because of MVCC.

The last step is achieved through synchronization, so that all shards are aware of transaction 1, even though transaction 1 doesn't touch all of them.

## Using database statistics for vacuuming

To get information on tuples that you might need to clean up, use the [limitless\\_stat\\_all\\_tables](#) view, which works similarly to [pg\\_stat\\_all\\_tables](#). The following example queries the view.

```
SELECT * FROM rds_aurora.limitless_stat_all_tables WHERE relname LIKE '%customer%';
```

Similarly, for database statistics use [limitless\\_stat\\_database](#) instead of [pg\\_stat\\_database](#), and [limitless\\_stat\\_activity](#) instead of [pg\\_stat\\_activity](#).

To check table disk usage, use the [limitless\\_stat\\_relation\\_sizes](#) function, which works similarly to [pg\\_relation\\_size](#). The following example queries the function.

```
SELECT * FROM rds_aurora.limitless_stat_relation_sizes('public', 'customer');
```

To track the progress of a VACUUM operation on Aurora PostgreSQL Limitless Database, use the [limitless\\_stat\\_progress\\_vacuum](#) view instead of [pg\\_stat\\_progress\\_vacuum](#). The following example queries the view.

```
SELECT * FROM rds_aurora.limitless_stat_progress_vacuum;
```

For more information, see [Aurora PostgreSQL Limitless Database views](#) and [Aurora PostgreSQL Limitless Database functions](#).

## Differences in vacuuming behavior between Aurora PostgreSQL and Aurora PostgreSQL Limitless Database

Some other differences between Aurora PostgreSQL and Aurora PostgreSQL Limitless Database in how vacuuming works are the following:

- Aurora PostgreSQL performs VACUUM operations on transaction IDs up to the oldest ongoing transaction. If there's no ongoing transaction in the database, VACUUM performs the operation until the last transaction.
- Aurora PostgreSQL Limitless Database synchronizes the oldest time snapshot every 10 seconds. Therefore, VACUUM might not perform the operation on any transactions that were run within the last 10 seconds.

For information on support for VACUUM in Aurora PostgreSQL Limitless Database, see [VACUUM](#) in the [Aurora PostgreSQL Limitless Database reference](#).

# Monitoring Aurora PostgreSQL Limitless Database

You can use Amazon CloudWatch, Enhanced Monitoring, and Performance Insights to monitor Aurora PostgreSQL Limitless Database. There are also new statistics functions and views, and wait events, for Aurora PostgreSQL Limitless Database that you can use for monitoring and diagnostics.

## Topics

- [Monitoring Aurora PostgreSQL Limitless Database with Amazon CloudWatch](#)
- [Monitoring Aurora PostgreSQL Limitless Database with CloudWatch Database Insights](#)
- [Monitoring Aurora PostgreSQL Limitless Database with Amazon CloudWatch Logs](#)
- [Monitoring Aurora PostgreSQL Limitless Database with Enhanced Monitoring](#)
- [Monitoring Aurora PostgreSQL Limitless Database with Performance Insights](#)
- [Monitoring Aurora PostgreSQL Limitless Database with Amazon GuardDuty RDS Protection](#)
- [Functions and views for Aurora PostgreSQL Limitless Database](#)
- [Wait events for Aurora PostgreSQL Limitless Database](#)

# Monitoring Aurora PostgreSQL Limitless Database with Amazon CloudWatch

CloudWatch metrics for Aurora PostgreSQL Limitless Database are reported under the following dimensions:

- [DBShardGroup](#)
- [DBShardGroupRouterAggregation](#)
- [DBShardGroupInstance](#)
- [DBClusterIdentifier](#)

For more information on CloudWatch metrics, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#).

## DBShardGroup metrics

To see DBShardGroup metrics for Aurora PostgreSQL Limitless Database in the CloudWatch console, choose **RDS**, and then choose **DBShardGroup**.

You can track the following CloudWatch metrics:

- `DBShardGroupACUUtilization` – Aurora capacity unit (ACU) usage as a percentage calculated from `DBShardGroupCapacity` divided by `DBShardGroupMaxACU`.
- `DBShardGroupCapacity` – Number of ACUs consumed by the writer instances of the DB shard group.
- `DBShardGroupComputeRedundancyCapacity` – Number of ACUs consumed by the standby instances of DB shard group.
- `DBShardGroupMaxACU` – Maximum number of ACUs configured for the DB shard group.
- `DBShardGroupMinACU` – Minimum number of ACUs required by the DB shard group.

The `DBShardGroupIdentifier` dimension key is available for aggregating the DBShardGroup metrics.

## DBShardGroupRouterAggregation metrics

To see DBShardGroupRouterAggregation metrics for Aurora PostgreSQL Limitless Database in the CloudWatch console, choose **RDS**, and then choose **DBShardGroupRouterAggregation**.

You can track the following CloudWatch metrics:

- `CommitThroughput` – The average number of commit operations per second across all of the router nodes in the DB shard group.
- `DatabaseConnections` – The sum of all connections across all of the router nodes in the DB shard group.

## DBShardGroupInstance metrics

A *DBShardGroupInstance* is the individual DB instance within each shard or router subcluster.

To see `DBShardGroupInstance` metrics for Aurora PostgreSQL Limitless Database in the CloudWatch console, choose **RDS**, and then choose **DBShardGroupInstance**.

You can track the following CloudWatch metrics:

- `ACUUtilization` – The percentage calculated as the `ServerlessDatabaseCapacity` metric divided by the maximum assigned ACU value of the subcluster.
- `AuroraReplicaLag` - For compute redundancy enabled Limitless clusters, this is the amount of lag when replicating updates from the primary instance in the subcluster.
- `AuroraReplicaLagMaximum` – For compute redundancy enabled Limitless clusters, this is the maximum amount of lag when replicating updates from the primary instance in the subcluster. When read replicas are deleted or renamed, there might be a temporary spike in replication lag as the old resource recycles. Use this metric to find if a failover occurred due to high replication lag on one of the it's readers.
- `AuroraReplicaLagMinimum` – For compute redundancy enabled Limitless clusters, this is the minimum amount of lag when replicating updates from the primary instance in the subcluster.
- `BufferCacheHitRatio` – The percentage of data and indexes served from an instance's memory cache (as opposed to the storage volume).
- `CommitLatency` – The average duration for the engine and storage to complete the commit operations for a particular node (router or shard).
- `CommitThroughput` – The average number of commit operations per second.
- `CPUUtilization` – CPU usage as a percentage of the maximum assigned ACU value of the subcluster.
- `FreeableMemory` – The amount of unused memory that's available when the shard group is scaled to its maximum capacity. This is determined by the assigned ACUs of the shard group.

For every ACU the current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB shard group is scaled up to the maximum limit.

- `MaximumUsedTransactionIDs` – The age of the oldest unvacuumed transaction ID, in transactions. If this value reaches 2,146,483,648 ( $2^{31} - 1,000,000$ ), the database is forced into read-only mode, to avoid transaction ID wraparound. For more information, see [Preventing transaction ID wraparound failures](#) in the PostgreSQL documentation.
- `NetworkReceiveThroughput` – The amount of network throughput received from clients by each instance in the DB shard group. This throughput doesn't include network traffic between instances in the DB shard group and the cluster volume.
- `NetworkThroughput` – The aggregated network throughput (both transmitted and received) between clients and routers, and routers and shards in the DB shard group. This throughput doesn't include network traffic between instances in the DB shard group and the cluster volume.
- `NetworkTransmitThroughput` – The amount of network throughput sent to clients by each instance in the DB shard group. This throughput doesn't include network traffic between instances in the DB shard group and the cluster volume.
- `ReadIOPS` – The average number of disk read input/output operations per second (IOPS).
- `ReadLatency` – The average amount time taken per disk read input/output (I/O) operation.
- `ReadThroughput` – The average number of bytes read from disk per second.
- `ServerlessDatabaseCapacity` – The current capacity of the DB shard or router subcluster within the DB shard group.
- `StorageNetworkReceiveThroughput` – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB shard group.
- `StorageNetworkThroughput` – The aggregated network throughput both transmitted to and received from the Aurora storage subsystem by each instance in the DB shard group.
- `StorageNetworkTransmitThroughput` – The amount of network throughput sent to the Aurora storage subsystem by each instance in the DB shard group.
- `SwapUsage` – The amount of swap space used by the DB shard group.
- `TempStorageIOPS` – The average number of I/O operations performed on local storage attached to the DB instance. It includes both read and write I/O operations.

`TempStorageIOPS` can be used with `TempStorageThroughput` to diagnose the rare cases where network activity for transfers between your DB instances and local storage devices is responsible for unexpected capacity increases.

- `TempStorageThroughput` – The amount of data transferred to and from local storage associated with either a router or a shard.
- `WriteIOPS` – The average number of disk write IOPS.
- `WriteLatency` – The average amount time taken per disk write I/O operation.
- `WriteThroughput` – The average number of bytes written to disk per second.

The following dimension keys are available for aggregating the `DBShardGroupInstance` metrics:

- `DBClusterIdentifier` – The Aurora PostgreSQL DB cluster.
- `DBShardGroupIdentifier` – The DB shard group to which the instance belongs.
- `DBShardGroupSubClusterType` – The node type, either `Distributed Transaction Router (router)` or `Data Access Shard (shard)`.
- `DBShardGroupSubClusterIdentifier` – The name of the router or shard to which the instance belongs.

The following are examples of aggregating CloudWatch metrics:

- Total `CPUUtilization` of all instances that belong to a particular shard or router in a DB shard group.
- Total `CPUUtilization` of all instances in a DB shard group.

## DBClusterIdentifier metrics

To see `DBClusterIdentifier` metrics for Aurora PostgreSQL Limitless Database in the CloudWatch console, choose **RDS**, and then choose **DBClusterIdentifier**.

When you use Aurora PostgreSQL Limitless Database, you might have more input/output (I/O) operations than you would for an Aurora DB cluster. You can track the following CloudWatch metrics for your Limitless Database cluster:

- `VolumeReadIops` – The number of billed read I/O operations from a cluster volume, reported at 5-minute intervals.
- `VolumeWriteIops` – The number of write disk I/O operations to the cluster volume, reported at 5-minute intervals.

Aurora PostgreSQL Limitless Database uses the Aurora I/O-Optimized cluster storage configuration. With Aurora I/O-Optimized, you pay a single monthly price for all I/O operations, rather than paying for every one million I/O requests. For more information, see [Storage configurations for Amazon Aurora DB clusters](#).

You might also use more storage than you would for an Aurora DB cluster. You can track the following CloudWatch metrics for storage:

- `BackupRetentionPeriodStorageUsed` – The total billed continuous backup storage usage of your Aurora PostgreSQL Limitless Database cluster.
- `SnapshotStorageUsed` – The total billed snapshot storage usage of your Aurora PostgreSQL Limitless Database cluster.
- `TotalBackupStorageBilled` – The sum of your costs for automated backup retention and DB cluster snapshots.

For more information on backup storage costs, see [Understanding Amazon Aurora backup storage usage](#).

- `VolumeBytesUsed` – The amount of storage used by your Aurora PostgreSQL Limitless Database cluster, reported at 5-minute intervals.

# Monitoring Aurora PostgreSQL Limitless Database with CloudWatch Database Insights

The Standard mode of Database Insights is required as part of enabling Aurora PostgreSQL Limitless Database. You can use it to monitor the database load (DB Load) of your Limitless Database DB instances in real time. DB Load measures the level of session activity in a database. You can use Database Insights to analyze and troubleshoot the performance of your Aurora PostgreSQL Limitless Database DB instances at scale.

For more information about CloudWatch Database Insights, see the following.

- [Monitoring Amazon Aurora databases with CloudWatch Database Insights](#)
- [CloudWatch Database Insights](#) in the *Amazon CloudWatch User Guide*
- [Get started with CloudWatch Database Insights](#) in the *Amazon CloudWatch User Guide*
- [Configuring your database to monitor slow SQL queries with Database Insights for Amazon Aurora](#)

For information about turning on the Advanced mode or Standard mode of Database Insights, see the following topics.

## Topics

- [Turning on the Advanced mode of Database Insights for Aurora PostgreSQL Limitless Database](#)
- [Turning on the Standard mode of Database Insights for Aurora PostgreSQL Limitless Database](#)

## Turning on the Advanced mode of Database Insights for Aurora PostgreSQL Limitless Database

To turn on the Advanced mode of Database Insights for your Aurora PostgreSQL Limitless Database, use the following procedures.

### Turning on the Advanced mode of Database Insights when creating a DB cluster for Aurora PostgreSQL Limitless Database

Turn on the Advanced mode of Database Insights when creating a database for Aurora PostgreSQL Limitless Database.

## Console

In the console, you can turn on the Advanced mode of Database Insights when you create a DB cluster. Settings for Database Insights apply to all DB instances in your DB cluster.

### To turn on the Advanced mode of Database Insights when creating a DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose **Create database**.
4. In the **Database Insights** section, select **Advanced mode**. Then, choose the following options:
  - **Retention** – The amount of time to retain Performance Insights data. The retention period must be 15-24 months for the Advanced mode of Database Insights.
  - **Amazon KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon Aurora resources](#).
5. Choose **Create database**.

## Amazon CLI

To turn on the Advanced mode of Database Insights when creating a DB cluster, call the [create-db-cluster](#) Amazon CLI command and supply the following values:

- `--db-cluster-identifier` – The identifier for the DB cluster.
- `--database-insights-mode` advanced to turn on the Advanced mode of Database Insights.
- `--engine` – The DB cluster must use the `aurora-postgresql` DB engine.
- `--engine-version` – The DB cluster must use one of the DB engine versions:
  - `16.4-limitless`
  - `16.6-limitless`
- `--storage-type` – The DB cluster must use the `aurora-iopt1` DB cluster storage configuration.

- `--cluster-scalability-type` – Specifies the scalability mode of the Aurora DB cluster. When set to `limitless`, the cluster operates as an Aurora PostgreSQL Limitless Database. When set to `standard` (the default), the cluster uses normal DB instance creation.

 **Note**

You can't modify this setting after you create the DB cluster.

- `--master-username` – The name of the master user for the DB cluster.
- `--master-user-password` – The password for the master user.
- `--enable-performance-insights` to turn on Performance Insights for Database Insights.
- `--performance-insights-retention-period` – The retention period for data for your DB cluster. To turn on Database Insights, the retention period must be at least 465 days.
- `--monitoring-interval` – The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB cluster. This value can't be 0.
- `--monitoring-role-arn` – The Amazon Resource Name (ARN) for the IAM role that permits RDS to send Enhanced Monitoring metrics to Amazon CloudWatch Logs.
- `--enable-cloudwatch-logs-exports` – You must export postgresql logs to CloudWatch Logs.

The following example enables the Advanced mode of Database Insights when creating a DB cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
--db-cluster-identifier my-limitless-cluster \  
--database-insights-mode advanced \  
--engine aurora-postgresql \  
--engine-version 16.6-limitless \  
--storage-type aurora-iopt1 \  
--cluster-scalability-type limitless \  
--master-username myuser \  
--master-user-password mypassword \  
--enable-performance-insights \  
--performance-insights-retention-period 465 \  
--monitoring-interval 5 \  

```

```
--monitoring-role-arn arn:aws:iam::123456789012:role/EMrole \  
--enable-cloudwatch-logs-exports postgresql
```

### For Windows:

```
aws rds create-db-cluster ^  
--db-cluster-identifier my-limitless-cluster ^  
--database-insights-mode advanced ^  
--engine aurora-postgresql ^  
--engine-version 16.6-limitless ^  
--storage-type aurora-iopt1 ^  
--cluster-scalability-type limitless ^  
--master-username myuser ^  
--master-user-password mypassword ^  
--enable-performance-insights ^  
--performance-insights-retention-period 465 ^  
--monitoring-interval 5 ^  
--monitoring-role-arn arn:aws:iam::123456789012:role/EMrole ^  
--enable-cloudwatch-logs-exports postgresql
```

## RDS API

To turn on the Advanced mode of Database Insights when you create a DB cluster, specify the following parameters for your [CreateDBCluster](#) Amazon RDS API operation.

- DatabaseInsightsMode to advanced
- Engine to aurora-postgresql
- EngineVersion to an available engine version for Limitless Database
- StorageType to aurora-iopt1
- ClusterScalabilityType to limitless
- MasterUsername
- MasterUserPassword
- EnablePerformanceInsights to True
- PerformanceInsightsRetentionPeriod to at least 465 days
- MonitoringInterval to a value that isn't 0
- MonitoringRoleArn to the Amazon Resource Name (ARN) for the IAM role that permits RDS to send Enhanced Monitoring metrics to Amazon CloudWatch Logs

## Turning on the Advanced mode of Database Insights when modifying a DB cluster for Aurora PostgreSQL Limitless Database

Turn on Database Insights when modifying a database for Aurora PostgreSQL Limitless Database.

### Note

To enable Database Insights, each DB instance in a DB cluster must have the same Performance Insights and Enhanced Monitoring settings.

## Console

In the console, you can turn on the Advanced mode of Database Insights when you modify a DB cluster. Settings for Database Insights apply to all DB instances in your DB cluster.

### To turn on the Advanced mode of Database Insights when modifying a DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose a DB cluster, and choose **Modify**.
4. In the **Database Insights** section, select **Advanced mode**. Then, choose the following options:
  - **Retention** – The amount of time to retain Performance Insights data. The retention period must be 15-24 months for the Advanced mode of Database Insights.
  - **Amazon KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon Aurora resources](#).
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose **Apply immediately**. If you choose **Apply during the next scheduled maintenance window**, your database ignores this setting and turns on the Advanced mode of Database Insights immediately.
7. Choose **Modify cluster**.

## Amazon CLI

To turn on the Advanced mode of Database Insights when modifying a DB cluster, call the [modify-db-cluster](#) Amazon CLI command and supply the following values:

- `--database-insights-mode advanced` to turn on the Advanced mode of Database Insights.
- `--db-cluster-identifier` – The identifier for the DB cluster.
- `--enable-performance-insights` to turn on Performance Insights for Database Insights.
- `--performance-insights-retention-period` – The retention period for data for your DB cluster. To turn on the Advanced mode of Database Insights, the retention period must be at least 465 days.

The following example enables the Advanced mode of Database Insights when modifying a DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --database-insights-mode advanced \  
  --db-cluster-identifier sample-db-identifier \  
  --enable-performance-insights \  
  --performance-insights-retention-period 465
```

For Windows:

```
aws rds modify-db-cluster ^  
  --database-insights-mode advanced ^  
  --db-cluster-identifier sample-db-identifier ^  
  --enable-performance-insights ^  
  --performance-insights-retention-period 465
```

## RDS API

To turn on the Advanced mode of Database Insights when you modify a DB cluster, specify the following parameters for your [ModifyDBCluster](#) Amazon RDS API operation.

- `DatabaseInsightsMode` to `advanced`

- `EnablePerformanceInsights` to `True`
- `PerformanceInsightsRetentionPeriod` to at least 465 days

## Turning on the Standard mode of Database Insights for Aurora PostgreSQL Limitless Database

To turn on the Standard mode of Database Insights for your Aurora PostgreSQL Limitless Database, use the following procedures.

### Turning on the Standard mode of Database Insights when creating a DB cluster for Aurora PostgreSQL Limitless Database

Turn on the Standard mode of Database Insights when creating a database for Aurora PostgreSQL Limitless Database.

#### Console

In the console, you can turn on the Standard mode of Database Insights when you create a DB cluster. Settings for Database Insights apply to all DB instances in your DB cluster.

#### To turn on the Standard mode of Database Insights when creating a DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose **Create database**.
4. In the **Database Insights** section, select **Standard mode**. Then, choose the following options:
  - **Retention** – The amount of time to retain Performance Insights data. To create a DB cluster for Aurora PostgreSQL Limitless Database, the retention period must be at least 31 days.
  - **Amazon KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon Aurora resources](#).
5. Choose **Create database**.

## Amazon CLI

To turn on the Standard mode of Database Insights when creating a DB cluster, call the [create-db-cluster](#) Amazon CLI command and supply the following values:

- `--db-cluster-identifier` – The identifier for the DB cluster.
- `--database-insights-mode standard` to turn on the Standard mode of Database Insights.
- `--engine` – The DB cluster must use the `aurora-postgresql` DB engine.
- `--engine-version` – The DB cluster must use one of the DB engine versions:
  - `16.4-limitless`
  - `16.6-limitless`
- `--storage-type` – The DB cluster must use the `aurora-iopt1` DB cluster storage configuration.
- `--cluster-scalability-type` – Specifies the scalability mode of the Aurora DB cluster. When set to `limitless`, the cluster operates as an Aurora PostgreSQL Limitless Database. When set to `standard` (the default), the cluster uses normal DB instance creation.

### Note

You can't modify this setting after you create the DB cluster.

- `--master-username` – The name of the master user for the DB cluster.
- `--master-user-password` – The password for the master user.
- `--enable-performance-insights` to turn on Performance Insights for Database Insights.
- `--performance-insights-retention-period` – The retention period for data for your DB cluster. To create a DB cluster for Aurora PostgreSQL Limitless Database, the retention period must be at least 31 days.
- `--monitoring-interval` – The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB cluster. This value can't be 0.
- `--monitoring-role-arn` – The Amazon Resource Name (ARN) for the IAM role that permits RDS to send Enhanced Monitoring metrics to Amazon CloudWatch Logs.
- `--enable-cloudwatch-logs-exports` – You must export `postgresql` logs to CloudWatch Logs.

The following example enables the Standard mode of Database Insights when creating a DB cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
--db-cluster-identifier my-limitless-cluster \  
--database-insights-mode standard \  
--engine aurora-postgresql \  
--engine-version 16.6-limitless \  
--storage-type aurora-iopt1 \  
--cluster-scalability-type limitless \  
--master-username myuser \  
--master-user-password mypassword \  
--enable-performance-insights \  
--performance-insights-retention-period 31 \  
--monitoring-interval 5 \  
--monitoring-role-arn arn:aws:iam::123456789012:role/EMrole \  
--enable-cloudwatch-logs-exports postgresql
```

For Windows:

```
aws rds create-db-cluster ^  
--db-cluster-identifier my-limitless-cluster ^  
--database-insights-mode standard ^  
--engine aurora-postgresql ^  
--engine-version 16.6-limitless ^  
--storage-type aurora-iopt1 ^  
--cluster-scalability-type limitless ^  
--master-username myuser ^  
--master-user-password mypassword ^  
--enable-performance-insights ^  
--performance-insights-retention-period 31 ^  
--monitoring-interval 5 ^  
--monitoring-role-arn arn:aws:iam::123456789012:role/EMrole ^  
--enable-cloudwatch-logs-exports postgresql
```

## RDS API

To turn on the Standard mode of Database Insights when you create a DB cluster, specify the following parameters for your [CreateDBCluster](#) Amazon RDS API operation.

- DatabaseInsightsMode to standard

- Engine to aurora-postgresql
- EngineVersion to an available engine version for Limitless Database
- StorageType to aurora-iopt1
- ClusterScalabilityType to limitless
- MasterUsername
- MasterUserPassword
- EnablePerformanceInsights to True
- PerformanceInsightsRetentionPeriod to at least 31 days
- MonitoringInterval to a value that isn't 0
- MonitoringRoleArn to the Amazon Resource Name (ARN) for the IAM role that permits RDS to send Enhanced Monitoring metrics to Amazon CloudWatch Logs

## Turning on the Standard mode of Database Insights when modifying a DB cluster for Aurora PostgreSQL Limitless Database

Turn on Database Insights when modifying a database for Aurora PostgreSQL Limitless Database.

### Note

To enable Database Insights, each DB instance in a DB cluster must have the same Performance Insights and Enhanced Monitoring settings.

## Console

In the console, you can turn on the Standard mode of Database Insights when you create a DB cluster. Settings for Database Insights apply to all DB instances in your DB cluster.

### To turn on the Standard mode of Database Insights when modifying a DB cluster using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose a DB cluster, and choose **Modify**.

4. In the **Database Insights** section, select **Standard mode**. Then, choose the following options:
  - **Retention** – The amount of time to retain Performance Insights data. To create a DB cluster for Aurora PostgreSQL Limitless Database, the retention period must be at least 31 days.
  - **Amazon KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon Aurora resources](#).
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose **Apply immediately**. If you choose **Apply during the next scheduled maintenance window**, your database ignores this setting and turns on the Standard mode of Database Insights immediately.
7. Choose **Modify cluster**.

## Amazon CLI

To turn on the Standard mode of Database Insights when modifying a DB cluster, call the [modify-db-cluster](#) Amazon CLI command and supply the following values:

- `--db-cluster-identifier` – The identifier for the DB cluster.
- `--database-insights-mode standard` to turn on the Standard mode of Database Insights.
- `--enable-performance-insights` to turn on Performance Insights for Database Insights.
- `--performance-insights-retention-period` – The retention period for data for your DB cluster. To turn on the Standard mode of Database Insights, the retention period must be at least 31 days.

The following example enables the Standard mode of Database Insights when modifying a DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --database-insights-mode standard \  
  --db-cluster-identifier sample-db-identifier \  
  --enable-performance-insights \  
  --no-cli-pager
```

```
--performance-insights-retention-period 31
```

### For Windows:

```
aws rds modify-db-cluster ^  
  --database-insights-mode standard ^  
  --db-cluster-identifier sample-db-identifier ^  
  --enable-performance-insights ^  
  --performance-insights-retention-period 31
```

### RDS API

To turn on the Standard mode of Database Insights when you modify a DB cluster, specify the following parameters for your [ModifyDBCluster](#) Amazon RDS API operation.

- DatabaseInsightsMode to standard
- EnablePerformanceInsights to True
- PerformanceInsightsRetentionPeriod to at least 31 days

# Monitoring Aurora PostgreSQL Limitless Database with Amazon CloudWatch Logs

Exporting PostgreSQL logs to CloudWatch Logs is required as part of enabling Aurora PostgreSQL Limitless Database. You can access and analyze these logs in CloudWatch Logs Insights, similar to accessing PostgreSQL logs for a standard Aurora PostgreSQL DB cluster. For more information, see [Analyzing PostgreSQL logs using CloudWatch Logs Insights](#).

The log group name for the DB cluster is the same as in Aurora PostgreSQL:

```
/aws/rds/cluster/DB_cluster_ID/postgresql
```

The log group name for the DB shard group takes the following form:

```
/aws/rds/cluster/DB_cluster_ID/DB_shard_group_ID/postgresql
```

There are log streams for each node (router or shard). Their names have the following form:

```
[DistributedTransactionRouter|  
DataAccessShard]/node_cluster_serial_ID-node_instance_serial_ID/n
```

For example:

- Router – DistributedTransactionRouter/6-6.2
- Shard – DataAccessShard/22-22.0

## Note

You can't view PostgreSQL log files for the DB shard group directly in the RDS console, Amazon CLI, or RDS API as you can for the DB cluster. You must use CloudWatch Logs Insights to view them.

## Monitoring Aurora PostgreSQL Limitless Database with Enhanced Monitoring

Enhanced Monitoring is required as part of enabling Aurora PostgreSQL Limitless Database. You can use it to monitor the operating system of your Limitless Database DB instances in real time.

Aurora publishes Enhanced Monitoring metrics in CloudWatch Logs. Some of the key metrics available include database connections, storage usage, and query latency. These can help identify performance bottlenecks.

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

# Monitoring Aurora PostgreSQL Limitless Database with Performance Insights

Use Performance Insights to monitor your Aurora PostgreSQL Limitless Database cluster. Performance Insights works similarly for Aurora PostgreSQL Limitless Database as it does for standard Aurora DB clusters. However, you track metrics at the shard group level for Aurora PostgreSQL Limitless Database.

The two main Performance Insights metrics to track are the following:

- Database load – Measures the level of activity in your database. The key metric in Performance Insights is DBLoad, which is collected every second.

The unit for the DBLoad metric in Performance Insights is average active sessions (AAS). To get the average active sessions, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples for a specific time period. For more information on DBLoad and AAS, see [Database load](#).

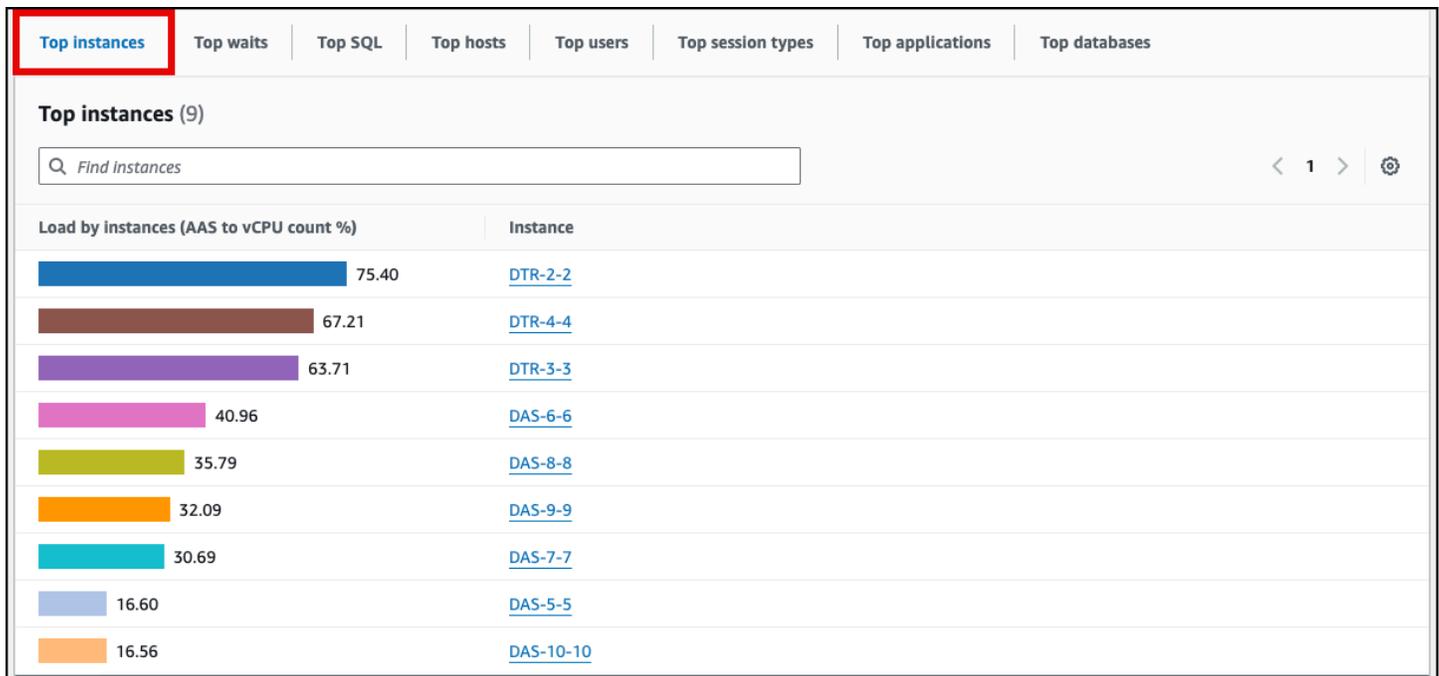

- Maximum CPU – The maximum computational power available to your database. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the Max vCPU line. The Max vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance. For more information on Max vCPU, see [Maximum CPU](#).

In addition, you can "slice" the DBLoad metric into *dimensions*, which are subcategories of the metric. The most useful dimensions are the following:

- Top instances – Shows the relative DB load for your instances (shards and routers) in descending order.
- Wait events – Cause SQL statements to wait for specific events to happen before they can continue running. Wait events indicate where work is impeded.
- Top SQL – Shows which queries contribute the most to DB load.

For more information about Performance Insights dimensions, see [Dimensions](#).

The following figure shows the **Top instances** dimension for a DB shard group.

## Topics

- [Analyzing DB load for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard](#)

## Analyzing DB load for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard

With Performance Insights, you can track metrics at the shard group level and at the instance level for an Aurora PostgreSQL Limitless Database. When analyzing DB load for an Aurora PostgreSQL Limitless Database, you might want to compare the DB load for each shard and router to the maximum vCPU.

### Note

Aurora PostgreSQL Limitless Database always has Performance Insights and Enhanced Monitoring enabled. The minimum retention period for Performance Insights data for Limitless Database is 31 days (1 month).

The **Absolute** view shows the number of Average active sessions (AAS) and the estimated vCPU. The **Relative** view shows the ratio of AAS to the estimated vCPU.

### Topics

- [Analyzing relative DB load for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard](#)
- [Analyzing DB load by waits for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard](#)
- [Analyzing load distribution for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard](#)

## Analyzing relative DB load for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard

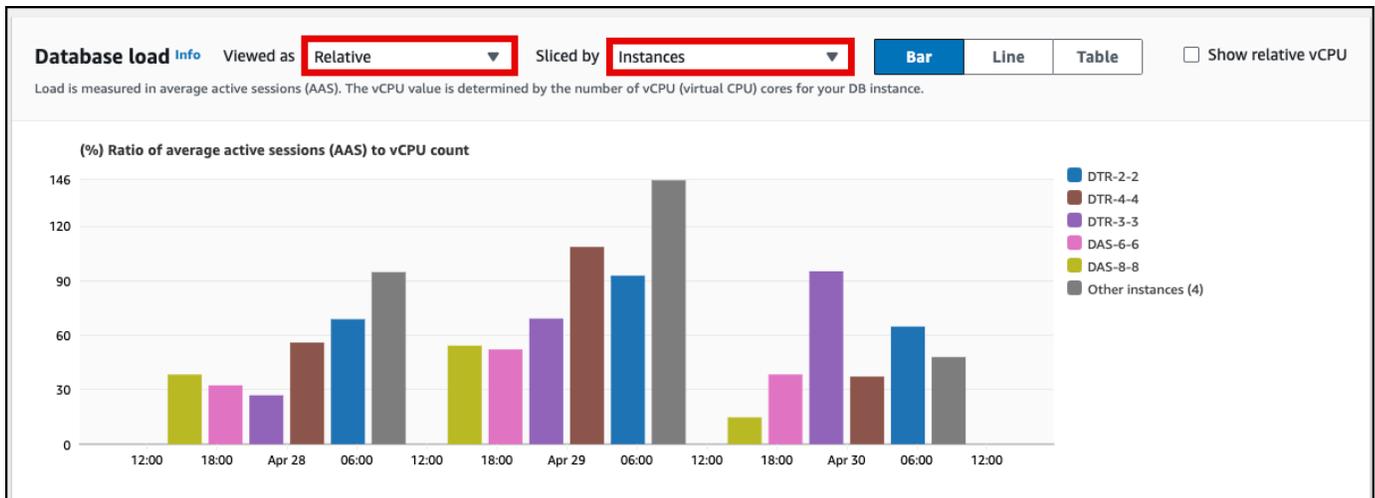

You might want to improve the performance of your Aurora PostgreSQL Limitless Database by tracking relative DB load. To analyze relative DB load by instance for your Aurora PostgreSQL Limitless Database, use the following procedure.

### To analyze relative DB load for Aurora PostgreSQL Limitless Database using the console

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.

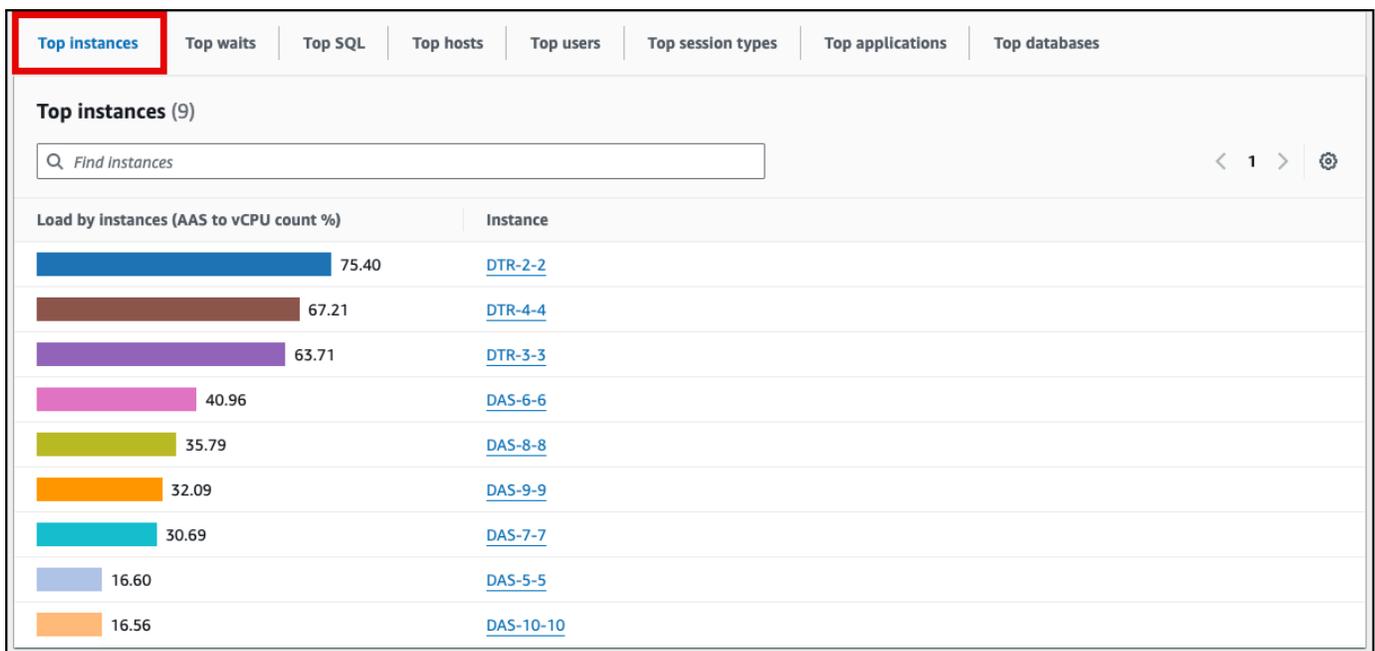

- Choose an Aurora PostgreSQL Limitless Database. The Performance Insights dashboard is displayed for that Aurora PostgreSQL Limitless Database.
- In the **Database load (DB load)** section, choose **Instances** for **Sliced by**. To see the ratio of Average active sessions (AAS) to vCPU cores for all of the instances in your Aurora PostgreSQL Limitless Database, choose **Relative** for **Viewed as**.

The Average active sessions chart shows the DB load for instances in your Aurora PostgreSQL Limitless Database.

- To view the top instances, choose the **Top instances** tab.

In the following example, the instance with the highest DB load is DTR-2-2.

6. (Optional) To analyze DB load for an instance in your Aurora PostgreSQL Limitless Database, choose the instance name in the **Instances** column. To view the DB load for DTR-2-2, choose DTR-2-2 in the **Instances** column.

 **Note**

You can view Performance Insights metrics only for instances in an Aurora PostgreSQL Limitless Database.

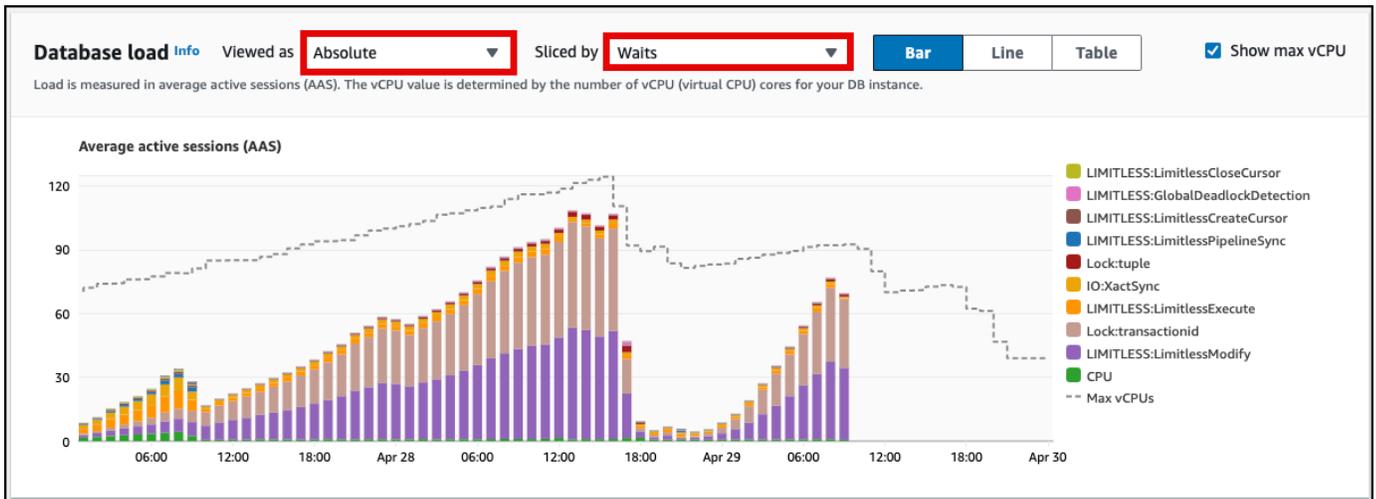

## Analyzing DB load by waits for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard

You might want to improve the performance for your Aurora PostgreSQL Limitless Database by tracking wait events. To analyze DB load by wait events for your Aurora PostgreSQL Limitless Database, use the following procedure.

### To analyze DB load by waits for Aurora PostgreSQL Limitless Database using the console

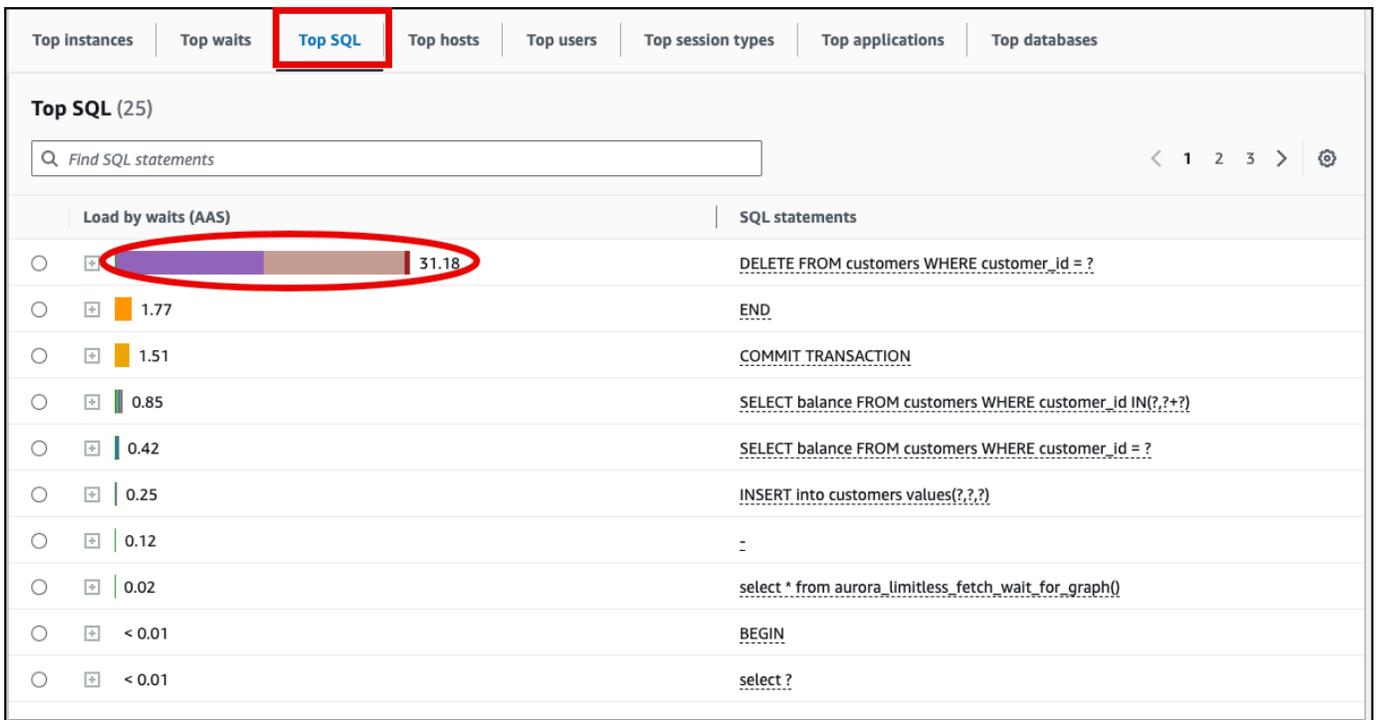

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose an Aurora PostgreSQL Limitless Database. The Performance Insights dashboard is displayed for that Aurora PostgreSQL Limitless Database.
4. In the **Database load (DB load)** section, choose **Waits** for **Sliced by**. To view the number of AAS and the estimated vCPU, choose **Absolute** for **Viewed as**.

The Average active sessions chart shows the DB load for instances in your Aurora PostgreSQL Limitless Database.

5. Scroll down to the **Top SQL** tab.

In the following example, the SQL statement with the highest load by waits is the DELETE statement.

6. Choose the SQL statement to expand it into its component statements.

In the following example, the SELECT statement has 3 component statements.

Top instances	Top waits	Top SQL	Top hosts	Top users	Top session types	Top applications	Top databases
<b>Top SQL (25)</b>							
<input type="text" value="Find SQL statements"/> <span style="float: right;">&lt; 1 2 3 &gt; ⚙</span>							
Load by waits (AAS)				SQL statements			
<input type="radio"/>	<input type="checkbox"/>		31.18	DELETE FROM customers WHERE customer_id = ?			
<input type="radio"/>	<input type="checkbox"/>		1.77	END			
<input type="radio"/>	<input type="checkbox"/>		1.51	COMMIT TRANSACTION			
<input checked="" type="radio"/>	<input type="checkbox"/>		0.85	SELECT balance FROM customers WHERE customer_id IN(?,?+?)			
<input type="radio"/>	<input type="checkbox"/>		0.70	SELECT balance FROM customers WHERE customer_id IN(?,?+?)			
<input type="radio"/>	<input type="checkbox"/>		0.14	SELECT balance FROM public.customers WHERE ((customer_id = ANY (?:integer[])))			
<input type="radio"/>	<input type="checkbox"/>		< 0.01	SELECT balance FROM public.customers customers_fs00005 WHERE (customer_id = ...			
<input type="radio"/>	<input type="checkbox"/>		0.42	SELECT balance FROM customers WHERE customer_id = ?			
<input type="radio"/>	<input type="checkbox"/>		0.25	INSERT into customers values(?,?,?)			
<input type="radio"/>	<input type="checkbox"/>		0.12	=			
<input type="radio"/>	<input type="checkbox"/>		0.02	select * from aurora_limitless_fetch_wait_for_graph()			
<input type="radio"/>	<input type="checkbox"/>		< 0.01	BEGIN			
<input type="radio"/>	<input type="checkbox"/>		< 0.01	select ?			

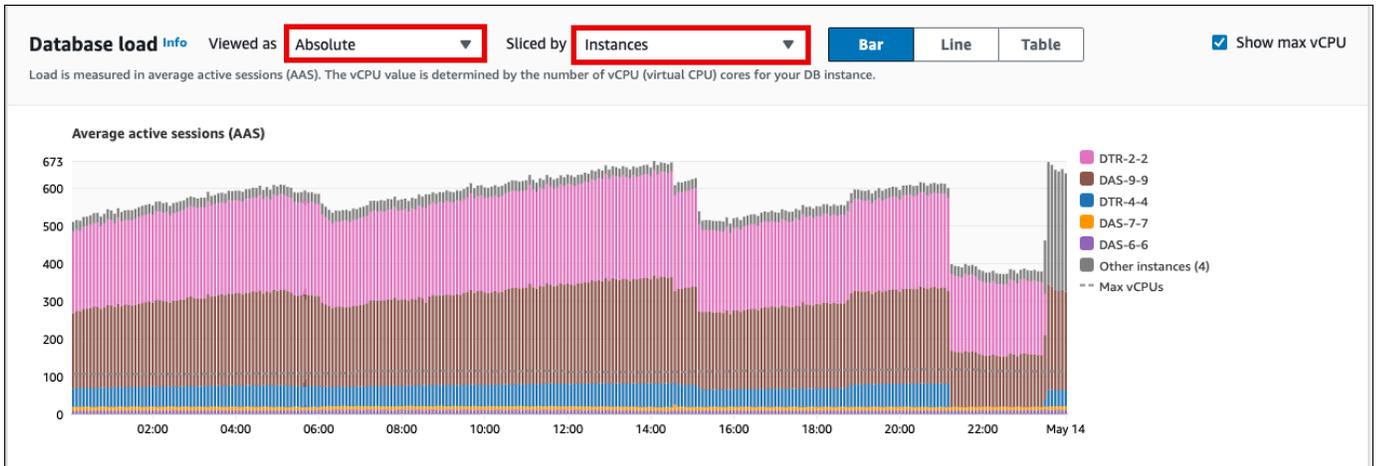

## Analyzing load distribution for Aurora PostgreSQL Limitless Database using the Performance Insights dashboard

You might want to balance the load distribution for instances on your Aurora PostgreSQL Limitless Database. To analyze load distribution of the instances on an Aurora PostgreSQL Limitless Database, use the following procedure.

### To analyze load distribution of the instances on an Aurora PostgreSQL Limitless Database using the console

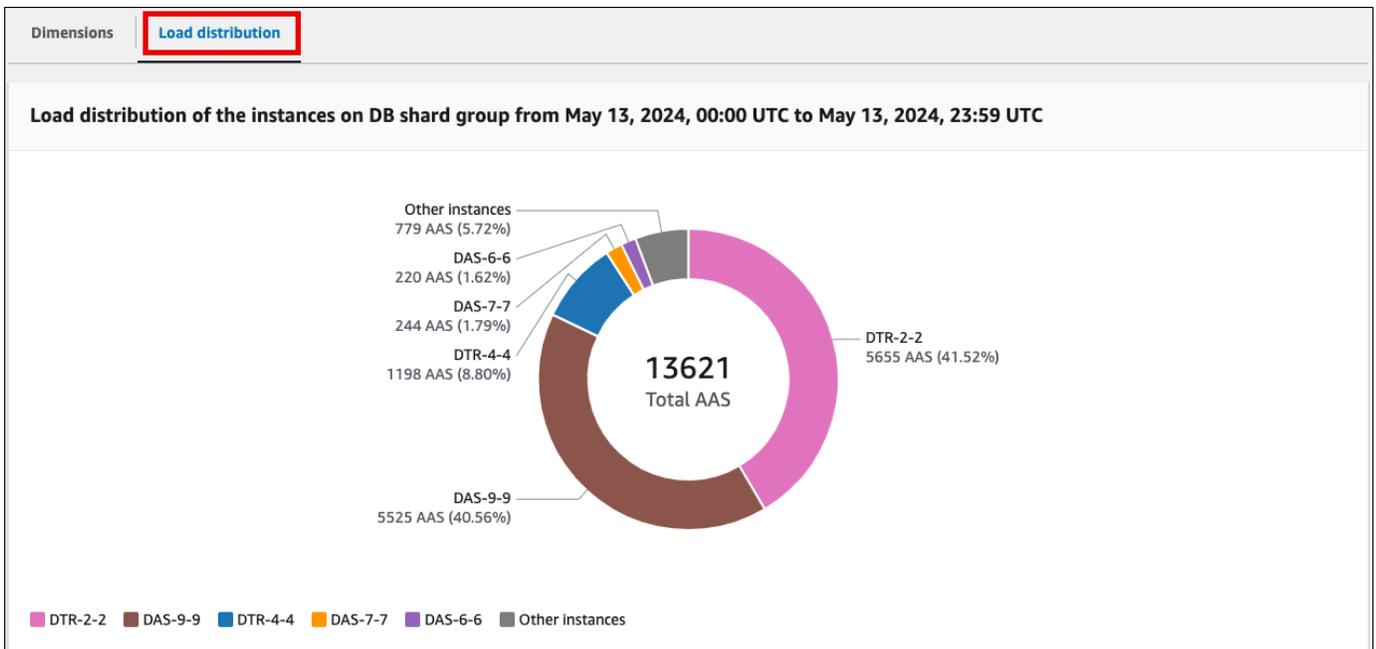

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose an Aurora PostgreSQL Limitless Database. The Performance Insights dashboard is displayed for that Aurora PostgreSQL Limitless Database.
4. In the **Database load (DB load)** section, choose **Instances** for **Sliced by**. To view the number of AAS and the estimated vCPU for all instances in your Aurora PostgreSQL Limitless Database, choose **Absolute** for **Viewed as**.

The Average active sessions chart shows the DB load for instances in your Aurora PostgreSQL Limitless Database.

- 5. To see a chart of the load distribution of the instances in your Aurora PostgreSQL Limitless Database, choose the **Load distribution** tab.

In the following example, the instance with the highest DB load is DTR-2-2.

## Monitoring Aurora PostgreSQL Limitless Database with Amazon GuardDuty RDS Protection

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your Amazon environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

GuardDuty RDS Protection analyzes and profiles login events for potential access threats to your Amazon Aurora databases. When you turn on RDS Protection, GuardDuty consumes RDS login events from your Aurora databases. RDS Protection monitors these events and profiles them for potential insider threats or external actors.

For more information about GuardDuty RDS Protection in Aurora, see [Monitoring threats with Amazon GuardDuty RDS Protection for Amazon Aurora](#).

For more information about enabling GuardDuty RDS Protection, see [GuardDuty RDS Protection](#) in the *Amazon GuardDuty User Guide*.

## Functions and views for Aurora PostgreSQL Limitless Database

Aurora PostgreSQL Limitless Database has added functions and views. They're based on the corresponding Aurora PostgreSQL functions and views.

### Note

Some statistics can return inconsistent results if there are transactions in progress.

### Topics

- [Aurora PostgreSQL Limitless Database functions](#)
- [Aurora PostgreSQL Limitless Database views](#)

## Aurora PostgreSQL Limitless Database functions

The following table shows the new functions for Aurora PostgreSQL Limitless Database.

### Note

The functions listed in this table are located in the `rds_aurora` schema. When using a Limitless Database function, make sure to include the fully qualified object name: `rds_aurora.object_name`.

Aurora PostgreSQL Limitless Database function	Corresponding Aurora PostgreSQL function
<a href="#">limitless_backend_dsid</a>	<code>pg_backend_pid</code>
<a href="#">limitless_cancel_session</a>	<code>pg_cancel_backend</code>
<a href="#">limitless_stat_clear_snapshot</a>	<code>pg_stat_clear_snapshot</code>
<a href="#">limitless_stat_database_size</a>	<code>pg_database_size</code>
<a href="#">limitless_stat_get_snapshot_timestamp</a>	<code>pg_stat_get_snapshot_timestamp</code>

Aurora PostgreSQL Limitless Database function	Corresponding Aurora PostgreSQL function
<a href="#">limitless_stat_prepared_xacts</a>	pg_prepared_xacts
<a href="#">limitless_stat_relation_sizes</a>	pg_indexes_size, pg_relation_size, pg_table_size, pg_total_relation_size
<a href="#">limitless_stat_reset</a>	pg_stat_reset
<a href="#">limitless_stat_statements_reset</a>	pg_stat_statements_reset
<a href="#">limitless_stat_system_waits</a>	aurora_stat_system_waits
<a href="#">limitless_terminate_session</a>	pg_terminate_backend
<a href="#">limitless_wait_report</a>	aurora_wait_report

The following examples provide details about the Aurora PostgreSQL Limitless Database functions. For more information on PostgreSQL functions, see [Functions and operators](#) in the PostgreSQL documentation.

### limitless\_backend\_dsid

The `limitless_backend_dsid` function returns the distributed session ID for the current session. A distributed session runs on a router in a DB shard group and involves backend processes on one or more shards in the DB shard group.

The following example shows how to use the `limitless_backend_dsid` function.

```
SELECT rds_aurora.limitless_backend_dsid();

limitless_backend_dsid
-----
8CACD7B04D0FC2A5
(1 row)
```

## limitless\_cancel\_session

The `limitless_cancel_session` function works similarly to `pg_cancel_backend`, but it tries to cancel all backend processes related to the provided distributed session ID by sending a SIGINT (interruption signal).

The input parameter is the following:

- `distributed_session_id` (text) – The ID of the distributed session to be canceled.

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `pid` (text) – The backend process ID.
- `success` (boolean) – Whether the cancellation was successful.

The following example shows how to use the `limitless_cancel_session` function.

```
SELECT * FROM rds_aurora.limitless_cancel_session('940CD5C81E3C796B');

subcluster_id | pid | success
-----+-----+-----
              1 | 26920 | t
(1 row)
```

## limitless\_stat\_clear\_snapshot

The `limitless_stat_clear_snapshot` function discards the current statistics snapshot or cached information on all nodes.

The following example shows how to use the `limitless_stat_clear_snapshot` function.

```
SELECT rds_aurora.limitless_stat_clear_snapshot();
```

## limitless\_stat\_database\_size

The `limitless_stat_database_size` function returns the sizes of a database in the DB shard group.

The input parameter is the following:

- `dbname` (name) – The database for which to get the sizes.

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.
- `db_size` – The size of the database in this subcluster in bytes.

The following example shows how to use the `limitless_stat_database_size` function.

```
SELECT * FROM rds_aurora.limitless_stat_database_size('postgres_limitless');
```

subcluster_id	subcluster_type	db_size
1	router	8895919
2	router	8904111
3	shard	21929391
4	shard	21913007
5	shard	21831087

(5 rows)

### `limitless_stat_get_snapshot_timestamp`

The `limitless_stat_get_snapshot_timestamp` function returns the timestamp of the current statistics snapshot, or NULL if no statistics snapshot has been taken. A snapshot is taken the first time cumulative statistics are accessed in a transaction if `stats_fetch_consistency` is set to `snapshot`. Returns a consolidated view of snapshot timestamps from all nodes. The `subcluster_id` and `subcluster_type` columns show which node the data is from.

The following example shows how to use the `limitless_stat_get_snapshot_timestamp` function.

```
SELECT * FROM rds_aurora.limitless_stat_get_snapshot_timestamp();
```

subcluster_id	subcluster_type	snapshot_timestamp
1	router	
2	router	
3	shard	
4	shard	
5	shard	

(5 rows)

## limitless\_stat\_prepared\_xacts

The `limitless_stat_prepared_xacts` function returns information about transactions on all nodes that are currently prepared for two-phase commit. For more information, see [pg\\_prepared\\_xacts](#) in the PostgreSQL documentation.

The following example shows how to use the `limitless_stat_prepared_xacts` function.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_stat_prepared_xacts;
```

subcluster_id	subcluster_type	transaction_id	gid
prepared	owner_id	database_id	
8	shard	5815978	7_4599899_postgres_limitless
2024-09-03 15:51:17.659603+00	auroraperf	postgres_limitless	
12	shard	4599138	7_4599899_postgres_limitless
2024-09-03 15:51:17.659637+00	auroraperf	postgres_limitless	

(2 rows)

## limitless\_stat\_relation\_sizes

The `limitless_stat_relation_sizes` function returns the different sizes of a table in the DB shard group.

The input parameters are the following:

- `relnspname` (name) – The name of the schema containing the table.
- `relname` (name) – The name of the table.

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.
- `main_size` – The size in bytes of the main data fork in this node.
- `fsm_size` – The size in bytes of the free space map for the table in this node.
- `vm_size` – The size in bytes of the visibility map for the table in this node.
- `init_size` – The size in bytes of the initialization of the table in this node.
- `toast_size` – The size in bytes of the toast table associated with the table in this fork.

- `index_size` – The size in bytes of all of the indexes for the table in this node.
- `total_size` – The size in bytes of all of the segments of the table in this node.

The following example shows how to use the `limitless_stat_relation_sizes` function (some columns are omitted).

```
SELECT * FROM rds_aurora.limitless_stat_relation_sizes('public','customers');
```

subcluster_id	subcluster_type	main_size	fsm_size	vm_size	toast_size	table_size	total_size
0	1   router	0	0	0	0	0	0
0	2   router	0	0	0	0	0	0
11132928	3   shard	4169728	4177920	1392640	1392640	11132928	11132928
11132928	4   shard	4169728	4177920	1392640	1392640	11132928	11132928
11026432	5   shard	3981312	4227072	1409024	1409024	11026432	11026432

(5 rows)

## limitless\_stat\_reset

The `limitless_stat_reset` function resets all statistics counters for the current database to zero (0). If `track_functions` is enabled, the `stats_reset` column in `limitless_stat_database` shows the last time statistics were reset for the database. By default, `limitless_stat_reset` can be run only by a superuser. Other users can be granted permission by using the `EXECUTE` privilege.

The following example shows how to use the `limitless_stat_reset` function.

```
SELECT tup_inserted, tup_deleted FROM pg_stat_database
WHERE datname = 'postgres_limitless';
```

tup_inserted	tup_deleted
896	0

(1 row)

```

SELECT rds_aurora.limitless_stat_reset();

limitless_stat_reset
-----
(1 row)

SELECT tup_inserted, tup_deleted FROM pg_stat_database
WHERE datname = 'postgres_limitless';

tup_inserted | tup_deleted
-----+-----
            0 |            0
(1 row)

```

### limitless\_stat\_statements\_reset

The `limitless_stat_statements_reset` function discards statistics gathered so far by `limitless_stat_statements` corresponding to the specified username, dbname, `distributed_query_id`, and `queryid` parameters. If any of the parameters aren't specified, the default value "" or 0 (invalid) is used for each of them, and the statistics that match with other parameters are reset. If no parameter is specified, or all the specified parameters are "" or 0 (invalid), the function discards all statistics. If all statistics in the `limitless_stat_statements` view are discarded, the function also resets the statistics in the `limitless_stat_statements_info` view.

The input parameters are the following:

- `username (name)` – The user that queried the statement.
- `dbname (name)` – The database where the query was run.
- `distributed_query_id (bigint)` – The query ID of the parent query from the coordinator node. This column is NULL if it's the parent query. The coordinator node pushes down the distributed query ID to the participant nodes. So for the participant nodes, the values for distributed query ID and query ID are different.
- `queryid (bigint)` – The query ID of the statement.

The following example shows how to use the `limitless_stat_statements_reset` function to reset all of the statistics gathered by `limitless_stat_statements`.

```

SELECT rds_aurora.limitless_stat_statements_reset();

```

## limitless\_stat\_system\_waits

The `limitless_stat_system_waits` function returns a consolidated view of the wait event data from `aurora_stat_system_waits`, which reports system wide wait activity in an instance, from all nodes. The `subcluster_id` and `subcluster_type` columns show which node the data is from.

The following example shows how to use the `limitless_stat_system_waits` function.

```
postgres_limitless=> SELECT *
FROM rds_aurora.limitless_stat_system_waits() lssw, pg_catalog.aurora_stat_wait_event()
  aswe
WHERE lssw.event_id=aswe.event_id and aswe.event_name='LimitlessTaskScheduler';

 subcluster_id | subcluster_type | type_id | event_id | waits | wait_time |
 event_name
-----+-----+-----+-----+-----+-----
+-----+
          1 | router          |      12 | 201326607 | 677068 | 616942216307 |
LimitlessTaskScheduler
          2 | router          |      12 | 201326607 | 678586 | 616939897111 |
LimitlessTaskScheduler
          3 | shard           |      12 | 201326607 | 756640 | 616965545172 |
LimitlessTaskScheduler
          4 | shard           |      12 | 201326607 | 755184 | 616958057620 |
LimitlessTaskScheduler
          5 | shard           |      12 | 201326607 | 757522 | 616963183539 |
LimitlessTaskScheduler
(5 rows)
```

## limitless\_terminate\_session

The `limitless_terminate_session` function works similarly to `pg_terminate_backend`, but it tries to end all backend processes related to the provided distributed session ID by sending a SIGTERM (end signal).

The input parameter is the following:

- `distributed_session_id` (text) – The ID of the distributed session to be ended.

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.

- `pid` (text) – The backend process ID.
- `success` (boolean) – Whether the process was successfully ended.

The following example shows how to use the `limitless_terminate_session` function.

```
SELECT * FROM rds_aurora.limitless_terminate_session('940CD5C81E3C796B');
```

```

subcluster_id | pid | success
-----+-----+-----
              1 | 26920 | t
(1 row)

```

## limitless\_wait\_report

The `limitless_wait_report` function returns the wait event activity over a period of time from all nodes. The `subcluster_id` and `subcluster_type` columns show which node the data is from.

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.

The rest of the columns are the same as in `aurora_wait_report`.

The following example shows how to use the `limitless_wait_report` function.

```
postgres_limitless=> select * from rds_aurora.limitless_wait_report();
```

```

subcluster_id | subcluster_type | type_name | event_name | waits | wait_time |
ms_per_wait  | waits_per_xact | ms_per_xact
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
              1 | router          | Client    | ClientRead | 57 | 741550.14 |
13009.652 | 0.19 | 2505.237
              5 | shard          | Client    | ClientRead | 54 | 738897.68 |
13683.290 | 0.18 | 2496.276
              4 | shard          | Client    | ClientRead | 54 | 738859.53 |
13682.584 | 0.18 | 2496.147
              2 | router          | Client    | ClientRead | 53 | 719223.64 |
13570.257 | 0.18 | 2429.810

```

8550.378		3		shard		Client		ClientRead		54		461720.40	
				0.18		1559.86							

## Aurora PostgreSQL Limitless Database views

The following table shows the new views for Aurora PostgreSQL Limitless Database.

### Note

The views listed in this table are located in the `rds_aurora` schema. When using a Limitless Database view, make sure to include the fully qualified object name: `rds_aurora.object_name`.

Aurora PostgreSQL Limitless Database view	Corresponding Aurora PostgreSQL view
<a href="#">limitless_database</a>	pg_database
<a href="#">limitless_locks</a>	pg_locks
<a href="#">limitless_stat_activity</a>	pg_stat_activity
<a href="#">limitless_stat_all_indexes</a>	pg_stat_all_indexes
<a href="#">limitless_stat_all_tables</a>	pg_stat_all_tables
<a href="#">limitless_stat_database</a>	pg_stat_database
<a href="#">limitless_stat_progress_vacuum</a>	pg_stat_progress_vacuum
<a href="#">limitless_stat_statements</a>	pg_stat_statements
<a href="#">limitless_stat_subclusters</a>	None
<a href="#">limitless_stat_statements_info</a>	pg_stat_statements_info
<a href="#">limitless_statio_all_indexes</a>	pg_statio_all_indexes
<a href="#">limitless_statio_all_tables</a>	pg_statio_all_tables
<a href="#">limitless_tables</a>	pg_tables
<a href="#">limitless_table_collocations</a>	None

Aurora PostgreSQL Limitless Database view	Corresponding Aurora PostgreSQL view
<a href="#">limitless_table_collocation_distributions</a>	None

The following examples provide details about the Aurora PostgreSQL Limitless Database views. For more information on PostgreSQL views, see [Viewing statistics](#) in the PostgreSQL documentation.

### Note

Some statistics views can return inconsistent results if you have ongoing transactions.

## limitless\_database

This view contains information about the available databases in the DB shard group. For example:

```
postgres_limitless=> SELECT subcluster_id, subcluster_type, oid, datname, datacl
FROM rds_aurora.limitless_database;
```

```
subcluster_id | subcluster_type | oid | datname |
              |                 |     |         |
              |                 |     |         |
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
 2          | router         |    4 | template0 | {=c/
rdsadmin,rdsadmin=CTc/rdsadmin}
 2          | router         |    5 | postgres  |
 2          | router         | 16384 | rdsadmin  |
{rdsadmin=CTc/rdsadmin,rds_aurora_limitless_metadata_admin=c/
rdsadmin,rds_aurora_limitless_heat_mgmt_admin=c/rdsadmin}
 2          | router         | 16477 | postgres_limitless |
 2          | router         |    1 | template1 | {=c/
rdsadmin,rdsadmin=CTc/rdsadmin}
 6          | shard          |    4 | template0 | {=c/
rdsadmin,rdsadmin=CTc/rdsadmin}
```

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster (node)
- `subcluster_type` (text) – The type of subcluster (node), router or shard

The rest of the columns are the same as in `pg_database`.

## limitless\_locks

This view contains one row per process per node. It provides access to information about the locks held by active processes in the database server.

### Example of creating a lock with two transactions

In this example, we run two transactions simultaneously on two routers.

```
# Transaction 1 (run on router 1)
BEGIN;
SET search_path = public;
SELECT * FROM customers;
INSERT INTO customers VALUES (400, 'foo', 'bar');

# Transaction 2 (run on router 2)
BEGIN;
SET search_path = public;
ALTER TABLE customers ADD COLUMN phone VARCHAR;
```

The first transaction is run. Subsequent transactions have to wait until the first transaction is completed. Therefore the second transaction is blocked with a lock. To check the root cause of it, we run a command by joining `limitless_locks` with `limitless_stat_activity`.

```
# Run on router 2
SELECT distributed_session_id, state, username, query, query_start
FROM rds_aurora.limitless_stat_activity
WHERE distributed_session_id in (
SELECT distributed_session_id
FROM rds_aurora.limitless_locks
WHERE relname = 'customers'
);
```

distributed_session_id	state	username	query
47BDE66E9A5E8477	idle in transaction	limitless_metadata_admin	INSERT INTO customers VALUES (400, 'foo', 'bar');
2AD7F370202D0FA9	active	limitless_metadata_admin	ALTER TABLE customers ADD COLUMN phone VARCHAR;

```

47BDE66E9A5E8477 | | limitless_auth_admin |
<insufficient privilege> |
2AD7F370202D0FA9 | | limitless_auth_admin |
<insufficient privilege> |
47BDE66E9A5E8477 | | limitless_auth_admin |
<insufficient privilege> |
2AD7F370202D0FA9 | | limitless_auth_admin |
<insufficient privilege> |
(6 rows)

```

## Example of creating a lock explicitly

In this example, we create a lock explicitly, then use the `limitless_locks` view to see the locks (some columns are omitted).

```

BEGIN;
SET search_path = public;
LOCK TABLE customers IN ACCESS SHARE MODE;
SELECT * FROM rds_aurora.limitless_locks WHERE relname = 'customers';

```

subcluster_id	subcluster_type	distributed_session_id	locktype	datname

(6 rows)

## limitless\_stat\_activity

This view contains one row per process per node. It can be used to track overall system health and triage processes that are taking a long time. For example:

```
postgres=# SELECT
  subcluster_id,
  subcluster_type,
  distributed_session_id,
  distributed_session_state,
  datname,
  distributed_query_id,
  is_sso_query
FROM
  rds_aurora.limitless_stat_activity
WHERE
  distributed_session_id in ('D2470C97E3D07E06', '5A3CD7B8E5FD13FF')
order by distributed_session_id;
```

subcluster_id	subcluster_type	distributed_session_id	distributed_session_state	datname	distributed_query_id	is_sso_query
2	router	5A3CD7B8E5FD13FF	coordinator	postgres_limitless		f
3	shard	5A3CD7B8E5FD13FF	participant	postgres_limitless	6808291725541680947	
4	shard	5A3CD7B8E5FD13FF	participant	postgres_limitless	6808291725541680947	
2	router	D2470C97E3D07E06	coordinator	postgres_limitless		t
3	shard	D2470C97E3D07E06	participant	postgres_limitless	4058400544464210222	

(5 rows)

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.

- `distributed_session_id` (text) – The ID of the distributed session to which this process belongs.
- `distributed_session_state` (text) – Whether this is a coordinator, participant, or standalone/nondistributed process (shown as NULL).
- `datname` (text) – The database to which this process is connected.
- `distributed_query_id` (bigint) – The query ID of the parent query from the coordinator node. This column is NULL if it's the parent query. The coordinator node pushes down the distributed query ID to the participant nodes. So for the participant nodes, the values for distributed query ID and query ID are different.
- `is_sso_query` (text) – This lets us know whether the query is single shard optimized or not.

The rest of the columns are the same as in `pg_stat_activity`.

### **limitless\_stat\_all\_indexes**

This view contains usage statistics on indexes in the DB shard group. For example:

```
postgres_limitless=> SELECT schemaname, relname, indexrelname, idx_scan
FROM rds_aurora.limitless_stat_all_indexes
WHERE relname LIKE 'orders_ts%' ORDER BY indexrelname LIMIT 10;
```

schemaname	relname	indexrelname	idx_scan
ec_sample	orders_ts00001	orders_ts00001_pkey	196801
ec_sample	orders_ts00002	orders_ts00002_pkey	196703
ec_sample	orders_ts00003	orders_ts00003_pkey	196376
ec_sample	orders_ts00004	orders_ts00004_pkey	197966
ec_sample	orders_ts00005	orders_ts00005_pkey	195301
ec_sample	orders_ts00006	orders_ts00006_pkey	195673
ec_sample	orders_ts00007	orders_ts00007_pkey	194475
ec_sample	orders_ts00008	orders_ts00008_pkey	191694
ec_sample	orders_ts00009	orders_ts00009_pkey	193744
ec_sample	orders_ts00010	orders_ts00010_pkey	195421

(10 rows)

### **limitless\_stat\_all\_tables**

This view contains statistics about all tables in the current database in the DB shard group. This is useful when tracking vacuum operations and Data Manipulation language (DML) operations. For example:

```
postgres_limitless=> SELECT subcluster_id, subcluster_type, relname,
n_ins_since_vacuum, n_tup_ins, last_vacuum
FROM rds_aurora.limitless_stat_all_tables
WHERE relname LIKE 'orders_ts%' ORDER BY relname LIMIT 10;
```

subcluster_id	subcluster_type	relname	n_ins_since_vacuum	n_tup_ins	last_vacuum
5	shard	orders_ts00001	34779	196083	
5	shard	orders_ts00002	34632	194721	
5	shard	orders_ts00003	34950	195965	
5	shard	orders_ts00004	34745	197283	
5	shard	orders_ts00005	34879	195754	
5	shard	orders_ts00006	34340	194605	
5	shard	orders_ts00007	33779	192203	
5	shard	orders_ts00008	33826	191293	
5	shard	orders_ts00009	34660	194117	
5	shard	orders_ts00010	34569	195560	

(10 rows)

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.
- `relname` (name) – The name of the table.

The rest of the columns are the same as in `pg_stat_all_tables`.

## limitless\_stat\_database

This view contains statistics about all databases in the DB shard group. Returns one row per database per node. For example:

```
postgres_limitless=> SELECT
    subcluster_id,
    subcluster_type,
    datname,
    blks_read,
    blks_hit
FROM
    rds_aurora.limitless_stat_database
```

```

WHERE
  datname='postgres_limitless';
 subcluster_id | subcluster_type |      datname      | blks_read | blks_hit
-----+-----+-----+-----+-----
           1 | router         | postgres_limitless |         484 | 34371314
           2 | router         | postgres_limitless |          673 | 33859317
           3 | shard          | postgres_limitless |         1299 | 17749550
           4 | shard          | postgres_limitless |         1094 | 17492849
           5 | shard          | postgres_limitless |         1036 | 17485098
           6 | shard          | postgres_limitless |         1040 | 17437257
(6 rows)

```

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.
- `datname` (name) – The name of the database.

The rest of the columns are the same as in `pg_stat_database`.

### `limitless_stat_progress_vacuum`

This view contains information about ongoing vacuuming operations. For example:

```

postgres_limitless=> SELECT * FROM rds_aurora.limitless_stat_progress_vacuum;

-[ RECORD 1 ]-----+-----
subcluster_id      | 3
subcluster_type    | shard
distributed_session_id | A56D96E2A5C9F426
pid                | 5270
datname            | postgres
nspname            | public
relname            | customer_ts2
phase              | vacuuming heap
heap_blks_total    | 130500
heap_blks_scanned  | 100036
heap_blks_vacuumed | 0
index_vacuum_count | 0
max_dead_tuples    | 11184810
num_dead_tuples    | 0

```

```

-[ RECORD 2 ]-----+-----
subcluster_id      | 3
subcluster_type    | shard
distributed_session_id | 56DF26A89EC23AB5
pid                | 6854
datname            | postgres
nspname            | public
relname            | sales_ts1
phase              | vacuuming heap
heap_blks_total    | 43058
heap_blks_scanned  | 24868
heap_blks_vacuumed | 0
index_vacuum_count | 0
max_dead_tuples    | 8569523
num_dead_tuples    | 0

```

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router or shard.
- `distributed_session_id` (text) – The identifier for the session that initiated the vacuuming operation.
- `datname` (name) – The database where the vacuuming is being done.
- `nspname` (name) – The name of the schema of the table that is being vacuumed. It's null if the table being vacuumed is not in the same database as the one to which the user is connected.
- `relname` (name) – The name of the table that is being vacuumed. It's null if the table being vacuumed is not in the same database as the one to which the user is connected.

The rest of the columns are the same as in `pg_stat_progress_vacuum`.

### limitless\_stat\_statements

This view provides a means for tracking planning and running statistics of all SQL statements run on all nodes.

#### Note

You must install the [pg\\_stat\\_statements](#) extension to use the `limitless_stat_statements` view.

```
-- CREATE EXTENSION must be run by a superuser
CREATE EXTENSION pg_stat_statements;

-- Verify that the extension is created on all nodes in the DB shard group
SELECT distinct node_id
   FROM rds_aurora.limitless_stat_statements
   LIMIT 10;
```

The following example shows the use of the `limitless_stat_statements` view.

```
postgres_limitless=> SELECT
  subcluster_id,
  subcluster_type,
  distributedqueryid,
  username,
  dbname,
  sso_calls
FROM
  rds_aurora.limitless_stat_statements;
```

subcluster_id	subcluster_type	distributedqueryid	username
	dbname	sso_calls	
2	router	0	postgres
2	postgres_limitless	0	postgres
2	router	0	postgres
2	postgres_limitless	0	postgres
2	router	0	postgres
2	postgres_limitless	0	postgres
2	router	1	postgres
3	shard	-7975178695405682176	postgres
	postgres_limitless		

[...]

The output parameters are the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.
- `subcluster_type` (text) – The type of subcluster to which this process belongs: router for or shard.
- `distributedqueryid` (bigint) – The query ID of the parent query from the coordinator node. This column is NULL if it's the parent query. The coordinator node pushes down the distributed query ID to the participant nodes. So for the participant nodes, the values for distributed query ID and query ID are different.
- `username` (name) – The user that queried the statement.
- `dbname` (name) – The database where the query was run.
- `sso_calls` (name) – The number of times statement was single-shard optimized.

The rest of the columns are the same as in [pg\\_stat\\_statements](#).

### limitless\_stat\_statements\_info

This view contains statistics for the `limitless_stat_statements` view. Each row contains data for the [pg\\_stat\\_statements\\_info](#) view from each node. The `subcluster_id` column identifies each node.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_stat_statements_info;
```

subcluster_id	subcluster_type	dealloc	stats_reset
1	router	0	2023-06-30 21:22:09.524781+00
2	router	0	2023-06-30 21:21:40.834111+00
3	shard	0	2023-06-30 21:22:10.709942+00
4	shard	0	2023-06-30 21:22:10.740179+00
5	shard	0	2023-06-30 21:22:10.774282+00
6	shard	0	2023-06-30 21:22:10.808267+00

(6 rows)

The output parameter is the following:

- `subcluster_id` (text) – The ID of the subcluster to which this process belongs.

The rest of the columns are the same as in [pg\\_stat\\_statements\\_info](#).

## limitless\_stat\_subclusters

This view contains network statistics between routers and other nodes. It contains a row per pair of router and other node, for example:

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_stat_subclusters;
```

orig_subcluster	orig_instance_az	dest_subcluster	dest_instance_az	latency_us	latest_collection	failed_requests	received_bytes	sent_bytes	same_az_requests	cross_az_requests	stat_reset_timestamp
3	us-west-2b	2	us-west-2a	847	2024-10-07 17:25:39.518617+00	0	35668633	92090171	0	302787	2024-10-05 12:39:55.239675+00
3	us-west-2b	4	us-west-2b	419	2024-10-07 17:25:39.546376+00	0	101190464	248795719	883478	0	2024-10-05 12:39:55.231218+00
3	us-west-2b	5	us-west-2c	1396	2024-10-07 17:25:39.52122+00	0	72864849	172086292	0	557726	2024-10-05 12:39:55.196412+00
3	us-west-2b	6	us-west-2c	729	2024-10-07 17:25:39.54828+00	0	35668584	92090171	0	302787	2024-10-05 12:39:55.247334+00
3	us-west-2b	7	us-west-2a	1702	2024-10-07 17:25:39.545307+00	0	71699576	171634844	0	556278	2024-10-05 12:39:52.715168+00
2	us-west-2a	3	us-west-2b	868	2024-10-07 17:25:40.293927+00	0	35659611	92011872	0	302817	2024-10-05 12:39:54.420758+00
2	us-west-2a	4	us-west-2b	786	2024-10-07 17:25:40.296863+00	0	102437253	251838024	0	895060	2024-10-05 12:39:54.404081+00
2	us-west-2a	5	us-west-2c	1232	2024-10-07 17:25:40.292021+00	0	71990027	168828110	0	545453	2024-10-05 12:39:36.769549+00

The output parameters are the following:

- `orig_subcluster` (text) – The ID of the router where the communications originate
- `orig_subcluster_az` (text) – The Availability Zone (AZ) of the originator router
- `dest_subcluster` (text) – The ID of the destination node

- `dest_subcluster_az` (text) – The last collected AZ of the destination node
- `latency_us` (bigint) – The last collected network latency between nodes, in microseconds. The value is 0 if the node is unreachable.
- `latest_collection` (timestamp) – The timestamp of the latest collection of AZ and latency for the destination node
- `failed_requests` (bigint) – The cumulative count of failed internal requests
- `received_bytes` (bigint) – The estimated cumulative number of bytes received from this node
- `sent_bytes` (bigint) – The estimated cumulative number of bytes sent to this node
- `same_az_requests` (bigint) – The cumulative number of internal DB requests to this node when it's in the same AZ as the originator router
- `cross_az_requests` (bigint) – The cumulative number of internal DB requests to this node when it's in a different AZ from the originator router
- `stat_reset_timestamp` (timestamp) – The timestamp when the cumulative statistics for this view were last reset

### limitless\_statio\_all\_indexes

This view contains input/output (I/O) statistics for all indexes in the DB shard group. For example:

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_statio_all_indexes WHERE
relname like 'customers_ts%';
```

subcluster_id	subcluster_type	schemaname	relname	indexrelname	idx_blks_read	idx_blks_hit
3	shard	public	customers_ts00002	customers_ts00002_customer_name_idx	1	0
3	shard	public	customers_ts00001	customers_ts00001_customer_name_idx	1	0
4	shard	public	customers_ts00003	customers_ts00003_customer_name_idx	1	0
4	shard	public	customers_ts00004	customers_ts00004_customer_name_idx	1	0
5	shard	public	customers_ts00005	customers_ts00005_customer_name_idx	1	0

```

      5 | shard          | public      | customers_ts00006 |
customers_ts00006_customer_name_idx |          1 |          0
      6 | shard          | public      | customers_ts00007 |
customers_ts00007_customer_name_idx |          1 |          0
      6 | shard          | public      | customers_ts00008 |
customers_ts00008_customer_name_idx |          1 |          0
(8 rows)

```

## limitless\_statio\_all\_tables

This view contains input/output (I/O) statistics for all tables in the DB shard group. For example:

```

postgres_limitless=> SELECT
  subcluster_id,
  subcluster_type,
  schemaname,
  relname,
  heap_blks_read,
  heap_blks_hit
FROM
  rds_aurora.limitless_statio_all_tables
WHERE
  relname LIKE 'customers_ts%';

```

subcluster_id	subcluster_type	schemaname	relname	heap_blks_read	heap_blks_hit
3	shard	public	customers_ts00002	305	57780
3	shard	public	customers_ts00001	300	56972
4	shard	public	customers_ts00004	302	57291
4	shard	public	customers_ts00003	302	57178
5	shard	public	customers_ts00006	300	56932
5	shard	public	customers_ts00005	302	57386
6	shard	public	customers_ts00008	300	56881
6	shard	public	customers_ts00007	304	57635

(8 rows)

## limitless\_tables

This view contains information about tables in Aurora PostgreSQL Limitless Database.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_tables;
```

table_gid	local_oid	schema_name	table_name	table_status	table_type	distribution_key
5	18635	public	placeholder	active	placeholder	
6	18641	public	ref	active	reference	
7	18797	public	orders	active	sharded	HASH (order_id)
2	18579	public	customer	active	sharded	HASH (cust_id)

(4 rows)

## limitless\_table\_collocations

This view contains information about collocated sharded tables.

In the following example, the orders and customers tables are collocated, and the users and followers tables are collocated. Collocated tables have the same collocation\_id.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_table_collocations ORDER BY collocation_id;
```

collocation_id	schema_name	table_name
2	public	orders
2	public	customers
5	public	users
5	public	followers

(4 rows)

## limitless\_table\_collocation\_distributions

This view shows the key distribution for each collocation.

```
postgres_limitless=> SELECT * FROM
rds_aurora.limitless_table_collocation_distributions ORDER BY collocation_id,
lower_bound;
```

collocation_id	subcluster_id	lower_bound	upper_bound
2	6	-9223372036854775808	-4611686018427387904
2	5	-4611686018427387904	0
2	4	0	4611686018427387904
2	3	4611686018427387904	9223372036854775807
5	6	-9223372036854775808	-4611686018427387904
5	5	-4611686018427387904	0
5	4	0	4611686018427387904
5	3	4611686018427387904	9223372036854775807

(8 rows)

## Wait events for Aurora PostgreSQL Limitless Database

A wait event in Aurora PostgreSQL indicates a resource for which a session is waiting, such as input/output (I/O) and locks. Wait events are helpful in finding out why sessions are waiting for resources, and identifying bottlenecks. For more information, see [Aurora PostgreSQL wait events](#).

Aurora PostgreSQL Limitless Database has its own wait events that are related to routers and shards. Many of them are for routers waiting on shards to complete tasks. Shard wait events contain details on tasks that are being performed.

### Topics

- [Querying for wait events](#)
- [Limitless Database wait events](#)

### Querying for wait events

You can use the [limitless\\_stat\\_activity](#) view to query for wait events, as shown in the following example.

```
SELECT wait_event FROM rds_aurora.limitless_stat_activity WHERE
wait_event_type='AuroraLimitless';
```

```

      wait_event
-----
RemoteStatementSetup
RemoteStatementSetup
(2 rows)
```

You can also use the `aurora_stat_system_waits` function to list the number of waits and the total time spent on each wait event, as shown in the following example.

```
postgres_limitless=> SELECT type_name,event_name,waits,wait_time
FROM aurora_stat_system_waits()
NATURAL JOIN aurora_stat_wait_event()
NATURAL JOIN aurora_stat_wait_type()
WHERE type_name='AuroraLimitless'
ORDER BY wait_time DESC;
```

```

type_name | event_name | waits | wait_time
-----+-----+-----+-----
```

AuroraLimitless	RemoteStatementSetup	7518	75236507897
AuroraLimitless	RemoteStatementExecution	40	132986
AuroraLimitless	Connect	5	1453

(3 rows)

## Limitless Database wait events

The following wait events apply to Aurora PostgreSQL Limitless Database. You can monitor these wait events to identify bottlenecks in Aurora PostgreSQL Limitless Database processing.

### **IO:TwophaseFilePoolWrite wait event**

Waiting for a write of a two-phase state file within the two-phase state file pool. This is an Aurora specific event.

#### **Causes**

Processes executing a PREPARED TRANSACTION command, including participants in a Limitless Database distributed transaction, must persist transaction state in a two-phase file. Aurora uses a file pool to improve performance of this operation.

#### **Action**

This is a synchronous write I/O operation and therefore a high latency in this event has similar causes to IO:XactSync and can be investigated in the same way. If using Limitless Database, you might need to reduce the number of distributed transactions being executed.

### **IO:TwophaseFilePoolRead wait event**

Waiting for a read of a two-phase state file within the two-phase state file pool.

#### **Causes**

Processes executing a COMMIT PREPARED command against a previously prepared transaction, including participants in a Limitless Database distributed transaction, might need to read previously

persisted transaction state from a two-phase file. Aurora uses a file pool to improve performance of this operation.

### Action

This is a read I/O operation. Therefore, a high latency in this event has similar causes to `IO:DataFileRead` and can be investigated the same. If using Limitless Database, you might need to reduce the number of distributed transactions being executed.

### **AuroraLimitless:Connect wait event**

The process is waiting for a connection to another node in the cluster to be established.

### Causes

Connections are established between processes and remote nodes to execute queries, distributed transactions, and perform DDLs.

### Action

Reduce the number of simultaneous connections to the cluster or tune the use of cross-shard queries.

### **AuroraLimitless:AsyncConnect wait event**

This event is similar to `Connect`, but represents a process waiting for parallel connections to a set of nodes to be established.

### Causes

Parallel connection establishment is most commonly done when executing DDL statements.

### Action

Reduce the number of DDL statements or combine multiple DDLs in the same session to improve connection reuse.

### **AuroraLimitless:RemoteStatementSetup wait event**

The process is waiting for remote query execution setup, such as cursor open, close, or prepared statement creation.

## Causes

This wait event increases with the number of scans on sharded tables where the statement could not be single-shard optimized.

## Action

Optimize queries to reduce the number of scan operations or increase eligibility for single-shard optimization.

### **AuroraLimitless:RemoteDDLExecution wait event**

The process is waiting for a remote DDL command to finish.

## Causes

When you issue a DDL command on a DB shard group, it must be distributed to other router and shard nodes before confirming the operation. Some DDL operations can run for a long time, because data must be adapted to schema changes.

## Action

Identify long-running DDL commands so that you can optimize them.

### **AuroraLimitless:RemoteStatementExecution wait event**

A process is waiting for a remote command to finish.

## Causes

A SQL command is running on a remote node. This event will appear frequently for internal communications, such as `auto_analyze` and heartbeat checks.

## Action

Identify long-running commands using the `limitless_stat_statements` view. In many cases this is an expected event, especially for background workers or internal processes and no action is needed.

### **AuroraLimitless:FetchRemoteResults wait event**

A process is waiting to retrieve rows from a remote node.

## Causes

This wait event can increase when fetching a large number of rows from a remote table, such as a sharded or reference table.

## Action

Identify unoptimized SELECT queries using the `limitless_stat_statements` view. Optimize queries to retrieve only necessary data. You can also tune the `rds_aurora.limitless_maximum_adaptive_fetch_size` parameter.

### **AuroraLimitless:AsyncGetInitialResponse wait event**

The process is waiting for an initial response when pipeline mode is used in query execution.

## Causes

This will typically be seen during router to shard execution for queries with single-shard data placement and is an expected part of normal execution.

## Action

No further action is required.

### **AuroraLimitless:AsyncGetNextResponse wait event**

The process is waiting for an additional responses when pipeline mode is used in query execution.

## Causes

This will typically be seen during router to shard execution for queries with single-shard data placement and is an expected part of normal execution.

## Action

No further action is required.

### **AuroraLimitless:AbortedCommandCleanup wait event**

The process is waiting for the result of a remote cleanup query. Cleanup queries are issued to shard nodes to return them to an appropriate state when a distributed transaction is ended.

## Causes

Transaction cleanup is done when a transaction is aborted either because an error was found or because an user issued an explicit ABORT command or canceled the running query.

## Action

Investigate the cause for the transaction being canceled.

### **AuroraLimitless:DistributedCommitPrepare wait event**

The process is committing a distributed transaction and is waiting for all the participants to acknowledge the prepare command.

## Causes

Transactions that modify multiple nodes must perform a distributed commit. A long wait in `DistributedCommitPrepare` could be caused by long waits in the `IO:TwophaseFilePoolWrite` event on participating nodes.

## Action

Reduce the number of transactions that modify data on multiple nodes. Investigate `IO:TwophaseFilePoolWrite` events in other nodes of the cluster.

### **AuroraLimitless:DistributedCommit wait event**

The process is committing a distributed transaction and is waiting for the lead participant to acknowledge the commit command.

## Causes

Transactions that modify multiple nodes must perform a distributed commit. A long wait in `DistributedCommit` could be caused by long waits in the `IO:XactSync` event on the lead participant.

## Action

Reduce the number of transactions that modify data on multiple nodes. Investigate `IO:XactSync` events in other nodes of the cluster.

## **AuroraLimitless:DistributedCommitPrepareThrottle wait event**

The process is attempting to prepare a distributed transaction and is being throttled to due to existing prepared transactions.

### **Causes**

Transactions that modify multiple nodes must perform a distributed commit. Participants in these transactions must perform a prepare operation as part of the commit protocol. Aurora limits the number of concurrent prepares, and if this limit is exceeded the process will wait in the `DistributedCommitPrepareThrottle` event.

### **Action**

Reduce the number of transactions that modify data on multiple nodes. Investigate `IO:TwophaseFilePoolWrite` events as increased time in those events could cause existing prepared transactions to build up, resulting in throttling for new prepare attempts.

## **AuroraLimitless:PreparedTransactionResolution wait event**

The process has encountered a tuple modified by a distributed transaction that is in the prepared state. The process must determine if the distributed transaction will become visible in its snapshot.

### **Causes**

Transactions that modify multiple nodes must perform a distributed commit which includes a prepare phase. A high number of distributed transactions or increased latency on distributed commits can cause other processes to encounter the `PreparedTransactionResolution` wait event.

### **Action**

Reduce the number of transactions that modify data on multiple nodes. Investigate distributed commit related events as increased time in those events could increase latency in the commit path of distributed transactions. You might also wish to investigate network and CPU loads.

## **AuroraLimitless:SendPreparedTransactionOutcome wait event**

The process is executing on a node that is coordinating a distributed transaction and another process has inquired as to the state of that transaction, or the process has committed a distributed transaction and is sending the outcome to participants.

## Causes

Processes that encounter the `PreparedTransactionResolution` wait event will query the transaction coordinator. The response on the transaction coordinator will encounter `SendPreparedTransactionOutcome`.

## Action

Reduce the number of transactions that modify data on multiple nodes. Investigate distributed commit related events and `IO:TwophaseFilePoolWrite` and `IO:TwophaseFilePoolRead` events as those events could increase latency in the commit path of distributed transactions. You might also wish to investigate network and CPU loads.

### **AuroraLimitless:CommitClockBarrier wait event**

The process is committing a transaction and must wait to ensure that the assigned commit time is guaranteed to be in the past for all nodes in the cluster.

## Causes

CPU or network saturation could cause increased clock drift, resulting in time spent in this wait event.

## Action

Investigate CPU or network saturation in your cluster.

### **AuroraLimitless:SnapshotClockBarrier wait event**

The process has received a snapshot time from another node with a clock in the future and is waiting for its own clock to reach that time.

## Causes

This typically occurs after the process has received results from a function that was pushed down to a shard and there is clock drift between the nodes. CPU or network saturation could cause increased clock drift, resulting in time spent in this wait event.

## Action

Investigate CPU or network saturation in your cluster.

## **AuroraLimitless:ReaderSnapshotClockBarrier wait event**

This event occurs on read nodes. The process is waiting for the read node to replay the write stream so that all writes that happened before the process snapshot time have been applied.

### **Causes**

An increase in Aurora replica lag can cause increased wait time in this event.

### **Action**

Investigate Aurora replica lag.

## **AuroraLimitless:GatherDistributedDeadlockGraph wait event**

The process is communicating with other nodes to collect lock graphs as part of distributed deadlock detection.

### **Causes**

When a process is waiting on a lock it will perform a distributed deadlock check after waiting longer than `rds_aurora.limitless_distributed_deadlock_timeout`.

### **Action**

Investigate causes of lock contention in your application and consider tuning `rds_aurora.limitless_distributed_deadlock_timeout`.

## **AuroraLimitless:DistributedDeadlockDetection wait event**

The process is communicating with other nodes to detect a distributed deadlock.

### **Causes**

When a process is waiting on a lock it will perform a distributed deadlock check after waiting longer than `rds_aurora.limitless_distributed_deadlock_timeout`.

### **Action**

Investigate causes of lock contention in your application and consider tuning `rds_aurora.limitless_distributed_deadlock_timeout`.

**AuroraLimitless:DistributedDeadlockAbort wait event**

The process is communicating with another node to abort a session chosen as the victim in a distributed deadlock.

**Causes**

Application patterns are resulting in distributed deadlocks.

**Action**

Investigate application patterns resulting in distributed deadlocks.

**AuroraLimitless:GatherRemoteStats wait event**

The process is gathering statistics from other nodes in the cluster.

**Causes**

Monitoring or activity queries and views, such as `limitless_stat_activity`, will retrieve statistics from other nodes.

**Action**

No further action is required.

**AuroraLimitless:GlobalSequenceRefresh wait event**

The process is generating a new sequence value and must request a new chunk from the global sequence.

**Causes**

A high rate of sequence value generation can result in stalls in this event if `rds_aurora.limitless_sequence_chunk_size` is insufficient.

**Action**

This is a normal occurrence. If you see excessive time in this event consider tuning `rds_aurora.limitless_sequence_chunk_size`. See documentation on sequences in Limitless Database.

**AuroraLimitless:GlobalVacuumTimeExchange wait event**

The process is exchanging snapshot data to support vacuum.

## Causes

Nodes in Limitless Database exchange oldest active snapshot time data with other nodes to compute the correct cutoff time for vacuum execution.

## Action

No further action is required.

### **AuroraLimitless:DistributedTransactionMonitorGather wait event**

The process is gathering transaction metadata from other nodes to support distributed transaction cleanup.

## Causes

Nodes in Limitless Database exchange transaction metadata with other nodes to determine when distributed transaction state can be purged.

## Action

No further action is required.

### **AuroraLimitlessActivity:AdminTaskSchedulerMain wait event**

Waiting in main loop of task scheduler process.

### **AuroraLimitlessActivity:AdminTaskExecutorMain wait event**

Waiting in main loop of task executor process.

### **AuroraLimitlessActivity:AdminTaskMonitorMain wait event**

Waiting in main loop of task monitor process.

### **AuroraLimitlessActivity:DatabaseCleanupMonitorMain wait event**

Waiting in main loop of database cleanup monitor process.

### **AuroraLimitlessActivity:TopologyCleanupMonitorMain wait event**

Waiting in main loop of topology cleanup monitor process.

**AuroraLimitlessActivity:TopologyChangeMonitorMain wait event**

Waiting in main loop of topology change monitor process.

**AuroraLimitlessActivity:DistributedTransactionMonitorMain wait event**

Waiting in main loop of distributed transaction monitor process.

**AuroraLimitlessActivity:GlobalVacuumMonitorMain wait event**

Waiting in main loop of global vacuum monitor process.

# Backing up and restoring Aurora PostgreSQL Limitless Database

You can back up and restore a DB cluster that uses Aurora PostgreSQL Limitless Database.

## Contents

- [Backing up a DB cluster that uses Aurora PostgreSQL Limitless Database](#)
  - [Creating a DB cluster snapshot](#)
- [Restoring a DB cluster that uses Aurora PostgreSQL Limitless Database](#)
  - [Restoring a DB cluster from a DB snapshot](#)
  - [Restoring a DB cluster using point-in-time recovery](#)
- [PostgreSQL backup and restore utilities not supported](#)

## Backing up a DB cluster that uses Aurora PostgreSQL Limitless Database

Backing up a DB cluster with Aurora PostgreSQL Limitless Database has similarities and differences in functionality compared to backing up a standard Aurora DB cluster.

- When you take a manual DB cluster snapshot of an Aurora DB cluster that uses Limitless Database, the snapshot includes data from the DB shard group.
- Continuous backups include data from the DB shard group.
- Automated daily snapshots include data from the DB shard group.
- Copying DB cluster snapshots is supported. For more information, see [DB cluster snapshot copying](#).
- Sharing DB cluster snapshots is supported. For more information, see [Sharing a DB cluster snapshot](#).
- You can't use the `pg_dump` or `pg_dumpall` utility to back up databases in the DB shard group.
- Taking final snapshots when deleting DB clusters is supported for Aurora PostgreSQL Limitless Database.
- Retaining automated backups when deleting DB clusters isn't supported for Aurora PostgreSQL Limitless Database.

## Creating a DB cluster snapshot

You create an Aurora PostgreSQL Limitless Database DB cluster snapshot in the same way as for a standard Aurora DB cluster, as shown in the following Amazon CLI example:

```
aws rds create-db-cluster-snapshot \  
  --db-cluster-identifier my-db-cluster \  
  --db-cluster-snapshot-identifier my-db-cluster-snapshot
```

For more information on backing up DB clusters, see [Overview of backing up and restoring an Aurora DB cluster](#).

## Restoring a DB cluster that uses Aurora PostgreSQL Limitless Database

Restoring a DB cluster with Aurora PostgreSQL Limitless Database has similarities and differences in functionality compared to restoring a standard Aurora DB cluster.

- You can restore a Limitless Database DB cluster only from a source DB cluster that uses a DB engine version compatible with Limitless Database, such as `16.4-limitless`.
- When you restore a DB cluster from a manual snapshot of a DB cluster that uses Limitless Database, the entire DB cluster storage is restored. This includes the storage of the DB shard group.

You must create a DB shard group to access the storage for your Limitless Database.

- You can restore a DB cluster using point-in-time recovery (PITR) to any point within the retention period. The restored DB cluster includes the storage of the DB shard group.

You must create a DB shard group to access the storage for your Limitless Database.

- PITR isn't supported for deleted Aurora PostgreSQL Limitless Database DB clusters.
- When you restore a DB cluster from an automated daily snapshot, the storage for the DB shard group is also restored.
- When you restore an Aurora PostgreSQL Limitless Database DB cluster, you must enable Enhanced Monitoring and Performance Insights. Make sure to include the Performance Insights KMS key ID.

After you restore an Aurora PostgreSQL Limitless Database DB cluster, make sure to verify its functionality by running your queries on it.

## Restoring a DB cluster from a DB snapshot

The following Amazon CLI examples show how to restore an Aurora PostgreSQL Limitless Database DB cluster from a DB cluster snapshot.

You must use the 16.4-limitless DB engine version.

### To restore a Limitless Database DB cluster from a DB cluster snapshot

#### 1. Restore the DB cluster:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier my-new-db-cluster \  
  --snapshot-identifier my-db-cluster-snapshot \  
  --engine aurora-postgresql \  
  --engine-version 16.4-limitless \  
  --enable-performance-insights \  
  --performance-insights-retention-period 31 \  
  --performance-insights-kms-key-id arn:aws-cn:kms:us-  
east-1:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab \  
  --monitoring-interval 5 \  
  --monitoring-role-arn arn:aws-cn:iam::123456789012:role/EMrole
```

#### 2. Create the DB shard group:

```
aws rds create-db-shard-group \  
  --db-cluster-identifier my-new-db-cluster \  
  --db-shard-group-identifier my-new-DB-shard-group \  
  --max-acu 1000
```

For more information, see [Adding a DB shard group to an existing Aurora PostgreSQL Limitless Database DB cluster](#).

For more information on restoring Aurora DB clusters from DB cluster snapshots, see [Restoring from a DB cluster snapshot](#).

## Restoring a DB cluster using point-in-time recovery

The following Amazon CLI examples show how to restore an Aurora PostgreSQL Limitless Database DB cluster using point-in-time recovery (PITR).

### To restore a Limitless Database DB cluster using PITR

#### 1. Restore the DB cluster:

```
aws rds restore-db-cluster-to-point-in-time \  
  --source-db-cluster-identifier my-db-cluster \  
  --db-cluster-identifier my-new-db-cluster \  
  --use-latest-restorable-time \  
  --enable-performance-insights \  
  --performance-insights-retention-period 31 \  
  --performance-insights-kms-key-id arn:aws-cn:kms:us-  
east-1:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab \  
  --monitoring-interval 5 \  
  --monitoring-role-arn arn:aws-cn:iam::123456789012:role/EMrole
```

#### 2. Create the DB shard group:

```
aws rds create-db-shard-group \  
  --db-cluster-identifier my-new-db-cluster \  
  --db-shard-group-identifier my-new-DB-shard-group \  
  --max-acu 1000
```

For more information, see [Adding a DB shard group to an existing Aurora PostgreSQL Limitless Database DB cluster](#).

For more information on PITR, see [Restoring a DB cluster to a specified time](#).

## PostgreSQL backup and restore utilities not supported

The following PostgreSQL utilities aren't supported for either the primary DB cluster or the DB shard group:

- `pg_dump`
- `pg_dumpall`
- `pg_restore`

While you might be able to use them by open source binaries or alternative methods, doing so could yield inconsistent results.

# Upgrading Amazon Aurora PostgreSQL Limitless Database

The following apply to upgrading Aurora PostgreSQL Limitless Database:

- Minor version upgrades are supported.
- Patching Aurora PostgreSQL Limitless Database is supported. Patches appear as pending maintenance to be applied during your maintenance window.

## Upgrading DB clusters that use Amazon Aurora PostgreSQL Limitless Database

You upgrade a DB cluster by modifying it and choosing a new DB engine version. You can use the Amazon Web Services Management Console or the Amazon CLI.

### Console

#### To upgrade your Limitless Database DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Navigate to the **Databases** page.
3. Select the Limitless Database DB cluster that you want to upgrade.
4. Choose **Modify**.

The **Modify DB cluster** page displays.

5. For **DB engine version**, choose the new DB engine version, for example **Aurora PostgreSQL with Limitless Database (Compatible with PostgreSQL 16.6)**.
6. Choose **Continue**.
7. On the summary page, select whether to apply the changes immediately or during the next scheduled maintenance window, then choose **Modify cluster**.

## CLI

Use the [modify-db-cluster](#) Amazon CLI command, as shown in the following example.

```
aws rds modify-db-cluster \  
  --db-cluster-identifier my-sv2-cluster \  
  --engine-version 16.6-limitless \  
  --apply-immediately
```

# Aurora PostgreSQL Limitless Database reference

We provide the following reference topics for Aurora PostgreSQL Limitless Database.

## Topics

- [Supported and unsupported Data Definition Language \(DDL\) SQL commands](#)
- [DDL limitations and other information for Aurora PostgreSQL Limitless Database](#)
- [Supported and unsupported Data Manipulation Language \(DML\) and query processing SQL commands](#)
- [DML limitations and other information for Aurora PostgreSQL Limitless Database](#)
- [Variables in Aurora PostgreSQL Limitless Database](#)
- [DB cluster parameters in Aurora PostgreSQL Limitless Database](#)

## Supported and unsupported Data Definition Language (DDL) SQL commands

The following table lists the DDL commands that are supported and not supported by Aurora PostgreSQL Limitless Database, with references to limitations or more information.

Command	Supported?	Limitations or more information
ALTER AGGREGATE	No	Not applicable
ALTER COLLATION	Yes	None
ALTER CONVERSION	Yes	None
ALTER DATABASE	No	Not applicable
ALTER DEFAULT PRIVILEGES	No	Not applicable
ALTER DOMAIN	No	Not applicable
ALTER EVENT TRIGGER	No	Not applicable
ALTER EXTENSION	Yes	<a href="#">Extensions</a>

Command	Supported?	Limitations or more information
ALTER FOREIGN DATA WRAPPER	No	Not applicable
ALTER FOREIGN TABLE	No	Not applicable
ALTER FUNCTION	Yes	<a href="#">Functions</a>
ALTER GROUP	Yes	None
ALTER INDEX	Yes	None
ALTER LANGUAGE	No	Not applicable
ALTER LARGE OBJECT	No	Not applicable
ALTER MATERIALIZED VIEW	No	Not applicable
ALTER OPERATOR	Yes	None
ALTER OPERATOR CLASS	Yes	None
ALTER OPERATOR FAMILY	Yes	None
ALTER POLICY	No	Not applicable

# DDL limitations and other information for Aurora PostgreSQL Limitless Database

The following topics describe limitations or provide more information for DDL SQL commands in Aurora PostgreSQL Limitless Database.

## Topics

- [ALTER TABLE](#)
- [CREATE DATABASE](#)
- [CREATE INDEX](#)
- [CREATE SCHEMA](#)
- [CREATE TABLE](#)
- [CREATE TABLE AS](#)
- [DROP DATABASE](#)
- [SELECT INTO](#)
- [Constraints](#)
- [Default values](#)
- [Extensions](#)
- [Foreign keys](#)
- [Functions](#)
- [Sequences](#)

## ALTER TABLE

The ALTER TABLE command is generally supported in Aurora PostgreSQL Limitless Database. For more information, see [ALTER TABLE](#) in the PostgreSQL documentation.

### Limitations

ALTER TABLE has the following limitations for supported options.

#### Removing a column

- On sharded tables, you can't remove columns that are part of the shard key.
- On reference tables, you can't remove primary key columns.

#### Changing a column's data type

- The USING expression isn't supported.
- On sharded tables, you can't change the type for columns that are part of the shard key.

#### Adding or removing a constraint

For details on what isn't supported, see [Constraints](#).

#### Changing a column's default value

Default values are supported. For more information, see [Default values](#).

### Unsupported options

Some options aren't supported because they depend on unsupported features, such as triggers.

The following table-level options for ALTER TABLE aren't supported:

- ALL IN TABLESPACE
- ATTACH PARTITION
- DETACH PARTITION
- ONLY flag
- RENAME CONSTRAINT

The following column-level options for ALTER TABLE aren't supported:

- ADD GENERATED

- DROP EXPRESSION [ IF EXISTS ]
- DROP IDENTITY [ IF EXISTS ]
- RESET
- RESTART
- SET
- SET COMPRESSION
- SET STATISTICS

## CREATE DATABASE

In Aurora PostgreSQL Limitless Database, only limitless databases are supported.

While CREATE DATABASE is running, databases that were successfully created in one or more nodes might fail in other nodes, because database creation is a nontransactional operation. In this case, the database objects that were successfully created are automatically removed from all of the nodes within a predetermined amount of time to keep consistency in the DB shard group. During this time, re-creation of a database with the same name might result in an error indicating that the database already exists.

The following options are supported:

- Collation:

```
CREATE DATABASE name WITH
  [LOCALE = locale]
  [LC_COLLATE = lc_collate]
  [LC_CTYPE = lc_ctype]
  [ICU_LOCALE = icu_locale]
  [ICU_RULES = icu_rules]
  [LOCALE_PROVIDER = locale_provider]
  [COLLATION_VERSION = collation_version];
```

- CREATE DATABASE WITH OWNER:

```
CREATE DATABASE name WITH OWNER = user_name;
```

The following options aren't supported:

- CREATE DATABASE WITH TABLESPACE:

```
CREATE DATABASE name WITH TABLESPACE = tablespace_name;
```

- CREATE DATABASE WITH TEMPLATE:

```
CREATE DATABASE name WITH TEMPLATE = template;
```

## CREATE INDEX

CREATE INDEX CONCURRENTLY is supported for sharded tables:

```
CREATE INDEX CONCURRENTLY index_name ON table_name(column_name);
```

CREATE UNIQUE INDEX is supported for all table types:

```
CREATE UNIQUE INDEX index_name ON table_name(column_name);
```

CREATE UNIQUE INDEX CONCURRENTLY isn't supported:

```
CREATE UNIQUE INDEX CONCURRENTLY index_name ON table_name(column_name);
```

For more information, see [UNIQUE](#). For general information on creating indexes, see [CREATE INDEX](#) in the PostgreSQL documentation.

### Showing indexes

Not all indexes are visible on routers when you use \d *table\_name* or similar commands. Instead, use the `pg_catalog.pg_indexes` view to get indexes, as shown in the following example.

```
SET rds_aurora.limitless_create_table_mode='sharded';
SET rds_aurora.limitless_create_table_shard_key='{"id"}';
CREATE TABLE items (id int PRIMARY KEY, val int);
CREATE INDEX items_my_index on items (id, val);

postgres_limitless=> SELECT * FROM pg_catalog.pg_indexes WHERE tablename='items';
```

```

schemaname | tablename | indexname | tablespace |
indexdef
-----+-----+-----+-----
+-----+-----+-----+-----
public | items | items_my_index | | CREATE INDEX items_my_index
ON ONLY public.items USING btree (id, val)
public | items | items_pkey | | CREATE UNIQUE INDEX
items_pkey ON ONLY public.items USING btree (id)
(2 rows)

```

## CREATE SCHEMA

CREATE SCHEMA with a schema element isn't supported:

```
CREATE SCHEMA my_schema CREATE TABLE (column_name INT);
```

This generates an error similar to the following:

```
ERROR: CREATE SCHEMA with schema elements is not supported
```

## CREATE TABLE

Relations in CREATE TABLE statements aren't supported, for example:

```
CREATE TABLE orders (orderid int, customerId int, orderDate date) WITH
(autovacuum_enabled = false);
```

IDENTITY columns aren't supported, for example:

```
CREATE TABLE orders (orderid INT GENERATED ALWAYS AS IDENTITY);
```

Aurora PostgreSQL Limitless Database supports up to 54 characters for sharded table names.

## CREATE TABLE AS

To create a table using CREATE TABLE AS, you must use the `rds_aurora.limitless_create_table_mode` variable. For sharded tables, you must also use the `rds_aurora.limitless_create_table_shard_key` variable. For more information, see [Creating limitless tables by using variables](#).

```
-- Set the variables.
SET rds_aurora.limitless_create_table_mode='sharded';
SET rds_aurora.limitless_create_table_shard_key='{ "a" }';

CREATE TABLE ctas_table AS SELECT 1 a;

-- "source" is the source table whose columns and data types are used to create the new
"ctas_table2" table.
CREATE TABLE ctas_table2 AS SELECT a,b FROM source;
```

You can't use `CREATE TABLE AS` to create reference tables, because they require primary key constraints. `CREATE TABLE AS` doesn't propagate primary keys to new tables.

For general information, see [CREATE TABLE AS](#) in the PostgreSQL documentation.

## DROP DATABASE

You can drop databases that you've created.

The `DROP DATABASE` command runs asynchronously in the background. While it's running, you will receive an error if you try to create a new database with the same name.

## SELECT INTO

`SELECT INTO` is functionally similar to [CREATE TABLE AS](#). You must use the `rds_aurora.limitless_create_table_mode` variable. For sharded tables, you must also use the `rds_aurora.limitless_create_table_shard_key` variable. For more information, see [Creating limitless tables by using variables](#).

```
-- Set the variables.
SET rds_aurora.limitless_create_table_mode='sharded';
SET rds_aurora.limitless_create_table_shard_key='{ "a" }';

-- "source" is the source table whose columns and data types are used to create the new
"destination" table.
SELECT * INTO destination FROM source;
```

Currently, the `SELECT INTO` operation is performed through the router, not directly through the shards. Therefore, performance can be slow.

For general information, see [SELECT INTO](#) in the PostgreSQL documentation.

## Constraints

The following limitations apply to constraints in Aurora PostgreSQL Limitless Database.

### CHECK

Simple constraints that involve comparison operators with literals are supported. More complex expressions and constraints that require function validations aren't supported, as shown in the following examples.

```
CREATE TABLE my_table (  
    id INT CHECK (id > 0) -- supported  
    , val INT CHECK (val > 0 AND val < 1000) -- supported  
    , tag TEXT CHECK (length(tag) > 0) -- not supported:  
    throws "Expression inside CHECK constraint is not supported"  
    , op_date TIMESTAMP WITH TIME ZONE CHECK (op_date <= now()) -- not supported:  
    throws "Expression inside CHECK constraint is not supported"  
);
```

You can give constraints explicit names, as shown in the following example.

```
CREATE TABLE my_table (  
    id INT CONSTRAINT positive_id CHECK (id > 0)  
    , val INT CONSTRAINT val_in_range CHECK (val > 0 AND val < 1000)  
);
```

You can use table-level constraint syntax with the CHECK constraint, as shown in the following example.

```
CREATE TABLE my_table (  
    id INT CONSTRAINT positive_id CHECK (id > 0)  
    , min_val INT CONSTRAINT min_val_in_range CHECK (min_val > 0 AND min_val < 1000)  
    , max_val INT  
    , CONSTRAINT max_val_in_range CHECK (max_val > 0 AND max_val < 1000 AND max_val >  
    min_val)  
);
```

### EXCLUDE

Exclusion constraints aren't supported in Aurora PostgreSQL Limitless Database.

## FOREIGN KEY

For more information, see [Foreign keys](#).

## NOT NULL

NOT NULL constraints are supported with no restrictions.

## PRIMARY KEY

Primary key implies unique constraints and therefore the same restrictions on unique constraints apply on primary key. This means:

- If a table is converted into a sharded table, the shard key must be a subset of the primary key. That is, the primary key contains all columns of the shard key.
- If a table is converted into a reference table, it must have a primary key.

The following examples illustrate the use of primary keys.

```
-- Create a standard table.
CREATE TABLE public.my_table (
    item_id INT
  , location_code INT
  , val INT
  , comment text
);

-- Change the table to a sharded table using the 'item_id' and 'location_code'
columns as shard keys.
CALL rds_aurora.limitless_alter_table_type_sharded('public.my_table',
ARRAY['item_id', 'location_code']);
```

Trying to add a primary key that doesn't contain a shard key:

```
-- Add column 'item_id' as the primary key.
-- Invalid because the primary key doesnt include all columns from the shard key:
-- 'location_code' is part of the shard key but not part of the primary key
ALTER TABLE public.my_table ADD PRIMARY KEY (item_id); -- ERROR

-- add column "val" as primary key
-- Invalid because primary key does not include all columns from shard key:
-- item_id and location_code iare part of shard key but not part of the primary key
ALTER TABLE public.my_table ADD PRIMARY KEY (item_id); -- ERROR
```

## Trying to add a primary key that does contain a shard key:

```
-- Add the 'item_id' and 'location_code' columns as the primary key.
-- Valid because the primary key contains the shard key.
ALTER TABLE public.my_table ADD PRIMARY KEY (item_id, location_code); -- OK

-- Add the 'item_id', 'location_code', and 'val' columns as the primary key.
-- Valid because the primary key contains the shard key.
ALTER TABLE public.my_table ADD PRIMARY KEY (item_id, location_code, val); -- OK
```

## Change a standard table to a reference table.

```
-- Create a standard table.
CREATE TABLE zipcodes (zipcode INT PRIMARY KEY, details VARCHAR);

-- Convert the table to a reference table.
CALL rds_aurora.limitless_alter_table_type_reference('public.zipcode');
```

For more information on creating sharded and reference tables, see [Creating Aurora PostgreSQL Limitless Database tables](#).

## UNIQUE

In sharded tables, the unique key must contain the shard key, that is, the shard key must be a subset of the unique key. This is checked when changing the table type to sharded. In reference tables there's no restriction.

```
CREATE TABLE customer (
    customer_id INT NOT NULL
    , zipcode INT
    , email TEXT UNIQUE
);
```

Table-level UNIQUE constraints are supported, as shown in the following example.

```
CREATE TABLE customer (
    customer_id INT NOT NULL
    , zipcode INT
    , email TEXT
    , CONSTRAINT zipcode_and_email UNIQUE (zipcode, email)
);
```

The following example shows the use of a primary key and a unique key together. Both keys must include the shard key.

```
SET rds_aurora.limitless_create_table_mode='sharded';
SET rds_aurora.limitless_create_table_shard_key='{"p_id"}';
CREATE TABLE t1 (
  p_id BIGINT NOT NULL,
  c_id BIGINT NOT NULL,
  PRIMARY KEY (p_id),
  UNIQUE (p_id, c_id)
);
```

For more information, see [Constraints](#) in the PostgreSQL documentation.

## Default values

Aurora PostgreSQL Limitless Database supports expressions in default values.

The following example shows the use of default values.

```
CREATE TABLE t (
  a INT DEFAULT 5,
  b TEXT DEFAULT 'NAN',
  c NUMERIC
);

CALL rds_aurora.limitless_alter_table_type_sharded('t', ARRAY['a']);
INSERT INTO t DEFAULT VALUES;
SELECT * FROM t;
```

a	b	c
5	NAN	

(1 row)

Expressions are supported, as shown in the following example.

```
CREATE TABLE t1 (a NUMERIC DEFAULT random());
```

The following example adds a new column that is NOT NULL and has a default value.

```
ALTER TABLE t ADD COLUMN d BOOLEAN NOT NULL DEFAULT FALSE;
SELECT * FROM t;
```

```
 a | b | c | d
---+-----+---+---
 5 | NAN |   | f
(1 row)
```

The following example alters an existing column with a default value.

```
ALTER TABLE t ALTER COLUMN c SET DEFAULT 0.0;
INSERT INTO t DEFAULT VALUES;
SELECT * FROM t;
```

```
 a | b | c | d
---+-----+---+---
 5 | NAN |   | f
 5 | NAN | 0.0 | f
(2 rows)
```

The following example drops a default value.

```
ALTER TABLE t ALTER COLUMN a DROP DEFAULT;
INSERT INTO t DEFAULT VALUES;
SELECT * FROM t;
```

```
 a | b | c | d
---+-----+---+---
 5 | NAN |   | f
 5 | NAN | 0.0 | f
   | NAN | 0.0 | f
(3 rows)
```

For more information, see [Default values](#) in the PostgreSQL documentation.

## Extensions

The following PostgreSQL extensions are supported in Aurora PostgreSQL Limitless Database:

- `aurora_limitless_fdw` – This extension is preinstalled. You can't drop it.
- `aws_s3` – This extension works in Aurora PostgreSQL Limitless Database similar to the way it does in Aurora PostgreSQL.

You can import data from an Amazon S3 bucket to an Aurora PostgreSQL Limitless Database DB cluster, or export data from an Aurora PostgreSQL Limitless Database DB cluster to an Amazon S3 bucket. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster](#) and [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).

- `btree_gin`
- `citext`
- `ip4r`
- `pg_buffercache` – This extension behaves differently in Aurora PostgreSQL Limitless Database from community PostgreSQL. For more information, see [pg\\_buffercache differences in Aurora PostgreSQL Limitless Database](#).
- `pg_stat_statements`
- `pg_trgm`
- `pgcrypto`
- `pgstattuple` – This extension behaves differently in Aurora PostgreSQL Limitless Database from community PostgreSQL. For more information, see [pgstattuple differences in Aurora PostgreSQL Limitless Database](#).
- `pgvector`
- `plpgsql` – This extension is preinstalled, but you can drop it.
- PostGIS – Long transactions and table management functions aren't supported. Modifying the spatial reference table isn't supported.
- `unaccent`
- `uuid`

Most PostgreSQL extensions currently aren't supported in Aurora PostgreSQL Limitless Database. However, you can still use the [shared\\_preload\\_libraries](#) (SPL) configuration setting to load

extensions into the Aurora PostgreSQL primary DB cluster. They are also loaded into Aurora PostgreSQL Limitless Database, but might not function correctly.

For example, you can load the `pg_hint_plan` extension, but loading it doesn't guarantee that the hints passed in query comments are used.

 **Note**

You can't modify objects associated with the [pg\\_stat\\_statements](#) extension. For information on installing `pg_stat_statements`, see [limitless\\_stat\\_statements](#).

You can use the `pg_available_extensions` and `pg_available_extension_versions` functions to find the extensions that are supported in Aurora PostgreSQL Limitless Database.

The following DDLs are supported for extensions:

## CREATE EXTENSION

You can create extensions, as in PostgreSQL.

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name
  [ WITH ] [ SCHEMA schema_name ]
  [ VERSION version ]
  [ CASCADE ]
```

For more information, see [CREATE EXTENSION](#) in the PostgreSQL documentation.

## ALTER EXTENSION

The following DDLs are supported:

```
ALTER EXTENSION name UPDATE [ TO new_version ]

ALTER EXTENSION name SET SCHEMA new_schema
```

For more information, see [ALTER EXTENSION](#) in the PostgreSQL documentation.

## DROP EXTENSION

You can drop extensions, as in PostgreSQL.

```
DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

For more information, see [DROP EXTENSION](#) in the PostgreSQL documentation.

The following DDLs aren't supported for extensions:

## ALTER EXTENSION

You can't add or drop member objects from extensions.

```
ALTER EXTENSION name ADD member_object
```

```
ALTER EXTENSION name DROP member_object
```

## pg\_buffercache differences in Aurora PostgreSQL Limitless Database

In Aurora PostgreSQL Limitless Database, when you install the [pg\\_buffercache](#) extension and use the `pg_buffercache` view, you receive buffer-related information only from the node to which you're currently connected: the router. Similarly, using the function `pg_buffercache_summary` or `pg_buffercache_usage_counts` provides information only from the connected node.

You can have numerous nodes and might need to access buffer information from any node to diagnose issues effectively. Therefore, Limitless Database provides the following functions:

- `rds_aurora.limitless_pg_buffercache(subcluster_id)`
- `rds_aurora.limitless_pg_buffercache_summary(subcluster_id)`
- `rds_aurora.limitless_pg_buffercache_usage_counts(subcluster_id)`

By inputting the subcluster ID of any node, whether it's a router or shard, you can easily access the buffer information specific to that node. These functions are directly available when you install the `pg_buffercache` extension in the limitless database.

### Note

Aurora PostgreSQL Limitless Database supports these functions for version 1.4 and higher of the `pg_buffercache` extension.

The columns shown in the `limitless_pg_buffercache` view differ slightly from those in the `pg_buffercache` view:

- `bufferid` – Remains unchanged from `pg_buffercache`.
- `relname` – Instead of displaying the file node number as in `pg_buffercache`, `limitless_pg_buffercache` presents the associated `relname` if available in the current database or shared system catalogs, otherwise NULL.
- `parent_relname` – This new column, not present in `pg_buffercache`, displays the parent `relname` if the value in the `relname` column represents a partitioned table (in the case of sharded tables). Otherwise, it displays NULL.
- `spcname` – Instead of displaying the tablespace object identifier (OID) as in `pg_buffercache`, `limitless_pg_buffercache` displays the tablespace name.
- `datname` – Instead of displaying the database OID as in `pg_buffercache`, `limitless_pg_buffercache` displays the database name.
- `relforknumber` – Remains unchanged from `pg_buffercache`.
- `relblocknumber` – Remains unchanged from `pg_buffercache`.
- `isdirty` – Remains unchanged from `pg_buffercache`.
- `usagecount` – Remains unchanged from `pg_buffercache`.
- `pinning_backends` – Remains unchanged from `pg_buffercache`.

The columns in `limitless_pg_buffercache_summary` and `limitless_pg_buffercache_usage_counts` views are the same as those in the regular `pg_buffercache_summary` and `pg_buffercache_usage_counts` views, respectively.

By using these functions, you can access detailed buffer cache information across all nodes in your Limitless Database environment, facilitating more effective diagnosis and management of your database systems.

## **pgstattuple differences in Aurora PostgreSQL Limitless Database**

In Aurora PostgreSQL, the [pgstattuple](#) extension currently doesn't support foreign tables, partitioned tables, or partitioned indexes. However, in Aurora PostgreSQL Limitless Database, user-created objects are often among these unsupported types. While there are regular tables and indexes (for example, catalog tables and their indexes), most objects reside on foreign nodes, making them foreign objects for the router.

We recognize the importance of this extension for obtaining tuple-level statistics, which is crucial for tasks such as removing bloat and gathering diagnostic information. Therefore, Aurora PostgreSQL Limitless Database provides support for the `pgstattuple` extension in limitless databases.

Aurora PostgreSQL Limitless Database includes the following functions in the `rds_aurora` schema:

### Tuple-level statistics functions

#### `rds_aurora.limitless_pgstattuple(relation_name)`

- Purpose: Extract tuple-level statistics for standard tables and their indexes
- Input: `relation_name` (text) – The name of the relation
- Output: Columns consistent with those returned by the `pgstattuple` function in Aurora PostgreSQL

#### `rds_aurora.limitless_pgstattuple(relation_name, subcluster_id)`

- Purpose: Extract tuple-level statistics for reference tables, sharded tables, catalog tables, and their indexes
- Input:
  - `relation_name` (text) – The name of the relation
  - `subcluster_id` (text) – The subcluster ID of the node where the statistics are to be extracted
- Output:
  - For reference and catalog tables (including their indexes), columns are consistent with those in Aurora PostgreSQL.
  - For sharded tables, the statistics represent only the partition of the sharded table residing on the specified subcluster.

### Index statistics functions

#### `rds_aurora.limitless_pgstatindex(relation_name)`

- Purpose: Extract statistics for B-tree indexes on standard tables
- Input: `relation_name` (text) – The name of the B-tree index
- Output: All columns except `root_block_no` are returned. The returned columns are consistent with the `pgstatindex` function in Aurora PostgreSQL.

**`rds_aurora.limitless_pgstatindex(relation_name, subcluster_id)`**

- Purpose: Extract statistics for B-tree indexes on reference tables, sharded tables, and catalog tables.
- Input:
  - `relation_name` (text) – The name of the B-tree index
  - `subcluster_id` (text) – The subcluster ID of the node where the statistics are to be extracted
- Output:
  - For reference and catalog table indexes, all columns (except `root_block_no`) are returned. The returned columns are consistent with Aurora PostgreSQL.
  - For sharded tables, the statistics represent only the partition of the sharded table index residing on the specified subcluster. The `tree_level` column shows the average across all table slices on the requested subcluster.

**`rds_aurora.limitless_pgstatginindex(relation_name)`**

- Purpose: Extract statistics for Generalized Inverted Indexes (GINs) on standard tables
- Input: `relation_name` (text) – The name of the GIN
- Output: Columns consistent with those returned by the `pgstatginindex` function in Aurora PostgreSQL

**`rds_aurora.limitless_pgstatginindex(relation_name, subcluster_id)`**

- Purpose: Extract statistics for GIN indexes on reference tables, sharded tables, and catalog tables.
- Input:
  - `relation_name` (text) – The name of the index
  - `subcluster_id` (text) – The subcluster ID of the node where the statistics are to be extracted
- Output:
  - For reference and catalog table GIN indexes, columns are consistent with those in Aurora PostgreSQL.
  - For sharded tables, the statistics represent only the partition of the sharded table index residing on the specified subcluster.

**`rds_aurora.limitless_pgstathashindex(relation_name)`**

- Purpose: Extract statistics for hash indexes on standard tables
- Input: `relation_name` (text) – The name of the hash index
- Output: Columns consistent with those returned by the `pgstathashindex` function in Aurora PostgreSQL

#### **`rds_aurora.limitless_pgstathashindex`(*relation\_name*, *subcluster\_id*)**

- Purpose: Extract statistics for hash indexes on reference tables, sharded tables, and catalog tables.
- Input:
  - `relation_name` (text) – The name of the index
  - `subcluster_id` (text) – The subcluster ID of the node where the statistics are to be extracted
- Output:
  - For reference and catalog table hash indexes, columns are consistent with Aurora PostgreSQL.
  - For sharded tables, the statistics represent only the partition of the sharded table index residing on the specified subcluster.

### Page count functions

#### **`rds_aurora.limitless_pg_relpages`(*relation\_name*)**

- Purpose: Extract the page count for standard tables and their indexes
- Input: `relation_name` (text) – The name of the relation
- Output: Page count of the specified relation

#### **`rds_aurora.limitless_pg_relpages`(*relation\_name*, *subcluster\_id*)**

- Purpose: Extract the page count for reference tables, sharded tables, and catalog tables (including their indexes)
- Input:
  - `relation_name` (text) – The name of the relation
  - `subcluster_id` (text) – The subcluster ID of the node where the page count is to be extracted
- Output: For sharded tables, the page count is the sum of pages across all table slices on the specified subcluster.

## Approximate tuple-level statistics functions

### `rds_aurora.limitless_pgstattuple_approx(relation_name)`

- Purpose: Extract approximate tuple-level statistics for standard tables and their indexes
- Input: `relation_name` (text) – The name of the relation
- Output: Columns consistent with those returned by the `pgstattuple_approx` function in Aurora PostgreSQL

### `rds_aurora.limitless_pgstattuple_approx(relation_name, subcluster_id)`

- Purpose: Extract approximate tuple-level statistics for reference tables, sharded tables, and catalog tables (including their indexes)
- Input:
  - `relation_name` (text) – The name of the relation
  - `subcluster_id` (text) – The subcluster ID of the node where the statistics are to be extracted
- Output:
  - For reference and catalog tables (including their indexes), columns are consistent with those in Aurora PostgreSQL.
  - For sharded tables, the statistics represent only the partition of the sharded table residing on the specified subcluster.

#### Note

Currently, Aurora PostgreSQL Limitless Database doesn't support the `pgstattuple` extension on materialized views, TOAST tables, or temporary tables.

In Aurora PostgreSQL Limitless Database, you must provide the input as text, although Aurora PostgreSQL supports other formats.

## Foreign keys

Foreign key (FOREIGN KEY) constraints are supported with some limitations:

- CREATE TABLE with FOREIGN KEY is supported only for standard tables. To create a sharded or reference table with FOREIGN KEY, first create the table without a foreign key constraint. Then modify it using the following statement:

```
ALTER TABLE ADD CONSTRAINT;
```

- Converting a standard table to a sharded or reference table isn't supported when the table has a foreign key constraint. Drop the constraint, then add it after conversion.
- The following limitations apply to table types for foreign key constraints:
  - A standard table can have a foreign key constraint to another standard table.
  - A sharded table can have a foreign key constraint if the parent and child tables are colocated and the foreign key is a superset of the shard key.
  - A sharded table can have a foreign key constraint to a reference table.
  - A reference table can have a foreign key constraint to another reference table.

### Topics

- [Foreign key options](#)
- [Examples](#)

### Foreign key options

Foreign keys are supported in Aurora PostgreSQL Limitless Database for some DDL options. The following table lists options that are supported and not supported between Aurora PostgreSQL Limitless Database tables.

DDL option	Reference to reference	Sharded to sharded (colocated)	Sharded to reference	Standard to standard
DEFERRABLE	Yes	Yes	Yes	Yes

DDL option	Reference to reference	Sharded to sharded (collocated)	Sharded to reference	Standard to standard
INITIALLY DEFERRED	Yes	Yes	Yes	Yes
INITIALLY IMMEDIATE	Yes	Yes	Yes	Yes
MATCH FULL	Yes	Yes	Yes	Yes
MATCH PARTIAL	No	No	No	No
MATCH SIMPLE	Yes	Yes	Yes	Yes
NOT DEFERRABLE	Yes	Yes	Yes	Yes
NOT VALID	Yes	No	No	Yes
ON DELETE CASCADE	Yes	Yes	Yes	Yes
ON DELETE NO ACTION	Yes	Yes	Yes	Yes
ON DELETE RESTRICT	Yes	Yes	Yes	Yes
ON DELETE SET DEFAULT	No	No	No	No
ON DELETE SET NULL	Yes	No	No	Yes
ON UPDATE CASCADE	No	No	No	Yes

DDL option	Reference to reference	Sharded to sharded (collocated)	Sharded to reference	Standard to standard
ON UPDATE NO ACTION	Yes	Yes	Yes	Yes
ON UPDATE RESTRICT	Yes	Yes	Yes	Yes
ON UPDATE SET DEFAULT	No	No	No	No
ON UPDATE SET NULL	Yes	No	No	Yes

## Examples

- Standard to standard:

```

set rds_aurora.limitless_create_table_mode='standard';

CREATE TABLE products(
  product_no integer PRIMARY KEY,
  name text,
  price numeric
);

CREATE TABLE orders (
  order_id integer PRIMARY KEY,
  product_no integer REFERENCES products (product_no),
  quantity integer
);

SELECT constraint_name, table_name, constraint_type
FROM information_schema.table_constraints WHERE constraint_type='FOREIGN KEY';

constraint_name      | table_name | constraint_type
-----+-----+-----
orders_product_no_fkey | orders     | FOREIGN KEY

```

(1 row)

- **Sharded to sharded (collocated):**

```
set rds_aurora.limitless_create_table_mode='sharded';
set rds_aurora.limitless_create_table_shard_key='{"product_no"}';
CREATE TABLE products(
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);

set rds_aurora.limitless_create_table_shard_key='{"order_id"}';
set rds_aurora.limitless_create_table_collocate_with='products';
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer,
    quantity integer
);

ALTER TABLE orders ADD CONSTRAINT order_product_fk FOREIGN KEY (product_no)
REFERENCES products (product_no);
```

- **Sharded to reference:**

```
set rds_aurora.limitless_create_table_mode='reference';
CREATE TABLE products(
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);

set rds_aurora.limitless_create_table_mode='sharded';
set rds_aurora.limitless_create_table_shard_key='{"order_id"}';
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer,
    quantity integer
);

ALTER TABLE orders ADD CONSTRAINT order_product_fk FOREIGN KEY (product_no)
REFERENCES products (product_no);
```

- Reference to reference:

```
set rds_aurora.limitless_create_table_mode='reference';
CREATE TABLE products(
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer,
    quantity integer
);

ALTER TABLE orders ADD CONSTRAINT order_product_fk FOREIGN KEY (product_no)
REFERENCES products (product_no);
```

## Functions

Functions are supported in Aurora PostgreSQL Limitless Database.

The following DDLs are supported for functions:

### CREATE FUNCTION

You can create functions, as in Aurora PostgreSQL, with the exception of changing their volatility while replacing them.

For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.

### ALTER FUNCTION

You can alter functions, as in Aurora PostgreSQL, with the exception of changing their volatility.

For more information, see [ALTER FUNCTION](#) in the PostgreSQL documentation.

### DROP FUNCTION

You can drop functions, as in Aurora PostgreSQL.

```
DROP FUNCTION [ IF EXISTS ] name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ]  
[ , ... ]  
[ CASCADE | RESTRICT ]
```

For more information, see [DROP FUNCTION](#) in the PostgreSQL documentation.

## Topics

- [Function distribution](#)
- [Function volatility](#)

### Function distribution

When all of the statements of a function are targeted to a single shard, it's beneficial to push the entire function down to the target shard. Then the result is propagated back to the router, rather than unraveling the function at the router itself. Function and stored procedure pushdown capability is useful for customers who want to run their function or stored procedure closer to the data source, that is the shard.

To distribute a function, first create the function, then call the `rds_aurora.limitless_distribute_function` procedure to distribute it. This function uses the following syntax:

```
SELECT rds_aurora.limitless_distribute_function('function_prototype',  
ARRAY['shard_key'], 'collocating_table');
```

The function takes the following parameters:

- *function\_prototype* – The function to be distributed. Mention only the input arguments, and not any of the output arguments.

If any of the arguments are defined as OUT parameters, don't include their type in the arguments of `function_prototype`.

- `ARRAY['shard_key']` – The list of function arguments that are identified as the shard key for the function.
- *collocating\_table* – The sharded table that contains the range of data on the target shard.

To identify the shard where to push down this function for running, the system takes the `ARRAY['shard_key']` argument, hashes it, and finds the shard from *collocating\_table* that hosts the range containing this hash value.

## Restrictions

When you distribute a function or procedure, it only deals with data that's bounded by the shard key range in that shard. In cases where the function or procedure tries to access data from a different shard, the results returned by the distributed function or procedure will be different compared to one that isn't distributed.

For example, you create a function containing queries that will touch multiple shards, but then call the `rds_aurora.limitless_distribute_function` procedure to distribute it. When you invoke this function by providing arguments for a shard key, it is likely that the results of running it will be bounded by the values present in that shard. These results are different from ones produced without distributing the function.

## Examples

Consider the following function `func` where we have the sharded table `customers` with the shard key `customer_id`.

```
postgres_limitless=> CREATE OR REPLACE FUNCTION func(c_id integer, sc integer)
RETURNS int
  language SQL
  volatile
  AS $$
  UPDATE customers SET score = sc WHERE customer_id = c_id RETURNING score;
  $$;
```

Now we distribute this function:

```
SELECT rds_aurora.limitless_distribute_function('func(integer, integer)',
  ARRAY['c_id'], 'customers');
```

The following are example query plans.

```
EXPLAIN(costs false, verbose true) SELECT func(27+1,10);
```

#### QUERY PLAN

```
-----
Foreign Scan
  Output: (func((27 + 1), 10))
  Remote SQL: SELECT func((27 + 1), 10) AS func
  Single Shard Optimized
(4 rows)
```

```
EXPLAIN(costs false, verbose true)
SELECT * FROM customers,func(customer_id, score) WHERE customer_id=10 AND score=27;
```

#### QUERY PLAN

```
-----
Foreign Scan
  Output: customer_id, name, score, func
  Remote SQL: SELECT customers.customer_id,
  customers.name,
  customers.score,
  func.func
  FROM public.customers,
  LATERAL func(customers.customer_id, customers.score) func(func)
  WHERE ((customers.customer_id = 10) AND (customers.score = 27))
  Single Shard Optimized
(10 rows)
```

The following example shows a procedure with IN and OUT parameters as arguments.

```
CREATE OR REPLACE FUNCTION get_data(OUT id INTEGER, IN arg_id INT)
AS $$
BEGIN
    SELECT customer_id,
    INTO id
    FROM customer
    WHERE customer_id = arg_id;
END;
$$ LANGUAGE plpgsql;
```

The following example distributes the procedure using only IN parameters.

```
EXPLAIN(costs false, verbose true) SELECT * FROM get_data(1);

          QUERY PLAN
-----
Foreign Scan
Output: id
Remote SQL:  SELECT customer_id
             FROM get_data(1) get_data(id)
Single Shard Optimized
(6 rows)
```

## Function volatility

You can determine whether a function is immutable, stable, or volatile by checking the `provolatile` value in the [pg\\_proc](#) view. The `provolatile` value indicates whether the function's result depends only on its input arguments, or is affected by outside factors.

The value is one of the following:

- `i` – Immutable functions, which always deliver the same result for the same inputs
- `s` – Stable functions, whose results (for fixed inputs) don't change within a scan
- `v` – Volatile functions, whose results might change at any time. Also use `v` for functions with side effects, so that calls to them can't be optimized away.

The following examples show volatile functions.

```
SELECT proname, provolatile FROM pg_proc WHERE proname='pg_sleep';
```

```

proname | provolatile
-----+-----
pg_sleep | v
(1 row)
```

```
SELECT proname, provolatile FROM pg_proc WHERE proname='uuid_generate_v4';
```

```

      proname      | provolatile
-----+-----
uuid_generate_v4 | v
(1 row)
```

```
SELECT proname, provolatile FROM pg_proc WHERE proname='nextval';
```

```

proname | provolatile
-----+-----
nextval | v
(1 row)
```

Changing the volatility of an existing function isn't supported in Aurora PostgreSQL Limitless Database. This applies to both `ALTER FUNCTION` and `CREATE OR REPLACE FUNCTION` commands, as shown in the following examples.

```

-- Create an immutable function
CREATE FUNCTION immutable_func1(name text) RETURNS text language plpgsql
AS $$
BEGIN
    RETURN name;
END;
$$IMMUTABLE;

-- Altering the volatility throws an error
ALTER FUNCTION immutable_func1 STABLE;

-- Replacing the function with altered volatility throws an error
CREATE OR REPLACE FUNCTION immutable_func1(name text) RETURNS text language plpgsql
AS $$
BEGIN
    RETURN name;
END;
```

```
$$VOLATILE;
```

We highly recommend that you assign the correct volatilities to functions. For example, if your function uses SELECT from multiple tables or references database objects, don't set it as IMMUTABLE. If the table contents ever change, the immutability is broken.

Aurora PostgreSQL allows SELECT inside immutable functions, but the results might be incorrect. Aurora PostgreSQL Limitless Database can return both errors and incorrect results. For more information on function volatility, see [Function volatility categories](#) in the PostgreSQL documentation.

## Sequences

Named sequences are database objects that generate unique numbers in ascending or descending order. `CREATE SEQUENCE` creates a new sequence number generator. Sequence values are guaranteed to be unique.

When you create a named sequence in Aurora PostgreSQL Limitless Database, a distributed sequence object is created. Then Aurora PostgreSQL Limitless Database distributes non-overlapping chunks of sequence values across all Distributed Transaction Routers (routers). Chunks are represented as local sequence objects on routers; therefore, sequence operations such as `nextval` and `currval` are run locally. Routers operate independently, and request new chunks from the distributed sequence when needed.

For more information on sequences, see [CREATE SEQUENCE](#) in the PostgreSQL documentation.

### Topics

- [Requesting a new chunk](#)
- [Limitations](#)
- [Unsupported options](#)
- [Examples](#)
- [Sequence views](#)
- [Troubleshooting sequence issues](#)

### Requesting a new chunk

You configure the sizes of chunks allocated on routers by using the `rds_aurora.limitless_sequence_chunk_size` parameter. The default value is `250000`. Each router initially owns two chunks: active and reserved. Active chunks are used to configure local sequence objects (setting `minvalue` and `maxvalue`), and reserved chunks are stored in an internal catalog table. When an active chunk reaches the minimum or maximum value, it's replaced by the reserved chunk. To do that, `ALTER SEQUENCE` is used internally, meaning that `AccessExclusiveLock` is acquired.

Background workers run every 10 seconds on router nodes to scan sequences for used reserved chunks. If a used chunk is found, the worker requests a new chunk from the distributed sequence. Make sure to set the chunk size large enough that the background workers have enough time to

request new ones. Remote requests never happen in the context of user sessions, which means that you can't request a new sequence directly.

## Limitations

The following limitations apply to sequences in Aurora PostgreSQL Limitless Database:

- The `pg_sequence` catalog, `pg_sequences` function, and `SELECT * FROM sequence_name` statement all show only the local sequence state, not the distributed state.
- Sequence values are guaranteed to be unique, and are guaranteed to be monotonic within a session. But they can be out of order with `nextval` statements run in other sessions, if those sessions are connected to other routers.
- Make sure that the sequence size (number of available values) is large enough to be distributed across all routers. Use the `rds_aurora.limitless_sequence_chunk_size` parameter to configure the `chunk_size`. (Each router has two chunks.)
- The `CACHE` option is supported, but the cache must be smaller than `chunk_size`.

## Unsupported options

The following options aren't supported for sequences in Aurora PostgreSQL Limitless Database.

## Sequence manipulation functions

The `setval` function isn't supported. For more information, see [Sequence Manipulation Functions](#) in the PostgreSQL documentation.

## CREATE SEQUENCE

The following options aren't supported.

```
CREATE [{ TEMPORARY | TEMP} | UNLOGGED] SEQUENCE
      [[ NO ] CYCLE]
```

For more information, see [CREATE SEQUENCE](#) in the PostgreSQL documentation.

## ALTER SEQUENCE

The following options aren't supported.

```
ALTER SEQUENCE
```

```
[[ NO ] CYCLE]
```

For more information, see [ALTER SEQUENCE](#) in the PostgreSQL documentation.

## ALTER TABLE

The ALTER TABLE command isn't supported for sequences.

## Examples

### CREATE/DROP SEQUENCE

```
postgres_limitless=> CREATE SEQUENCE s;
CREATE SEQUENCE

postgres_limitless=> SELECT nextval('s');

 nextval
-----
      1
(1 row)

postgres_limitless=> SELECT * FROM pg_sequence WHERE seqrelid='s'::regclass;

 seqrelid | seqtypeid | seqstart | seqincrement | seqmax | seqmin | seqcache |
 seqcycle
-----+-----+-----+-----+-----+-----+-----+
+-----+
      16960 |      20 |      1 |      1 | 10000 |      1 |      1 | f
(1 row)

% connect to another router
postgres_limitless=> SELECT nextval('s');

 nextval
-----
     10001
(1 row)

postgres_limitless=> SELECT * FROM pg_sequence WHERE seqrelid='s'::regclass;

 seqrelid | seqtypeid | seqstart | seqincrement | seqmax | seqmin | seqcache |
 seqcycle
```

```

-----+-----+-----+-----+-----+-----+-----
+-----
      16959 |      20 |   10001 |           1 |   20000 |   10001 |           1 | f
(1 row)

postgres_limitless=> DROP SEQUENCE s;
DROP SEQUENCE

```

## ALTER SEQUENCE

```

postgres_limitless=> CREATE SEQUENCE s;
CREATE SEQUENCE

postgres_limitless=> ALTER SEQUENCE s RESTART 500;
ALTER SEQUENCE

postgres_limitless=> SELECT nextval('s');

nextval
-----
      500
(1 row)

postgres_limitless=> SELECT currval('s');

currval
-----
      500
(1 row)

```

## Sequence manipulation functions

```

postgres=# CREATE TABLE t(a bigint primary key, b bigint);
CREATE TABLE

postgres=# CREATE SEQUENCE s minvalue 0 START 0;
CREATE SEQUENCE

postgres=# INSERT INTO t VALUES (nextval('s'), currval('s'));

INSERT 0 1

postgres=# INSERT INTO t VALUES (nextval('s'), currval('s'));

```

```
INSERT 0 1
```

```
postgres=# SELECT * FROM t;
```

```
 a | b  
---+---  
 0 | 0  
 1 | 1  
(2 rows)
```

```
postgres=# ALTER SEQUENCE s RESTART 10000;  
ALTER SEQUENCE
```

```
postgres=# INSERT INTO t VALUES (nextval('s'), currval('s'));
```

```
INSERT 0 1
```

```
postgres=# SELECT * FROM t;
```

```
  a  |  b  
-----+-----  
   0 |    0  
   1 |    1  
10000 | 10000  
(3 rows)
```

## Sequence views

Aurora PostgreSQL Limitless Database provides the following views for sequences.

### `rds_aurora.limitless_distributed_sequence`

This view shows a distributed sequence state and configuration. The `minvalue`, `maxvalue`, `start`, `inc`, and `cache` columns have the same meaning as in the [pg\\_sequences](#) view, and show the options with which the sequence was created. The `lastval` column shows the latest allocated or reserved value in a distributed sequence object. This doesn't mean that the value was already used, as routers keep sequence chunks locally.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_distributed_sequence WHERE
sequence_name='test_serial_b_seq';
```

schema_name	sequence_name	lastval	minvalue	maxvalue	start	inc	cache
public	test_serial_b_seq	1250000	1	2147483647	1	1	1

(1 row)

### `rds_aurora.limitless_sequence_metadata`

This view shows distributed sequence metadata and aggregates sequence metadata from cluster nodes. It uses the following columns:

- `subcluster_id` – The cluster node ID that owns a chunk.
- Active chunk – A chunk of a sequence that is being used (`active_minvalue`, `active_maxvalue`).
- Reserved chunk – The local chunk that will be used next (`reserved_minvalue`, `reserved_maxvalue`).
- `local_last_value` – The last observed value from a local sequence.
- `chunk_size` – The size of a chunk, as configured on creation.

```
postgres_limitless=> SELECT * FROM rds_aurora.limitless_sequence_metadata WHERE
sequence_name='test_serial_b_seq' order by subcluster_id;
```

```

subcluster_id | sequence_name | schema_name | active_minvalue | active_maxvalue
| reserved_minvalue | reserved_maxvalue | chunk_size | chunk_state |
local_last_value
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
1          | test_serial_b_seq | public      |          500001 |          750000
|          1000001 |          1250000 |          250000 |          1 |
550010
2          | test_serial_b_seq | public      |          250001 |          500000
|          750001 |          1000000 |          250000 |          1 |

(2 rows)

```

## Troubleshooting sequence issues

The following issues can occur with sequences.

### Chunk size not large enough

If the chunk size isn't set large enough and the transaction rate is high, the background workers might not have enough time to request new chunks before the active chunks are exhausted. This can lead to contention and wait events such as `LIMITLESS:AuroraLimitlessSequenceReplace`, `LWLock:LockManager`, `Lockrelation`, and `LWlock:bufferscontent`.

Increase the value of the `rds_aurora.limitless_sequence_chunk_size` parameter.

### Sequence cache set too high

In PostgreSQL, sequence caching happens at the session level. Each session allocates successive sequence values during one access to the sequence object, and increases the sequence object's `last_value` accordingly. Then, the next uses of `nextval` within that session simply return the pre-allocated values without touching the sequence object.

Any numbers allocated but not used within a session are lost when that session ends, resulting in "holes" in the sequence. This can consume the `sequence_chunk` quickly and lead to contention and wait events such as `LIMITLESS:AuroraLimitlessSequenceReplace`, `LWLock:LockManager`, `Lockrelation`, and `LWlock:bufferscontent`.

Reduce the sequence cache setting.

The following figure shows wait events caused by sequence issues.

## Supported and unsupported Data Manipulation Language (DML) and query processing SQL commands

The following table lists the DML commands that are supported and not supported by Aurora PostgreSQL Limitless Database, with references to limitations or more information.

Command	Supported?	Limitations or more information
ABORT	Yes	None
ANALYZE	Yes	<a href="#">ANALYZE</a>
BEGIN	Yes	None
CALL	Yes	None
CHECKPOINT	Yes	None
CLOSE	Yes	None
CLUSTER	Yes	<a href="#">CLUSTER</a>
COMMIT	Yes	None
COMMIT PREPARED	No	Not applicable
COPY	Yes	None
DEALLOCATE	Yes	None
DECLARE	Yes	None
DELETE	Yes	None
DISCARD	Yes	None
DO	Yes	None
END	Yes	None

Command	Supported?	Limitations or more information
EXECUTE	Yes	None
EXPLAIN	Yes	<a href="#">EXPLAIN</a>
FETCH	Yes	None
IMPORT FOREIGN SCHEMA	No	Not applicable
INSERT	Yes	<a href="#">INSERT</a>
LISTEN	No	Not applicable
LOCK	Yes	None
MERGE	No	Not applicable
MOVE	Yes	None
NOTIFY	No	Not applicable
OPEN	Yes	None
PREPARE	Yes	None
PREPARE TRANSACTION	No	Not applicable
REFRESH MATERIALIZED VIEW	No	Not applicable
REINDEX	No	Not applicable
RELEASE SAVEPOINT	Yes	None
ROLLBACK	Yes	None
ROLLBACK PREPARED	No	Not applicable
ROLLBACK TO SAVEPOINT	Yes	None

Command	Supported?	Limitations or more information
SAVEPOINT	Yes	None
SELECT	Yes	None
SELECT INTO	Yes	None
SHOW	Yes	None
START TRANSACTION	Yes	None
UNLISTEN	No	None
UPDATE	Yes	<a href="#">UPDATE</a>
UPDATE ... WHERE CURRENT OF	No	Not applicable
VACUUM	Yes	<a href="#">VACUUM</a>
VALUES	Yes	None

# DML limitations and other information for Aurora PostgreSQL Limitless Database

The following topics describe limitations or provide more information for DML and query processing SQL commands in Aurora PostgreSQL Limitless Database.

## Topics

- [ANALYZE](#)
- [CLUSTER](#)
- [EXPLAIN](#)
- [INSERT](#)
- [UPDATE](#)
- [VACUUM](#)

## ANALYZE

The ANALYZE command collects statistics about the contents of tables in the database. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries. For more information, see [ANALYZE](#) in the PostgreSQL documentation.

In Aurora PostgreSQL Limitless Database, the ANALYZE command collects table statistics across all routers and shards when it runs.

To prevent the calculation of statistics on every router during ANALYZE runs, table statistics are calculated on one of the routers and then copied to peer routers.

## CLUSTER

The CLUSTER command physically reorders a table based on an index. The index must already have been defined on the table. In Aurora PostgreSQL Limitless Database, the clustering is local to the part of the index that's present on each shard.

For more information, see [CLUSTER](#) in the PostgreSQL documentation.

## EXPLAIN

You use the following parameter to configure the output from the EXPLAIN command:

- `rds_aurora.limitless_explain_options` – What to include in the EXPLAIN output. The default value is `single_shard_optimization`: whether plans are single-shard optimized is shown, but shard plans aren't included.

In this example, the EXPLAIN output doesn't show plans from shards.

```
postgres_limitless=> EXPLAIN SELECT * FROM employees where id =25;
```

### QUERY PLAN

```
-----
Foreign Scan (cost=100.00..101.00 rows=100 width=0)
  Single Shard Optimized
(2 rows)
```

Now we set the `rds_aurora.limitless_explain_options` to include `shard_plans` and `single_shard_optimization`. We can view the execution plans of statements on both routers and shards. In addition, we disable the `enable_seqscan` parameter to enforce that index scan is used on the shard layer.

```
postgres_limitless=> SET rds_aurora.limitless_explain_options = shard_plans,
  single_shard_optimization;
```

```
SET
```

```
postgres_limitless=> SET enable_seqscan = OFF;
```

```
SET
```

```
postgres_limitless=> EXPLAIN SELECT * FROM employees WHERE id = 25;
```

### QUERY PLAN

```
-----
Foreign Scan (cost=100.00..101.00 rows=100 width=0)
  Remote Plans from Shard postgres_s4:
    Index Scan using employees_ts00287_id_idx on employees_ts00287
  employees_fs00003 (cost=0.14..8.16 rows=1 width=15)
    Index Cond: (id = 25)
  Single Shard Optimized
(5 rows)
```

For more information on the EXPLAIN command, see [EXPLAIN](#) in the PostgreSQL documentation.

## INSERT

Most INSERT commands are supported in Aurora PostgreSQL Limitless Database.

PostgreSQL doesn't have an explicit UPSERT command, but it does support INSERT ... ON CONFLICT statements.

INSERT ... ON CONFLICT isn't supported if the conflict action has a subquery or a mutable function:

```
-- RANDOM is a mutable function.
INSERT INTO sharded_table VALUES (1, 100) ON CONFLICT (id) DO UPDATE SET other_id =
  RANDOM();

ERROR: Aurora Limitless Tables doesn't support pushdown-unsafe functions with DO UPDATE
clauses.
```

For more information on the INSERT command, see [INSERT](#) in the PostgreSQL documentation.

## UPDATE

Updating the shard key isn't supported. For example, you have a sharded table called customers, with a shard key customer\_id. The following DML statements cause errors:

```
postgres_limitless=> UPDATE customers SET customer_id = 11 WHERE customer_id =1;
ERROR:  Shard key column update is not supported

postgres_limitless=> UPDATE customers SET customer_id = 11 WHERE customer_name='abc';
ERROR:  Shard key column update is not supported
```

To update a shard key, first you have to DELETE the row with the shard key, then INSERT a new row with the updated shard key value.

For more information on the UPDATE command, see [Updating data](#) in the PostgreSQL documentation.

## VACUUM

You can perform vacuuming on both sharded and reference tables. The following VACUUM functions are fully supported in Aurora PostgreSQL Limitless Database:

- VACUUM
- [ANALYZE](#)
- DISABLE\_PAGE\_SKIPPING
- FREEZE
- FULL
- INDEX\_CLEANUP
- PARALLEL
- PROCESS\_TOAST
- TRUNCATE
- VERBOSE

VACUUM on Aurora PostgreSQL Limitless Database has the following limitations:

- The [pg\\_visibility\\_map](#) extension isn't supported.
- Checking for unused indexes with the [pg\\_stat\\_all\\_indexes](#) view isn't supported.
- Consolidated views for [pg\\_stat\\_user\\_indexes](#), [pg\\_class](#), and [pg\\_stats](#) aren't implemented.

For more information on the VACUUM command, see [VACUUM](#) in the PostgreSQL documentation. For more information on how vacuuming works in Aurora PostgreSQL Limitless Database, see [Reclaiming storage space by vacuuming](#).

## Variables in Aurora PostgreSQL Limitless Database

You can use the following variables to configure Aurora PostgreSQL Limitless Database.

### **rds\_aurora.limitless\_active\_shard\_key**

Sets a single shard key while querying the database, causing all SELECT and DML queries to be appended with the shard key as a constant predicate. For more information, see [Setting an active shard key](#).

### **rds\_aurora.limitless\_create\_table\_collocate\_with**

Set this variable to a specific table name to collocate newly created tables with that table. For more information, see [Creating limitless tables by using variables](#).

### **rds\_aurora.limitless\_create\_table\_mode**

Sets the table creation mode. For more information, see [Creating limitless tables by using variables](#).

### **rds\_aurora.limitless\_create\_table\_shard\_key**

Set this variable to an array of column names to use as shard keys. For more information, see [Creating limitless tables by using variables](#).

### **rds\_aurora.limitless\_explain\_options**

What to include in the EXPLAIN output. For more information, see [EXPLAIN](#).

## DB cluster parameters in Aurora PostgreSQL Limitless Database

You can use the following DB cluster parameters to configure Aurora PostgreSQL Limitless Database.

### **rds\_aurora.limitless\_adaptive\_fetch\_size**

Enhances batch prefetching. When set to `true`, this parameter allows a self-adjusting (adaptive) fetch size for prefetching. When set to `false`, the fetch size is constant.

### **rds\_aurora.limitless\_auto\_scale\_options**

Sets the options available for adding routers or splitting shards in a DB shard group. The value can be `add_router`, `split_shard`, or `both`.

For more information, see [Adding a router to a DB shard group](#) and [Splitting a shard in a DB shard group](#).

### **rds\_aurora.limitless\_distributed\_deadlock\_timeout**

The amount of time to wait on a lock before checking whether there is a distributed deadlock condition, in milliseconds. The default is `1000` (1 second).

For more information, see [Distributed deadlocks in Aurora PostgreSQL Limitless Database](#).

### **rds\_aurora.limitless\_enable\_auto\_scale**

Enables the adding of routers and splitting of shards in a DB shard group.

For more information, see [Adding a router to a DB shard group](#) and [Splitting a shard in a DB shard group](#).

### **rds\_aurora.limitless\_finalize\_split\_shard\_mode**

Determines how system-initiated shard splits are finalized. For more information, see [Splitting a shard in a DB shard group](#).

### **rds\_aurora.limitless\_maximum\_adaptive\_fetch\_size**

Sets the upper limit for the adaptive fetch size. The range is `1-INT_MAX`. The default is `1000`.

# Using Amazon Aurora Global Database

With the Amazon Aurora Global Database feature, you set up multiple Aurora DB clusters that span multiple Amazon Web Services Regions. Aurora automatically synchronizes all changes made in the primary DB cluster to one or more secondary clusters. An Aurora global database has a primary DB cluster in one Region, and up to 10 secondary DB clusters in different Regions. This multi-Region configuration provides fast recovery from the rare outage that might affect an entire Amazon Web Services Region. Having a full copy of all your data in multiple geographic locations also enables low-latency read operations for applications that connect from widely separated locations around the world.

## Topics

## Overview of Amazon Aurora Global Database

By using the Amazon Aurora Global Database feature, you can run your globally distributed applications using a single Aurora database that spans multiple Amazon Web Services Regions.

An Aurora global database consists of one *primary* Amazon Web Services Region where your data is written, and up to 10 read-only *secondary* Amazon Web Services Regions. You issue write

operations to the primary DB cluster in the primary Amazon Web Services Region. The most convenient way to do so is to connect to the Aurora Global Database writer endpoint, which always points to the primary DB cluster, even after a switchover or failover to a different Amazon Web Services Region. After any write operation, Aurora replicates data to the secondary Amazon Web Services Regions using dedicated infrastructure, with latency typically under a second.

In the following diagram, you can find an example Aurora global database that spans two Amazon Web Services Regions.

You can scale up each secondary cluster independently, by adding one or more Aurora reader instances to serve read-only workloads. You can use Aurora Serverless v2 for the reader instances for even more granular and flexible scaling.

Only the primary cluster performs write operations. Clients that perform write operations connect to the Aurora Global Database writer endpoint, which always points to the writer DB instance of the primary cluster. As shown in the diagram, Aurora uses the cluster storage volume and not the database engine for fast, low-overhead replication. To learn more, see [Overview of Amazon Aurora storage](#).

Aurora Global Database is designed for applications with a worldwide footprint. The read-only secondary DB clusters in multiple Amazon Web Services Regions help to optimize read operations closer to application users. By using the write forwarding feature, you can also configure your global database so that secondary clusters send write requests to the primary. For more information, see [Using write forwarding in an Amazon Aurora global database](#).

Aurora Global Database supports two different operations for changing the Region of your primary DB cluster, depending on the scenario: *Aurora Global Database switchover* and *Aurora Global Database failover*.

- For planned operational procedures such as Regional rotation, use the switchover mechanism (previously called "managed planned failover"). With this feature, you can relocate the primary cluster of a healthy Aurora Global Database to one of its secondary Regions with no data loss. To learn more, see [Performing switchovers for Amazon Aurora global databases](#).
- To recover your Aurora Global Database after an outage in the primary Region, use the failover mechanism. With this feature, you perform a failover from your primary DB cluster to another Region (cross-Region failover). To learn more, see [Performing managed failovers for Aurora global databases](#).

## Advantages of Amazon Aurora Global Database

By using Aurora Global Database, you can get the following advantages:

- **Global reads with local latency** – If you have offices around the world, you can use Aurora Global Database to keep your main sources of information updated in the primary Amazon Web Services Region. Offices in your other Regions can access the information in their own Region, with local latency.
- **Scalable secondary Aurora DB clusters** – You can scale your secondary clusters by adding more read-only instances to a secondary Amazon Web Services Region. The secondary cluster is read-only, so it can support up to 16 read-only DB instances rather than the usual limit of 15 for a single Aurora cluster.
- **Fast replication from primary to secondary Aurora DB clusters** – The replication performed by Aurora Global Database has little performance impact on the primary DB cluster. The resources of the DB instances are fully devoted to serve application read and write workloads.
- **Recovery from Region-wide outages** – The secondary clusters allow you to make an Aurora Global Database available in a new primary Amazon Web Services Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.

## Region and version availability

Feature availability and support vary across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora Global Database, see [Supported Regions and DB engines for Aurora global databases](#).

## Limitations of Amazon Aurora Global Database

The following limitations currently apply to Aurora Global Database:

- Aurora Global Database is available in certain Amazon Web Services Regions and for specific Aurora MySQL and Aurora PostgreSQL versions. For more information, see [Supported Regions and DB engines for Aurora global databases](#).
- Aurora Global Database has specific configuration requirements for supported Aurora DB instance classes, maximum number of Amazon Web Services Regions, and so on. For more information, see [Configuration requirements of an Amazon Aurora global database](#).
- For Aurora MySQL with MySQL 5.7 compatibility, Aurora Global Database switchovers require version 2.09.1 or a higher minor version.
- You can perform managed cross-Region switchovers or failovers with Aurora Global Database only if the primary and secondary DB clusters have the same major and minor engine versions. Depending on the engine and engine versions, the patch levels might need to be identical or the patch levels can be different. For a list of engines and engine versions that allow these operations between primary and secondary clusters with different patch levels, see [Patch level compatibility for managed cross-Region switchovers and failovers](#). If your engine versions require identical patch levels, you can perform the failover manually by following the steps in [Performing manual failovers for Aurora global databases](#).
- Aurora Global Database currently doesn't support the following Aurora features:
  - Aurora Serverless v1
  - Backtracking in Aurora
- For limitations with using the RDS Proxy feature with Aurora Global Database, see [Limitations for RDS Proxy with global databases](#).
- Automatic minor version upgrade doesn't apply to Aurora MySQL and Aurora PostgreSQL clusters that are part of a global database. Note that you can specify this setting for a DB instance that is part of a global database cluster, but the setting has no effect.
- Aurora Global Database currently doesn't support Aurora Auto Scaling for secondary DB clusters.

- To use Database Activity Streams (DAS) on Aurora Global Database running Aurora MySQL 5.7, the engine version must be version 2.08 or higher. For information about DAS, see [Monitoring Amazon Aurora with Database Activity Streams](#).
- The following limitations currently apply to upgrading Aurora Global Database:
  - You can't apply a custom parameter group to the global database cluster while you're performing a major version upgrade of that Aurora global database. You create your custom parameter groups in each Region of the global cluster and you apply them manually to the Regional clusters after the upgrade.
  - With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on. For more information on the methods that you can use, see [Major version upgrades](#).
  - With Aurora Global Database, you can't perform a major version upgrade of the Aurora PostgreSQL DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see [Managing RPOs for Aurora PostgreSQL-based global databases](#).
  - With an Aurora Global Database, you can't perform a minor version upgrade from Aurora MySQL version 3.01 or 3.02 to 3.03 or higher by using the standard process. For details about the process to use, see [Upgrading Aurora MySQL by modifying the engine version](#).

For information about upgrading Aurora Global Database, see [Upgrading an Amazon Aurora global database](#).

- You can't stop or start the Aurora DB clusters in your global database individually. To learn more, see [Stopping and starting an Amazon Aurora DB cluster](#).
- Aurora reader DB instances attached to the secondary Aurora DB cluster can restart under certain circumstances. If the primary Amazon Web Services Region's writer DB instance undergoes a restart or failover, reader DB instances in secondary Regions also restart. The secondary cluster is then unavailable until all reader DB instances are back in sync with the primary DB cluster's writer instance. The behavior of the primary cluster when rebooting or during a failover is the same as for a singular, nonglobal DB cluster. For more information, see [Replication with Amazon Aurora](#).

Be sure that you understand the impacts to your global database before making changes to your primary DB cluster. To learn more, see [Recovering an Amazon Aurora global database from an unplanned outage](#).

- Aurora Global Database currently doesn't support the `inaccessible-encryption-credentials-recoverable` status when Amazon Aurora loses access to the Amazon KMS key for the DB cluster. In these cases, the encrypted DB cluster goes directly into the terminal `inaccessible-encryption-credentials` state. For more information about these states, see [Viewing DB cluster status](#).
- Secrets Manager doesn't support Aurora Global Database. When you add a Region to a global database, you must first turn off Secrets Manager integration for the DB instance.
- Aurora PostgreSQL-based DB clusters that use Aurora Global Database have the following limitations:
  - Cluster cache management isn't supported for Aurora PostgreSQL secondary DB clusters that are part of Aurora global databases.
  - If the primary DB cluster of your global database is based on a replica of an Amazon RDS PostgreSQL instance, you can't create a secondary cluster. Don't attempt to create a secondary from that cluster using the Amazon Web Services Management Console, the Amazon CLI, or the `CreateDBCluster` API operation. Attempts to do so time out, and the secondary cluster isn't created.

We recommend that you create secondary DB clusters for your global databases by using the same version of the Aurora DB engine as the primary. For more information, see [Creating an Amazon Aurora global database](#).

## Getting started with Amazon Aurora Global Database

To get started with Aurora Global Database, first decide which Aurora DB engine you want to use and in which Amazon Web Services Regions. Only specific versions of the Aurora MySQL and Aurora PostgreSQL database engines in certain Amazon Web Services Regions support Aurora Global Database. For the complete list, see [Supported Regions and DB engines for Aurora global databases](#).

You can create an Aurora Global Database in one of the following ways:

- **Create a new Aurora Global Database with new Aurora DB clusters and Aurora DB instances** – You can do this by following the steps in [Creating an Amazon Aurora global database](#). After you create the primary Aurora DB cluster, you then add the secondary Amazon Web Services Region by following the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

- **Use an existing Aurora DB cluster that supports the Aurora Global Database feature and add an Amazon Web Services Region to it** – You can do this only if your existing Aurora DB cluster uses a DB engine version that is global-compatible.

Check whether you can choose **Add region** for **Action** on the Amazon Web Services Management Console when your Aurora DB cluster is selected. If you can, you can use that Aurora DB cluster for your Aurora global cluster. For more information, see [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

Before creating an Aurora Global Database, we recommend that you understand all configuration requirements.

### Topics

- [Configuration requirements of an Amazon Aurora global database](#)
- [Creating an Amazon Aurora global database](#)
- [Adding an Amazon Web Services Region to an Amazon Aurora global database](#)
- [Creating a headless Aurora DB cluster in a secondary Region](#)
- [Creating an Amazon Aurora global database from an Aurora or Amazon RDS snapshot](#)

## Configuration requirements of an Amazon Aurora global database

Before you start working with your global database, plan the cluster and instance names, Amazon Regions, number of instances and instance classes that you intend to use. Make sure that your choices agree with the following configuration requirements.

An Aurora global database spans at least two Amazon Web Services Regions. The primary Amazon Web Services Region supports an Aurora DB cluster that has one writer Aurora DB instance. A secondary Amazon Web Services Region runs a read-only Aurora DB cluster made up entirely of Aurora Replicas. At least one secondary Amazon Web Services Region is required, but an Aurora global database can have up to 10 secondary Amazon Web Services Regions. The table lists the maximum Aurora DB clusters, Aurora DB instances, and Aurora Replicas allowed in an Aurora global database.

Description	Primary Amazon Web Services Region	Secondary Amazon Web Services Regions
Aurora DB clusters	1	10 (maximum)
Writer instances	1	0
Read-only instances (Aurora replicas), per Aurora DB cluster	15 (max)	16 (total)
Read-only instances (max allowed, given actual number of secondary Regions)	15 - s	s = total number of secondary Amazon Web Services Regions

The Aurora DB clusters that make up an Aurora global database have the following specific requirements:

- **DB instance class requirements** – An Aurora global database requires DB instance classes that are optimized for memory-intensive applications. For information about the memory optimized DB instance classes, see [DB instance class types](#). We recommend that you use a db.r5 or higher instance class.
- **Amazon Web Services Region requirements** – An Aurora global database needs a primary Aurora DB cluster in one Amazon Web Services Region, and at least one secondary Aurora DB cluster in a different Region. You can create up to 10 secondary (read-only) Aurora DB clusters, and each must be in a different Region. In other words, no two Aurora DB clusters in an Aurora global database can be in the same Amazon Web Services Region.

For information about which combinations of Aurora DB engine, engine version, and Amazon Web Services Region you can use with Aurora Global Database, see [Supported Regions and DB engines for Aurora global databases](#).

- **Naming requirements** – The names you choose for each of your Aurora DB clusters must be unique, across all Amazon Web Services Regions. You can't use the same name for different Aurora DB clusters even though they're in different Regions.
- **Capacity requirements for Aurora Serverless v2** – For a global database with Aurora Serverless v2, the [minimum recommended capacity](#) for the DB cluster in the primary Amazon Web Services Region is 8 ACUs.

Before you can follow the procedures in this section, you need an Amazon Web Services account. Complete the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster](#).

When you are ready to set up your global database, see [Creating an Amazon Aurora global database](#) for the procedure to create all the necessary resources. You can also follow the procedure in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#) to create a global database using an existing Aurora cluster as the primary cluster.

## Creating an Amazon Aurora global database

To create an Aurora global database and its associated resources by using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API, use the following steps.

### Note

If you have an existing Aurora DB cluster running an Aurora database engine that's global-compatible, you can use a shorter form of this procedure. In that case, you can add another Amazon Web Services Region to the existing DB cluster to create your Aurora global database. To do so, see [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

### Console

The steps for creating an Aurora global database begin by signing in to an Amazon Web Services Region that supports the Aurora global database feature. For a complete list, see [Supported Regions and DB engines for Aurora global databases](#).

One of the following steps is choosing a virtual private cloud (VPC) based on Amazon VPC for your Aurora DB cluster. To use your own VPC, we recommend that you create it in advance so it's available for you to choose. At the same time, create any related subnets, and as needed a subnet group and security group. To learn how, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

For general information about creating an Aurora DB cluster, see [Creating an Amazon Aurora DB cluster](#).

## To create an Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Create database**. On the **Create database** page, do the following:
  - For the database creation method, choose **Standard create**. (Don't choose Easy create.)
  - For Engine type in the **Engine options** section, choose the applicable engine type, **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.
3. Continue creating your Aurora global database by using the steps from the following procedures.

## Creating a global database using Aurora MySQL

The following steps apply to all versions of Aurora MySQL.

### To create an Aurora global database using Aurora MySQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:
  - For **Engine version**, choose the version of Aurora MySQL that you want to use for your Aurora global database.
2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate for your use case. Don't use Dev/Test in production environments.
3. For **Settings**, do the following:
  - a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.
  - b. Enter your own password for the admin user account for the DB instance, or have Aurora generate one for you. If you choose to autogenerate a password, you get an option to copy the password.

### Settings

**DB cluster identifier** [Info](#)  
Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your   account in the current   Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

---

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

1 to 32 alphanumeric characters. First character must be a letter.

**Manage master credentials in**   **Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

ⓘ If you manage the master user credentials in Secrets Manager, some RDS features aren't supported.  
[Learn more](#) ↗

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

**Confirm master password** [Info](#)

4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.
5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different Availability Zone (AZ) for you. If you don't create an Aurora Replica now, you need to do it later.

### Availability & durability

**Multi-AZ deployment** [Info](#)

Don't create an Aurora Replica

**Create an Aurora Replica or Reader node in a different AZ (recommended for scaled availability)**  
Creates an Aurora Replica for fast failover and high availability.

6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

7. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up Amazon Identity and Access Management (IAM) later.
8. For **Additional configuration**, do the following:
  - a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

- b. Clear the **Enable backtrack** check box if it's selected. Aurora global databases don't support backtracking. Otherwise, accept the other default settings for **Additional configuration**.
9. Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

DB identifier	Role	Engine	Region & AZ	Size	Status
lab-demo-db-cluster	Regional	Aurora PostgreSQL	us-west-1	1 instance	Available
lab-west-db-cluster	Regional	Aurora MySQL	us-west-1	2 instances	Available
lab-west-db-cluster-instance-1	Writer	Aurora MySQL	us-west-1b	db.r4.large	Available
lab-west-db-cluster-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r4.large	Available

When your primary DB cluster is available, create the Aurora global database by adding a secondary cluster to it. To do this, follow the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

## Creating a global database using Aurora PostgreSQL

### To create an Aurora global database using Aurora PostgreSQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:
  - For **Engine version**, choose the version of Aurora PostgreSQL that you want to use for your Aurora global database.
2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate. Don't use Dev/Test in production environments.
3. For **Settings**, do the following:
  - a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.
  - b. Enter your own password for the default admin account for the DB cluster, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.

## Settings

---

**DB cluster identifier** [Info](#)  
Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your   account in the current   Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

---

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in**   **Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

ⓘ If you manage the master user credentials in Secrets Manager, some RDS features aren't supported.  
[Learn more](#) ↗

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

**Confirm master password** [Info](#)

4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.
5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
7. (Optional) Complete the **Database authentication** settings. Password authentication is always enabled. To simplify the process, you can skip this section and set up IAM or password and Kerberos authentication later.
8. For **Additional configuration**, do the following:

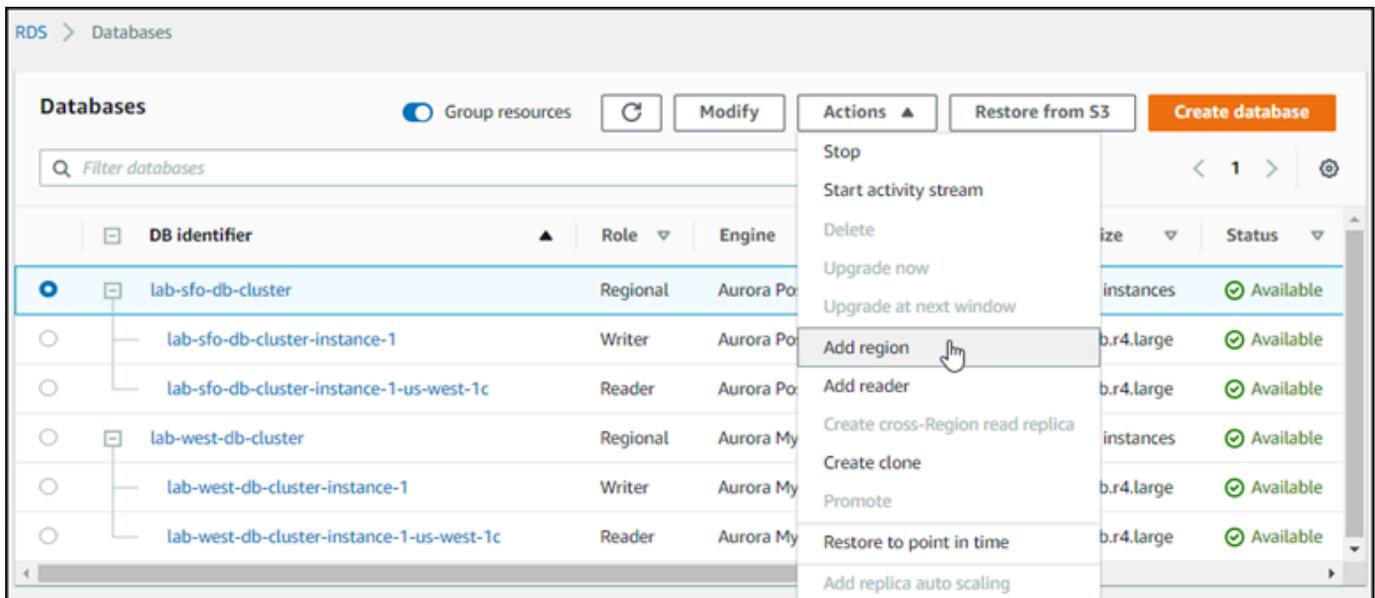

- a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

- b. Accept all other default settings for **Additional configuration**, such as Encryption, Log exports, and so on.

## 9. Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. When the cluster is ready to use, the Aurora DB cluster and its writer and replica nodes display **Available** status. This becomes the primary DB cluster of your Aurora global database, after you add a secondary.

When your primary DB cluster is available, create one or more secondary clusters by following the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

## Amazon CLI

The Amazon CLI commands in the procedures following accomplish the following tasks:

1. Create an Aurora global database, giving it a name and specifying the Aurora database engine type that you plan to use.
2. Create an Aurora DB cluster for the Aurora global database.

3. Create the Aurora DB instance for the cluster. This is the primary Aurora DB cluster for the global database.
4. Create a second DB instance for Aurora DB cluster. This is a reader to complete the Aurora DB cluster.
5. Create a second Aurora DB cluster in another Region and then add it to your Aurora global database, by following the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

Follow the procedure for your Aurora database engine.

## Creating a global database using Aurora MySQL

### To create an Aurora global database using Aurora MySQL

1. Use the [create-global-cluster](#) CLI command, passing the name of the Amazon Web Services Region, Aurora database engine, and version.

For Linux, macOS, or Unix:

```
aws rds create-global-cluster --region primary_region \  
  --global-cluster-identifier global_database_id \  
  --engine aurora-mysql \  
  --engine-version version # optional
```

For Windows:

```
aws rds create-global-cluster ^  
  --global-cluster-identifier global_database_id ^  
  --engine aurora-mysql ^  
  --engine-version version # optional
```

This creates an "empty" Aurora global database, with just a name (identifier) and Aurora database engine. It can take a few minutes for the Aurora global database to be available. Before going to the next step, use the [describe-global-clusters](#) CLI command to see if it's available.

```
aws rds describe-global-clusters --region primary_region --global-cluster-  
  identifier global_database_id
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the [create-db-cluster](#) CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --region primary_region \  
  --db-cluster-identifier primary_db_cluster_id \  
  --master-username userid \  
  --master-user-password password \  
  --engine aurora-mysql \  
  --engine-version version \  
  --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^  
  --region primary_region ^  
  --db-cluster-identifier primary_db_cluster_id ^  
  --master-username userid ^  
  --master-user-password password ^  
  --engine aurora-mysql ^  
  --engine-version version ^  
  --global-cluster-identifier global_database_id
```

Use the [describe-db-clusters](#) Amazon CLI command to confirm that the Aurora DB cluster is ready. To single out a specific Aurora DB cluster, use `--db-cluster-identifier` parameter. Or you can leave out the Aurora DB cluster name in the command to get details about all your Aurora DB clusters in the given Region.

```
aws rds describe-db-clusters --region primary_region --db-cluster-  
  identifier primary_db_cluster_id
```

When the response shows "Status": "available" for the cluster, it's ready to use.

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the [create-db-instance](#) CLI command. Give the command your Aurora DB cluster's name, and specify the

configuration details for the instance. You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see [DB instance class types](#).

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-cluster-identifier primary_db_cluster_id \  
  --db-instance-class instance_class \  
  --db-instance-identifier db_instance_id \  
  --engine aurora-mysql \  
  --engine-version version \  
  --region primary_region
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier primary_db_cluster_id ^  
  --db-instance-class instance_class ^  
  --db-instance-identifier db_instance_id ^  
  --engine aurora-mysql ^  
  --engine-version version ^  
  --region primary_region
```

The `create-db-instance` operation might take some time to complete. Check the status to see if the Aurora DB instance is available before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```

When the command returns a status of `available`, you can create another Aurora DB instance for your primary DB cluster. This is the reader instance (the Aurora Replica) for the Aurora DB cluster.

4. To create another Aurora DB instance for the cluster, use the [create-db-instance](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-cluster-identifier primary_db_cluster_id \  
  --db-instance-class instance_class \  
  --db-instance-identifier replica_db_instance_id \  
  --engine aurora-mysql
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier primary_db_cluster_id ^  
  --db-instance-class instance_class ^  
  --db-instance-identifier replica_db_instance_id ^  
  --engine aurora-mysql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the [describe-db-instances](#) CLI command.

At this point, you have an Aurora global database with its primary Aurora DB cluster containing a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

### Creating a global database using Aurora PostgreSQL

When you create Aurora objects for an Aurora global database by using the following commands, it can take a few minutes for each to become available. We recommend that after completing any given command, you check the specific Aurora object's status to make sure that the status is available.

To do so, use the [describe-global-clusters](#) CLI command.

```
aws rds describe-global-clusters --region primary_region  
  --global-cluster-identifier global_database_id
```

## To create an Aurora global database using Aurora PostgreSQL

1. Use the [create-global-cluster](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-global-cluster --region primary_region \  
  --global-cluster-identifier global_database_id \  
  --engine aurora-postgresql \  
  --engine-version version # optional
```

For Windows:

```
aws rds create-global-cluster ^  
  --global-cluster-identifier global_database_id ^  
  --engine aurora-postgresql ^  
  --engine-version version # optional
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the [create-db-cluster](#) CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier` parameter.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --region primary_region \  
  --db-cluster-identifier primary_db_cluster_id \  
  --master-username userid \  
  --master-user-password password \  
  --engine aurora-postgresql \  
  --engine-version version \  
  --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^  
  --region primary_region ^  
  --db-cluster-identifier primary_db_cluster_id ^  
  --master-username userid ^
```

```
--master-user-password password ^  
--engine aurora-postgresql ^  
--engine-version version ^  
--global-cluster-identifier global_database_id
```

Check that the Aurora DB cluster is ready. When the response from the following command shows "Status": "available" for the Aurora DB cluster, you can continue.

```
aws rds describe-db-clusters --region primary_region --db-cluster-  
identifier primary_db_cluster_id
```

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the [create-db-instance](#) CLI command.

Pass the name of your Aurora DB cluster with the `--db-cluster-identifier` parameter.

You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see [DB instance class types](#).

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
--db-cluster-identifier primary_db_cluster_id \  
--db-instance-class instance_class \  
--db-instance-identifier db_instance_id \  
--engine aurora-postgresql \  
--engine-version version \  
--region primary_region
```

For Windows:

```
aws rds create-db-instance ^  
--db-cluster-identifier primary_db_cluster_id ^  
--db-instance-class instance_class ^  
--db-instance-identifier db_instance_id ^  
--engine aurora-postgresql ^  
--engine-version version ^
```

```
--region primary_region
```

4. Check the status of the Aurora DB instance before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier primary_db_cluster_id
```

If the response shows that Aurora DB instance status is available, you can create another Aurora DB instance for your primary DB cluster.

5. To create an Aurora Replica for Aurora DB cluster, use the [create-db-instance](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-cluster-identifier primary_db_cluster_id \  
  --db-instance-class instance_class \  
  --db-instance-identifier replica_db_instance_id \  
  --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^  
  --db-cluster-identifier primary_db_cluster_id ^  
  --db-instance-class instance_class ^  
  --db-instance-identifier replica_db_instance_id ^  
  --engine aurora-postgresql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the [describe-db-instances](#) CLI command.

Your Aurora global database exists, but it has only its primary Region with an Aurora DB cluster made up of a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

## RDS API

To create an Aurora global database with the RDS API, run the [CreateGlobalCluster](#) operation.

## Adding an Amazon Web Services Region to an Amazon Aurora global database

You can use the following procedure to add an additional secondary cluster to an existing global database. You can also create a global database from a standalone Aurora DB cluster by using this procedure to add the first secondary Amazon Region.

An Aurora global database needs at least one secondary Aurora DB cluster in a different Amazon Web Services Region than the primary Aurora DB cluster. You can attach up to 10 secondary DB clusters to your Aurora global database. Repeat the following procedure for each new secondary DB cluster. For each secondary DB cluster that you add to your Aurora global database, reduce the number of Aurora Replicas allowed to the primary DB cluster by one.

For example, if your Aurora global database has 10 secondary Regions, your primary DB cluster can have only 5 (rather than 15) Aurora Replicas. For more information, see [Configuration requirements of an Amazon Aurora global database](#).

The number of Aurora Replicas (reader instances) in the primary DB cluster determines the number of secondary DB clusters you can add. The total number of reader instances in the primary DB cluster plus the number of secondary clusters can't exceed 15. For example, if you have 14 reader instances in the primary DB cluster and 1 secondary cluster, you can't add another secondary cluster to the global database.

### Note

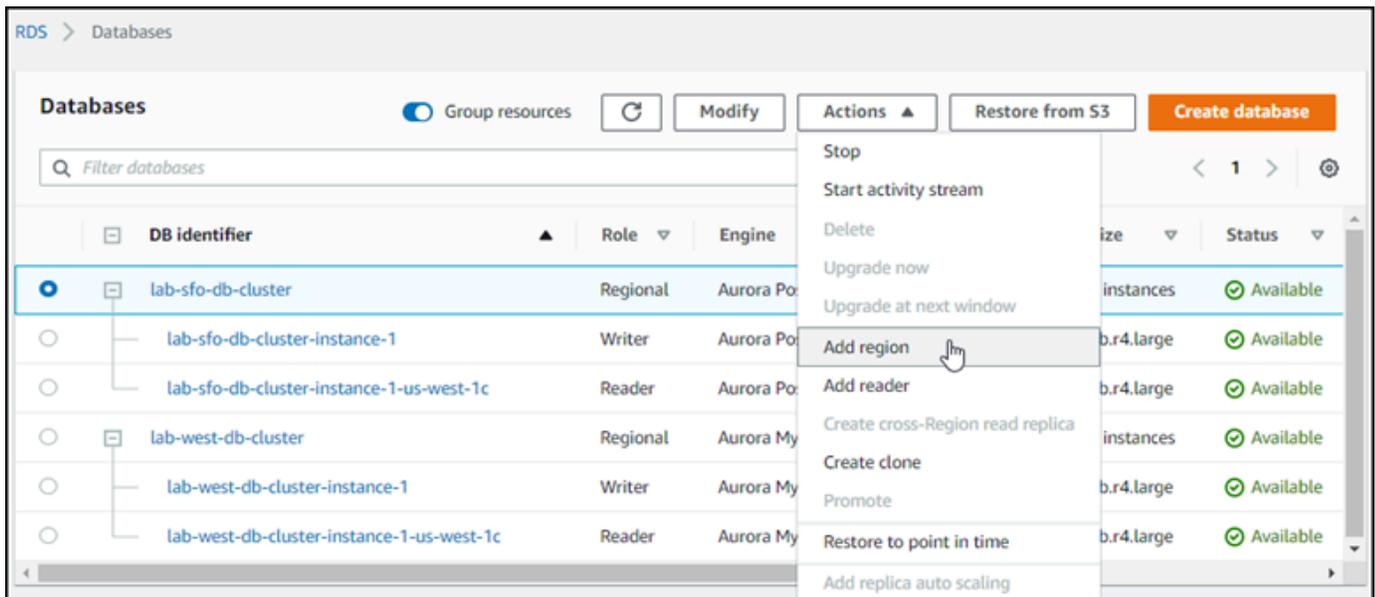

For Aurora MySQL version 3, when you create a secondary cluster, make sure that the value of `lower_case_table_names` matches the value in the primary cluster. This setting is a database parameter that affects how the server handles identifier case sensitivity. For more information about database parameters, see [Parameter groups for Amazon Aurora](#).

We recommend that when you create a secondary cluster, you use the same DB engine version for the primary and secondary. If necessary, upgrade the primary to be the same version as the secondary. For more information, see [Patch level compatibility for managed cross-Region switchovers and failovers](#).

## Console

### To add an Amazon Web Services Region to an Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane of the Amazon Web Services Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For **Actions**, choose **Add Amazon Region**.

5. On the **Add a region** page, choose the secondary Amazon Web Services Region.

You can't choose an Amazon Web Services Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

#### **Note**

Babelfish for Aurora PostgreSQL global databases works in secondary regions only if the parameters that control Babelfish preferences are turned on in those regions. For more information, see [DB cluster parameter group settings for Babelfish](#)

RDS > Databases

## Add a region

You are creating a global database and adding a secondary region within it. Secondary regions can serve low latency reads. In the unlikely event your database becomes degraded or isolated in the primary region, you can promote your secondary region.

### Global database settings

**Global database identifier**  
Enter a name for your global database. The name must be unique across all global databases in your account.

lab-east-west-global

The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

### Region

**Secondary region**

US East (N. Virginia)

- Complete the remaining fields for the secondary Aurora cluster in the new Amazon Region. These are the same configuration options as for any Aurora DB cluster instance, except for the following option for Aurora MySQL–based Aurora global databases only:
  - Enable read replica write forwarding – This optional setting let's your Aurora global database's secondary DB clusters forward write operations to the primary cluster. For more information, see [Using write forwarding in an Amazon Aurora global database](#).

### Read replica write forwarding

Issue cross-Region writes from secondary Region locations. [Info](#)

Enable read replica write forwarding

- Choose **Add Amazon Region**.

After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the Amazon Web Services Management Console as shown in the screenshot.

DB identifier	Role	Engine	Region & AZ	Size	Status
lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters	Available
lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	Available
lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	Available
lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	Available
lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	Available
lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large	Available
lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	Available

## Amazon CLI

### To add a secondary Amazon Web Services Region to an Aurora global database

To add a secondary cluster to your global database using the CLI, you must already have the global cluster container object. If you haven't already run the `create-global-cluster` command, see the CLI procedure in [Creating an Amazon Aurora global database](#).

1. Use the `create-db-cluster` CLI command with the name (`--global-cluster-identifier`) of your Aurora global database. For other parameters, do the following:
2. For `--region`, choose a different Amazon Web Services Region than that of your Aurora primary Region.
3. Choose specific values for the `--engine` and `--engine-version` parameters. These values are the same as those for the primary Aurora DB cluster in your Aurora global database.
4. For an encrypted cluster, specify your primary Amazon Web Services Region as the `--source-region` for encryption.

The following example creates a new Aurora DB cluster and attaches it to an Aurora global database as a read-only secondary Aurora DB cluster. In the last step, an Aurora DB instance is added to the new Aurora DB cluster.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \  
  create-db-cluster \  
    --db-cluster-identifier secondary_cluster_id \  
    --global-cluster-identifier global_database_id \  
    --engine aurora-mysql | aurora-postgresql \  
    --engine-version version  
  
aws rds --region secondary_region \  
  create-db-instance \  
    --db-instance-class instance_class \  
    --db-cluster-identifier secondary_cluster_id \  
    --db-instance-identifier db_instance_id \  
    --engine aurora-mysql | aurora-postgresql
```

For Windows:

```
aws rds --region secondary_region ^  
  create-db-cluster ^  
    --db-cluster-identifier secondary_cluster_id ^  
    --global-cluster-identifier global_database_id_id ^  
    --engine aurora-mysql | aurora-postgresql ^  
    --engine-version version  
  
aws rds --region secondary_region ^  
  create-db-instance ^  
    --db-instance-class instance_class ^  
    --db-cluster-identifier secondary_cluster_id ^  
    --db-instance-identifier db_instance_id ^  
    --engine aurora-mysql | aurora-postgresql
```

## RDS API

To add a new Amazon Web Services Region to an Aurora global database with the RDS API, run the [CreateDBCluster](#) operation. Specify the identifier of the existing global database using the `GlobalClusterIdentifier` parameter.

## Creating a headless Aurora DB cluster in a secondary Region

Although an Aurora global database requires at least one secondary Aurora DB cluster in a different Amazon Web Services Region than the primary, you can use a *headless* configuration for the secondary cluster. A headless secondary Aurora DB cluster is one without a DB instance. This

type of configuration can lower expenses for an Aurora global database. In an Aurora DB cluster, compute and storage are decoupled. Without the DB instance, you're not charged for compute, only for storage. If it's set up correctly, a headless secondary's storage volume is kept in-sync with the primary Aurora DB cluster.

You add the secondary cluster as you normally do when creating an Aurora global database. If you are creating all the clusters in the global database, follow the procedure in [Creating an Amazon Aurora global database](#). If you already have a DB cluster to use as the primary cluster, follow the procedure in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

After the primary Aurora DB cluster begins replication to the secondary, you delete the Aurora read-only DB instance from the secondary Aurora DB cluster. This secondary cluster is now considered "headless" because it no longer has a DB instance. Even without any DB instance in the secondary cluster, Aurora keeps the storage volume in sync with the primary Aurora DB cluster.

#### **Warning**

With Aurora PostgreSQL, to create a headless cluster in a secondary Amazon Web Services Region, use the Amazon CLI or RDS API to add the secondary Amazon Web Services Region. Skip the step to create the reader DB instance for the secondary cluster. Currently, creating a headless cluster isn't supported in the RDS Console. For the CLI and API procedures to use, see [Adding an Amazon Web Services Region to an Amazon Aurora global database](#). If your global database is using an Aurora PostgreSQL engine version lower than 13.4, 12.8, or 11.13, creating a reader DB instance in a secondary Region and subsequently deleting it could lead to an Aurora PostgreSQL vacuum issue on the primary Region's writer DB instance. If you encounter this issue, restart the primary Region's writer DB instance after you delete the secondary Region's reader DB instance.

### To add a headless secondary Aurora DB cluster to your Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane of the Amazon Web Services Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For **Actions**, choose **Add Amazon Region**.

5. On the **Add a region** page, choose the secondary Amazon Web Services Region.

You can't choose an Amazon Web Services Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

6. Complete the remaining fields for the secondary Aurora cluster in the new Amazon Web Services Region. These are the same configuration options as for any Aurora DB cluster instance.

For an Aurora MySQL–based Aurora global database, disregard the **Enable read replica write forwarding** option. This option has no function after you delete the reader instance.

7. Choose **Add Amazon Region**. After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the Amazon Web Services Management Console as shown in the screenshot.

DB identifier	Role	Engine	Region & AZ	Size	Status	CPU	Current
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available	-	
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available	-	
ams57west-instance-1	Writer	Aurora MySQL	us-west-1b	db.r5.large	Available	-	
ams57west-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r5.large	Available	-	
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	1 instance	Available	-	
west-coast-global-instance-1	Reader	Aurora MySQL	us-west-2a	db.r5.large	Available	5.00%	

8. Check the status of the secondary Aurora DB cluster and its reader instance before continuing, by using the Amazon Web Services Management Console or the Amazon CLI. For example:

```
$ aws rds describe-db-clusters --db-cluster-identifier secondary-cluster-id --query '*[].[Status]' --output text
```

It can take several minutes for the status of a newly added secondary Aurora DB cluster to change from `creating` to `available`. When the Aurora DB cluster is available, you can delete the reader instance.

9. Select the reader instance in the secondary Aurora DB cluster, and then choose **Delete**.

DB identifier	Role	Engine	Region & AZ	Size	Status	CPU
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available	-
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available	-
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	1 instance	Available	-
west-coast-global-instance-1	Reader	Aurora MySQL	us-west-2a	db.r5.large	Available	5.00%

After deleting the reader instance, the secondary cluster remains part of the Aurora global database. It has no instance associated with it, as shown following.

DB identifier	Role	Engine	Region & AZ	Size	Status	CPU
apg119cluster	Regional	Aurora PostgreSQL	us-west-1	2 instances	Available	-
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available	-
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available	-
ams57west-instance-1	Writer	Aurora MySQL	us-west-1b	db.r5.large	Available	7.00%
ams57west-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r5.large	Available	5.00%
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	0 instances	Available	-

You can use this headless secondary Aurora DB cluster to [manually recover your Amazon Aurora global database from an unplanned outage in the primary Amazon Web Services Region](#) if such an outage occurs.

## Creating an Amazon Aurora global database from an Aurora or Amazon RDS snapshot

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora provisioned DB cluster at the same time. You then add another Amazon Web Services Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.

The snapshot that you use can be from a provisioned or from a serverless Aurora DB cluster.

During the restore process, choose the same DB engine type as the snapshot. For example, suppose that you want to restore a snapshot that was made from an Aurora Serverless DB cluster running Aurora PostgreSQL. In this case, you create an Aurora PostgreSQL DB cluster using that same Aurora DB engine and version.

The restored DB cluster assumes the role of primary cluster for the Aurora global database when you add an Amazon Web Services Region to it. All data contained in this primary cluster is replicated to any secondary clusters that you add to your Aurora global database.

## Restore snapshot

You are creating a new DB instance or DB cluster from a snapshot. The default VPC security group and parameter group are selected for the new DB instance or DB cluster, but you can change these settings.

### DB instance settings

Show versions that support the parallel query feature

Available versions (2/0)

Aurora (MySQL 5.7) 2.11.1

To see more versions, modify the capacity types. [Info](#)

**⚠** Parallel query is off by default. To enable it, use a DB instance parameter group with the `aurora_parallel_query` parameter enabled. [Learn more](#)

## Managing an Amazon Aurora global database

You perform most management operations on the individual clusters that make up an Aurora global database. When you choose **Group related resources** on the **Databases** page in the console,

you see the primary cluster and secondary clusters grouped under the associated global database. To find the Amazon Web Services Regions where a global database's DB clusters are running, its Aurora DB engine and version, and its identifier, use its **Configuration** tab.

The cross-Region database failover processes are available to Aurora global databases only, not for a single Aurora DB cluster. To learn more, see [Using switchover or failover in Amazon Aurora Global Database](#).

To recover an Aurora global database from an unplanned outage in its primary Region, see [Recovering an Amazon Aurora global database from an unplanned outage](#).

## Topics

- [Modifying parameters for an Aurora global database](#)
- [Removing a cluster from an Amazon Aurora global database](#)
- [Deleting an Amazon Aurora global database](#)
- [Tagging Amazon Aurora Global Database resources](#)

## Modifying an Amazon Aurora global database

The **Databases** page in the Amazon Web Services Management Console lists all your Aurora global databases, showing the primary cluster and secondary clusters for each one. The Aurora global database has its own configuration settings. Specifically, it has Amazon Web Services Regions associated with its primary and secondary clusters, as shown in the screenshot following.

RDS > Databases > lab-east-west-global

## lab-east-west-global

Modify Actions

### Related

Filter databases

DB identifier	Role	Engine	Region & AZ	Size	Status
lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters	Available
lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	Available
lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	Available
lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	Available
lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	Available

### Configuration

#### Instance

Configuration	Availability	Regions
Engine Aurora PostgreSQL	Encryption Enabled	us-west-1 (N. California) us-east-1 (N. Virginia)
Engine version 11.7		
Global database identifier lab-east-west-global		

When you make changes to the Aurora global database, you have a chance to cancel changes, as shown in the following screenshot.

The screenshot shows the AWS Management Console interface for modifying a global database. The breadcrumb navigation at the top reads 'RDS > Databases > Modify global database'. The main heading is 'Modify global database: lab-east-west-global'. Below this, there are two main sections: 'Settings' and 'Additional configuration'. In the 'Settings' section, the 'Global database identifier' is set to 'lab-east-west-global-database-01'. A text box below the identifier provides constraints: 'The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.' The 'Additional configuration' section shows 'Encryption' with the instruction 'Configure encryption keys by modifying member DB clusters.' At the bottom right, there are two buttons: 'Cancel' and 'Continue'.

When you choose **Continue**, you confirm the changes.

## Modifying parameters for an Aurora global database

You can configure the Aurora DB cluster parameter groups independently for each Aurora cluster within the Aurora global database. Most parameters work the same as for other kinds of Aurora clusters. We recommend that you keep settings consistent among all the clusters in a global database. Doing this helps to avoid unexpected behavior changes if you promote a secondary cluster to be the primary.

For example, use the same settings for time zones and character sets to avoid inconsistent behavior if a different cluster takes over as the primary cluster.

The `aurora_enable_repl_bin_log_filtering` and `aurora_enable_replica_log_compression` configuration settings have no effect.

## Removing a cluster from an Amazon Aurora global database

You can remove Aurora DB clusters from your Aurora global database for several different reasons. For example, you might want to remove an Aurora DB cluster from an Aurora global database

if the primary cluster becomes degraded or isolated. It then becomes a standalone provisioned Aurora DB cluster that could be used to create a new Aurora global database. To learn more, see [Recovering an Amazon Aurora global database from an unplanned outage](#).

You also might want to remove Aurora DB clusters because you want to delete an Aurora global database that you no longer need. You can't delete the Aurora global database until after you remove (detach) all associated Aurora DB clusters, leaving the primary for last. For more information, see [Deleting an Amazon Aurora global database](#).

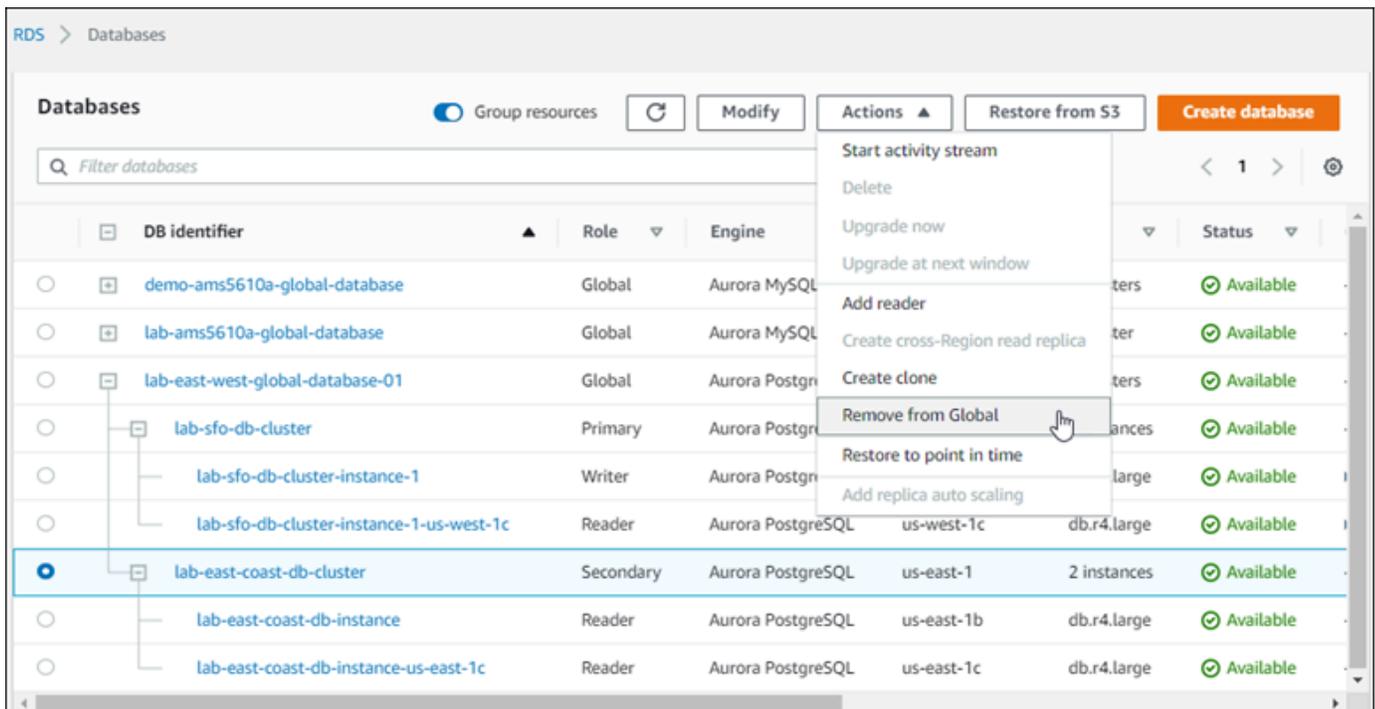

When an Aurora DB cluster is detached from the Aurora global database, it's no longer synchronized with the primary. It becomes a standalone provisioned Aurora DB cluster with full read/write capabilities.

You can remove Aurora DB clusters from your Aurora global database using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

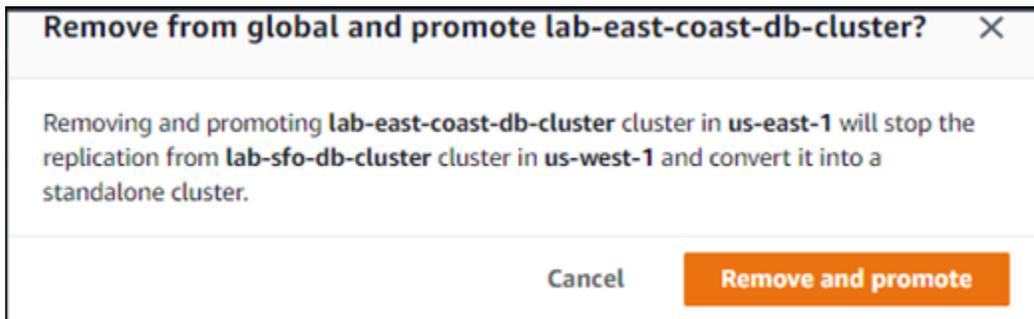

## Console

### To remove an Aurora cluster from an Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose the cluster on the **Databases** page.
3. For **Actions**, choose **Remove from Global**.

You see a prompt to confirm that you want to detach the secondary from the Aurora global database.

4. Choose **Remove and promote** to remove the cluster from the global database.

The Aurora DB cluster is no longer serving as a secondary in the Aurora global database, and is no longer synchronized with the primary DB cluster. It is a standalone Aurora DB cluster with full read/write capability.

<input type="radio"/>	<input type="checkbox"/>	lab-east-coast-db-cluster	Regional	Aurora PostgreSQL	us-east-1	2 instances	<input checked="" type="checkbox"/> Available
<input type="radio"/>		lab-east-coast-db-instance	Writer	Aurora PostgreSQL	us-east-1b	db.r4.large	<input checked="" type="checkbox"/> Available
<input type="radio"/>		lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	<input checked="" type="checkbox"/> Available
<input type="radio"/>	<input type="checkbox"/>	lab-east-west-global-database-01	Global	Aurora PostgreSQL	1 region	1 cluster	<input checked="" type="checkbox"/> Available
<input type="radio"/>	<input type="checkbox"/>	lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	<input checked="" type="checkbox"/> Available
<input type="radio"/>		lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	<input checked="" type="checkbox"/> Available
<input type="radio"/>		lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	<input checked="" type="checkbox"/> Available

After you remove or delete all secondary clusters, then you can remove the primary cluster the same way. You can't detach (remove) the primary Aurora DB cluster from an Aurora global database until after you remove all secondary clusters.

The Aurora global database might remain in the **Databases** list, with zero Regions and AZs. You can delete if you no longer want to use this Aurora global database. For more information, see [Deleting an Amazon Aurora global database](#).

## Amazon CLI

To remove an Aurora cluster from an Aurora global database, run the [remove-from-global-cluster](#) CLI command with the following parameters:

- `--global-cluster-identifier` – The name (identifier) of your Aurora global database.
- `--db-cluster-identifier` – The name of each Aurora DB cluster to remove from the Aurora global database. Remove all secondary Aurora DB clusters before removing the primary.

The following examples first remove a secondary cluster and then the primary cluster from an Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
  remove-from-global-cluster \
    --db-cluster-identifier secondary_cluster_ARN \
    --global-cluster-identifier global_database_id

aws rds --region primary_region \
  remove-from-global-cluster \
    --db-cluster-identifier primary_cluster_ARN \
    --global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary Amazon Web Services Region in your Aurora global database.

For Windows:

```
aws rds --region secondary_region ^
  remove-from-global-cluster ^
    --db-cluster-identifier secondary_cluster_ARN ^
    --global-cluster-identifier global_database_id

aws rds --region primary_region ^
  remove-from-global-cluster ^
    --db-cluster-identifier primary_cluster_ARN ^
    --global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary Amazon Web Services Region in your Aurora global database.

## RDS API

To remove an Aurora cluster from an Aurora global database with the RDS API, run the [RemoveFromGlobalCluster](#) action.

## Deleting an Amazon Aurora global database

Because an Aurora global database typically holds business-critical data, you can't delete the global database and its associated clusters in a single step. To delete an Aurora global database, do the following:

- Remove all secondary DB clusters from the Aurora global database. Each cluster becomes a standalone Aurora DB cluster. To learn how, see [Removing a cluster from an Amazon Aurora global database](#).
- From each standalone Aurora DB cluster, delete all Aurora Replicas.
- Remove the primary DB cluster from the Aurora global database. This becomes a standalone Aurora DB cluster.
- From the Aurora primary DB cluster, first delete all Aurora Replicas, then delete the writer DB instance.

Deleting the writer instance from the newly standalone Aurora DB cluster also typically removes the Aurora DB cluster and the Aurora global database.

For more general information, see [Deleting a DB instance from an Aurora DB cluster](#).

To delete an Aurora global database, you can use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

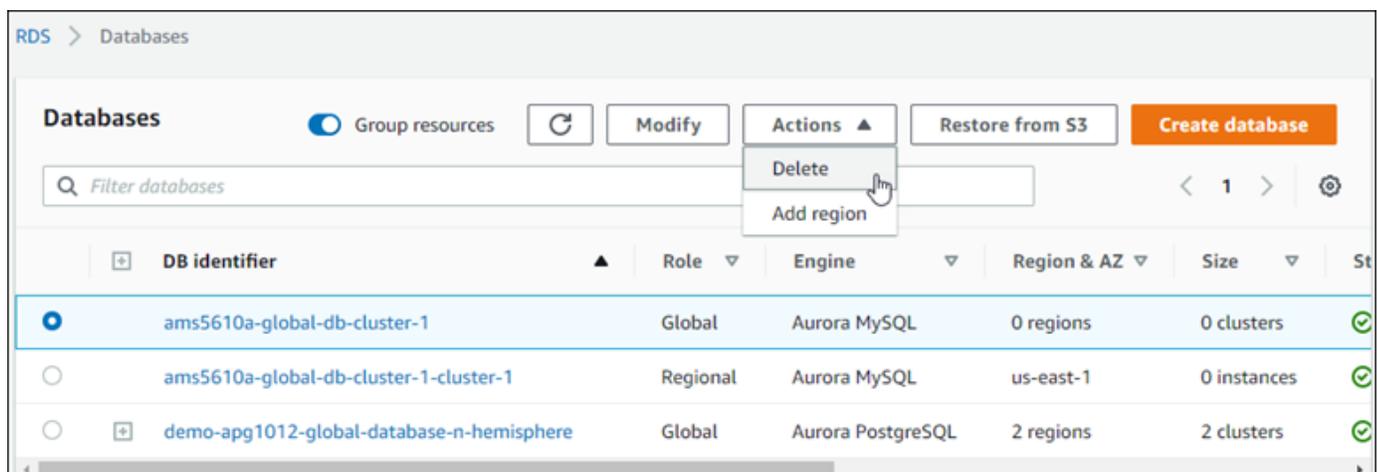

## Console

### To delete an Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** and find the Aurora global database you want to delete in the listing.
3. Confirm that all clusters are removed from the Aurora global database. The Aurora global database should show 0 Regions and AZs and a size of 0 clusters.

If the Aurora global database contains any Aurora DB clusters, you can't delete it. If necessary, detach the primary and secondary Aurora DB clusters from the Aurora global database. For more information, see [Removing a cluster from an Amazon Aurora global database](#).

4. Choose your Aurora global database in the list, and then choose **Delete** from the **Actions** menu.

## Amazon CLI

To delete an Aurora global database, run the [delete-global-cluster](#) CLI command with the name of the Amazon Web Services Region and the Aurora global database identifier, as shown in the following example.

For Linux, macOS, or Unix:

```
aws rds --region primary_region delete-global-cluster \  
--global-cluster-identifier global_database_id
```

For Windows:

```
aws rds --region primary_region delete-global-cluster ^  
--global-cluster-identifier global_database_id
```

## RDS API

To delete a cluster that is part of an Aurora global database, run the [DeleteGlobalCluster](#) API operation.

## Tagging Amazon Aurora Global Database resources

With the Aurora Global Database feature, you can apply RDS tags to resources at different levels within a global database. If you aren't familiar with how tags are used with Amazon or Aurora resources, see [Tagging Amazon Aurora and Amazon RDS resources](#) before applying tags within your global database.

### Note

Because Amazon processes tag data as part of its cost-reporting mechanisms, don't include any sensitive data or personally identifiable information (PII) in the tag names or values.

You can apply tags to the following kinds of resources within a global database:

- The container object for your entire global database. This resource is known as the global cluster.

After you create the global cluster by performing an **Add Amazon Region** operation in the console, you can add tags by using the details page for the global cluster. On the **Tags** tab within

the global cluster details page, you can add, remove, or modify tags and their associated values by choosing **Manage tags**.

With the Amazon CLI and RDS API, you can add tags to the global cluster at the same time you create it. You can also add, remove, or modify tags for an existing global cluster.

- The primary cluster. You use the same procedures for working with tags here as for standalone Aurora clusters. You can set up the tags before turning the original Aurora cluster into a global database. You can also add, remove, or modify tags and their associated values by choosing **Manage tags** on the **Tags** tab within the DB cluster details page.
- Any secondary clusters. You use the same procedures for working with tags here as for standalone Aurora clusters. You can set up the tags at the same time as you create a secondary Aurora cluster by using the **Add Amazon Region** action in the console. You can also add, remove, or modify tags and their associated values by choosing **Manage tags** on the **Tags** tab within the DB cluster details page.
- Individual DB instances within the primary or secondary clusters. You use the same procedures for working with tags here as for Aurora or RDS DB instances. You can set up the tags at the same time as you add a new DB instance to the Aurora cluster by using the **Add reader** action in the console. You can also add, remove, or modify tags and their associated values by choosing **Manage tags** on the **Tags** tab within the DB instance details page.

Here are some examples of the kinds of tags you might assign within a global database:

- You might add tags to the global cluster to record overall information about your application, such as anonymized identifiers representing owners and contacts within your organization. You might use tags to represent properties of the application that uses the global database.
- You might add tags to the primary cluster and secondary clusters to track costs for your application at the Amazon Region level. For details about that procedure, see [How Amazon billing works with tags in Amazon RDS](#).
- You might add tags to specific DB instances with the Aurora clusters to indicate their special purpose. For example, within the primary cluster, you might have a reader instance with a low failover priority that is used exclusively for report generation. A tag can distinguish this special-purpose DB instance from other instances that are dedicated to high availability within the primary cluster.
- You might use tags at all levels of your global database resources to control access through IAM policies. For more information, see [Controlling access to Amazon resources](#) in the *Amazon Identity and Access Management User Guide*.

**Tip**

In the Amazon Web Services Management Console, you add tags to the global cluster container as a separate step after you create it. If you want to avoid any time interval when the global cluster exists without access control tags, you can apply the tags during the `CreateGlobalCluster` operation by creating that resource through Amazon CLI, RDS API, or a Amazon CloudFormation template.

- You might use tags at the cluster level, or for the global cluster, to record information about quality assurance and testing of your application. For example, you might specify a tag on a DB cluster to record the last time you performed a switchover to that cluster. You might specify a tag on the global cluster to record the time of the last disaster recovery drill for the entire application.

## Amazon CLI examples of tagging for global databases

The following Amazon CLI examples show how you can specify and examine tags for all the types of Aurora resources in your global database.

You can specify tags for the global cluster container with the `create-global-cluster` command. The following example creates a global cluster and assigns two tags to it. The tags have keys `tag1` and `tag2`.

```
$ aws rds create-global-cluster --global-cluster-identifier my_global_cluster_id \
  --engine aurora-mysql --tags Key=tag1,Value=val1 Key=tag2,Value=val2
```

You can list the tags on the global cluster container with the `describe-global-clusters` command. When working with tags, you typically run this command first to retrieve the Amazon Resource Name (ARN) of the global cluster. You use the ARN as a parameter in subsequent commands for working with tags. The following command displays the tag information in the `TagList` attribute. It also shows the ARN, which is used as a parameter in the later examples.

```
$ aws rds describe-global-clusters --global-cluster-identifier my_global_cluster_id
{
  "GlobalClusters": [
    {
      "Status": "available",
      "Engine": "aurora-mysql",
```

```

    "GlobalClusterArn": "my_global_cluster_arn",
    ...
    "TagList": [
      {
        "Value": "val1",
        "Key": "tag1"
      },
      {
        "Value": "val2",
        "Key": "tag2"
      }
    ]
  }
]
}

```

You can add new tags with the `add-tags-to-resource` command. With this command, you specify the Amazon Resource Name (ARN) of the global cluster instead of its identifier. Adding a tag with the same name as an existing tag overwrites the value of that tag. If you include spaces or special characters in the tag values, quote the values as appropriate for your operating system or command shell. The following example modifies the tags of the global cluster from the previous example. Originally, the cluster had tags with keys `tag1` and `tag2`. After the command finishes, the global cluster has a new tag with key `tag3`, and the tag with key `tag1` has a different value.

```

$ aws rds add-tags-to-resource --resource-name my_global_cluster_arn \
  --tags Key=tag1,Value="new value for tag1" Key=tag3,Value="entirely new tag"

$ aws rds describe-global-clusters --global-cluster-identifier my_global_cluster_id
{
  "GlobalClusters": [
    {
      "Status": "available",
      "Engine": "aurora-mysql",
      ...
      "TagList": [
        {
          "Value": "new value for tag1",
          "Key": "tag1"
        },
        {
          "Value": "val2",
          "Key": "tag2"
        }
      ]
    }
  ]
}

```

```

    },
    {
      "Value": "entirely new tag",
      "Key": "tag3"
    }
  ]
}
]
}

```

You can delete a tag from the global cluster with the `remove-tags-from-resource` command. With this command, you specify only a set of tag keys, without any tag values. The following example modifies the tags of the global cluster from the previous example. Originally, the cluster had tags with keys `tag1`, `tag2`, and `tag3`. After the command finishes, only the tag with key `tag1` remains.

```

$ aws rds remove-tags-from-resource --resource-name my_global_cluster_arn --tag-keys
tag2 tag3

$ aws rds describe-global-clusters --global-cluster-identifier my_global_cluster_id
{
  "GlobalClusters": [
    {
      "Status": "available",
      "Engine": "aurora-mysql",
      ...
      "TagList": [
        {
          "Value": "new value for tag1",
          "Key": "tag1"
        }
      ]
    }
  ]
}

```

## Connecting to Amazon Aurora Global Database

Each Aurora Global Database comes with a writer endpoint that is automatically updated by Aurora to route requests to the current writer instance of the primary DB cluster. With the writer endpoint, you don't have to modify your connection string after you change the location of the

primary Region using the managed Aurora Global Database switchover and failover capabilities. To learn more about using the writer endpoint along with Aurora Global Database switchover and failover, see [Using switchover or failover in Amazon Aurora Global Database](#). For information about connecting to an Aurora Global Database with RDS Proxy, see [Using RDS Proxy with Aurora global databases](#).

## Topics

- [Choosing the endpoint that meets your application needs](#)
- [Viewing the endpoints of an Amazon Aurora global database](#)
- [Considerations with using Global writer endpoints](#)

## Choosing the endpoint that meets your application needs

Connecting to an Aurora Global Database depends on your need to read or write from the database and the Amazon Region you want to route your requests to. Here are a few typical use cases:

- **Routing requests to the writer instance:** Connect to the Aurora Global Database writer endpoint if you need to run data manipulation language (DML) and data definition language (DDL) statements, or if you need strong consistency between reads and writes. That endpoint routes requests to the writer instance in your global database's primary cluster. This endpoint is automatically updated to route requests to the writer instance, eliminating the need to update your application each time you change the writer location in your global cluster. You can also use the global endpoint to send cross-Region read/write requests to your writer.

### Note

If you set up your global database before the Aurora Global Database writer endpoint was available, your application might connect to the cluster endpoint of the primary cluster. In this case, we recommend switching your connection settings to use the global writer endpoint instead. Doing so avoids the need to change your connection settings after every Aurora Global Database switchover or failover.

The first part of the writer endpoint name is the name of your Aurora Global Database. Thus, if you rename your Aurora Global Database, the writer endpoint name changes, and any code that uses it must be updated with the new name.

- **Scaling reads closer to your application's region:** To scale read-only requests in the same or nearby Amazon Region as your application, connect to the reader endpoint of the primary or secondary Aurora clusters.
- **Scaling reads with occasional cross-region writes:** For occasional DML statements such as for maintenance and data cleanup, connect to the reader endpoint of a secondary cluster that has write forwarding enabled. With write forwarding, Aurora automatically forwards the write statements to the writer in the primary Region of your Aurora Global Database. Write forwarding provides the following benefits:
  - You don't need to do the heavy lifting to establish connectivity between the secondary and primary clusters to send cross-region writes.
  - You don't need to split read and write requests in the application.
  - You don't need to develop complex logic to manage consistency for read-after-write requests.

However, with write forwarding, you do need to update your application code or configuration to connect to the newly promoted primary Region's reader endpoint after performing a cross-Region failover or switchover. We recommend that you monitor the latency of operations done through write forwarding, to check overhead of processing the write requests. Finally, write forwarding doesn't support certain MySQL or PostgreSQL operations, such as making data definition language (DDL) changes or `SELECT FOR UPDATE` statements.

To learn more about using write forwarding across Amazon Regions, see [Using write forwarding in an Amazon Aurora global database](#).

For details about the different kinds of Aurora endpoints, see [Connecting to an Amazon Aurora DB cluster](#).

## Viewing the endpoints of an Amazon Aurora global database

When you view an Aurora Global Database in the console, you can see all of the endpoints associated with all of its clusters. The following figure shows an example of the types of endpoints you see when you view the details for your primary DB cluster:

- **Global writer** – The single read/write endpoint that always points to the current writer DB instance for the global database cluster.
- **Writer** – The connection endpoint for read/write requests to the primary DB cluster in the global database cluster.

- **Reader** – The connection endpoint for read-only requests to a primary or secondary DB cluster in the global database cluster. To minimize latency, choose whichever reader endpoint is in your Amazon Web Services Region or the Amazon Web Services Region closest to you.

**Global endpoint - new** [Info](#)  
Endpoint to send requests to the writer instance of the primary cluster.

Endpoint name	Status	Type	Port
rds-global-database.global-...global.rds.amazonaws.com	Available	Global	-

## Console

### To view the endpoints of a global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list, choose the global database, or the primary or secondary DB cluster whose endpoints you want to view.
4. Choose the **Connectivity & security** tab to see the endpoint details. The endpoints displayed depend on the type of cluster you selected, as follows:
  - **Global database** – The global writer endpoint.

- Primary DB cluster – The global writer endpoint, and the cluster endpoint and reader endpoint for the primary cluster.
- Secondary DB cluster – The cluster endpoint and reader endpoint for the secondary cluster. On a secondary cluster, the cluster endpoint displays a status of **inactive** because it doesn't handle write requests. You can still connect to the cluster endpoint, but only for read queries.

## Amazon CLI

To view the global cluster's writer endpoint, use the Amazon CLI [describe-global-clusters](#) command, as in the following example.

```
aws rds describe-global-clusters --region aws_region
{
  "GlobalClusters": [
    {
      "GlobalClusterIdentifier": "global_cluster_id",
      "GlobalClusterResourceId": "cluster-unique_string",
      "GlobalClusterArn": "arn:aws:rds::123456789012:global-
cluster:global_cluster_id",
      "Status": "available",
      "Engine": "aurora-mysql",
      "EngineVersion": "5.7.mysql_aurora.2.11.2",
      "GlobalClusterMembers": [
        ...
      ],
      "Endpoint":
"global_cluster_id.global-unique_string.global.rds.amazonaws.com"
    }
  ]
}
```

To view the cluster and reader endpoints for member DB clusters of the global cluster, use the Amazon CLI [describe-db-clusters](#) command, as in the following example. The values returned for `Endpoint` and `ReaderEndpoint` are the cluster and reader endpoints, respectively.

```
aws rds describe-db-clusters --region primary_region --db-cluster-
identifier db_cluster_id
{
```

```

"DBClusters": [
  {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
      "az_1",
      "az_2",
      "az_3"
    ],
    "BackupRetentionPeriod": 1,
    "DBClusterIdentifier": "db_cluster_id",
    "DBClusterParameterGroup": "default.aurora-mysql5.7",
    "DBSubnetGroup": "default",
    "Status": "available",
    "EarliestRestorableTime": "2023-08-01T18:21:11.301Z",
    "Endpoint":
      "db_cluster_id.cluster-unique_string.primary_region.rds.amazonaws.com",
    "ReaderEndpoint": "db_cluster_id.cluster-
ro-unique_string.primary_region.rds.amazonaws.com",
    "MultiAZ": false,
    "Engine": "aurora-mysql",
    "EngineVersion": "5.7.mysql_aurora.2.11.2",

    "ReadReplicaIdentifiers": [
      "arn:aws:rds:secondary_region:123456789012:cluster:db_cluster_id"
    ],
    "DBClusterMembers": [
      {
        "DBInstanceIdentifier": "db_instance_id",
        "IsClusterWriter": true,
        "DBClusterParameterGroupStatus": "in-sync",
        "PromotionTier": 1
      }
    ],

    ...
    "TagList": [],
    "GlobalWriteForwardingRequested": false
  }
]
}

```

## RDS API

To view the global cluster's writer endpoint, use the RDS API [DescribeGlobalClusters](#) operation. To view the cluster and reader endpoints for member DB clusters of the global cluster, use the RDS API [DescribeDBClusters](#) operation.

## Considerations with using Global writer endpoints

You can make effective use of the Aurora Global Database writer endpoints by following these guidelines and best practices:

- To minimize disruption after a cross-Region failover or switchover, you can set up VPC connectivity between your application compute and your primary and secondary Amazon Regions. For example, suppose that you have applications or client systems that are running in the same VPC as the primary cluster. If the secondary cluster is promoted, the global writer endpoint automatically changes to point to that cluster. Although the global writer endpoint lets you avoid changing the connection settings for your application, your applications can't access the IP addresses in the newly promoted primary Amazon Region's VPC until you set up networking between the two VPCs. See [Amazon VPC-to-Amazon VPC connectivity options](#) to evaluate different options for setting up this connectivity.
- The global writer endpoint update after a global database failover or switchover can take a long time depending upon your Domain Name Service (DNS) caching duration. See [Amazon Aurora MySQL Database Administrator's Handbook](#) to learn more. Aurora Global Database emits an RDS Event when it sees the DNS change on the global writer endpoint. You can use the event to devise strategies to ensure the DNS cache doesn't extend beyond the time after the event is generated. For more information, see [DB cluster events](#).
- Aurora Global Database replicates data asynchronously. The cross-Region failover methods can result in some write transaction data that wasn't replicated to the chosen secondary before the failover initiated. Although Aurora attempts on best-effort basis to block writes in the original primary Amazon Region, failover can be susceptible to split-brain issues. The considerations to minimize data loss and split-brain risk apply to Aurora Global Database writer endpoints as well. For more information, see [Performing managed failovers for Aurora global databases](#).

## Using write forwarding in an Amazon Aurora global database

You can reduce the number of endpoints that you need to manage for applications running on your Aurora global database, by using *write forwarding*. With write forwarding enabled, secondary

clusters in an Aurora global database forward SQL statements that perform write operations to the primary cluster. The primary cluster updates the source and then propagates resulting changes back to all secondary Amazon Regions.

The write forwarding configuration saves you from implementing your own mechanism to send write operations from a secondary Amazon Region to the primary Region. Aurora handles the cross-Region networking setup. Aurora also transmits all necessary session and transactional context for each statement. The data is always changed first on the primary cluster and then replicated to the secondary clusters in the Aurora global database. This way, the primary cluster is the source of truth and always has an up-to-date copy of all your data.

## Region and version availability of write forwarding in Aurora MySQL

Write forwarding is supported with Aurora MySQL 2.08.1 and higher versions, in every Region where Aurora MySQL-based global databases are available.

For information on version and Region availability of Aurora MySQL global databases, see [Aurora global databases with Aurora MySQL](#).

## Enabling write forwarding in Aurora MySQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database.

To enable write forwarding using the Amazon Web Services Management Console, select the **Turn on global write forwarding** check box under **Read replica write forwarding** when you add a Region for a global database. For an existing secondary cluster, modify the cluster to **Turn on global write forwarding**. To turn off write forwarding, clear the **Turn on global write forwarding** check box when adding the Region or modifying the secondary cluster.

To enable write forwarding using the Amazon CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the `create-db-cluster` command. It also works when you modify an existing secondary cluster using the `modify-db-cluster` command. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by using the `--no-enable-global-write-forwarding` option with these same CLI commands.

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the `CreateDBCluster` operation. It also works when you modify an existing secondary cluster using the `ModifyDBCluster` operation. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by setting the `EnableGlobalWriteForwarding` parameter to `false`.

### Note

For a database session to use write forwarding, specify a setting for the `aurora_replica_read_consistency` configuration parameter. Do this in every session that uses the write forwarding feature. For information about this parameter, see [Isolation and consistency for write forwarding in Aurora MySQL](#).

The RDS Proxy feature doesn't support the `SESSION` value for the `aurora_replica_read_consistency` variable. Setting this value can cause unexpected behavior.

The following CLI examples show how you can set up an Aurora global database with write forwarding enabled or disabled. The highlighted items represent the commands and options that are important to specify and keep consistent when setting up the infrastructure for an Aurora global database.

The following example creates an Aurora global database, a primary cluster, and a secondary cluster with write forwarding enabled. Substitute your own choices for the user name, password, and primary and secondary Amazon Regions.

```
# Create overall global database.
aws rds create-global-cluster --global-cluster-identifier write-forwarding-test \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

# Create primary cluster, in the same Amazon Region as the global database.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-1 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --master-username user_name --master-user-password password \
  --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
  --db-instance-identifier write-forwarding-test-cluster-1-instance-1 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
  --db-instance-identifier write-forwarding-test-cluster-1-instance-2 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-1

# Create secondary cluster, in a different Amazon Region than the global database,
# with write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-2 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
  --region us-east-2 \
  --enable-global-write-forwarding

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
```

```
--db-instance-class db.r5.large \  
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \  
--region us-east-2  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \  
--db-instance-identifier write-forwarding-test-cluster-2-instance-2 \  
--db-instance-class db.r5.large \  
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \  
--region us-east-2
```

The following example continues from the previous one. It creates a secondary cluster without write forwarding enabled, then enables write forwarding. After this example finishes, all secondary clusters in the global database have write forwarding enabled.

```
# Create secondary cluster, in a different Amazon Region than the global database,  
# without write forwarding enabled.  
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \  
--db-cluster-identifier write-forwarding-test-cluster-2 \  
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \  
--region us-west-1  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \  
--db-instance-identifier write-forwarding-test-cluster-2-instance-1 \  
--db-instance-class db.r5.large \  
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \  
--region us-west-1  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \  
--db-instance-identifier write-forwarding-test-cluster-2-instance-2 \  
--db-instance-class db.r5.large \  
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \  
--region us-west-1  
  
aws rds modify-db-cluster --db-cluster-identifier write-forwarding-test-cluster-2 \  
--region us-east-2 \  
--enable-global-write-forwarding
```

## Checking if a secondary cluster has write forwarding enabled in Aurora MySQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the Amazon Web Services Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Global read replica write forwarding**.

To see the status of the global write forwarding setting for all of your clusters, run the following Amazon CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

### Example

```
aws rds describe-db-clusters \
--query '*['].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus}

[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  },
  {
    "GlobalWriteForwardingStatus": "disabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
  },
  {
    "GlobalWriteForwardingStatus": null,
    "DBClusterIdentifier": "non-global-cluster"
  }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

## Example

```
aws rds describe-db-clusters --query 'DBClusters[.
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus
 | [?GlobalWriteForwardingStatus == `enabled`]'
[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-
cnpexample.us-west-2.rds.amazonaws.com",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  }
]
```

## Application and SQL compatibility with write forwarding in Aurora MySQL

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- SELECT ... LOCK IN SHARE MODE and SELECT FOR UPDATE statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the EnableGlobalWriteForwarding setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on secondary clusters with write forwarding enabled at the cluster level. This approach works if write forwarding isn't turned on within the session by the aurora\_replica\_read\_consistency configuration parameter. Trying to use a statement when it's not allowed because of write forwarding causes an error message with the following format.

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation' with write forwarding'.
```

## Data definition language (DDL)

Connect to the primary cluster to run DDL statements. You can't run them from reader DB instances.

### Updating a permanent table using data from a temporary table

You can use temporary tables on secondary clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an `INSERT . . . SELECT` statement that takes the data from a temporary table. The temporary table exists on the secondary cluster and isn't available when the statement runs on the primary cluster.

### XA transactions

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is empty. Before turning on write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

### LOAD statements for permanent tables

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

You can load data into a temporary table on a secondary cluster. However, make sure that you run any `LOAD` statements that refer to permanent tables only on the primary cluster.

### Plugin statements

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

## SAVEPOINT statements

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before turning on write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```

## Isolation and consistency for write forwarding in Aurora MySQL

In sessions that use write forwarding, you can only use the `REPEATABLE READ` isolation level. Although you can also use the `READ COMMITTED` isolation level with read-only clusters in secondary Amazon Regions, that isolation level doesn't work with write forwarding. For information about the `REPEATABLE READ` and `READ COMMITTED` isolation levels, see [Aurora MySQL isolation levels](#).

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose a value for the session-level parameter `aurora_replica_read_consistency`.

### Important

Always set the `aurora_replica_read_consistency` parameter for any session for which you want to forward writes. If you don't, Aurora doesn't enable write forwarding for

that session. This parameter has an empty value by default, so choose a specific value when you use this parameter. The `aurora_replica_read_consistency` parameter has an effect only on secondary clusters that have write forwarding enabled.

For Aurora MySQL version 2 and version 3 lower than 3.04, use `aurora_replica_read_consistency` as a session variable. For Aurora MySQL version 3.04 and higher, you can use `aurora_replica_read_consistency` as either a session variable or as a DB cluster parameter.

For the `aurora_replica_read_consistency` parameter, you can specify the values `EVENTUAL`, `SESSION`, and `GLOBAL`.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between Amazon Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With the read consistency set to `EVENTUAL`, queries in a secondary Amazon Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

With the read consistency set to `SESSION`, all queries in a secondary Amazon Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

With the read consistency set to `GLOBAL`, a session in a secondary Amazon Region sees changes made by that session. It also sees all committed changes from both the primary Amazon Region and other secondary Amazon Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

For more information about all the parameters involved with write forwarding, see [Configuration parameters for write forwarding in Aurora MySQL](#).

## Examples of using write forwarding

These examples use `aurora_replica_read_consistency` as a session variable. For Aurora MySQL version 3.04 and higher, you can use `aurora_replica_read_consistency` as either a session variable or as a DB cluster parameter.

In the following example, the primary cluster is in the US East (N. Virginia) Region. The secondary cluster is in the US East (Ohio) Region. The example shows the effects of running `INSERT` statements followed by `SELECT` statements. Depending on the value of the `aurora_replica_read_consistency` setting, the results might differ depending on the timing of the statements. To achieve higher consistency, you might wait briefly before issuing the `SELECT` statement. Or Aurora can automatically wait until the results finish replicating before proceeding with `SELECT`.

In this example, there is a read consistency setting of `eventual`. Running an `INSERT` statement immediately followed by a `SELECT` statement still returns the value of `COUNT(*)`. This value reflects the number of rows before the new row is inserted. Running the `SELECT` again a short time later returns the updated row count. The `SELECT` statements don't wait.

```
mysql> set aurora_replica_read_consistency = 'eventual';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|         5 |
+-----+
1 row in set (0.00 sec)
mysql> insert into t1 values (6); select count(*) from t1;
+-----+
| count(*) |
+-----+
|         5 |
+-----+
1 row in set (0.00 sec)
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|         6 |
+-----+
1 row in set (0.00 sec)
```

With a read consistency setting of `session`, a `SELECT` statement immediately after an `INSERT` waits until the changes from the `INSERT` statement are visible. Subsequent `SELECT` statements don't wait.

```
mysql> set aurora_replica_read_consistency = 'session';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|         6 |
+-----+
1 row in set (0.01 sec)
mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+-----+
| count(*) |
+-----+
|         7 |
+-----+
1 row in set (0.37 sec)
+-----+
| count(*) |
+-----+
|         7 |
+-----+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `session`, introducing a brief wait after performing an `INSERT` statement makes the updated row count available by the time the next `SELECT` statement runs.

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+-----+
| sleep(2) |
+-----+
|         0 |
+-----+
1 row in set (2.01 sec)
+-----+
| count(*) |
+-----+
```

```
|          8 |
+-----+
1 row in set (0.00 sec)
```

With a read consistency setting of `global`, each `SELECT` statement waits to ensure that all data changes as of the start time of the statement are visible before performing the query. The amount of waiting for each `SELECT` statement varies, depending on the amount of replication lag between the primary and secondary clusters.

```
mysql> set aurora_replica_read_consistency = 'global';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|          8 |
+-----+
1 row in set (0.75 sec)
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|          8 |
+-----+
1 row in set (0.37 sec)
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|          8 |
+-----+
1 row in set (0.66 sec)
```

## Running multipart statements with write forwarding in Aurora MySQL

A DML statement might consist of multiple parts, such as a `INSERT . . . SELECT` statement or a `DELETE . . . WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

## Transactions with write forwarding in Aurora MySQL

Whether the transaction is forwarded to the primary cluster depends on the access mode of the transaction. You can specify the access mode for the transaction by using the `SET TRANSACTION`

statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the [transaction\\_read\\_only](#) session variable. You can change this session value only while you're connected to a DB cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can increase it up to one day. A transaction that exceeds the idle timeout is canceled by the primary cluster. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the primary cluster or if you turn off the write forwarding configuration setting.

## Configuration parameters for write forwarding in Aurora MySQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Name	Scope	Type	Default value	Valid values
<code>aurora_fwd_master_idle_timeout</code> (Aurora MySQL version 2)	Global	unsigned integer	60	1–86,400
<code>aurora_fwd_master_max_connections_pct</code> (Aurora MySQL version 2)	Global	unsigned long integer	10	0–90
<code>aurora_fwd_writer_idle_timeout</code> (Aurora MySQL version 3)	Global	unsigned integer	60	1–86,400
<code>aurora_fwd_writer_max_connections_pct</code> (Aurora MySQL version 3)	Global	unsigned long integer	10	0–90

Name	Scope	Type	Default value	Valid values
<code>aurora_replica_read_consistency</code>	Session for version 2 and version 3 lower than 3.04, Global for version 3.04 and higher	Enum	" (null)	EVENTUAL, SESSION, GLOBAL

To control incoming write requests from secondary clusters, use these settings on the primary cluster:

- `aurora_fwd_master_idle_timeout`, `aurora_fwd_writer_idle_timeout`: The number of seconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora cancels the session.
- `aurora_fwd_master_max_connections_pct`, `aurora_fwd_writer_max_connections_pct`: The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from readers. It's expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is 800 and `aurora_fwd_master_max_connections_pct` or `aurora_fwd_writer_max_connections_pct` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting.

This setting applies only on the primary cluster, when one or more secondary clusters have write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a secondary cluster. The default value is 10, representing 10% of the `max_connections` value. If you enable query forwarding on any of the secondary clusters, this setting must have a nonzero value for write operations from secondary clusters to succeed. If the value is zero, the

write operations receive the error code `ER_CON_COUNT_ERROR` with the message `Not enough connections on writer to handle your request`.

The `aurora_replica_read_consistency` parameter enables write forwarding. You use it in each session. You can specify `EVENTUAL`, `SESSION`, or `GLOBAL` for read consistency level. To learn more about consistency levels, see [Isolation and consistency for write forwarding in Aurora MySQL](#). The following rules apply to this parameter:

- The default value is "" (empty).
- Write forwarding is available in a session only if `aurora_replica_read_consistency` is set to `EVENTUAL` or `SESSION` or `GLOBAL`. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- You can't set this variable (when empty) or unset (when already set) inside a multistatement transaction. However, you can change it from one valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) to another valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) during such a transaction.
- The variable can't be `SET` when write forwarding isn't enabled on the secondary cluster.

## Amazon CloudWatch metrics for write forwarding in Aurora MySQL

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

CloudWatch metric	Unit	Description
<code>AuroraDMLRejectedMasterFull</code>	Count	The number of forwarded queries that are rejected because the session is full on the writer DB instance.  For Aurora MySQL version 2.
<code>AuroraDMLRejectedWriterFull</code>	Count	The number of forwarded queries that are rejected because the session is full on the writer DB instance.

CloudWatch metric	Unit	Description
		For Aurora MySQL version 3.
ForwardingMasterDMLLatency	Milliseconds	<p>Average time to process each forwarded DML statement on the writer DB instance.</p> <p>It doesn't include the time for the secondary cluster to forward the write request, or the time to replicate changes back to the secondary cluster.</p> <p>For Aurora MySQL version 2.</p>
ForwardingMasterDMLThroughput	Count per second	<p>Number of forwarded DML statements processed each second by this writer DB instance.</p> <p>For Aurora MySQL version 2.</p>
ForwardingMasterOpenSessions	Count	<p>Number of forwarded sessions on the writer DB instance.</p> <p>For Aurora MySQL version 2.</p>
ForwardingWriterDMLLatency	Milliseconds	<p>Average time to process each forwarded DML statement on the writer DB instance.</p> <p>It doesn't include the time for the secondary cluster to forward the write request, or the time to replicate changes back to the secondary cluster.</p> <p>For Aurora MySQL version 3.</p>

CloudWatch metric	Unit	Description
ForwardingWriterDMLThroughput	Count per second	Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 3.
ForwardingWriterOpenSessions	Count	Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 3.

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch metric	Unit	Description
ForwardingReplicaDMLLatency	Milliseconds	Average response time of forwarded DMLs on the replica.
ForwardingReplicaDMLThroughput	Count per second	Number of forwarded DML statements processed each second.
ForwardingReplicaOpenSessions	Count	Number of sessions that are using write forwarding on a reader DB instance.
ForwardingReplicaReaderWaitLatency	Milliseconds	Average wait time that a SELECT statement on a reader DB instance waits to catch up to the primary cluster.

CloudWatch metric	Unit	Description
		The degree to which the reader DB instance waits before processing a query depends on the <code>aurora_replica_read_consistency</code> setting.
<code>ForwardingReplicaReadWaitThroughput</code>	Count per second	Total number of SELECT statements processed each second in all sessions that are forwarding writes.
<code>ForwardingReplicaSelectLatency</code>	Milliseconds	Forwarded SELECT latency, average over all forwarded SELECT statements within the monitoring period.
<code>ForwardingReplicaSelectThroughput</code>	Count per second	Forwarded SELECT throughput per second average within the monitoring period.

## Aurora MySQL status variables for write forwarding

The following Aurora MySQL status variables apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

Aurora MySQL status variable	Unit	Description
<code>Aurora_fwd_master_dml_stmt_count</code>	Count	Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.

Aurora MySQL status variable	Unit	Description
Aurora_fwd_master_dml_stmt_duration	Microseconds	Total duration of DML statements forwarded to this writer DB instance.  For Aurora MySQL version 2.
Aurora_fwd_master_open_sessions	Count	Number of forwarded sessions on the writer DB instance.  For Aurora MySQL version 2.
Aurora_fwd_master_select_stmt_count	Count	Total number of SELECT statements forwarded to this writer DB instance.  For Aurora MySQL version 2.
Aurora_fwd_master_select_stmt_duration	Microseconds	Total duration of SELECT statements forwarded to this writer DB instance.  For Aurora MySQL version 2.
Aurora_fwd_writer_dml_stmt_count	Count	Total number of DML statements forwarded to this writer DB instance.  For Aurora MySQL version 3.
Aurora_fwd_writer_dml_stmt_duration	Microseconds	Total duration of DML statements forwarded to this writer DB instance.

Aurora MySQL status variable	Unit	Description
<code>Aurora_fwd_writer_open_sessions</code>	Count	Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 3.
<code>Aurora_fwd_writer_select_stmt_count</code>	Count	Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 3.
<code>Aurora_fwd_writer_select_stmt_duration</code>	Microseconds	Total duration of SELECT statements forwarded to this writer DB instance.  For Aurora MySQL version 3.

The following Aurora MySQL status variables apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

Aurora MySQL status variable	Unit	Description
<code>Aurora_fwd_replica_dml_stmt_count</code>	Count	Total number of DML statements forwarded from this reader DB instance.
<code>Aurora_fwd_replica_dml_stmt_duration</code>	Microseconds	Total duration of all DML statements forwarded from this reader DB instance.
<code>Aurora_fwd_replica_errors_session_limit</code>	Count	Number of sessions rejected by the primary cluster due to one of the following error conditions:

Aurora MySQL status variable	Unit	Description
		<ul style="list-style-type: none"> <li>• writer full</li> <li>• Too many forwarded statements in progress.</li> </ul>
Aurora_fwd_replica_open_sessions	Count	Number of sessions that are using write forwarding on a reader DB instance.
Aurora_fwd_replica_read_wait_count	Count	Total number of read-after-write waits on this reader DB instance.
Aurora_fwd_replica_read_wait_duration	Microseconds	Total duration of waits due to the read consistency setting on this reader DB instance.
Aurora_fwd_replica_select_stmt_count	Count	Total number of SELECT statements forwarded from this reader DB instance.
Aurora_fwd_replica_select_stmt_duration	Microseconds	Total duration of SELECT statements forwarded from this reader DB instance.

## Using write forwarding in an Aurora PostgreSQL global database

### Topics

- [Amazon CloudWatch metrics for write forwarding in Aurora PostgreSQL](#)
- [Wait events for write forwarding in Aurora PostgreSQL](#)

## Region and version availability of write forwarding in Aurora PostgreSQL

In Aurora PostgreSQL version 16 and higher major versions, global write forwarding is supported in all minor versions. For earlier Aurora PostgreSQL versions, global write forwarding is supported with version 15.4 and higher minor versions, and version 14.9 and higher minor versions. Write forwarding is available in every Amazon Region where Aurora PostgreSQL-based global databases are available.

For more information on version and Region availability of Aurora PostgreSQL global databases, see [Aurora global databases with Aurora PostgreSQL](#).

## Enabling write forwarding in Aurora PostgreSQL

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database. You can enable write forwarding for your secondary DB cluster while you're creating it or anytime after you create it. If needed, you can disable it later. Enabling or disabling write forwarding doesn't cause downtime or a reboot.

### Note

You can use local write forwarding for your applications that have occasional writes and require read-after-write consistency, which is the ability to read the latest write in a transaction.

## Console

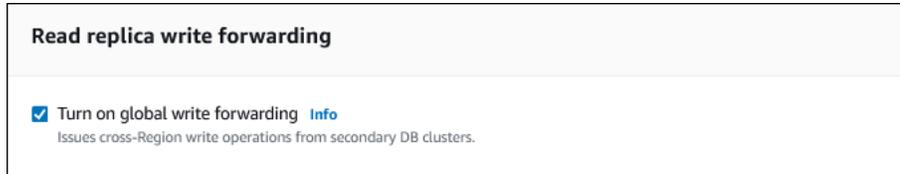

In the console, you can enable or disable write forwarding when you create or modify a secondary DB cluster.

### Enabling or disabling write forwarding when creating a secondary DB cluster

When you create a new secondary DB cluster, you enable write forwarding by selecting the **Turn on global write forwarding** check box under **Read replica write forwarding**. Or clear the check box to

disable it. To create a secondary DB cluster, follow the instructions for your DB engine in [Creating an Amazon Aurora DB cluster](#).

The following screenshot shows the **Read replica write forwarding** section with the **Turn on global write forwarding** check box selected.

## Enabling or disabling write forwarding when modifying a secondary DB cluster

In the console, you can modify a secondary DB cluster to enable or disable write forwarding.

### To enable or disable write forwarding for a secondary DB cluster by using the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases**.
3. Choose the secondary DB cluster, and choose **Modify**.
4. In the **Read replica write forwarding** section, check or clear the **Turn on global write forwarding** check box.
5. Choose **Continue**.
6. For **Schedule modifications**, choose **Apply immediately**. If you choose **Apply during the next scheduled maintenance window**, Aurora ignores this setting and turns on write forwarding immediately.
7. Choose **Modify cluster**.

## Amazon CLI

To enable write forwarding by using the Amazon CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the [create-db-cluster](#) command. It also works when you modify an existing secondary cluster using the [modify-db-cluster](#) command. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by using the `--no-enable-global-write-forwarding` option with these same CLI commands.

The following procedures describe how to enable or disable write forwarding for a secondary DB cluster in your global cluster by using the Amazon CLI.

### To enable or disable write forwarding for an existing secondary DB cluster

- Call the [modify-db-cluster](#) Amazon CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--enable-global-write-forwarding` to turn on or `--no-enable-global-write-forwarding` to turn off.

The following example enables write forwarding for DB cluster `sample-secondary-db-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier sample-secondary-db-cluster \  
  --enable-global-write-forwarding
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier sample-secondary-db-cluster ^  
  --enable-global-write-forwarding
```

## RDS API

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the [CreateDBCluster](#) operation. It also works when you modify an existing secondary cluster using the [ModifyDBCluster](#) operation. It requires that the global database uses an Aurora version that supports write forwarding. You can disable write forwarding by setting the `EnableGlobalWriteForwarding` parameter to `false`.

## Checking if a secondary cluster has write forwarding enabled in Aurora PostgreSQL

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the Amazon Web Services Management Console, you see Read replica write forwarding on the **Configuration** tab of the details page for the cluster. To see the status of the global write forwarding setting for all of your clusters, run the following Amazon CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

### Example

```
aws rds describe-db-clusters --query '*[].[
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus
[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  },
  {
    "GlobalWriteForwardingStatus": "disabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
  },
  {
    "GlobalWriteForwardingStatus": null,
    "DBClusterIdentifier": "non-global-cluster"
  }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint when you use write forwarding from the secondary to the primary in your Aurora global database.

## Example

```
aws rds describe-db-clusters --query 'DBClusters[.
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus
 | [?GlobalWriteForwardingStatus == `enabled`]'
[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-
cnpexample.us-west-2.rds.amazonaws.com",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  }
]
```

## Application and SQL compatibility with write forwarding in Aurora PostgreSQL

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. In addition, user defined functions and user defined procedures aren't supported. Thus, the `EnableGlobalWriteForwarding` setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`
- `SELECT FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE }` statements
- `PREPARE` and `EXECUTE` statements
- `EXPLAIN` statements with the statements in this list

The following kinds of SQL statements aren't supported with write forwarding:

- Data definition language (DDL) statements
- `ANALYZE`
- `CLUSTER`
- `COPY`
- Cursors – Cursors aren't supported, so make sure to close them before using write forwarding.
- `GRANT|REVOKE|REASSIGN OWNED|SECURITY LABEL`

- LOCK
- SAVEPOINT statements
- SELECT INTO
- SET CONSTRAINTS
- TRUNCATE
- VACUUM

## Isolation and consistency for write forwarding in Aurora PostgreSQL

In sessions that use write forwarding, you can use the `REPEATABLE READ` and `READ COMMITTED` isolation levels. However, the `SERIALIZABLE` isolation level isn't supported.

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose the appropriate value for the `apg_write_forward.consistency_mode` parameter. The `apg_write_forward.consistency_mode` parameter has an effect only on secondary clusters that have write forwarding enabled.

### Note

For the `apg_write_forward.consistency_mode` parameter, you can specify the value `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF`. By default, the value is set to `SESSION`. Setting the value to `OFF` disables write forwarding in the session.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between Amazon Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With each available consistency mode setting, the effect is as follows:

- **SESSION** – All queries in a secondary Amazon Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.
- **EVENTUAL** – Queries in a secondary Amazon Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.
- **GLOBAL** – A session in a secondary Amazon Region sees changes made by that session. It also sees all committed changes from both the primary Amazon Region and other secondary Amazon Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.
- **OFF** – Write forwarding is disabled in the session.

For more information about all the parameters involved with write forwarding, see [Configuration parameters for write forwarding in Aurora PostgreSQL](#).

## Transaction access modes with write forwarding

If the transaction access mode is set to read only, write forwarding isn't used. You can set the access mode to read write only while you're connected to a DB cluster and session that has write forwarding enabled.

For more information on the transaction access modes, see [SET TRANSACTION](#).

## Running multipart statements with write forwarding in Aurora PostgreSQL

A DML statement might consist of multiple parts, such as a `INSERT . . . SELECT` statement or a `DELETE . . . WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

## Configuration parameters for write forwarding in Aurora PostgreSQL

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Name	Scope	Type	Default value	Valid values
<code>apg_write_forward.connect_timeout</code>	Session	seconds	30	0–2147483647
<code>apg_write_forward.consistency_mode</code>	Session	enum	Session	SESSION, EVENTUAL, GLOBAL, OFF
<code>apg_write_forward.idle_in_transaction_session_timeout</code>	Session	milliseconds	86400000	0–2147483647
<code>apg_write_forward.idle_session_timeout</code>	Session	milliseconds	300000	0–2147483647
<code>apg_write_forward.max_forwarding_connections_percent</code>	Global	int	25	1–100

The `apg_write_forward.max_forwarding_connections_percent` parameter is the upper limit on database connection slots that can be used to handle queries forwarded from readers. It is expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is 800 and `apg_write_forward.max_forwarding_connections_percent` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same

connection pool managed by the `max_connections` setting. This setting applies only on the primary cluster when at least one secondary clusters has write forwarding enabled.

Use the following settings on the secondary cluster:

- `apg_write_forward.consistency_mode` – A session-level parameter that controls the degree of read consistency on the secondary cluster. Valid values are `SESSION`, `EVENTUAL`, `GLOBAL`, or `OFF`. By default, the value is set to `SESSION`. Setting the value to `OFF` disables write forwarding in the session. To learn more about consistency levels, see [Isolation and consistency for write forwarding in Aurora PostgreSQL](#). This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- `apg_write_forward.connect_timeout` – The maximum number of seconds the secondary cluster waits when establishing a connection to the primary cluster before giving up. A value of `0` means to wait indefinitely.
- `apg_write_forward.idle_in_transaction_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster that has an open transaction before closing it. If the session remains idle in transaction beyond this period, Aurora terminates the session. A value of `0` disables the timeout.
- `apg_write_forward.idle_session_timeout` – The number of milliseconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora terminates the session. A value of `0` disables the timeout.

## Amazon CloudWatch metrics for write forwarding in Aurora PostgreSQL

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

CloudWatch Metric	Units and description
<code>AuroraForwardingWriterDMLThroughput</code>	Count (per second). Number of forwarded DML statements processed each second by this writer DB instance.
<code>AuroraForwardingWriterOpenSessions</code>	Count. Number of open sessions on this writer DB instance processing forwarded queries.

CloudWatch Metric	Units and description
AuroraForwardingWriterTotalSessions	Count. Total number of forwarded sessions on this writer DB instance.

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch Metric	Unit and description
AuroraForwardingReplicaCommitThroughput	Count (per second). Number of commits in sessions forwarded by this replica each second.
AuroraForwardingReplicaDMLLatency	Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.
AuroraForwardingReplicaDMLThroughput	Count (per second). Number of forwarded DML statements processed on this replica each second.
AuroraForwardingReplicaErrorSessionsLimit	Count. Number of sessions rejected by the primary cluster because the limit for max connections or max write forward connections was reached.
AuroraForwardingReplicaOpenSessions	Count. The number of sessions that are using write forwarding on a replica instance.
AuroraForwardingReplicaReadWaitLatency	Milliseconds. Average wait time in milliseconds that the replica waits to be consistent with the LSN of the primary cluster. The degree to which the reader DB instance waits depends on the <code>apg_write_forward.consistency_mode</code> setting. For information about this setting, see <a href="#">the section called "Configuration"</a>

CloudWatch Metric	Unit and description
	<a href="#">parameters for write forwarding in Aurora PostgreSQL</a> .

## Wait events for write forwarding in Aurora PostgreSQL

Amazon Aurora generates the following wait events when you use write forwarding with Aurora PostgreSQL.

### Topics

- [IPC:AuroraWriteForwardConnect](#)
- [IPC:AuroraWriteForwardConsistencyPoint](#)
- [IPC:AuroraWriteForwardExecute](#)
- [IPC:AuroraWriteForwardGetGlobalConsistencyPoint](#)
- [IPC:AuroraWriteForwardXactAbort](#)
- [IPC:AuroraWriteForwardXactCommit](#)
- [IPC:AuroraWriteForwardXactStart](#)

### IPC:AuroraWriteForwardConnect

The `IPC:AuroraWriteForwardConnect` event occurs when a backend process on the secondary DB cluster is waiting for a connection to the writer node of the primary DB cluster to be opened.

#### Likely causes of increased waits

This event increases as the number of connection attempts from a secondary Region's reader node to the writer node of the primary DB cluster increases.

#### Actions

Reduce the number of simultaneous connections from a secondary node to the primary Region's writer node.

### IPC:AuroraWriteForwardConsistencyPoint

The `IPC:AuroraWriteForwardConsistencyPoint` event describes how long a query from a node on the secondary DB cluster will wait for the results of forwarded write operations to

be replicated to the current Region. This event is only generated if the session-level parameter `apg_write_forward.consistency_mode` is set to one of the following:

- **SESSION** – queries on a secondary node wait for the results of all changes made in that session.
- **GLOBAL** – queries on a secondary node wait for the results of changes made by that session, plus all committed changes from both the primary Region and other secondary Regions in the global cluster.

For more information about the `apg_write_forward.consistency_mode` parameter settings, see [the section called “Configuration parameters for write forwarding in Aurora PostgreSQL”](#).

### Likely causes of increased waits

Common causes for longer wait times include the following:

- Increased replica lag, as measured by the Amazon CloudWatch `ReplicaLag` metric. For more information about this metric, see [Monitoring Aurora PostgreSQL replication](#).
- Increased load on the primary Region's writer node or on the secondary node.

### Actions

Change your consistency mode, depending on your application's requirements.

### IPC:AuroraWriteForwardExecute

The `IPC:AuroraWriteForwardExecute` event occurs when a backend process on the secondary DB cluster is waiting for a forwarded query to complete and obtain results from the writer node of the primary DB cluster.

### Likely causes of increased waits

Common causes for increased waits include the following:

- Fetching a large number of rows from the primary Region's writer node.
- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.

- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

## Actions

We recommend different actions depending on the causes of your wait event.

- Optimize queries to retrieve only necessary data.
- Optimize data manipulation language (DML) operations to only modify necessary data.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## IPC:AuroraWriteForwardGetGlobalConsistencyPoint

The `IPC:AuroraWriteForwardGetGlobalConsistencyPoint` event occurs when a backend process on the secondary DB cluster that's using the GLOBAL consistency mode is waiting to obtain the global consistency point from the writer node before executing a query.

## Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

## Actions

We recommend different actions depending on the causes of your wait event.

- Change your consistency mode, depending on your application's requirements.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## **IPC:AuroraWriteForwardXactAbort**

The `IPC:AuroraWriteForwardXactAbort` event occurs when a backend process on the secondary DB cluster is waiting for the result of a remote cleanup query. Cleanup queries are issued to return the process to the appropriate state after a write-forwarded transaction is aborted. Amazon Aurora performs them either because an error was found or because a user issued an explicit `ABORT` command or cancelled a running query.

### **Likely causes of increased waits**

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the cleanup query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

### **Actions**

We recommend different actions depending on the causes of your wait event.

- Investigate the cause of the aborted transaction.
- If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## **IPC:AuroraWriteForwardXactCommit**

The `IPC:AuroraWriteForwardXactCommit` event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded commit transaction command.

### **Likely causes of increased waits**

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.

- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

## Actions

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

## IPC:AuroraWriteForwardXactStart

The `IPC:AuroraWriteForwardXactStart` event occurs when a backend process on the secondary DB cluster is waiting for the result of a forwarded start transaction command.

## Likely causes of increased waits

Common causes for increased waits include the following:

- Increased network latency between the secondary node and primary Region's writer node increases the time it takes the secondary node to receive data from the writer node.
- Increased load on the secondary node can delay transmission of the query request from the secondary node to the primary Region's writer node.
- Increased load on the primary Region's writer node can delay transmission of data from the writer node to the secondary node.

## Actions

If the secondary node or primary Region's writer node is constrained by CPU or network bandwidth, consider changing it to an instance type with more CPU capacity or more network bandwidth.

# Using switchover or failover in Amazon Aurora Global Database

The Aurora Global Database feature provides more business continuity and disaster recovery (BCDR) protection than the standard [high availability](#) provided by an Aurora DB cluster in a single

Amazon Web Services Region. By using Aurora Global Database, you can plan for faster recovery from rare, unplanned Regional disasters or complete service-level outages quickly.

You can consult the following guidance and procedures to plan, test, and implement your BCDR strategy using the Aurora Global Database feature.

## Topics

- [Planning for business continuity and disaster recovery](#)
- [Performing switchovers for Amazon Aurora global databases](#)
- [Recovering an Amazon Aurora global database from an unplanned outage](#)
- [Managing RPOs for Aurora PostgreSQL–based global databases](#)
- [Cross-Region resiliency for Global Database secondary clusters](#)

## Planning for business continuity and disaster recovery

To plan your business continuity and disaster recovery strategy, it's helpful to understand the following industry terminology and how those terms relate to Aurora Global Database features.

Recovery from disaster is typically driven by the following two business objectives:

- **Recovery time objective (RTO)** – The time it takes a system to return to a working state after a disaster or service outage. In other words, RTO measures downtime. For Aurora Global Database, RTO can be in the order of minutes.
- **Recovery point objective (RPO)** – The amount of data that can be lost (measured in time) after a disaster or service outage. This data loss is usually due to asynchronous replication lag. For an Aurora global database, RPO is typically measured in seconds. With an Aurora PostgreSQL–based global database, you can use the `rds.global_db_rpo` parameter to set and track the upper bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node. For more information, see [Managing RPOs for Aurora PostgreSQL–based global databases](#).

Performing a switchover or failover with Aurora Global Database involves promoting a secondary DB cluster to be the primary DB cluster. The term "regional outage" is often used to describe a variety of failure scenarios. A worst case scenario could be a wide-spread outage from a catastrophic event that affects hundreds of square miles. However, most outages are much more localized, affecting only a small subset of cloud services or customer systems. Consider the full scope of the outage to make sure cross-Region failover is the proper solution and to choose the

appropriate failover method for the situation. Whether you should use the failover or switchover approach depends on the specific outage scenario:

- **Failover** – Use this approach to recover from an unplanned outage. With this approach, you perform a cross-Region failover to one of the secondary DB clusters in your Aurora global database. The RPO for this approach is typically a non-zero value measured in seconds. The amount of data loss depends on the Aurora global database replication lag across the Amazon Web Services Regions at the time of the failure. To learn more, see [Recovering an Amazon Aurora global database from an unplanned outage](#).
- **Switchover** – This operation was previously called "managed planned failover". Use this approach for controlled scenarios, such as operational maintenance and other planned operational procedures where all the Aurora clusters and other services they interact with are in a healthy state. Because this feature synchronizes secondary DB clusters with the primary before making any other changes, RPO is 0 (no data loss). To learn more, see [Performing switchovers for Amazon Aurora global databases](#).

#### Note

Before you can perform a switchover or failover to a headless secondary Aurora DB cluster, you must add a DB instance to it. For more information about headless DB clusters, see [Creating a headless Aurora DB cluster in a secondary Region](#).

## Performing switchovers for Amazon Aurora global databases

#### Note

Switchovers were previously called **managed planned failovers**.

By using switchovers, you can change the Region of your primary cluster on a routine basis. This approach is intended for controlled scenarios, such as operational maintenance and other planned operational procedures.

There are three common use cases for using switchovers.

- For "regional rotation" requirements imposed on specific industries. For example, financial service regulations might want tier-0 systems to switch to a different Region for several months to ensure that disaster recovery procedures are regularly exercised.
- For multi-Region "follow-the-sun" applications. For example, a business might want to provide lower latency writes in different Regions based on business hours across different time zones.
- As a zero-data-loss method to fail back to the original primary Region after a failover.

### Note

Switchovers are designed to be used on an Aurora global database where all the Aurora clusters and other services they interact with are in a healthy state. To recover from an unplanned outage, follow the appropriate procedure in [Recovering an Amazon Aurora global database from an unplanned outage](#).

You can perform managed cross-Region switchovers with Aurora Global Database only if the primary and secondary DB clusters have the same major and minor engine versions. Depending on the engine and engine versions, the patch levels might need to be identical or the patch levels can be different. For a list of engines and engine versions that allow these operations between primary and secondary clusters with different patch levels, see [Patch level compatibility for managed cross-Region switchovers and failovers](#). Before you begin the switchover, check the engine versions in your global cluster to make sure that they support managed cross-Region switchover, and upgrade them if needed.

During a switchover, Aurora makes the cluster in your chosen secondary Region be your primary cluster. The switchover mechanism maintains your global database's existing replication topology: it still has the same number of Aurora clusters in the same Regions. Before Aurora starts the switchover process, it waits for the target secondary Region clusters to be fully synchronized with the primary Region cluster. Then, the DB cluster in the primary Region becomes read-only. The chosen secondary cluster promotes one of its read-only nodes to full writer status, which allows that secondary cluster to assume the role of primary cluster. Because the target secondary cluster was synchronized with the primary at the beginning of the process, the new primary continues operations for the Aurora global database without losing any data. Your database is unavailable for a short time while the primary and selected secondary clusters are assuming their new roles.

**Note**

To manage replication slots for Aurora PostgreSQL after performing a switchover, see [Managing logical slots for Aurora PostgreSQL](#).

To optimize application availability, we recommend that you do the following before using this feature:

- Perform this operation during nonpeak hours or at another time when writes to the primary DB cluster are minimal.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. For all Aurora PostgreSQL-based global databases and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher or 2.12.0 and higher, use Amazon CloudWatch to view the `AuroraGlobalDBRPOLag` metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the `AuroraGlobalDBReplicationLag` metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster. This value is directly proportional to the time it takes for Aurora to complete the switchover. Therefore, the larger the lag value, the longer the switchover will take. When you examine these metrics, do so from the current primary cluster.

For more information about CloudWatch metrics for Aurora, see [Cluster-level metrics for Amazon Aurora](#).

- The secondary DB cluster that's promoted during a switchover might have different configuration settings than the old primary DB cluster. We recommend that you keep the following types of configuration settings consistent across all the clusters in your Aurora global database clusters. Doing so helps to minimize performance issues, workload incompatibilities, and other anomalous behavior after a switchover.
  - **Configure Aurora DB cluster parameter group for the new primary, if necessary** – When you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see [Modifying parameters for an Aurora global database](#).
  - **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't

inherited from the primary during the switchover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a switchover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards. For more information about Aurora DB clusters and monitoring, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#).

- **Configure integrations with other Amazon services** – If your Aurora global database integrates with Amazon services, such as Amazon Secrets Manager, Amazon Identity and Access Management, Amazon S3, and Amazon Lambda, make sure to configure your integrations with these services as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see [Using Amazon Aurora global databases with other Amazon services](#). To learn more about Secrets Manager, see [How to automate replication of secrets in Amazon Secrets Manager across Amazon Web Services Regions](#).

If you are using the Aurora Global Database writer endpoint, you don't need to change the connection settings in your application. Verify that the DNS changes have propagated and that you can connect and perform write operations on the new primary cluster. Then you can resume full operation of your application.

Suppose that your application connections use the cluster endpoint of the old primary cluster, instead of the global writer endpoint. In that case, make sure to change the your application connection settings to use the cluster endpoint of the new primary cluster. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application. For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaabbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaabbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

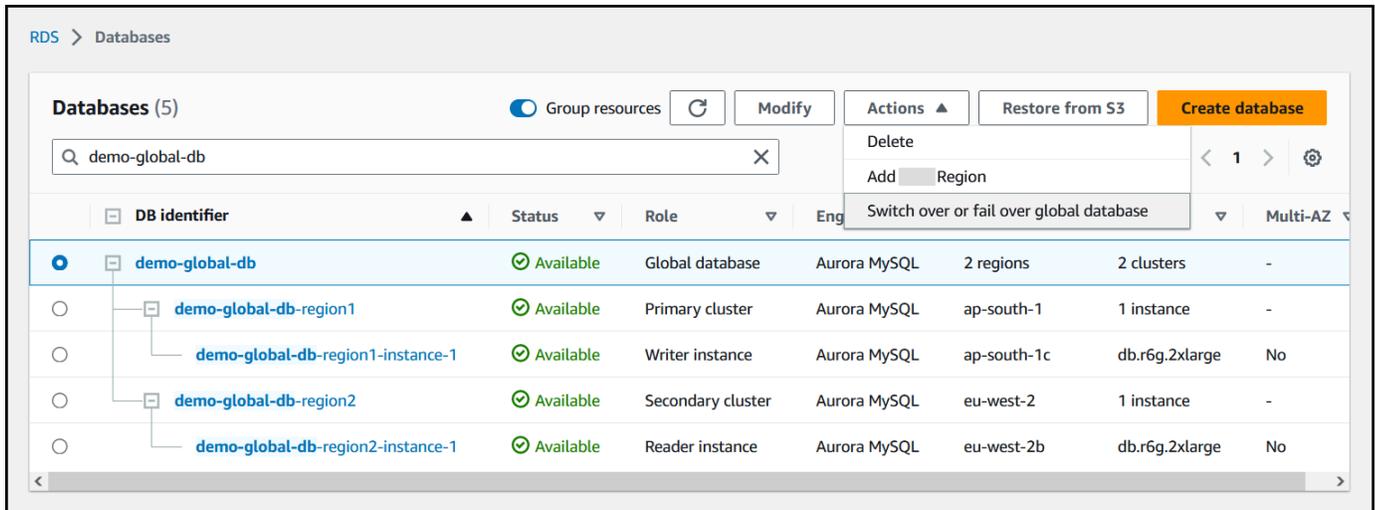

If you're using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see [How RDS Proxy endpoints work with global databases](#).

You can perform an Aurora Global Database switchover using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

### To perform the switchover on your Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** and find the Aurora global database where you intend to perform the switchover.
3. Choose **Switch over or fail over global database** from the **Actions** menu.

4. Choose **Switchover**.

### Switch over or fail over global database demo-global-db ✕

Promote a secondary DB cluster to be the new primary DB cluster for your global database by choosing the applicable operation and the target DB cluster.

**Switchover**  
Switch the roles of your primary and chosen secondary DB cluster. Use this operation on a healthy global cluster for planned events, such as Regional rotation or failing back to the old primary after a failover. This change might take several minutes to complete. No data loss should occur, but you can't write to your global database during this time. [Learn more](#)

**Failover (allow data loss)**  
Fail over the primary DB cluster to the specified secondary DB cluster to respond to unplanned events, such as a Regional disaster in the primary Region. This operation can result in data loss of any uncommitted work and committed transactions that were not replicated to the secondary cluster. [Learn more](#)

**New primary cluster**  
Choose an active cluster in one of your secondary  Regions to be the new primary cluster.

Cancel Confirm

5. For **New primary cluster**, choose an active cluster in one of your secondary Amazon Web Services Regions to be the new primary cluster.
6. Choose **Confirm**.

When the switchover completes, you can see the Aurora DB clusters and their current roles in the **Databases** list, as shown in the following image.

Failover of the database demo-global-db was successful  
demo-global-db-region2 in EU (London) is now the primary cluster for demo-global-db. Secondary clusters for your global database now include demo-global-db-region1 in Asia Pacific (Mumbai).

RDS > Databases

Databases (5) Group resources Refresh Modify Actions Restore from S3 Create database

Q demo-global-db

DB identifier	Status	Role	Engine	Region & AZ	Size	Multi-AZ
demo-global-db	Available	Global database	Aurora MySQL	2 regions	2 clusters	-
demo-global-db-region1	Available	Secondary cluster	Aurora MySQL	ap-south-1	1 instance	-
demo-global-db-region1-instance-1	Available	Reader instance	Aurora MySQL	ap-south-1c	db.r6g.2xlarge	No
demo-global-db-region2	Available	Primary cluster	Aurora MySQL	eu-west-2	1 instance	-
demo-global-db-region2-instance-1	Available	Writer instance	Aurora MySQL	eu-west-2b	db.r6g.2xlarge	No

## Amazon CLI

### To perform the switchover on an Aurora global database

Use the [switchover-global-cluster](#) CLI command to perform a switchover for Aurora Global Database. With the command, pass values for the following parameters.

- `--region` – Specify the Amazon Web Services Region where the primary DB cluster of the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the primary for the Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region region_of_primary \
  switchover-global-cluster --global-cluster-identifier global_database_id \
  --target-db-cluster-identifier arn_of_secondary_to_promote
```

For Windows:

```
aws rds --region region_of_primary ^
```

```
switchover-global-cluster --global-cluster-identifier global_database_id ^  
--target-db-cluster-identifier arn_of_secondary_to_promote
```

## RDS API

To perform a switchover for Aurora Global Database, run the [SwitchoverGlobalCluster](#) API operation.

## Recovering an Amazon Aurora global database from an unplanned outage

On rare occasions, your Aurora global database might experience an unexpected outage in its primary Amazon Web Services Region. If this happens, your primary Aurora DB cluster and its writer node aren't available, and the replication between the primary and secondary DB clusters stops. To minimize both downtime (RTO) and data loss (RPO), you can work quickly to perform a cross-Region failover.

Aurora Global Database has two failover methods that you can use in a disaster recovery situation:

- **Managed failover** – This method is recommended for disaster recovery. When you use this method, Aurora automatically adds back the old primary Region to the global database as a secondary Region when it becomes available again. Thus, the original topology of your global cluster is maintained. To learn how to use this method, see [Performing managed failovers for Aurora global databases](#).
- **Manual failover** – This alternative method can be used when managed failover isn't an option, for example, when your primary and secondary Regions are running incompatible engine versions. To learn how to use this method, see [Performing manual failovers for Aurora global databases](#).

### Important

Both failover methods can result in a loss of write transaction data that wasn't replicated to the chosen secondary before the failover event occurred. However, the recovery process that promotes a DB instance on the chosen secondary DB cluster to be the primary writer DB instance guarantees that the data is in a transactionally consistent state. Failovers are also susceptible to *split-brain* issues.

## Performing managed failovers for Aurora global databases

This approach is intended for business continuity in the event of a true Regional disaster or complete service-level outage.

During a managed failover, the secondary cluster in your chosen secondary Region becomes the new primary cluster. The chosen secondary cluster promotes one of its read-only nodes to full writer status. This step allows the cluster to assume the role of primary cluster. Your database is unavailable for a short time while this cluster is assuming its new role. As soon as that old primary Region is healthy and available again, Aurora automatically adds it back to the global cluster as a secondary Region. Thus, your Aurora global database's existing replication topology is maintained.

### Note

To manage replication slots for Aurora PostgreSQL after performing a failover, see [Managing logical slots for Aurora PostgreSQL](#).

### Note

You can perform managed cross-Region failovers with Aurora Global Database only if the primary and secondary DB clusters have the same major and minor engine versions. Depending on the engine and engine versions, the patch levels might need to be identical or the patch levels can be different. For a list of engines and engine versions that allow these operations between primary and secondary clusters with different patch levels, see [Patch level compatibility for managed cross-Region switchovers and failovers](#). Before you begin the failover, check the engine versions in your global cluster to make sure that they support managed cross-Region switchover, and upgrade them if needed. If your engine versions require identical patch levels but are running different patch levels, you can perform the failover manually by following the steps in [Performing manual failovers for Aurora global databases](#).

Managed failover doesn't wait for data to synchronize between the chosen secondary Region and the current primary Region. Because Aurora Global Database replicates data asynchronously, it's possible that not all transactions replicated to the chosen secondary Amazon Region before it's promoted to accept full read/write capabilities.

To ensure the data is in a consistent state, Aurora creates a new storage volume for the old primary Region after it recovers. Before creating the new storage volume in the Amazon Region, Aurora attempts to take a snapshot of the old storage volume at the point of failure. That way, you can restore the snapshot and recover any of the missing data from it. If this operation is successful, Aurora places this snapshot named `rdsh:unplanned-global-failover-name-of-old-primary-DB-cluster-timestamp` in the snapshot section of the Amazon Web Services Management Console. You can also use the `describe-db-cluster-snapshots` Amazon CLI command or the `DescribeDBClusterSnapshots` API operation to see details for the snapshot.

When you initiate a managed failover, Aurora also attempts to halt write traffic through the highly-available Aurora storage layer. We refer to this mechanism as "write fencing". If the process succeeds, Aurora emits an RDS Event letting you know that writes were stopped. In the unlikely event of multiple AZ failures in a Region, it's possible that the write fencing process doesn't succeed in a timely manner. In that case, Aurora emits an RDS event informing you that the process to stop writes timed out. If the old primary cluster is reachable on the network, Aurora records these events there. If not, Aurora records the events on the new primary cluster. To learn more about these events, see [DB cluster events](#). Because fencing writes is a best-effort attempt, it's possible that writes might be momentarily accepted in the old primary Region, causing split-brain issues.

We recommend that you complete the following tasks before you perform a failover with Aurora Global Database. Doing so minimizes the possibility of split-brain issues, or recovering unreplicated data from the snapshot of the old primary cluster.

- To prevent writes from being sent to the primary cluster of Aurora Global Database, take applications offline.
- Make sure that any applications that connect to the primary DB cluster are using the global writer endpoint. This endpoint has a value that remains the same even when a new Region becomes the primary cluster because of switchover or failover. Aurora implements additional safeguards to minimize the possibility of data loss for write operations submitted through the global endpoint. For more information about global writer endpoints, see [Connecting to Amazon Aurora Global Database](#).
- If you are using the global writer endpoint and your application or networking layers cache DNS values, reduce the time-to-live (TTL) of your DNS cache to a low value such as 5 seconds. That way, your application quickly registers DNS changes with the global writer endpoint. Although Aurora attempts to block writes in the old primary Region, the action is not guaranteed to succeed. Reducing the DNS cache duration further reduces the likelihood of split-brain issues.

As an alternative, you can check for the RDS event that informs you when Aurora observed the DNS changes for the global writer endpoint. That way, you can validate that your application also registered the DNS change before restarting your application write traffic.

- Check lag times for all secondary Aurora DB clusters in the Aurora Global Database. Choosing the secondary Region with the least replication lag can minimize data loss with the current failed primary Region.

For all versions of Aurora PostgreSQL-based global databases, and for Aurora MySQL-based global databases starting with engine versions 3.04.0 and higher or 2.12.0 and higher, use Amazon CloudWatch to view the `AuroraGlobalDBRPOLag` metric for all secondary DB clusters. For lower minor versions of Aurora MySQL-based global databases, view the `AuroraGlobalDBReplicationLag` metric instead. These metrics show you how far behind (in milliseconds) replication to a secondary cluster is to the primary DB cluster.

For more information about CloudWatch metrics for Aurora, see [Cluster-level metrics for Amazon Aurora](#).

During a managed failover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora Global Database. Therefore, when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see [Modifying parameters for an Aurora global database](#).
- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the failover process. Some CloudWatch metrics, such as replication lag, are only available for secondary Regions. Thus, a failover changes how to view those metrics and set alarms on them, and could require changes to any predefined dashboards.

For more information about monitoring Aurora DB clusters, see [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#).

- **Configure integrations with other Amazon services** – If your Aurora Global Database integrates with other Amazon services, such as Amazon Secrets Manager, Amazon Identity and Access Management, Amazon S3, and Amazon Lambda, you need to make sure these are configured as required for access from any secondary Regions. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see [Using Amazon Aurora global databases with other Amazon services](#). To learn more about Secrets Manager, see [How to automate replication of secrets in Amazon Secrets Manager across Amazon Web Services Regions](#).

Typically, the chosen secondary cluster assumes the primary role within a few minutes. As soon as the new primary Region's writer DB instance is available, you can connect your applications to it and resume your workloads. After Aurora promotes the new primary cluster, it automatically rebuilds all additional secondary Region clusters.

Because Aurora global databases use asynchronous replication, the replication lag in each secondary Region can vary. Aurora rebuilds these secondary Regions to have the exact same point-in-time data as the new primary Region cluster. The duration of the complete rebuilding task can take a few minutes to several hours, depending on the size of the storage volume and the distance between the Regions. When the secondary Region clusters finish rebuilding from the new primary Region, they become available for read access.

As soon as the new primary writer is promoted and available, the new primary Region's cluster can handle read and write operations for the Aurora global database.

If you are using the global endpoint, you don't need to change the connection settings in your application. Verify that the DNS changes have propagated and that you can connect and perform write operations on the new primary cluster. Then you can resume full operation of your application.

If you aren't using the global endpoint, make sure to change the endpoint for your application to use the cluster endpoint for the newly promoted primary DB cluster. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaabbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaabbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see [How RDS Proxy endpoints work with global databases](#).

To restore the global database cluster's original topology, Aurora monitors the availability of the old primary Region. As soon as that Region is healthy and available again, Aurora automatically adds it back to the global cluster as a secondary Region. Before creating the new storage volume in the old primary Region, Aurora tries to take a snapshot of the old storage volume at the point of failure. It does this so that you can use it to recover any of the missing data. If this operation is successful, Aurora creates a snapshot named `rds:unplanned-global-failover-name-of-old-primary-DB-cluster-timestamp`. You can find this snapshot in the **Snapshots** section of the Amazon Web Services Management Console. You can also see this snapshot listed in the information returned by the [DescribeDBClusterSnapshots](#) API operation.

#### Note

The snapshot of the old storage volume is a system snapshot that's subject to the backup retention period configured on the old primary cluster. To preserve this snapshot outside of the retention period, you can copy it to save it as a manual snapshot. To learn more about copying snapshots, including pricing, see [DB cluster snapshot copying](#).

After the original topology is restored, you can fail back your global database to the original primary Region by performing a switchover operation when it makes the most sense for your business and workload. To do so, follow the steps in [Performing switchovers for Amazon Aurora global databases](#).

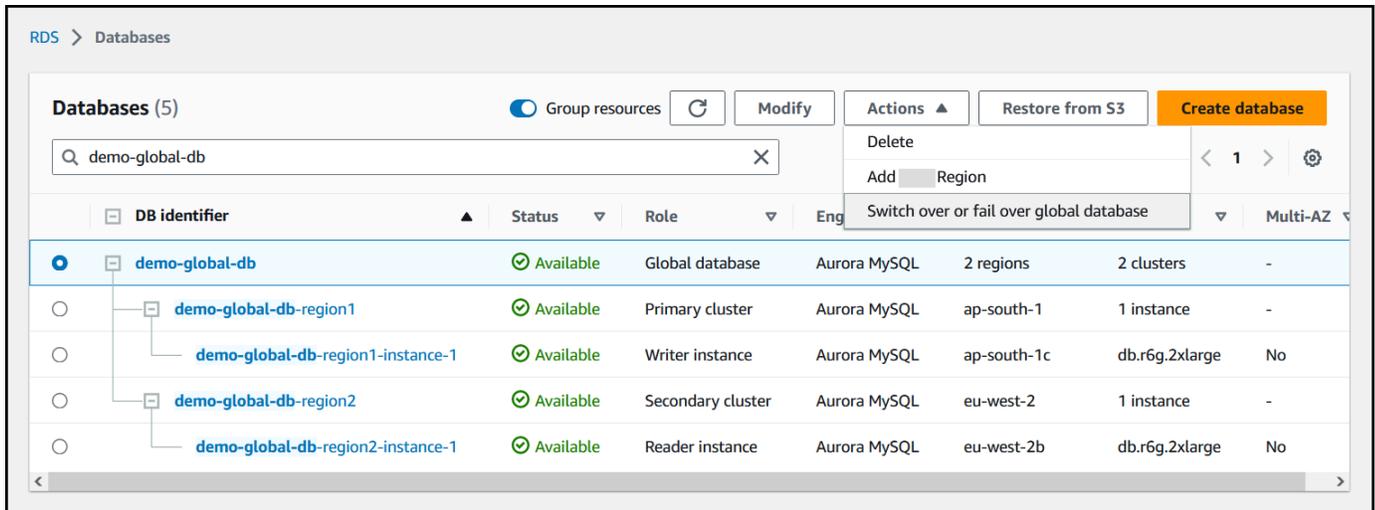

You can perform a failover with Aurora Global Database using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

### To perform the managed failover on your Aurora global database

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** and find the Aurora global database where you want to perform the failover.

### 3. Choose **Switch over or fail over global database** from the **Actions** menu.

### 4. Choose **Failover (allow data loss)**.

#### Switch over or fail over global database demo-global-db

Promote a secondary DB cluster to be the new primary DB cluster for your global database by choosing the applicable operation and the target DB cluster.

**Switchover**  
Switch the roles of your primary and chosen secondary DB cluster. Use this operation on a healthy global cluster for planned events, such as Regional rotation or failing back to the old primary after a failover. This change might take several minutes to complete. No data loss should occur, but you can't write to your global database during this time. [Learn more](#)

**Failover (allow data loss)**  
Fail over the primary DB cluster to the specified secondary DB cluster to respond to unplanned events, such as a Regional disaster in the primary Region. This operation can result in data loss of any uncommitted work and committed transactions that were not replicated to the secondary cluster. [Learn more](#)

**New primary cluster**  
Choose an active cluster in one of your secondary Regions to be the new primary cluster.

Choose an option

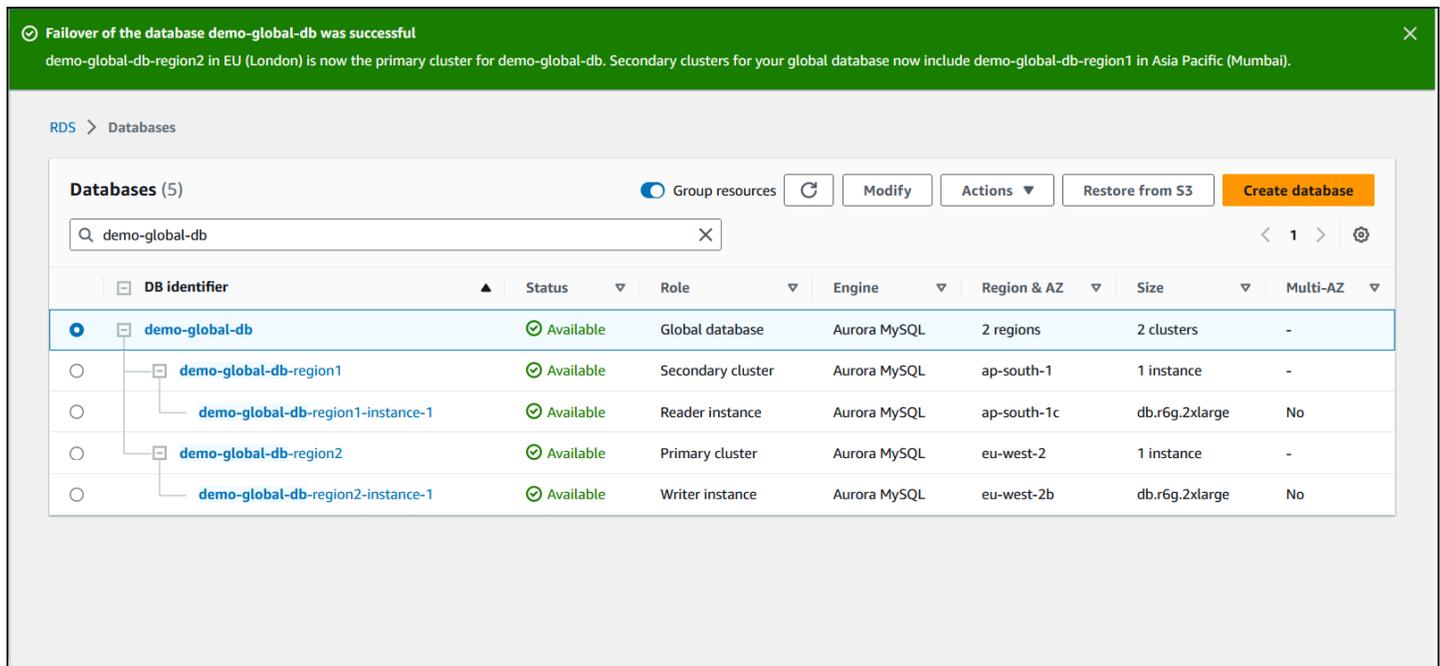

To confirm failover (allow data loss), enter **confirm**.

confirm

### 5. For **New primary cluster**, choose an active cluster in one of your secondary Amazon Web Services Regions to be the new primary cluster.

### 6. Enter **confirm**, and then choose **Confirm**.

When the failover completes, you can view the Aurora DB clusters and their current state in the **Databases** list, as shown in the following image.

## Amazon CLI

### To perform the managed failover on an Aurora global database

Use the [failover-global-cluster](#) CLI command to perform a failover with Aurora Global Database. With the command, pass values for the following parameters.

- `--region` – Specify the Amazon Web Services Region where the secondary DB cluster that you want to be the new primary for the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the new primary for the Aurora global database.
- `--allow-data-loss` – Explicitly make this a failover operation instead of a switchover operation. A failover operation can result in some data loss if the asynchronous replication components haven't completed sending all replicated data to the secondary Region.

For Linux, macOS, or Unix:

```
aws rds --region region_of_selected_secondary \
```

```
failover-global-cluster --global-cluster-identifier global_database_id \  
--target-db-cluster-identifier arn_of_secondary_to_promote \  
--allow-data-loss
```

For Windows:

```
aws rds --region region_of_selected_secondary ^  
failover-global-cluster --global-cluster-identifier global_database_id ^  
--target-db-cluster-identifier arn_of_secondary_to_promote ^  
--allow-data-loss
```

## RDS API

To perform a failover with Aurora Global Database, run the [FailoverGlobalCluster](#) API operation.

## Performing manual failovers for Aurora global databases

In some scenarios, you might not be able to use the managed failover process. One example is if your primary and secondary DB clusters aren't running compatible engine versions. In this case, you can follow this manual process to perform a failover to your target secondary Region.

### Tip

We recommend that you understand this process before using it. Have a plan ready to quickly proceed at the first sign of a Region-wide issue. You can be ready to identify the secondary Region with the least replication lag by using Amazon CloudWatch regularly to track lag times for the secondary clusters. Make sure to test your plan to check that your procedures are complete and accurate, and that staff are trained to perform a disaster recovery failover before it really happens.

## To perform a manual failover to a secondary cluster after an unplanned outage in the primary Region

1. Stop issuing DML statements and other write operations to the primary Aurora DB cluster in the Amazon Web Services Region with the outage.
2. Identify an Aurora DB cluster from a secondary Amazon Web Services Region to use as a new primary DB cluster. If you have two or more secondary Amazon Web Services Regions in your Aurora global database, choose the secondary cluster that has the least replication lag.

3. Detach your chosen secondary DB cluster from the Aurora global database.

Removing a secondary DB cluster from an Aurora global database immediately stops the replication from the primary to this secondary and promotes it to a standalone provisioned Aurora DB cluster with full read/write capabilities. Any other secondary Aurora DB clusters associated with the primary cluster in the Region with the outage are still available and can accept calls from your application. They also consume resources. Because you're recreating the Aurora global database, remove the other secondary DB clusters before creating the new Aurora global database in the following steps. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

For detailed steps for detaching, see [Removing a cluster from an Amazon Aurora global database](#).

4. Reconfigure your application to send all write operations to this now standalone Aurora DB cluster using its new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaabbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaabbbbb.us-west-1.rds.amazonaws.com` when that cluster is detached from the Aurora global database.

This Aurora DB cluster becomes the primary cluster of a new Aurora global database when you start adding Regions to it in the next step.

If you are using RDS Proxy, make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint. For more information see [How RDS Proxy endpoints work with global databases](#).

5. Add an Amazon Web Services Region to the DB cluster. When you do this, the replication process from primary to secondary begins. For detailed steps to add a Region, see [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).
6. Add more Amazon Web Services Regions as needed to recreate the topology needed to support your application.

Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

If you reconfigured in response to an outage in an Amazon Web Services Region, you can make that Amazon Web Services Region the primary again after the outage is resolved. To do so, you add the old Amazon Web Services Region to your new global database, and then use the switchover process to switch its role. Your Aurora global database must use a version of Aurora PostgreSQL or Aurora MySQL that supports switchovers. For more information, see [Performing switchovers for Amazon Aurora global databases](#).

## Managing RPOs for Aurora PostgreSQL–based global databases

With an Aurora PostgreSQL–based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using the `rds.global_db_rpo` parameter. RPO represents the maximum amount of data that can be lost in the event of an outage.

When you set an RPO for your Aurora PostgreSQL–based global database, Aurora monitors the *RPO lag time* of all secondary clusters to make sure that at least one secondary cluster stays within the target RPO window. RPO lag time is another time-based metric.

The RPO is used when your database resumes operations in a new Amazon Web Services Region after a failover. Aurora evaluates RPO and RPO lag times to commit (or block) transactions on the primary as follows:

- Commits the transaction if at least one secondary DB cluster has an RPO lag time less than the RPO.
- Blocks the transaction if all secondary DB clusters have RPO lag times that are larger than the RPO. It also logs the event to the PostgreSQL log file and emits "wait" events that show the blocked sessions.

In other words, if all secondary clusters are behind the target RPO, Aurora pauses transactions on the primary cluster until at least one of the secondary clusters catches up. Paused transactions are resumed and committed as soon as the lag time of at least one secondary DB cluster becomes less than the RPO. The result is that no transactions can commit until the RPO is met.

The `rds.global_db_rpo` parameter is dynamic. If you decide that you don't want all write transactions to stall until the lag decreases sufficiently, you can reset it quickly. In this case, Aurora recognizes and implements the change after a short delay.

### Important

In a global database with only two Amazon Regions, we recommend keeping the `rds.global_db_rpo` parameter's default value in the secondary Region's parameter group. Otherwise, performing a failover due to a loss of the primary Amazon Region could cause Aurora to pause transactions. Instead, wait until Aurora completes rebuilding the cluster in the old failed Amazon Region before changing this parameter to enforce a maximum RPO.

If you set this parameter as outlined in the following, you can also monitor the metrics that it generates. You can do so by using `psql` or another tool to query the Aurora global database's primary DB cluster and obtain detailed information about your Aurora PostgreSQL-based global database's operations. To learn how, see [Monitoring Aurora PostgreSQL-based global databases](#).

### Topics

- [Setting the recovery point objective](#)
- [Viewing the recovery point objective](#)
- [Disabling the recovery point objective](#)

## Setting the recovery point objective

The `rds.global_db_rpo` parameter controls the RPO setting for a PostgreSQL database. This parameter is supported by Aurora PostgreSQL. Valid values for `rds.global_db_rpo` range from 20 seconds to 2,147,483,647 seconds (68 years). Choose a realistic value to meet your business need and use case. For example, you might want to allow up to 10 minutes for your RPO, in which case you set the value to 600.

You can set this value for your Aurora PostgreSQL-based global database by using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

### Console

#### To set the RPO

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

2. Choose the primary cluster of your Aurora global database and open the **Configuration** tab to find its DB cluster parameter group. For example, the default parameter group for a primary DB cluster running Aurora PostgreSQL 11.7 is `default.aurora-postgresql11`.

Parameter groups can't be edited directly. Instead, you do the following:

- Create a custom DB cluster parameter group using the appropriate default parameter group as the starting point. For example, create a custom DB cluster parameter group based on the `default.aurora-postgresql11`.
- On your custom DB parameter group, set the value of the `rds.global_db_rpo` parameter to meet your use case. Valid values range from 20 seconds up to the maximum integer value of 2,147,483,647 (68 years).
- Apply the modified DB cluster parameter group to your Aurora DB cluster.

For more information, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

## Amazon CLI

To set the `rds.global_db_rpo` parameter, use the [modify-db-cluster-parameter-group](#) CLI command. In the command, specify the name of your primary cluster's parameter group and values for RPO parameter.

The following example sets the RPO to 600 seconds (10 minutes) for the primary DB cluster's parameter group named `my_custom_global_parameter_group`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name my_custom_global_parameter_group \  
  --parameters  
  "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name my_custom_global_parameter_group ^  
  --parameters  
  "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

## RDS API

To modify the `rds.global_db_rpo` parameter, use the Amazon RDS [ModifyDBClusterParameterGroup](#) API operation.

### Viewing the recovery point objective

The recovery point objective (RPO) of a global database is stored in the `rds.global_db_rpo` parameter for each DB cluster. You can connect to the endpoint for the secondary cluster you want to view and use `psql` to query the instance for this value.

```
db-name=>show rds.global_db_rpo;
```

If this parameter isn't set, the query returns the following:

```
rds.global_db_rpo
-----
-1
(1 row)
```

This next response is from a secondary DB cluster that has 1 minute RPO setting.

```
rds.global_db_rpo
-----
60
(1 row)
```

You can also use the CLI to get values for find out if `rds.global_db_rpo` is active on any of the Aurora DB clusters by using the CLI to get values of all user parameters for the cluster.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \  
  --db-cluster-parameter-group-name lab-test-apg-global \  
  --source user
```

For Windows:

```
aws rds describe-db-cluster-parameters ^  
  --db-cluster-parameter-group-name lab-test-apg-global *
```

```
--source user
```

The command returns output similar to the following for all user parameters. that aren't default-engine or system DB cluster parameters.

```
{
  "Parameters": [
    {
      "ParameterName": "rds.global_db_rpo",
      "ParameterValue": "60",
      "Description": "(s) Recovery point objective threshold, in seconds, that
blocks user commits when it is violated.",
      "Source": "user",
      "ApplyType": "dynamic",
      "DataType": "integer",
      "AllowedValues": "20-2147483647",
      "IsModifiable": true,
      "ApplyMethod": "immediate",
      "SupportedEngineModes": [
        "provisioned"
      ]
    }
  ]
}
```

To learn more about viewing parameters of the cluster parameter group, see [Viewing parameter values for a DB cluster parameter group in Amazon Aurora](#).

## Disabling the recovery point objective

To disable the RPO, reset the `rds.global_db_rpo` parameter. You can reset parameters using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

### Console

#### To disable the RPO

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose your primary DB cluster parameter group.

4. Choose **Edit parameters**.
5. Choose the box next to the **rds.global\_db\_rpo** parameter.
6. Choose **Reset**.
7. When the screen shows **Reset parameters in DB parameter group**, choose **Reset parameters**.

For more information on how to reset a parameter with the console, see [Modifying parameters in a DB cluster parameter group in Amazon Aurora](#).

## Amazon CLI

To reset the `rds.global_db_rpo` parameter, use the [reset-db-cluster-parameter-group](#) command.

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name global_db_cluster_parameter_group \  
  --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^  
  --db-cluster-parameter-group-name global_db_cluster_parameter_group ^  
  --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

## RDS API

To reset the `rds.global_db_rpo` parameter, use the Amazon RDS API [ResetDBClusterParameterGroup](#) operation.

## Cross-Region resiliency for Global Database secondary clusters

Aurora PostgreSQL versions 16.6, 15.10, 14.15, 13.18, 12.22, or higher and Aurora MySQL versions 3.09 or higher contain availability improvements that enable secondary Region read replicas to maintain service continuity during unplanned events such as hardware failures, network disruptions across Amazon Regions, large volumes of data transfers between the clusters, and others.

Although the read replicas remain available for your application requests, the replication lag may continue to increase until the resolution of the unplanned event. You can monitor the lag

between primary and secondary clusters using the `AuroraGlobalDBProgressLag` CloudWatch metric. To measure the end-to-end lag, including any lag between the cluster volume and DB instances of the secondary cluster, add the values of the `AuroraGlobalDBProgressLag` and `AuroraReplicaLag` CloudWatch metrics. For more information about metrics, refer to [Metrics reference for Amazon Aurora](#).

The Global Database read availability for Aurora MySQL and earlier versions of Aurora PostgreSQL may be impacted during such unplanned events.

For more information about new features in Aurora PostgreSQL 16.6, 15.10, 14.15, 13.18, and 12.22, see [PostgreSQL 16.6](#) in the *Aurora PostgreSQL Release Notes*.

For more information about new features in Aurora MySQL versions 3.09 and higher, see [Database engine updates for Amazon Aurora MySQL version 3](#) in the *Aurora MySQL Release Notes*.

## Monitoring an Amazon Aurora global database

When you create the Aurora DB clusters that make up your Aurora global database, you can choose many options that let you monitor your DB cluster's performance. These options include the following:

- Amazon RDS Performance Insights – Enables performance schema in the underlying Aurora database engine. To learn more about Performance Insights and Aurora global databases, see [Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights](#).
- Enhanced monitoring – Generates metrics for process or thread utilization on the CPU. To learn about enhanced monitoring, see [Monitoring OS metrics with Enhanced Monitoring](#).
- Amazon CloudWatch Logs – Publishes specified log types to CloudWatch Logs. Error logs are published by default, but you can choose other logs specific to your Aurora database engine.
  - For Aurora MySQL-based Aurora DB clusters, you can export the audit log, general log, and slow query log.
  - For Aurora PostgreSQL-based Aurora DB clusters, you can export the PostgreSQL log.
- For Aurora MySQL-based global databases, you can query specific `information_schema` tables to check the status of your Aurora global database and its instances. To learn how, see [Monitoring Aurora MySQL-based global databases](#).
- For Aurora PostgreSQL-based global databases, you can use specific functions to check the status of your Aurora global database and its instances. To learn how, see [Monitoring Aurora PostgreSQL-based global databases](#).

The following screenshot shows some of the options available on the Monitoring tab of a primary Aurora DB cluster in an Aurora global database.

Cluster Name	Role	Engine	Region	Instances
lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters
lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances
lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large
lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large
lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances
lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large
lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large

Performance Insights

For more information, see [Monitoring metrics in an Amazon Aurora cluster](#).

## Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights

You can use Amazon RDS Performance Insights for your Aurora global databases. You enable this feature individually, for each Aurora DB cluster in your Aurora global database. To do so, you choose **Enable Performance Insights** in the **Additional configuration** section of the Create database page. Or you can modify your Aurora DB clusters to use this feature after they are up and running. You can enable or turn off Performance Insights for each cluster that's part of your Aurora global database.

The reports created by Performance Insights apply to each cluster in the global database. When you add a new secondary Amazon Web Services Region to an Aurora global database that's already

using Performance Insights, be sure that you enable Performance Insights in the newly added cluster. It doesn't inherit the Performance Insights setting from the existing global database.

You can switch Amazon Web Services Regions while viewing the Performance Insights page for a DB instance that's attached to a global database. However, you might not see performance information immediately after switching Amazon Web Services Regions. Although the DB instances might have identical names in each Amazon Web Services Region, the associated Performance Insights URL is different for each DB instance. After switching Amazon Web Services Regions, choose the name of the DB instance again in the Performance Insights navigation pane.

For DB instances associated with a global database, the factors affecting performance might be different in each Amazon Web Services Region. For example, the DB instances in each Amazon Web Services Region might have different capacity.

To learn more about using Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

## Monitoring Aurora global databases with Database Activity Streams

By using the Database Activity Streams feature, you can monitor and set alarms for auditing activity in the DB clusters in your global database. You start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own Amazon Web Services Region. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](#).

## Monitoring Aurora MySQL-based global databases

To view the status of an Aurora MySQL-based global database, query the [information\\_schema.aurora\\_global\\_db\\_status](#) and [information\\_schema.aurora\\_global\\_db\\_instance\\_status](#) tables.

### Note

The `information_schema.aurora_global_db_status` and `information_schema.aurora_global_db_instance_status` tables are only available with Aurora MySQL version 3.04.0 and higher global databases.

## To monitor an Aurora MySQL-based global database

1. Connect to the global database primary cluster endpoint using a MySQL client. For more information about how to connect, see [Connecting to Amazon Aurora Global Database](#).
2. Query the `information_schema.aurora_global_db_status` table in a `mysql` command to list the primary and secondary volumes. This query returns the lag times of the global database secondary DB clusters, as in the following example.

```
mysql> select * from information_schema.aurora_global_db_status;
```

```
AWS_REGION | HIGHEST_LSN_WRITTEN | DURABILITY_LAG_IN_MILLISECONDS |
RPO_LAG_IN_MILLISECONDS | LAST_LAG_CALCULATION_TIMESTAMP | OLDEST_READ_VIEW_TRX_ID
-----+-----+-----
+-----+-----+-----
us-east-1 |          183537946 |          0 |
0 | 1970-01-01 00:00:00.000000 |          0
us-west-2 |          183537944 |          428 |
0 | 2023-02-18 01:26:41.925000 |        20806982
(2 rows)
```

The output includes a row for each DB cluster of the global database containing the following columns:

- **AWS\_REGION** – The Amazon Web Services Region that this DB cluster is in. For tables listing Amazon Web Services Regions by engine, see [Region availability](#).
- **HIGHEST\_LSN\_WRITTEN** – The highest log sequence number (LSN) currently written on this DB cluster.

A *log sequence number (LSN)* is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.

- **DURABILITY\_LAG\_IN\_MILLISECONDS** – The difference in the timestamp values between the `HIGHEST_LSN_WRITTEN` on a secondary DB cluster and the `HIGHEST_LSN_WRITTEN` on the primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.
- **RPO\_LAG\_IN\_MILLISECONDS** – The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB

cluster after it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database.

In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.

- **LAST\_LAG\_CALCULATION\_TIMESTAMP** – The timestamp that specifies when values were last calculated for `DURABILITY_LAG_IN_MILLISECONDS` and `RPO_LAG_IN_MILLISECONDS`. A time value such as `1970-01-01 00:00:00+00` means this is the primary DB cluster.
  - **OLDEST\_READ\_VIEW\_TRX\_ID** – The ID of the oldest transaction that the writer DB instance can purge to.
3. Query the `information_schema.aurora_global_db_instance_status` table to list all secondary DB instances for both the primary DB cluster and the secondary DB clusters.

```
mysql> select * from information_schema.aurora_global_db_instance_status;
```

```
SERVER_ID          |          SESSION_ID          | AWS_REGION
| DURABLE_LSN | HIGHEST_LSN_RECEIVED | OLDEST_READ_VIEW_TRX_ID |
OLDEST_READ_VIEW_LSN | VISIBILITY_LAG_IN_MSEC
-----+-----+-----
+-----+-----+-----
ams-gdb-primary-i2 | MASTER_SESSION_ID          | us-east-1 |
183537698 |          0 |          0 |
0 |          0
ams-gdb-secondary-i1 | cc43165b-bdc6-4651-abbf-4f74f08bf931 | us-west-2 |
183537689 |          183537692 |          20806928 |
183537682 |          0
ams-gdb-secondary-i2 | 53303ff0-70b5-411f-bc86-28d7a53f8c19 | us-west-2 |
183537689 |          183537692 |          20806928 |
183537682 |          677
ams-gdb-primary-i1 | 5af1e20f-43db-421f-9f0d-2b92774c7d02 | us-east-1 |
183537697 |          183537698 |          20806930 |
183537691 |          21
(4 rows)
```

The output includes a row for each DB instance of the global database containing the following columns:

- **SERVER\_ID** – The server identifier for the DB instance.
- **SESSION\_ID** – A unique identifier for the current session. A value of MASTER\_SESSION\_ID identifies the Writer (primary) DB instance.
- **AWS\_REGION** – The Amazon Web Services Region that this DB instance is in. For tables listing Amazon Web Services Regions by engine, see [Region availability](#).
- **DURABLE\_LSN** – The LSN made durable in storage.
- **HIGHEST\_LSN\_RECEIVED** – The highest LSN received by the DB instance from the writer DB instance.
- **OLDEST\_READ\_VIEW\_TRX\_ID** – The ID of the oldest transaction that the writer DB instance can purge to.
- **OLDEST\_READ\_VIEW\_LSN** – The oldest LSN used by the DB instance to read from storage.
- **VISIBILITY\_LAG\_IN\_MSEC** – For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
mysql> BEGIN;
mysql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
mysql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the BEGIN statement. If so, the secondary DB cluster's **DURABILITY\_LAG\_IN\_MILLISECONDS** value starts increasing. At the end of the INSERT statement, the **DURABILITY\_LAG\_IN\_MILLISECONDS** value is 1 hour. However, the **RPO\_LAG\_IN\_MILLISECONDS** value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the COMMIT statement completes, the **RPO\_LAG\_IN\_MILLISECONDS** value increases.

## Monitoring Aurora PostgreSQL-based global databases

To view the status of an Aurora PostgreSQL-based global database, use the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

**Note**

Only Aurora PostgreSQL supports the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

**To monitor an Aurora PostgreSQL-based global database**

1. Connect to the global database primary cluster endpoint using a PostgreSQL utility such as `psql`. For more information about how to connect, see [Connecting to Amazon Aurora Global Database](#).
2. Use the `aurora_global_db_status` function in a `psql` command to list the primary and secondary volumes. This shows the lag times of the global database secondary DB clusters.

```
postgres=> select * from aurora_global_db_status();
```

```
aws_region | highest_lsn_written | durability_lag_in_msec | rpo_lag_in_msec |
last_lag_calculation_time | feedback_epoch | feedback_xmin
-----+-----+-----+-----+
+-----+-----+-----+-----+
us-east-1 |          93763984222 |          -1 |          -1 |
1970-01-01 00:00:00+00 |          0 |          0
us-west-2 |          93763984222 |          900 |         1090 |
2020-05-12 22:49:14.328+00 |          2 |        3315479243
(2 rows)
```

The output includes a row for each DB cluster of the global database containing the following columns:

- **aws\_region** – The Amazon Web Services Region that this DB cluster is in. For tables listing Amazon Web Services Regions by engine, see [Region availability](#).
- **highest\_lsn\_written** – The highest log sequence number (LSN) currently written on this DB cluster.

A *log sequence number (LSN)* is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.

- **durability\_lag\_in\_msec** – The timestamp difference between the highest log sequence number written on a secondary DB cluster (`highest_lsn_written`) and the `highest_lsn_written` on the primary DB cluster.
- **rpo\_lag\_in\_msec** – The recovery point objective (RPO) lag. This lag is the time difference between the most recent user transaction commit stored on a secondary DB cluster and the most recent user transaction commit stored on the primary DB cluster.
- **last\_lag\_calculation\_time** – The timestamp when values were last calculated for `durability_lag_in_msec` and `rpo_lag_in_msec`.
- **feedback\_epoch** – The epoch a secondary DB cluster uses when it generates hot standby information.

*Hot standby* is when a DB cluster can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB cluster when it's in hot standby. For more information, see [Hot standby](#) in the PostgreSQL documentation.

- **feedback\_xmin** – The minimum (oldest) active transaction ID used by a secondary DB cluster.

3. Use the `aurora_global_db_instance_status` function to list all secondary DB instances for both the primary DB cluster and secondary DB clusters.

```
postgres=> select * from aurora_global_db_instance_status();
```

```
server_id | session_id
| aws_region | durable_lsn | highest_lsn_rcvd | feedback_epoch | feedback_xmin |
oldest_read_view_lsn | visibility_lag_in_msec
-----+-----
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
apg-global-db-rpo-mammothrw-elephantro-1-n1 | MASTER_SESSION_ID
| us-east-1 | 93763985102 | | | |
|
apg-global-db-rpo-mammothrw-elephantro-1-n2 | f38430cf-6576-479a-b296-dc06b1b1964a
| us-east-1 | 93763985099 | 93763985102 | 2 | 3315479243 |
93763985095 | 10
apg-global-db-rpo-elephantro-mammothrw-n1 | 0d9f1d98-04ad-4aa4-8fdd-e08674cbbbfe
| us-west-2 | 93763985095 | 93763985099 | 2 | 3315479243 |
93763985089 | 1017
(3 rows)
```

The output includes a row for each DB instance of the global database containing the following columns:

- **server\_id** – The server identifier for the DB instance.
- **session\_id** – A unique identifier for the current session.
- **aws\_region** – The Amazon Web Services Region that this DB instance is in. For tables listing Amazon Web Services Regions by engine, see [Region availability](#).
- **durable\_lsn** – The LSN made durable in storage.
- **highest\_lsn\_rcvd** – The highest LSN received by the DB instance from the writer DB instance.
- **feedback\_epoch** – The epoch the DB instance uses when it generates hot standby information.

*Hot standby* is when a DB instance can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB instance when it's in hot standby. For more information, see the PostgreSQL documentation on [Hot standby](#).

- **feedback\_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
- **oldest\_read\_view\_lsn** – The oldest LSN used by the DB instance to read from storage.
- **visibility\_lag\_in\_msec** – How far this DB instance is lagging behind the writer DB instance.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
psql> BEGIN;  
psql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;  
psql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the BEGIN statement. If so, the secondary DB cluster's `durability_lag_in_msec` value starts increasing. At the end of the INSERT statement, the `durability_lag_in_msec` value is 1 hour. However, the `rpo_lag_in_msec` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the COMMIT statement completes, the `rpo_lag_in_msec` value increases.

# Using Blue/Green Deployments for Amazon Aurora Global Database

Amazon RDS Blue/Green Deployments provide a capability for testing database changes safely. For your global database, blue/green deployments allow you to perform upgrades and maintenance operations with minimal downtime. You can create a fully managed staging environment (green) that mirrors your entire production environment (blue), including the primary cluster and all associated secondary regions across multiple Amazon Regions. The staging environment reflects your production setup, enabling you to reliably test changes before switching over to the new environment. Throughout the process, blue/green deployments keep the staging and production environments in sync. When ready to make your staging environment the new production environment, perform a blue/green switchover. This operation transitions your primary and all secondary regions to the green environment, with downtime typically under one minute. The service automatically renames clusters, instances, and endpoints to match the original production environment, enabling your applications to access the new production environment without requiring any configuration changes and minimizing operational overhead.

## Topics

- [Benefits of using Blue/Green Deployments with Aurora Global Database](#)
- [How Blue/Green Deployments work with Aurora Global Database](#)

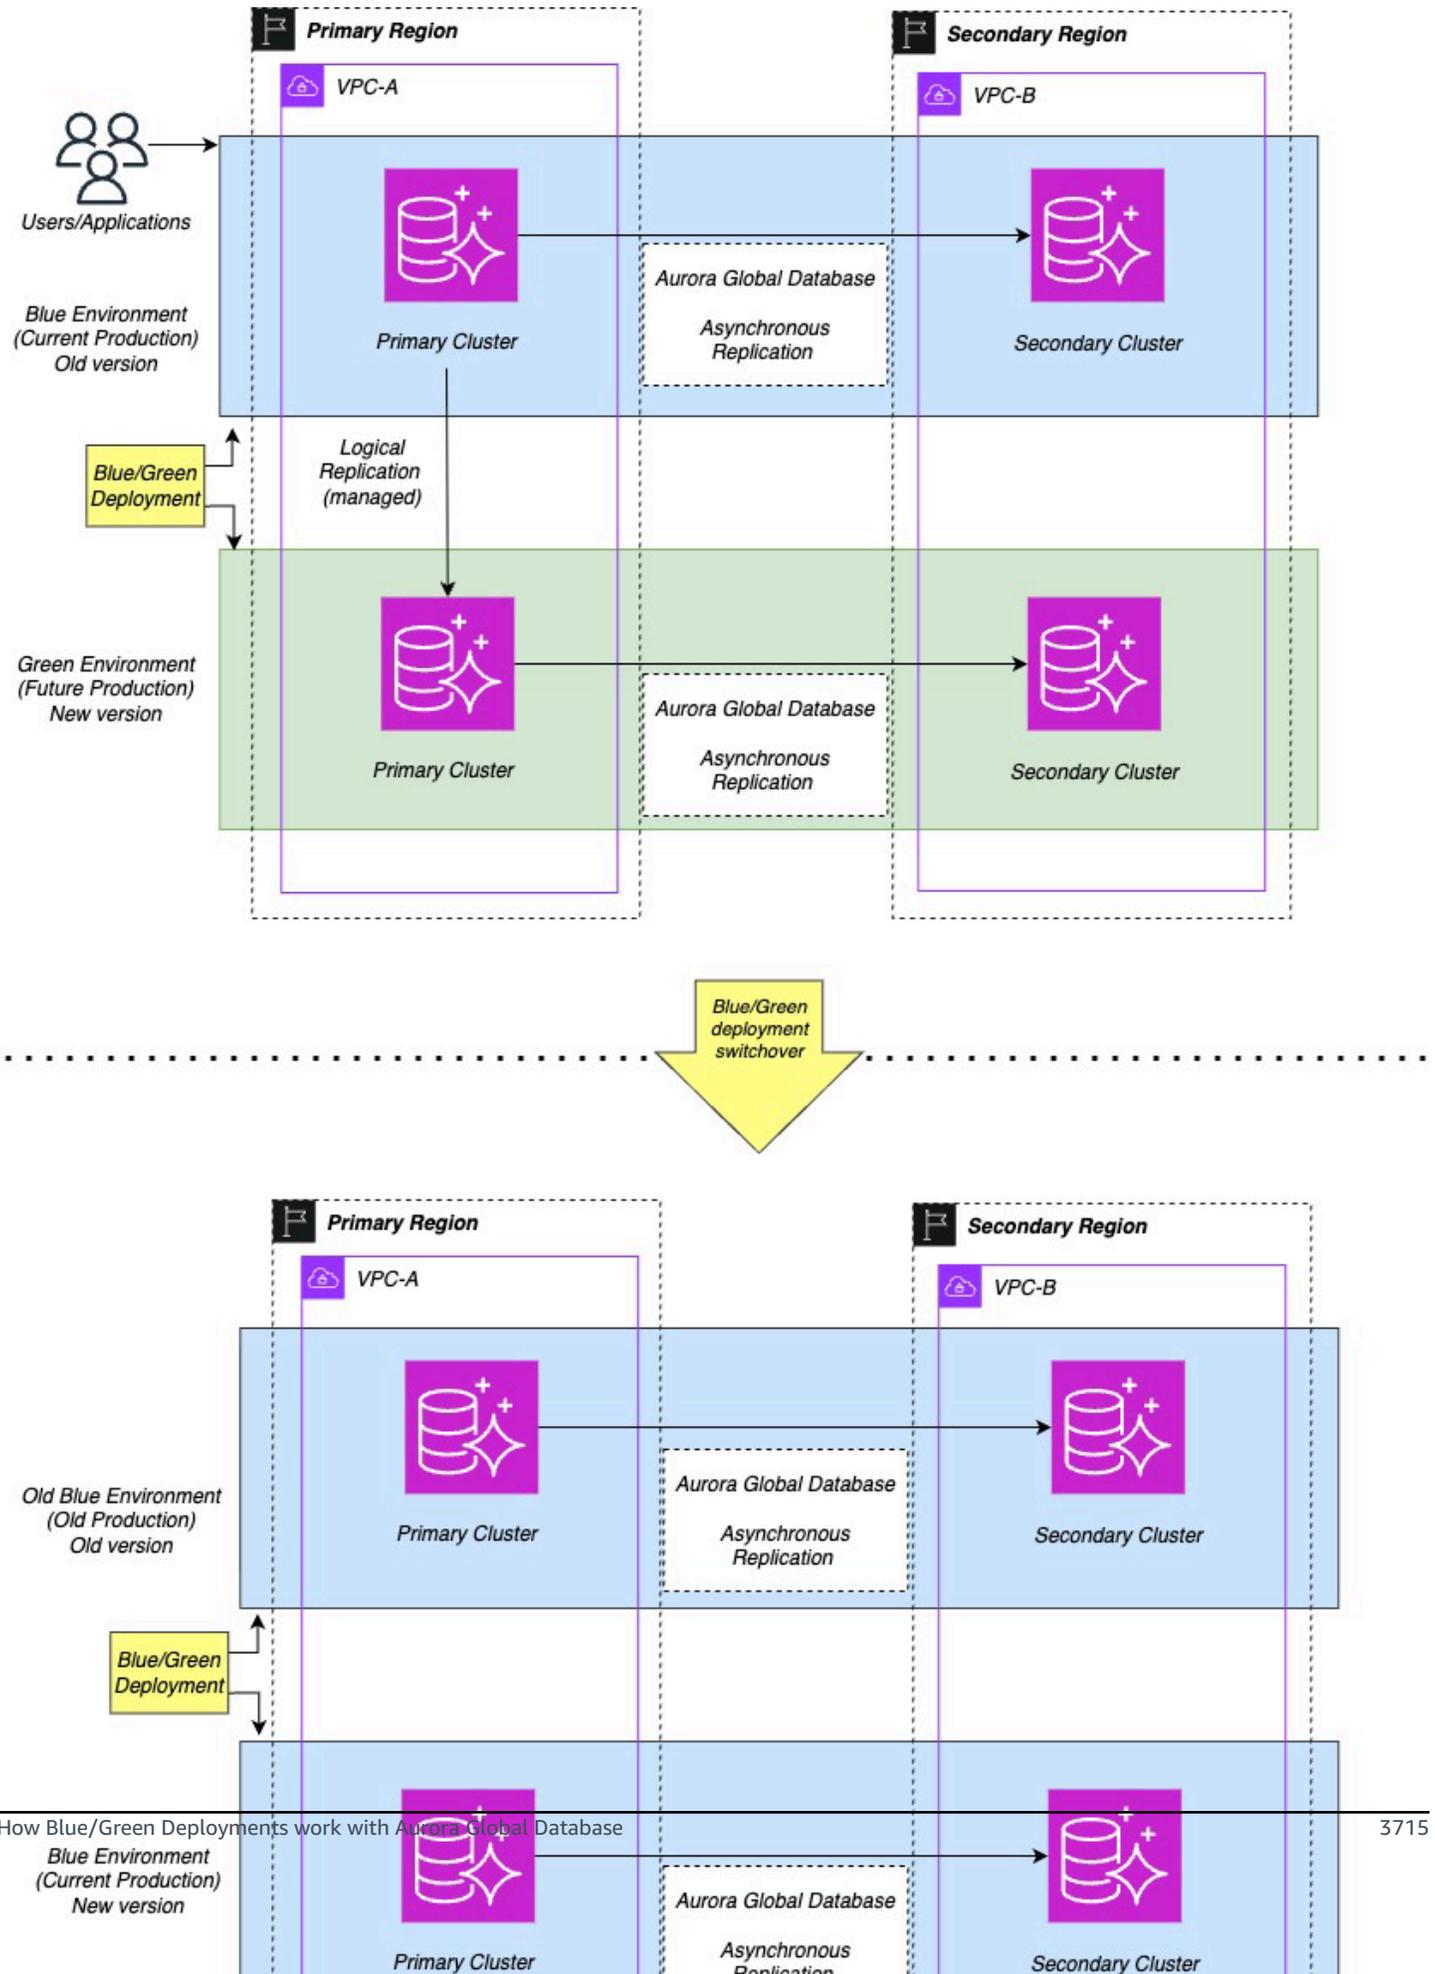

## Benefits of using Blue/Green Deployments with Aurora Global Database

- Perform major version, minor version, and system updates including database patches and OS upgrades on Aurora Global Databases, while maintaining minimal downtime.
- Create a production-ready staging (green) environment in both primary and secondary regions of the global database to test and implement newer database features.
- Switchover safely using built-in switchover guardrails with downtime typically under one minute, depending on your workload.
- Maintains disaster recovery capabilities during the Blue/Green switchover process, allowing Global Database failover during the Blue/Green switchover.
- Your traffic will be directed to the new production environment without requiring any application changes.

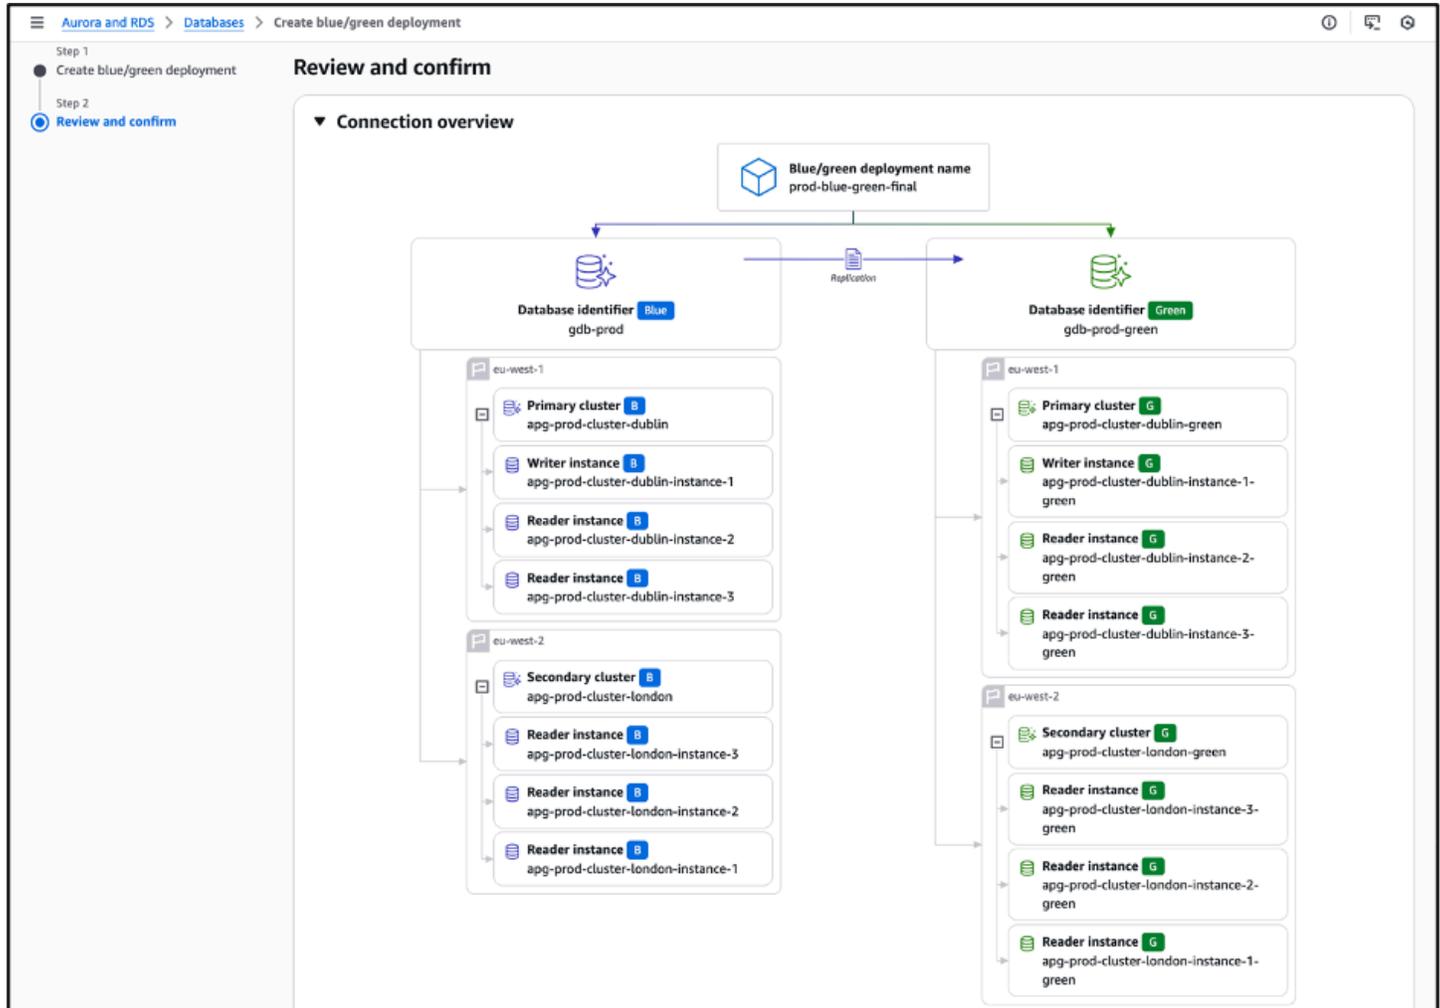

## How Blue/Green Deployments work with Aurora Global Database

For details on how to create, view, switch, and delete a Blue/Green Deployment, see [Using Amazon Aurora Blue/Green Deployments for database updates](#). You can use this for major or minor version upgrades, database performance improvements through parameter updates, and adoption of new database features, with minimal downtime.

A representation of how a blue/green deployment for Aurora Global Database with one secondary region looks before and after a blue/green switchover is shown below.

You can create a blue/green deployment from the primary Region of your Global Database. Select the engine configurations such as major or minor Engine version, DB Parameter group, and DB cluster Parameter group for the green environment. Amazon RDS copies the blue environment's topology for the green environment. A visual representation in Amazon Web Services Management Console is as shown below.

### Note

Global failover is supported during a blue/green switchover, but Global switchover is not supported during a blue/green switchover.

When you initiate a global failover during an RDS blue/green switchover, the target region automatically rolls back to the blue environment or rolls forward to the green environment before the global failover occurs.

For information on creating, viewing, switching, and deleting blue/green deployments, see [Using Amazon Aurora Blue/Green Deployments for database updates](#). Follow the same workflow for Global Databases, with specific instructions noted in the relevant steps.

## Using Amazon Aurora global databases with other Amazon services

You can use your Aurora global databases with other Amazon services, such as Amazon S3 and Amazon Lambda. Doing so requires that all Aurora DB clusters in your global database have the same privileges, external functions, and so on in the respective Amazon Web Services Regions. Because a read-only Aurora secondary DB cluster in an Aurora global database can be promoted to the role of primary, we recommend that you set up write privileges ahead of time, on all Aurora DB clusters for any services you plan to use with your Aurora global database.

The following procedures summarize the actions to take for each Amazon Web Services service.

### To invoke Amazon Lambda functions from an Aurora global database

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](#).
2. For each cluster in the Aurora global database, set the (ARN) of the new IAM (IAM) role.
3. To permit database users in an Aurora global database to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with each cluster in the Aurora global database.
4. Configure each cluster in the Aurora global database to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

### To load data from Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).
2. For each Aurora cluster in the global database, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the

new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

3. To permit database users in an Aurora global database to access S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

### To save queried data to Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#) or [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).
2. For each Aurora cluster in the global database, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access Amazon services](#) with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see [Enabling network communication from Amazon Aurora to other Amazon services](#).

## Upgrading an Amazon Aurora global database

Upgrading an Aurora global database follows the same procedures as upgrading Aurora DB clusters. However, following are some important differences to take note of before you start the process.

We recommend that you upgrade the primary and secondary DB clusters to the same version. You can only perform a managed cross-Region database failover on an Aurora global database if the primary and secondary DB clusters have the same major, minor, and patch level engine versions.

However, the patch levels can be different, depending on the minor engine version. For more information, see [Patch level compatibility for managed cross-Region switchovers and failovers](#).

## Major version upgrades

When you perform a major version upgrade of an Amazon Aurora global database, you upgrade the global database cluster instead the individual clusters that it contains.

To learn how to upgrade an Aurora PostgreSQL global database to a higher major version, see [Major upgrades for global databases](#).

### Note

With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see [Managing RPOs for Aurora PostgreSQL-based global databases](#).

To learn how to upgrade an Aurora MySQL global database to a higher major version, see [In-place major upgrades for global databases](#).

### Note

With an Aurora global database based on Aurora MySQL, you can perform an in-place upgrade from Aurora MySQL version 2 to version 3 only if you set the `lower_case_table_names` parameter to default and you reboot your global database. To perform a major version upgrade to Aurora MySQL version 3 when using `lower_case_table_names`, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in [Removing a cluster from an Amazon Aurora global database](#).
2. Upgrade the engine version of the primary Region to Aurora MySQL version 3. Follow the steps in [How to perform an in-place upgrade](#).
3. Add secondary Regions to the global cluster. Follow the steps in [Adding an Amazon Web Services Region to an Amazon Aurora global database](#).

You can also use the snapshot restore method instead. For more information, see [Restoring from a DB cluster snapshot](#).

## Minor version upgrades

For a minor upgrade on an Aurora global database, you upgrade all of the secondary clusters before you upgrade the primary cluster.

To learn how to upgrade an Aurora PostgreSQL global database to a higher minor version, see [How to perform minor version upgrades and apply patches](#). To learn how to upgrade an Aurora MySQL global database to a higher minor version, see [Upgrading Aurora MySQL by modifying the engine version](#).

Before you perform the upgrade, review the following considerations:

- Upgrading the minor version of a secondary cluster doesn't affect availability or usage of the primary cluster in any way.
- A secondary cluster must have at least one DB instance to perform a minor upgrade.
- If you upgrade an Aurora MySQL global database to version 2.11.\*, you must upgrade your primary and secondary DB clusters to exactly the same version, including the patch level.
- If you upgrade an Aurora PostgreSQL global database, you must upgrade your primary and secondary DB clusters to exactly the same version and patch level. To update the patch level, apply all pending maintenance actions on the secondary cluster.
- To support managed cross-Region switchovers or failovers, you might need to upgrade your primary and secondary DB clusters to the exact same version, including the patch level. This requirement applies to Aurora MySQL and some Aurora PostgreSQL versions. For a list of versions that allow switchovers and failovers between clusters running different patch levels, see [Patch level compatibility for managed cross-Region switchovers and failovers](#).

## Patch level compatibility for managed cross-Region switchovers and failovers

If your Aurora Global Database is running one of the following minor engine versions, you can perform managed cross-Region switchovers or failovers even if the patch levels of your primary and secondary DB clusters don't match. For minor engine versions lower than the ones on this

list, your primary and secondary DB clusters must be running the same major, minor, and patch levels to perform managed cross-Region switchovers or failovers. Make sure to review the version information and the notes in the following table when planning upgrades for your primary cluster, secondary clusters, or both.

 **Note**

For manual cross-Region failovers, you can perform the failover process as long as the target secondary DB cluster is running the same major and minor engine version as the primary DB cluster. In this case, the patch levels don't need to match.

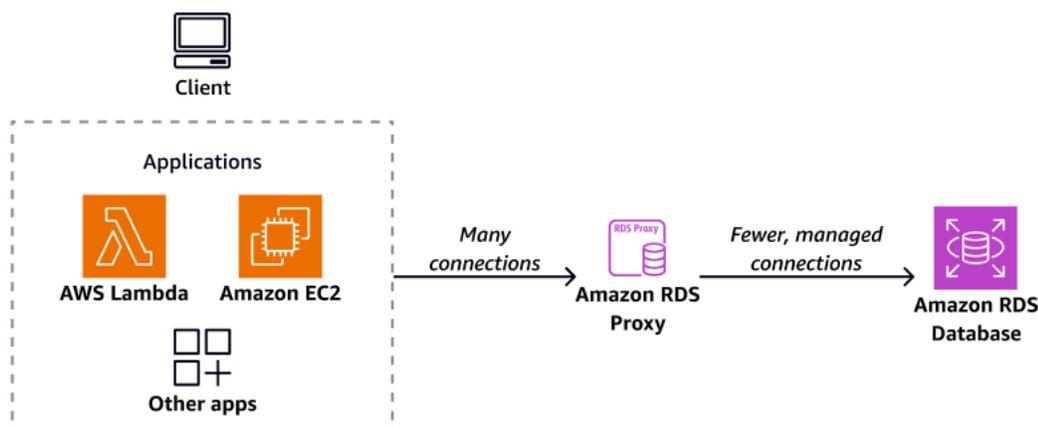

If your engine versions require identical patch levels, you can perform the failover manually by following the steps in [Performing manual failovers for Aurora global databases](#).

Database engine	Minor engine versions	Notes
Aurora MySQL	No minor versions	None of the Aurora MySQL minor versions allow managed cross-Region switchovers or failovers with differing patch levels between the primary and secondary DB clusters.
Aurora PostgreSQL	<ul style="list-style-type: none"> <li>• Version 15 or higher major versions</li> <li>• Version 14.5 or higher minor versions</li> <li>• Version 13.8 or higher minor versions</li> <li>• Version 12.12 or higher minor versions</li> <li>• Version 11.17 or higher minor versions</li> </ul>	<p>With the engine versions listed in the previous column, you can perform managed cross-Region switchovers or failovers from a primary DB cluster with one patch level to a secondary DB cluster with a different patch level.</p> <p>With minor versions lower than these, you can perform managed cross-Region switchovers or failovers only if the patch levels of the primary and secondary DB clusters match.</p>

Database engine	Minor engine versions	Notes
		<p><b>⚠ Warning</b></p> <p>When you update a cluster in your global database to any of the following patch versions, you won't be able to perform cross-Region switchovers or failovers until all of the clusters in your global database are running one of these patch versions or a newer one.</p> <ul style="list-style-type: none"><li>• Patch versions 16.1.6, 16.2.4, 16.3.2, and 16.4.2</li><li>• Patch versions 15.3.8, 15.4.9, 15.5.6, 15.6.4, 15.7.2, and 15.8.2</li><li>• Patch versions 14.8.8, 14.9.9, 14.10.6, 14.11.4, 14.12.2, and 14.13.2</li></ul>

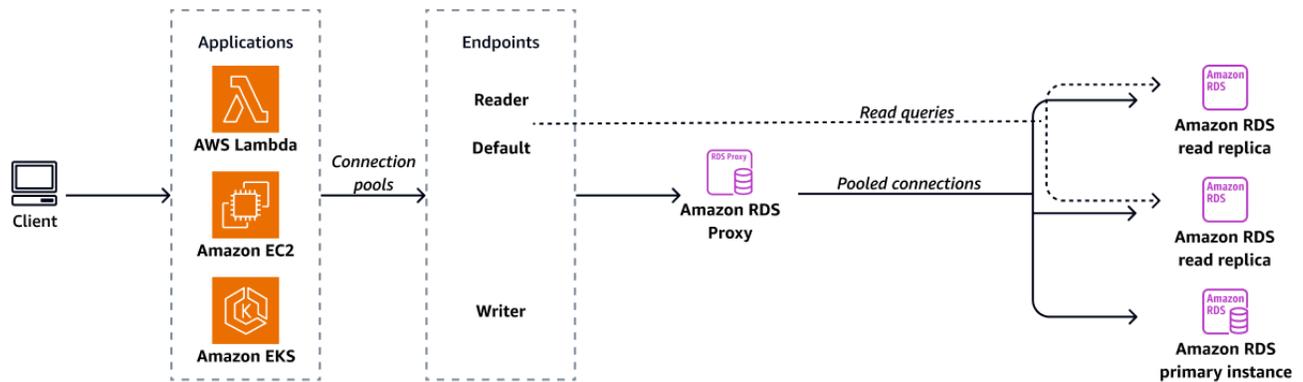

# Amazon RDS Proxy for Aurora

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can enforce Amazon Identity and Access Management (IAM) authentication for clients connecting to the proxy, and the proxy can connect to databases using either IAM database authentication or credentials stored in Amazon Secrets Manager.

Using RDS Proxy, you can handle unpredictable surges in database traffic. Otherwise, these surges might cause issues due to oversubscribing connections or new connections being created at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool. This approach avoids the memory and CPU overhead of opening a new database connection each time. To protect a database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the connection pool. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that RDS can serve with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy is fully compatible with the engine versions that it supports. You can enable RDS Proxy for most applications with no code changes. For a list of supported engine versions, see [Supported Regions and Aurora DB engines for Amazon RDS Proxy](#).

## Topics

- [Using RDS Proxy with Aurora global databases](#)

## Region and version availability

For information about database engine version support and availability of RDS Proxy in a given Amazon Web Services Region, see [Supported Regions and Aurora DB engines for Amazon RDS Proxy](#).

## Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- Each Amazon Web Services account ID is limited to 20 proxies. If your application requires more proxies, request an increase via the **Service Quotas** page within the Amazon Web Services Management Console. In the **Service Quotas** page, select **Amazon Relational Database Service (Amazon RDS)** and locate **Proxies** to request a quota increase. Amazon can automatically increase your quota or pending review of your request by Amazon Web Services Support.
- Each proxy can have up to 200 associated Secrets Manager secrets, thus limiting connections to up to 200 different user accounts when using secrets.
- Each proxy has a default endpoint. You can also add up to 20 proxy endpoints for each proxy. You can create, view, modify, and delete these endpoints.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see [Overview of proxy endpoints](#).
- You can use RDS Proxy with Aurora Serverless v2 clusters, but not with Aurora Serverless v1 clusters.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping your database on a local host, you can't connect to your proxy unless you set up the necessary network requirements to allow connection to the proxy. This is because your local host is outside of the proxy's VPC.

**Note**

For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see [Accessing Aurora databases across VPCs](#).

- You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.
- You can't use RDS Proxy in a VPC that has encryption controls with Enforce Mode enabled.
- For IPv6 endpoint network types, configure your VPC and subnets to support only IPv6. For both IPv4 and IPv6 target connection network types, configure your VPC and subnets to support dual-stack mode.
- If you use RDS Proxy with an Aurora DB cluster that has IAM authentication enabled, the proxy can connect to the database using either IAM authentication or credentials stored in Secrets Manager. Clients connecting to the proxy must authenticate using IAM credentials. For detailed configuration instructions, see [Setting up database credentials for RDS Proxy](#) and [Configuring IAM authentication for RDS Proxy](#).
- You can't use RDS Proxy with custom DNS when using SSL hostname validation.
- Each proxy can be associated with a single target DB cluster. However, you can associate multiple proxies with the same DB cluster.
- Any statement with a text size greater than 16 KB causes the proxy to pin the session to the current connection.
- Certain Regions have Availability-Zone (AZ) restrictions to consider while creating your proxy. US East (N. Virginia) Region does not support RDS Proxy in the use1-az3 Availability Zone. US West (N. California) Region does not support RDS Proxy in the usw1-az2 Availability Zone. When selecting subnets while creating your proxy, make sure that you don't select subnets in the Availability Zones mentioned above.
- Currently, RDS Proxy doesn't support any global condition context keys.

For more information about global condition context keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

- You can't use RDS Proxy with RDS Custom for SQL Server.
- To reflect any database parameter group modification to your proxy, an instance reboot is required even if you chose to apply your changes immediately. For cluster-level parameters, a cluster-wide reboot is required.

- Your proxy automatically creates the `rdsproxyadmin` DB user when you register a proxy target. This is a protected user that is essential for proxy functionality. You should avoid tampering with the `rdsproxyadmin` user in any capacity. Deleting or modifying the `rdsproxyadmin` user or its permissions can result in complete unavailability of the proxy to your application.

For additional limitations for each DB engine, see the following sections:

- [Additional limitations for Aurora MySQL](#)
- [Additional limitations for Aurora PostgreSQL](#)

## Additional limitations for Aurora MySQL

The following additional limitations apply to RDS Proxy with Aurora MySQL databases:

- RDS Proxy support for `caching_sha2_password` authentication requires a secure (TLS) connection.
- RDS Proxy support for `caching_sha2_password` is known to have compatibility issues with certain go-sql driver versions.
- When using the MySQL 8.4 C driver, the `mysql_stmt_bind_named_param` API might form malformed packets if parameter count exceeds placeholder count in a prepared statements. This results in incorrect responses. For more information, see [MySQL bug report](#).
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the `read_only` parameter in its DB parameter group set to 1.
- RDS Proxy doesn't support MySQL compressed mode. For example, it doesn't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Database connections processing a `GET DIAGNOSTIC` command might return inaccurate information when RDS Proxy reuses the same database connection to run another query. This can happen when RDS Proxy multiplexes database connections.
- Some SQL statements and functions such as `SET LOCAL` can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning an RDS Proxy](#).

- Using the `ROW_COUNT()` function in a multi-statement query is not supported.
- RDS Proxy does not support client applications that can't handle multiple response messages in one TLS record.
- RDS Proxy does not support the MySQL dual passwords.
- RDS Proxy might not work as expected when you configure the `init_connect` parameter in your RDS DB parameter group to set session state variables. Instead, set the initialization query for your proxy to run session initialization statements when using proxy to connect to your database.

### Important

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

## Additional limitations for Aurora PostgreSQL

The following additional limitations apply to RDS Proxy with Aurora PostgreSQL databases:

- RDS Proxy doesn't support session pinning filters for PostgreSQL.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case, for example, when you cancel a long-running query in an interactive psql session by using `Ctrl+C`.
- The results of the PostgreSQL function [lastval](#) aren't always accurate. As a work-around, use the [INSERT](#) statement with the `RETURNING` clause.
- RDS Proxy currently doesn't support streaming replication mode.
- The default `postgres` database must exist on the RDS for PostgreSQL instance for RDS Proxy to function. Don't delete this database even if your application uses different databases.
- If you use `ALTER ROLE` to change the user role with `SET ROLE`, subsequent connections as that user to the proxy might not use this role setting, if those connections encounter pinning. To prevent this, when using proxy, use `SET ROLE` in the initialization query of the proxy. For more information, see **Initialization query** in [Creating a proxy for Amazon Aurora](#).

### Important

For existing proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

## Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. This is often characterized by a high value of the `ConnectionAttempts` CloudWatch metric. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB cluster.
- For DB clusters that use smaller Amazon instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB cluster is handling many short-lived connections. Opening and closing such proxy connections can impose performance overhead on your database. For information about the metrics to monitor, see [Monitoring RDS Proxy metrics with Amazon CloudWatch](#).
- Amazon Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that typically open and close large numbers of database connections and don't have built-in connection pooling mechanisms are good candidates for using a proxy.

- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB cluster.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB clusters. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- RDS Proxy can help make applications more resilient and transparent to database failures. RDS Proxy bypasses Domain Name System (DNS) caches to reduce failover times by up to 66% for Aurora Multi-AZ databases. RDS Proxy also automatically routes traffic to a new database instance while preserving application connections. This makes failovers more transparent for applications.

## RDS Proxy concepts and terminology

You can simplify connection management for your Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your Aurora DB cluster. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

- [Transactions](#)

## Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the **Proxies** page.

Each proxy handles connections to a single Aurora DB cluster. The proxy automatically determines the current writer instance for Aurora provisioned clusters.

The connections that a proxy keeps open and available for your database applications to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an Amazon Aurora DB cluster. You do so instead of connecting to the read/write endpoint that connects directly to the cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints](#).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within a cluster. If you use other Amazon services such as Amazon Lambda

to connect to RDS databases, change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The Aurora DB cluster associated with a proxy are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

## Connection pooling

Each proxy performs connection pooling separately for the writer and reader instance of its associated Aurora DB. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one. Examples include Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection. RDS then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

## RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and Amazon Identity and Access Management (IAM). For general information about those security features, see [Security in](#)

[Amazon Aurora](#). Also, make sure to familiarize yourself with how Aurora work with authentication, authorization, and other areas of security.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.3, even if the underlying DB instance supports an older version of TLS. You can connect to the proxy using an IAM role even if the proxy connects to the database using the database user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You can use the following methods of authentication with RDS Proxy:

- **Database credentials**
- **Standard IAM authentication**
- **End-to-end IAM authentication**

## Using IAM with RDS Proxy

RDS Proxy offers two methods of IAM authentication:

- **Standard IAM authentication:** Enforce IAM authentication for connections to your proxy while the proxy connects to the database using credentials stored in Secrets Manager. This enforces IAM authentication for database access even if the databases use native password authentication. The proxy retrieves the database credentials from Secrets Manager and handles the authentication to the database on behalf of your application.
- **End-to-end IAM authentication:** Enforces IAM authentication for connections directly from your applications to your database through the proxy. End-to-end IAM authentication simplifies your security configuration and avoids database credential management in Secrets Manager. This additional layer of security enforces IAM-based access control from the client application to the database.

To use standard IAM authentication, configure your proxy to use Secrets Manager secrets for authentication and enable IAM authentication for client connections. Your applications authenticate to the proxy using IAM, while the proxy authenticates to the database using the credentials retrieved from Secrets Manager.

To use end-to-end IAM authentication, configure your proxy to use IAM authentication when setting the default authentication scheme when creating or modifying your proxy.

For end-to-end IAM authentication, you must update the IAM role associated with the proxy to grant the `rds-db:connect` permission. With end-to-end IAM authentication, this eliminates the need to register individual database users with the proxy through Secrets Manager secrets.

## Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

### Note

RDS Proxy uses certificates from the Amazon Certificate Manager (ACM). If you are using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy in the Amazon Web Services Management Console.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, 1.2, and 1.3. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

### **PREFERRED**

SSL is the first choice, but it isn't required.

## DISABLED

No SSL is allowed.

## REQUIRED

Enforce SSL.

## VERIFY\_CA

Enforce SSL and verify the certificate authority (CA).

## VERIFY\_IDENTITY

Enforce SSL and verify the CA and CA hostname.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For the `.pem` file to use, download all root CA PEMs from [Amazon Trust Services](#) and place them into a single `.pem` file.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

## Failover

*Failover* is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your applications more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. This helps speed up and simplify the failover process. This is less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on the database in failover. Any existing database connections are disrupted, and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted in place of one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

## Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the Aurora MySQL `autocommit` setting is turned on.
- Conversely, when the `autocommit` setting is turned off, the first statement you issue in a session begins a new transaction. For example, suppose that you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements. In this case, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as COMMIT or ROLLBACK appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see [Avoiding pinning an RDS Proxy](#).

## Getting started with RDS Proxy

Use the information in the following pages to set up and manage [Amazon RDS Proxy for Aurora](#) and set related security options. The security options control who can access each proxy and how each proxy connects to DB instances.

If you're new to RDS Proxy, we recommend following the pages in the order that we present them.

### Topics

- [Setting up network prerequisites for RDS Proxy](#)
- [Setting up database credentials for RDS Proxy](#)
- [Configuring IAM authentication for RDS Proxy](#)
- [Creating a proxy for Amazon Aurora](#)
- [Viewing a proxy](#)
- [Connecting to a database through RDS Proxy](#)

## Setting up network prerequisites for RDS Proxy

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see [Work with shared VPCs](#).

For IPv6 support, additional network configuration is required:

- **IPv6 endpoint network types** – Your VPC and subnets must be configured to support IPv6. This includes having IPv6 CIDR blocks assigned to your VPC and subnets.

- **Dual-stack endpoint network types** – Your VPC and subnets must support both IPv4 and IPv6 addressing.
- **IPv6 target connection network types** – Your database must be configured for dual-stack mode to support IPv6 connections from the proxy.

Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC as the proxy. Or they can be in a separate VPC from the proxy. If you successfully connected to any Aurora DB clusters, you already have the required network resources.

## Topics

- [Getting information about your subnets](#)
- [Planning for IP address capacity](#)

## Getting information about your subnets

If you're just getting started with Aurora, you can learn the basics of connecting to a database by following the procedures in [Setting up your environment for Amazon Aurora](#). You can also follow the tutorial in [Getting started with Amazon Aurora](#).

To create a proxy, you must provide the subnets and the VPC that the proxy operates within. The following Linux example shows Amazon CLI commands that examine the VPCs and subnets owned by your Amazon Web Services account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows Amazon CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster.

For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance. To do so, examine the nested fields within the DBSubnetGroup and Subnets attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Find the ID of any DB instance in the cluster.
```

```
$ aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[].[DBClusterMembers][0][0][*].DBInstanceIdentifier' --output text
```

```
my_instance_id  
instance_id_2  
instance_id_3
```

After finding the DB instance identifier, examine the associated VPC to find its subnets. The following Linux example shows how.

```
$ #From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet IDs.  
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0][Subnets][0][*].SubnetIdentifier' --output text
```

```
subnet_id_1  
subnet_id_2  
subnet_id_3  
...
```

```
$ #From the DB instance, find the VPC.  
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0][0].VpcId' --output text
```

```
my_vpc_id
```

```
$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]' --output text
```

```
subnet_id_1  
subnet_id_2  
subnet_id_3  
subnet_id_4  
subnet_id_5  
subnet_id_6
```

## Planning for IP address capacity

RDS Proxy automatically adjusts its capacity based on the configuration of DB instances registered with it. For provisioned instances, this is determined by the instance size and for Aurora Serverless v2 instances, this is determined by the maximum ACU capacity. Certain operations might also require additional capacity such as increasing the size of a registered database or internal RDS Proxy maintenance operations. During these operations, your proxy might need more IP addresses to provision the extra capacity. These additional addresses allow your proxy to scale without affecting your workload. A lack of free IP addresses in your subnets prevents a proxy from scaling up. This can lead to higher query latencies or client connection failures. RDS notifies you through event RDS-EVENT-0243 when there aren't enough free IP addresses in your subnets. For information about this event, see [Working with RDS Proxy events](#).

Reserve the following minimum numbers of free IP addresses in your subnets for your proxy, based on DB instance class sizes.

DB instance class	Minimum free IP addresses
db.*.xlarge or smaller	10
db.*.2xlarge	15
db.*.4xlarge	25
db.*.8xlarge	45
db.*.12xlarge	60
db.*.16xlarge	75
db.*.24xlarge	110

For Aurora Serverless v2, reserve the following minimum numbers of free IP addresses in your subnets for your proxy, based on maximum ACU capacity.

Maximum ACU Capacity	Minimum free IP addresses
16 or smaller	10

Maximum ACU Capacity	Minimum free IP addresses
32	15
64	25
96	30
128	40
160	50
192	55
224	65
256	75

**Note**

RDS Proxy doesn't consume more than 215 IP addresses for each proxy in a VPC.

RDS Proxy requires a minimum of 10 IP addresses for your Aurora database. These recommended numbers of IP addresses are estimates for a proxy with only the default endpoint. For each additional custom endpoint, we recommend reserving three more IP addresses. For each Aurora reader instance, we recommend that you reserve additional IP addresses as specified in the table based on that reader's maximum ACUs for Aurora Serverless v2 target or DB instance size for a provisioned target.

To estimate the required IP addresses for a proxy that's associated with an Aurora DB cluster with:

- 1 provisioned writer instance of size `db.r5.8xlarge` and 1 provisioned reader instance of size `db.r5.2xlarge`.
- The proxy attached to this cluster has a default endpoint and a custom endpoint with the read-only role.

In this case, the proxy needs approximately 63 free IP addresses (45 for the writer instance, 15 for reader instance, and 3 for the additional custom endpoint).

To estimate the required IP addresses for a proxy that's associated with an Aurora DB cluster that has:

- 1 Aurora Serverless v2 writer instance with maximum capacity of 256 ACUs and 1 Serverless v2 reader instance with maximum capacity of 192 ACUs.
- The proxy that's attached to this cluster has the default endpoint and 1 custom endpoint with the read-only role.

In this case, the proxy needs approximately 133 free IP addresses (75 for the writer instance, 55 for reader instance, and 3 for the additional custom endpoint).

To estimate the required IP addresses for a proxy that's associated with an Aurora cluster that has:

- 1 provisioned writer instance with DB instance size of db.r5.4xlarge and 1 Serverless v2 reader instance with maximum capacity of 64 ACUs.
- The proxy that's attached to this cluster has the default endpoint and 1 custom endpoint with the read-only role.

In this case, the proxy needs approximately 53 free IP addresses (25 for the writer instance, 25 for reader instance, and 3 for the additional custom endpoint).

To estimate the required IP addresses for a proxy that's associated with an Aurora DB cluster that has:

- 1 provisioned writer instance of size db.r5.24xlarge and 3 provisioned reader instance of size db.r5.8xlarge.
- The proxy that's attached to this DB cluster has the default endpoint and 1 custom endpoint with the read-only role.

In this case, the proxy needs 215 free IP addresses. While calculations suggest 248 IPs ( $110 + (3 \cdot 45) + 3$ ), RDS Proxy doesn't consume more than 215 IP addresses for each proxy in a VPC.

## Setting up database credentials for RDS Proxy

RDS Proxy in Amazon RDS uses Amazon Secrets Manager to store and manage database credentials securely. Instead of embedding credentials in your application, you associate a proxy with a Secrets Manager secret that contains the necessary authentication details. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the Aurora DB cluster.

Alternatively, you can configure RDS Proxy to use end-to-end IAM authentication, which eliminates the need to store database credentials in Secrets Manager. RDS Proxy uses IAM authentication for both client-to-proxy and proxy-to-database connections. This provides a fully integrated IAM-based authentication solution that doesn't require managing secrets or passwords. For information about adding a new IAM DB user, see [Creating a database account using IAM authentication](#).

### Topics

- [Creating secrets to use with RDS Proxy](#)

## Creating secrets to use with RDS Proxy

Before you create a proxy, you must first create at least one secret that stores your database credentials.

### Console

#### To create a secret

1. Open the Secrets Manager console at <https://console.amazonaws.cn/secretsmanager/>.
2. Choose **Store a new secret**.
3. Choose **Credentials for Amazon RDS database**.
4. Enter a user name and password. The credentials that you enter must match the credentials of a database user that exists in the associated RDS database. RDS Proxy uses these credentials to authenticate and establish connections to the database on behalf of applications.

If there's a mismatch, you can update the secret to match the database password. Until you update the secret, attempts to connect through the proxy using that secret fail, but connections using other valid secrets still work.

**Note**

For RDS for SQL Server, RDS Proxy requires a case-sensitive secret in Secrets Manager, regardless of the DB instance collation settings. If your application allows usernames with different capitalizations, such as "Admin" and "admin," you must create separate secrets for each. RDS Proxy doesn't support case-insensitive username authentication between the client and proxy.

For more information about collation in SQL Server, see the [Microsoft SQL Server](#) documentation.

5. For **Database**, select the Amazon RDS database that the secret will access.
6. Fill in other settings for the secret, then choose **Store**. For comprehensive instructions, see [Creating an Amazon Secrets Manager secret](#) in the *Amazon Secrets Manager User Guide*.

## Amazon CLI

When you create a proxy through the Amazon CLI, you specify the Amazon Resource Names (ARNs) of the corresponding secrets. You do so for all the DB user accounts that the proxy can access. In the Amazon Web Services Management Console, you choose the secrets by their descriptive names.

- To create a Secrets Manager secret for use with RDS Proxy, use the [create-secret](#) command:

```
aws secretsmanager create-secret \  
  --name "secret_name" \  
  --description "secret_description" \  
  --region region_name \  
  --secret-string '{"username":"db_user","password":"db_user_password"}'
```

- You can also create a custom key to encrypt your Secrets Manager secret. The following command creates an example key.

```
aws kms create-key --description "test-key" --policy '{  
  "Id":"kms-policy",  
  "Version": "2012-10-17",  
  "Statement":  
    [  
      {  
        "Sid":"Enable IAM User Permissions",  
        "Effect":"Allow",
```

```

    "Principal":{"AWS":"arn:aws-cn:iam::account_id:root"},
    "Action":"kms:*","Resource":""
  },
  {
    "Sid":"Allow access for Key Administrators",
    "Effect":"Allow",
    "Principal":
      {
        "AWS":
          ["$USER_ARN","arn:aws-cn:iam:account_id::role/Admin"]
      },
    "Action":
      [
        "kms:Create*",
        "kms:Describe*",
        "kms:Enable*",
        "kms:List*",
        "kms:Put*",
        "kms:Update*",
        "kms:Revoke*",
        "kms:Disable*",
        "kms:Get*",
        "kms>Delete*",
        "kms:TagResource",
        "kms:UntagResource",
        "kms:ScheduleKeyDeletion",
        "kms:CancelKeyDeletion"
      ],
    "Resource":""
  },
  {
    "Sid":"Allow use of the key",
    "Effect":"Allow",
    "Principal":{"AWS":"$ROLE_ARN"},
    "Action":["kms:Decrypt","kms:DescribeKey"],
    "Resource":""
  }
]
}'

```

For example, the following commands create Secrets Manager secrets for two database users:

```
aws secretsmanager create-secret \  
  --name secret_name_1 --description "db admin user" \  
  --secret-string '{"username":"admin","password":"choose_your_own_password"}'  
  
aws secretsmanager create-secret \  
  --name secret_name_2 --description "application user" \  
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To create these secrets encrypted with your custom Amazon KMS key, use the following commands:

```
aws secretsmanager create-secret \  
  --name secret_name_1 --description "db admin user" \  
  --secret-string '{"username":"admin","password":"choose_your_own_password"}' \  
  --kms-key-id arn:aws-cn:kms:us-east-2:account_id:key/key_id  
  
aws secretsmanager create-secret \  
  --name secret_name_2 --description "application user" \  
  --secret-string '{"username":"app-user","password":"choose_your_own_password"}' \  
  --kms-key-id arn:aws-cn:kms:us-east-2:account_id:key/key_id
```

To see the secrets owned by your Amazon account, use the [list-secrets](#) command:

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the `--auth` parameter. The following example shows how to prepare a report with only the name and ARN of each secret owned by your Amazon account. This example uses the `--output table` parameter that is available in Amazon CLI version 2. If you are using Amazon CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To confirm that the secret contains the correct credentials in the proper format, use the [get-secret-value](#) command. Replace *your\_secret\_name* with the secret's short name or ARN.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output contains a line with a JSON-encoded value similar to the following:

```
...  
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",  
...
```

## Configuring IAM authentication for RDS Proxy

To set up Amazon Identity and Access Management (IAM) authentication for RDS Proxy in Amazon RDS, create and configure an IAM policy that grants the necessary permissions.

This topic provides the steps to configure IAM authentication for RDS Proxy, including creating the required IAM policy and attaching it to an IAM role.

### Tip

This procedure is only necessary if you want to create your own IAM role. Otherwise, RDS can automatically create the required role when you set up the proxy, so you can skip these steps.

## Prerequisites

Before you set up IAM authentication for RDS Proxy, make sure that you have the following:

- **Amazon Secrets Manager** – At least one stored secret that contains database credentials. For instructions to create secrets, see [the section called “Setting up database credentials”](#).

This is not required if you are using end-to-end IAM authentication.

- **IAM permissions** – An IAM role or user with permissions to create and manage IAM policies, roles, and secrets in Amazon Secrets Manager.

## Creating an IAM policy for end-to-end IAM authentication

When using end-to-end IAM authentication, RDS Proxy connects to your database using IAM authentication instead of retrieving credentials from Secrets Manager. This requires configuring your IAM role with `rds-db:connect` permissions for the database accounts you want to use with the proxy.

To authenticate your RDS Proxy to the database using IAM, create an IAM role with a policy that grants the necessary database connection permissions.

## Console

### To create a role for end-to-end IAM authentication with your proxy

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Create a permissions policy for the role. For general steps, see [Create IAM policies \(console\)](#).

Paste this policy into the JSON editor and make the following changes:

- Substitute your own account ID.
- Substitute `us-east-2` with the where the proxy must reside.
- Substitute the database resource IDs and user names with the ones you want to use. The resource ID format differs between RDS instances and Aurora clusters.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "rds-db:connect",
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:account_id:dbuser:db_instance_resource_id/db_user_name_1",
        "arn:aws-cn:rds-db:us-east-2:account_id:dbuser:db_instance_resource_id/db_user_name_2"
      ]
    }
  ]
}
```

3. Create the role and attach the permissions policy to it. For general steps, see [Create a role to delegate permissions to an Amazon service](#).

For the **Trusted entity type**, choose **Amazon service**. Under **Use case**, select **RDS** and choose **RDS - Add Role to Database** for the use case.

4. For **Permissions policies**, choose the policy that you created.
5. For **Select trusted entities**, enter the following trust policy for the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

## Amazon CLI

To create the role using the Amazon CLI, send the following request:

```
aws iam create-role \
  --role-name my_e2e_iam_role_name \

  --assume-role-policy-document '{"Version":"2012-10-17",
    "Statement":[{"Effect":"Allow","Principal":{"Service":
["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'
```

Then, attach the policy to the role:

```
aws iam put-role-policy \
  --role-name my_e2e_iam_role_name \
  --policy-name e2e_iam_db_connect_policy \
  --policy-document '{

  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "rds-db:connect",
      "Resource": [
        "arn:aws-cn:rds-db:us-
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_1",
```

```
        "arn:aws-cn:rds-db:us-  
east-2:account_id:dbuser:db_instance_resource_id/db_user_name_2"  
      ]  
    }  
  ]  
'
```

With the IAM role and permissions configured for end-to-end IAM authentication, you can now create a proxy with `DefaultAuthScheme` set to `IAM_AUTH`. This proxy directly authenticates to the database using IAM without requiring Secrets Manager secrets. For instructions, see [the section called "Creating a proxy"](#).

When using end-to-end IAM authentication, ensure that your database users are configured for IAM authentication as described in [Creating a database account using IAM authentication](#).

## Creating an IAM policy for Secrets Manager access

To allow RDS Proxy to retrieve database credentials from Secrets Manager, create an IAM role with a policy that grants the necessary permissions.

### Console

#### To create a role to access your secrets for use with your proxy

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Create a permissions policy for the role. For general steps, see [Create IAM policies \(console\)](#).

Paste this policy into the JSON editor and make the following changes:

- Substitute your own account ID.
- Substitute `us-east-2` with the Region where the proxy will reside.
- Substitute the secret names with the ones you created. For more information, see [Specifying KMS keys in IAM policy statements](#).
- Substitute the KMS key ID with the one you used to encrypt the Secrets Manager secrets, either the default key or your own key.

## JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": [
        "arn:aws-cn:secretsmanager:us-east-2:111122223333:secret:secret_name_1",
        "arn:aws-cn:secretsmanager:us-east-2:111122223333:secret:secret_name_2"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "kms:Decrypt",
      "Resource": "arn:aws-cn:kms:us-east-2:111122223333:key/key_id",
      "Condition": {
        "StringEquals": {
          "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
        }
      }
    }
  ]
}

```

3. Create the role and attach the permissions policy to it. For general steps, see [Create a role to delegate permissions to an Amazon service](#).

For the **Trusted entity type**, choose **Amazon service**. Under **Use case**, select **RDS** and choose **RDS - Add Role to Database** for the use case.

4. For **Permissions policies**, choose the policy that you created.
5. For **Select trusted entities**, enter the following trust policy for the role:

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

## Amazon CLI

To create the role using the Amazon CLI, send the following request:

```
aws iam create-role \
  --role-name my_role_name \
  --assume-role-policy-document '{"Version": "2012-10-17",
    "Statement": [{"Effect": "Allow", "Principal": {"Service":
["rds.amazonaws.com"]}, "Action": "sts:AssumeRole"}]}'
```

Then, attach the policy to the role:

```
aws iam put-role-policy \
  --role-name my_role_name \
  --policy-name secret_reader_policy \
  --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "secretsmanager:GetSecretValue",
      "Resource": [
        "arn:aws-cn:secretsmanager:us-east-2:account_id:secret:secret_name_1",
```

```
        "arn:aws-cn:secretsmanager:us-east-2:account_id:secret:secret_name_2"
    ]
},
{
    "Sid": "VisualEditor1",
    "Effect": "Allow",
    "Action": "kms:Decrypt",
    "Resource": "arn:aws-cn:kms:us-east-2:account_id:key/key_id",
    "Condition": {
        "StringEquals": {
            "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
        }
    }
}
]
```

With the IAM role and permissions configured, you can now create a proxy and associate it with this role. This allows the proxy to retrieve database credentials securely from Amazon Secrets Manager and enable IAM authentication for your applications. For instructions, see [the section called “Creating a proxy”](#).

## Creating a proxy for Amazon Aurora

You can use Amazon RDS Proxy to improve the scalability, availability, and security of your database applications by pooling connections and managing database failovers more efficiently. This topic walks you through creating a proxy. Before you start, make sure your database meets the necessary prerequisites, including IAM permissions and VPC configuration.

You can associate a proxy with an Aurora MySQL or Aurora PostgreSQL DB cluster.

### Console

#### To create a proxy

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Configure the following settings for your proxy.

Setting	Description
<b>Engine family</b>	<p>The database network protocol the proxy recognizes when it interprets network traffic to and from the database.</p> <div data-bbox="592 378 1507 646"><p> <b>Note</b></p><p>To use Aurora PostgreSQL, make sure to retain the postgres database in your instance. See <a href="#">Troubleshooting deleted postgres database</a>.</p></div>
<b>Proxy identifier</b>	<p>A name that is unique within your Amazon account ID and current Amazon Region.</p>
<b>Idle client connection timeout</b>	<p>The proxy closes a client connection if it remains idle for a set period. By default, this is 1,800 seconds (30 minutes). A connection is idle when the application doesn't submit a new request within the specified time after completing the previous request. The proxy keeps the underlying database connection open and returns it to the connection pool, making it available for new client connections.</p> <p>To proactively remove stale connections, reduce the idle client connection timeout. To minimize connection costs during workload spikes, increase the timeout.</p>
<b>Database</b>	<p>The Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in <a href="#">Creating an Amazon Aurora DB cluster</a>. Then, try creating the proxy again.</p>

Setting	Description
<b>Connection pool maximum connections</b>	A value between 1 and 100 to define the percentage of the <code>max_connections</code> limit that RDS Proxy can use. If you only intend to use one proxy with this DB instance or cluster, set this value to 100. For more information about how RDS Proxy uses this setting, see <a href="#">the section called "MaxConnectionsPercent"</a> .
<b>Session pinning filters</b>	<p>Prevents RDS Proxy from pinning certain detected session states, which bypasses default safety measures for multiplexing connections. Currently, PostgreSQL doesn't support this setting, and the only available option is <code>EXCLUDE_VARIABLE_SETS</code>. Enabling it might cause session variables from one connection to affect others, leading to errors or correctness issues if queries rely on session variables set outside the current transaction. Use this option only after confirming that your applications can safely share database connections.</p> <p>The following patterns are considered safe:</p> <ul style="list-style-type: none"><li>• SET statements where there is no change to the effective session variable value. In other words, there is no change to the session variable.</li><li>• You change the session variable value and execute a statement in the same transaction.</li></ul> <p>For more information, see <a href="#">Avoiding pinning an RDS Proxy</a>.</p>
<b>Connection borrow timeout</b>	If you expect the proxy to use all available database connections, set the wait time before it returns a timeout error. You can specify up to five minutes. This setting applies only when the proxy has reached the maximum number of connections and all are in use.

Setting	Description
<b>Initialization query</b>	<p>(Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings. Make sure that the query you add is valid. To include multiple variables in a single SET statement, use comma separators. For example:</p> <pre data-bbox="597 583 1507 667">SET <i>variable1</i> =<i>value1</i>, <i>variable2</i> =<i>value2</i></pre> <p>For multiple statements, use semicolons as the separator.</p> <div data-bbox="597 779 1507 1234"><p><b>⚠ Important</b></p><p>Since you can access initialization query as part of target group configuration, it is not protected by authentication or cryptographic methods. Anyone with access to view or manage your proxy target group configuration can view the initialization query. You should not add sensitive data, such as passwords or long-lived encryption keys, to this option.</p></div>
<b>Amazon Identity and Access Management (IAM) role</b>	<p>An IAM role with permission to access the Secrets Manager secrets, which represent the credentials for database user accounts that the proxy can use. Alternatively, you can create a new IAM role from the Amazon Web Services Management Console.</p>

Setting	Description
<b>Secrets Manager secrets</b>	<p>Create or choose Secrets Manager secrets representing the credentials for database users accounts that can use the proxy.</p> <p>When <b>Default authentication scheme</b> is set to <b>None</b>, this field is required. When <b>Default authentication scheme</b> is set to <b>IAM authentication</b>, this field becomes optional and is marked as such in the console.</p> <p>You can choose one or more secrets from the dropdown or create a new secret using the <b>Create a new secret</b> link.</p>
<b>Client authentication type</b>	<p>The type of authentication the proxy uses for connections from clients. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different client authentication type for each secret, create your proxy by using the Amazon CLI or the API instead. Specify this option only when your client connection uses database credentials for authentication.</p>
<b>IAM authentication</b>	<p>Specify <b>Required</b> or <b>Not Allowed</b> for IAM authentication for connections to your proxy. Your choice applies to all Secrets Manager secrets that you associate with this proxy. If you need to specify a different IAM authentication for each secret, create your proxy by using the Amazon CLI or the API instead.</p>

Setting	Description
<b>Default authentication scheme</b>	<p>Choose the default type of authentication that the proxy uses for client connections to the proxy and the connections from the proxy to the underlying database. You have the following options:</p> <ul style="list-style-type: none"><li>• <b>None</b> (default) - The proxy retrieves database credentials from Secrets Manager secrets.</li><li>• <b>IAM authentication</b> - The proxy uses IAM authentication to connect to the database, enabling end-to-end IAM authentication.</li></ul> <p>When you select <b>IAM authentication</b>, an information alert appears reminding you to enable IAM database authentication for the databases in the target group configuration.</p> <div data-bbox="594 932 1507 1150"><p> <b>Note</b></p><p>This option is supported for MySQL, PostgreSQL, and MariaDB engine families only.</p></div>

Setting	Description
<b>Database accounts for IAM authentication</b>	<p>This field appears only when <b>Default authentication scheme</b> is set to <b>IAM authentication</b> and <b>Identity and access management (IAM) role</b> is set to <b>Create IAM role</b>.</p> <p>Name the database user accounts for the proxy to use with IAM authentication. This is a required field. Specify multiple accounts by:</p> <ul style="list-style-type: none"><li>• Typing a database user name to add it as a tag</li><li>• Using specific database user names (e.g., <code>db_user</code>, <code>jane_doe</code>)</li><li>• Using wildcard patterns for multiple users (e.g., <code>db_test_*</code>)</li></ul> <p>Each account appears as a removable tag that you can delete by clicking the X icon. The console uses these values to create the appropriate <code>rds-db:connect</code> permissions in the IAM role policy.</p>
<b>Require Transport Layer Security</b>	<p>Enforces TLS/SSL for all client connections. The proxy uses the same encryption setting for its connection to the underlying database, whether the client connection is encrypted or unencrypted.</p>

Setting	Description
<b>Target connection network type</b>	<p>The IP version that the proxy uses to connect to the target database. Choose from the following options:</p> <ul style="list-style-type: none"><li>• <b>IPv4</b> – The proxy connects to the database using IPv4 addresses.</li><li>• <b>IPv6</b> – The proxy connects to the database using IPv6 addresses.</li></ul> <p>The default is IPv4. To use IPv6, your database must support dual-stack mode. Dual-stack mode is not available for target connections.</p>
<b>Endpoint network type</b>	<p>The IP version for the proxy endpoint that clients use to connect to the proxy. Choose from the following options:</p> <ul style="list-style-type: none"><li>• <b>IPv4</b> – The proxy endpoint uses IPv4 addresses only.</li><li>• <b>IPv6</b> – The proxy endpoint uses IPv6 addresses only.</li><li>• <b>Dual-stack</b> – The proxy endpoint supports both IPv4 and IPv6 addresses.</li></ul> <p>The default is IPv4. To use IPv6 or dual-stack, your VPC and subnets must be configured to support the selected network type.</p>
<b>Subnets</b>	<p>This field is prepopulated with all subnets associated with your VPC. You can remove any subnets not needed for the proxy, but you must leave at least two subnets. For IPv6 or dual-stack endpoint network types, ensure that the selected subnets support the chosen network type.</p>

Setting	Description
<b>VPC security group</b>	<p>Choose an existing VPC security group or create a new one from the Amazon Web Services Management Console. Configure the inbound rules to allow your applications to access the proxy and the outbound rules to permit traffic from your database targets.</p> <div data-bbox="591 491 1510 1188" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"><p><b>Note</b></p><p>The security group must allow connections from the proxy to the database. It serves both for ingress from your applications to the proxy and egress from the proxy to the database. For example, if you use the same security group for both the database and the proxy, make sure that resources within that security group can communicate with each other.</p><p>When you use a shared VPC, avoid using the default security group for the VPC or one associated with another account. Instead, select a security group that belongs to your account. If none exists, create one. For more information, see <a href="#">Work with shared VPCs</a>.</p></div> <p>RDS deploys a proxy across multiple Availability Zones to ensure high availability. To enable cross-AZ communication, the network access control list (ACL) for your proxy subnet must allow egress on the engine port and ingress on all ports. For more information about network ACLs, see <a href="#">Control traffic to subnets using network ACLs</a>. If the network ACL for your proxy and target are identical, you must add a <b>TCP</b> protocol ingress rule where the <b>Source</b> is set to the VPC CIDR. You must also add an engine port specific <b>TCP</b> protocol egress rule where the <b>Destination</b> is set to the VPC CIDR.</p>

Setting	Description
<b>Activate enhanced logging</b>	<p>Enable this setting to troubleshoot proxy compatibility or performance issues. When enabled, RDS Proxy logs detailed performance information to help you debug SQL behavior or proxy connection performance and scalability.</p> <p>Only enable this setting for debugging and ensure proper security measures are in place to protect sensitive information in the logs. To minimize overhead, RDS Proxy automatically disables this setting 24 hours after activation. Use it temporarily to troubleshoot specific issues.</p>

## 5. Choose **Create proxy**.

### Amazon CLI

To create a proxy by using the Amazon CLI, call the [create-db-proxy](#) command with the following required parameters:

- `--db-proxy-name`
- `--engine-family`
- `--role-arn`
- `--vpc-subnet-ids`

The `--engine-family` value is case-sensitive.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \  
  --db-proxy-name proxy_name \  
  --engine-family { MYSQL | POSTGRESQL | SQLSERVER } \  
  --role-arn iam_role \  
  --vpc-subnet-ids space_separated_list \  
  [--default-auth-scheme { NONE | IAM_AUTH }] \  
  [--auth ProxyAuthenticationConfig_JSON_string] \  
  \
```

```

[--vpc-security-group-ids space_separated_list] \
[--require-tls | --no-require-tls] \
[--idle-client-timeout value] \
[--debug-logging | --no-debug-logging] \
[--endpoint-network-type { IPV4 | IPV6 | DUAL }] \
[--target-connection-network-type { IPV4 | IPV6 }] \
[--tags comma_separated_list]

```

### For Windows:

```

aws rds create-db-proxy ^
  --db-proxy-name proxy_name ^
  --engine-family { MYSQL | POSTGRESQL | SQLSERVER } ^
  --role-arn iam_role ^
  --vpc-subnet-ids space_separated_list ^
  [--default-auth-scheme { NONE | IAM_AUTH }] ^
  [--auth ProxyAuthenticationConfig_JSON_string] ^
  [--vpc-security-group-ids space_separated_list] ^
  [--require-tls | --no-require-tls] ^
  [--idle-client-timeout value] ^
  [--debug-logging | --no-debug-logging] ^
  [--endpoint-network-type { IPV4 | IPV6 | DUAL }] ^
  [--target-connection-network-type { IPV4 | IPV6 }] ^
  [--tags comma_separated_list]

```

The following is an example of the JSON value for the `--auth` option. This example applies a different client authentication type to each secret.

```

[
  {
    "Description": "proxy description 1",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:123456789123:secret/1234abcd-12ab-34cd-56ef-1234567890ab",
    "IAMAuth": "DISABLED",
    "ClientPasswordAuthType": "POSTGRES_SCRAM_SHA_256"
  },
  {
    "Description": "proxy description 2",
    "AuthScheme": "SECRETS",
    "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122223333:secret/1234abcd-12ab-34cd-56ef-1234567890cd",

```

```
"IAMAuth": "DISABLED",
"ClientPasswordAuthType": "POSTGRES_MD5"

},

{
  "Description": "proxy description 3",
  "AuthScheme": "SECRETS",
  "SecretArn": "arn:aws:secretsmanager:us-
west-2:111122221111:secret/1234abcd-12ab-34cd-56ef-1234567890ef",
  "IAMAuth": "REQUIRED"
}

]
```

The `--endpoint-network-type` parameter specifies the IP version for the proxy endpoint that clients use to connect to the proxy. Valid values are:

- IPV4 – The proxy endpoint uses IPv4 addresses only (default).
- IPV6 – The proxy endpoint uses IPv6 addresses only.
- DUAL – The proxy endpoint supports both IPv4 and IPv6 addresses.

The `--target-connection-network-type` parameter specifies the IP version that the proxy uses to connect to the target database. Valid values are:

- IPV4 – The proxy connects to the database using IPv4 addresses (default).
- IPV6 – The proxy connects to the database using IPv6 addresses.

To use IPv6 or dual-stack endpoint network types, your VPC and subnets must be configured to support the selected network type. To use IPv6 target connection network type, your database must support dual-stack mode.

 **Tip**

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see [Setting up network prerequisites for RDS Proxy](#) for examples of how to find them.

**Note**

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

To create the right associations for the proxy, you also use the [register-db-proxy-targets](#) command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
  --db-proxy-name value
  [--target-group-name target_group_name]
  [--db-instance-identifiers space_separated_list] # rds db instances, or
  [--db-cluster-identifiers cluster_id]           # rds db cluster (all instances)
```

**RDS API**

To create an RDS proxy, call the Amazon RDS API operation [CreateDBProxy](#). You pass a parameter with the [AuthConfig](#) data structure.

RDS Proxy automatically creates a target group named default when you create each proxy. You associate an Aurora DB cluster with the target group by calling the function [RegisterDBProxyTargets](#).

**Important**

When you select **IAM authentication** for the default authentication scheme:

- You must enable IAM database authentication on your target database instances or clusters before the proxy can successfully connect.

- If you choose **Create IAM role**, the **Database accounts for IAM authentication** field is required.
- If you select an existing IAM role, the console does not automatically update the role with database connection permissions. Check that the role has the necessary `rds-db:connect` permissions.

## Viewing a proxy

After you create one or more RDS proxies, you can view and manage them in the Amazon Web Services Management Console, the Amazon CLI, or the RDS API. You can review their configuration details, monitor performance, and determine which proxies to modify or delete as needed.

To enable database applications to route traffic through a proxy, you must specify the proxy endpoint in the connection string.

### Console

#### To view a proxy in the console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Select the proxy name to view its details.
4. On the details page, the **Target groups** section shows how the proxy is linked to a specific Aurora DB cluster. You can navigate to the default target group page for a deeper view of this association, including configuration settings defined during proxy creation. These settings include the maximum connection percentage, connection borrow timeout, engine family, and session pinning filters.

### CLI

To view your proxy using the CLI, use the [describe-db-proxies](#) command. By default, the request returns all proxies owned by your Amazon account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name

aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run [describe-db-proxies](#).
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run [describe-db-proxy-target-groups](#) --db-proxy-name. Use the name of the proxy as the parameter value.
3. To see the details of the Aurora DB cluster associated with the returned target group, run [describe-db-proxy-targets](#).

## RDS API

To view your proxies using the RDS API, use the [DescribeDBProxies](#) operation. It returns values of the [DBProxy](#) data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the [DescribeDBProxyTargetGroups](#) operation. It returns values of the [DBProxyTargetGroup](#) data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the [DescribeDBProxyTargets](#) operation. It returns values of the [DBProxyTarget](#) data type.

## Connecting to a database through RDS Proxy

You connect to an Aurora DB cluster or cluster that uses Aurora Serverless v2 through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the cluster endpoint. By default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy. You can use that endpoint the same way. For more information, see [Overview of proxy endpoints](#).

### Topics

- [Connecting to a database using database credentials](#)

- [Connecting to a database using IAM authentication](#)
- [Considerations for connecting to PostgreSQL](#)

## Connecting to a database using database credentials

Use the following steps to connect to a proxy using database credentials:

1. Find the proxy endpoint. In the Amazon Web Services Management Console, you can find the endpoint on the details page for the corresponding proxy. With the Amazon CLI, you can use the [describe-db-proxies](#) command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*]'.
{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
  [
    {
      "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy"
    },
    {
      "Endpoint": "the-proxy-other-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy-other-secret"
    },
    {
      "Endpoint": "the-proxy-rds-secret.proxy-demo.us-
east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy-rds-secret"
    },
    {
      "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
      "DBProxyName": "the-proxy-t3"
    }
  ]
]
```

2. Specify the endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

## Connecting to a database using IAM authentication

When you use IAM authentication with RDS Proxy, you have two options for authentication between your client and proxy:

- Set up your database users to authenticate with regular user names and passwords. RDS Proxy retrieves the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.
- You can also use end-to-end IAM authentication, which connects to your database through the proxy using IAM without requiring database credentials.

To connect to RDS Proxy using IAM authentication, use the same general connection procedure as for IAM authentication with an Aurora DB cluster. For general information about using IAM, see [Security in Amazon Aurora](#). If you are using end-to-end IAM authentication, provide the IAM authentication plugin to your DB user. See [Creating a database account using IAM authentication](#).

The major differences in IAM usage for RDS Proxy include the following:

- With standard IAM authentication, database users have regular credentials within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager. The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.
- With end-to-end IAM authentication, you don't need to configure Secrets Manager secrets for database credentials. The IAM authentication applies to the connection between the client to the proxy and proxy to the database.
- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see [Connecting to your DB cluster using IAM authentication](#).
- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws-cn:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

**Tip**

When configuring IAM authentication for RDS Proxy connections, follow these important guidelines to avoid connection issues:

- Do not grant the `rds_iam` role while maintaining general password authentication for the same database user or role.
- Remember that while clients connect to RDS Proxy using IAM authentication, RDS Proxy always connects to the database using password authentication through Secrets Manager.
- If you experience frequent connection terminations and reconnections, remove any existing `rds_iam` grants from the user or role and use only password authentication.
- Ensure your password policy satisfies SCRAM-SHA-256 safe character requirements.

Mixing IAM and password authentication methods for the same database user can cause connection instability.

## Considerations for connecting to PostgreSQL

If you create a new PostgreSQL database user for connecting to RDS Proxy, make sure that you grant the user `CONNECT` privilege on the database. Without this, the user can't establish a connection. For more information, see [the section called "Adding a new database user to a PostgreSQL database when using RDS Proxy"](#).

When a client starts a connection to a PostgreSQL database, it sends a startup message. This message includes pairs of parameter name and value strings. For details, see the `StartupMessage` in [PostgreSQL message formats](#) in the PostgreSQL documentation.

When you connect through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`

The startup message can also include the following additional runtime parameters:

- [application\\_name](#)
- [client\\_encoding](#)
- [DateStyle](#)
- [TimeZone](#)
- [extra\\_float\\_digits](#)
- [search\\_path](#)

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](#) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC, we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. This prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to *any/your-application-name* to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.

For more information, see [Avoiding pinning an RDS Proxy](#). For more information about connecting using JDBC, see [Connecting to the database](#) in the PostgreSQL documentation.

## Managing an RDS Proxy

This section provides information on how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

### Topics

## Modifying an RDS Proxy

You can change specific settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

### Amazon Web Services Management Console

#### Important

The values in the **Client authentication type** and **IAM authentication** fields apply to all Secrets Manager secrets that are associated with this proxy. To specify different values for each secret, modify your proxy by using the Amazon CLI or the API instead.

### To modify the settings for a proxy

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:
  - **Proxy identifier** – Rename the proxy by entering a new identifier.
  - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
  - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.

**Note**

You can't create a new IAM role if you set **Default authentication scheme** to **IAM authentication**.

- **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
- **Client authentication type** – Change the type of authentication for client connections to the proxy.
- **IAM authentication** – Require or disallow IAM authentication for connections to the proxy.
- **Default authentication scheme** – Change the default authentication scheme the proxy uses for client connections to the proxy and connections from the proxy to the underlying database.
- **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
- **VPC security group** – Add or remove VPC security groups for the proxy to use.
- **Enable enhanced logging** – Enable or disable enhanced logging.

**6. Choose Modify.**

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy. You can't rename the default target group.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

**To modify the settings for a proxy target group**

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:

- **Database** – Choose a different Aurora cluster.
- **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
- **Session pinning filters** – (Optional) Choose a session pinning filter. This circumvents the default safety measures for multiplexing database connections across client connections. Currently, the setting isn't supported for PostgreSQL. The only choice is `EXCLUDE_VARIABLE_SETS`.

Enabling this setting can cause session variables of one connection to impact other connections. This can cause errors or correctness issues if your queries depend on session variable values set outside of the current transaction. Consider using this option after verifying it is safe for your applications to share database connections across client connections.

The following patterns can be considered safe:

- SET statements where there is no change to the effective session variable value, i.e., there is no change to the session variable.
- You change the session variable value and execute a statement in the same transaction.

For more information, see [Avoiding pinning an RDS Proxy](#).

- **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
- **Initialization query.** (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with SET statements to make sure that each connection has identical settings. Make sure that the query you add is valid. To include multiple variables in a single SET statement, use comma separators. For example:

```
SET variable1=value1, variable2=value2
```

For multiple statements, use semicolons as the separator.

You can't change certain properties, such as the target group identifier and the database engine.

## 5. Choose **Modify target group**.

### Amazon CLI

To modify a proxy using the Amazon CLI, use the commands [modify-db-proxy](#), [modify-db-proxy-target-group](#), [deregister-db-proxy-targets](#), and [register-db-proxy-targets](#).

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.
- The default authentication scheme associated with the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When you work with this target group, you specify the name of the proxy and `default` for the name of the target group. You can't rename the default target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy  
  
{
```

```

"TargetGroups": [
  {
    "Status": "available",
    "UpdatedDate": "2019-11-30T16:49:30.342Z",
    "ConnectionPoolConfig": {
      "MaxIdleConnectionsPercent": 50,
      "ConnectionBorrowTimeout": 120,
      "MaxConnectionsPercent": 100,
      "SessionPinningFilters": []
    },
    "TargetGroupName": "default",
    "CreatedDate": "2019-11-30T16:49:27.940Z",
    "DBProxyName": "the-proxy",
    "IsDefault": true
  }
]
}

```

```

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name
default --connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

```

```

{
  "DBProxyTargetGroup": {
    "Status": "available",
    "UpdatedDate": "2019-12-02T04:09:50.420Z",
    "ConnectionPoolConfig": {
      "MaxIdleConnectionsPercent": 75,
      "ConnectionBorrowTimeout": 120,
      "MaxConnectionsPercent": 100,
      "SessionPinningFilters": []
    },
    "TargetGroupName": "default",
    "CreatedDate": "2019-11-30T16:49:27.940Z",
    "DBProxyName": "the-proxy",
    "IsDefault": true
  }
}

```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which Aurora DB clusters the proxy is associated with through its target group. Currently, each proxy can connect to one Aurora DB cluster. The target group tracks the connection details for all the all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
  "Targets": [
    {
      "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-9814"
    },
    {
      "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-8898"
    },
    {
      "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-1018"
    },
    {
      "Type": "TRACKED_CLUSTER",
      "Port": 0,
      "RdsResourceId": "cluster-56-2020-02-25-1399"
    },
    {
      "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "instance-4330"
    }
  ]
}
```

```

}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
  "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
provisioned-cluster

{
  "DBProxyTargets": [
    {
      "Type": "TRACKED_CLUSTER",
      "Port": 0,
      "RdsResourceId": "provisioned-cluster"
    },
    {
      "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "gkldje"
    },
    {
      "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
      "Type": "RDS_INSTANCE",
      "Port": 3306,
      "RdsResourceId": "provisioned-1"
    }
  ]
}

```

## RDS API

To modify a proxy using the RDS API, you use the operations [ModifyDBProxy](#), [ModifyDBProxyTargetGroup](#), [DeregisterDBProxyTargets](#), and [RegisterDBProxyTargets](#) operations.

With `ModifyDBProxy`, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.

- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With `ModifyDBProxyTargetGroup`, you can modify connection-related settings. Currently, all proxies have a single target group named `default`. When you work with this target group, you specify the name of the proxy and `default` for the name of the target group. You can't rename the default target group.

With `DeregisterDBProxyTargets` and `RegisterDBProxyTargets`, you change which Aurora cluster the proxy is associated with through its target group. Currently, each proxy can connect to one Aurora cluster. The target group tracks the connection details for the DB instances in an Aurora cluster.

## Adding a new database user when using RDS Proxy

In some cases, you might add a new database user to an Aurora cluster that's associated with a proxy. Proceed depending on whether you're using standard authentication with Secrets Manager secrets or end-to-end IAM authentication.

If you are using the standard IAM authentication, follow these instructions:

1. Create a new Secrets Manager secret, using the procedure described in [Setting up database credentials for RDS Proxy](#).
2. Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
3. Modify the RDS Proxy to add the new Secrets Manager secret under **Secrets Manager secrets**.
4. If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

If you're using end-to-end IAM authentication, you need to create the database user and configure IAM permissions. To do this, run through the following steps:

1. Create a new database user in your database that matches the IAM user or role name you want to use for authentication.

2. Ensure the database user is configured with IAM authentication plugin at the database. See [Creating a database account using IAM authentication](#).
3. Update the IAM policy to grant the `rds-db:connect` permission to the IAM user or role, as described in [Creating an IAM policy for end-to-end IAM authentication](#).
4. Ensure your proxy is configured to use IAM authentication as the default authentication scheme.

With end-to-end IAM authentication, you don't need to manage database credentials in Secrets Manager secrets, as IAM credentials are used for authentication from the client to the proxy and from the proxy to the database.

## Adding a new database user to a PostgreSQL database when using RDS Proxy

When adding a new user to your PostgreSQL database, if you have run the following command:

```
REVOKE CONNECT ON DATABASE postgres FROM PUBLIC;
```

Grant the `rdsproxyadmin` user the `CONNECT` privilege so the user can monitor connections on the target database.

```
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

You can also allow other target database users to perform health checks by changing `rdsproxyadmin` to the database user in the command above.

## Changing the password for a database user when using RDS Proxy

In some cases, you might change the password for a database user in an Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

If you're using end-to-end IAM authentication, you don't need to update any passwords in Secrets Manager secrets.

## Moving from standard IAM authentication to end-to-end IAM authentication for RDS Proxy

If you currently use standard IAM authentication for RDS Proxy, where clients authenticate to the proxy using IAM but the proxy connects to the database using secrets, you can migrate to end-to-

end IAM authentication where both client-to-proxy and proxy-to-database connections use IAM authentication.

## To move to end-to-end IAM authentication

### 1. Update RDS Proxy IAM role permissions

Create an updated proxy permission policy that includes both Secrets Manager and `rds:db-connect` permissions:

```
# Create updated proxy permission policy
cat > updated-proxy-policy.json # EOF
```

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetSecretsValue",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:secretName-1234f"
      ]
    },
    {
      "Sid": "RdsDBConnect",
      "Action": [
        "rds-db:connect"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws-cn:rds-db:us-east-1:123456789012:dbuser:cluster-ABCDEFGHijkl01234/
jane_doe"
      ]
    }
  ]
}
```

Update proxy your role policy:

```
aws iam put-role-policy \  
    --role-name RDSProxyRole \  
    --policy-name UpdatedProxyPermissions \  
    --policy-document file://updated-proxy-policy.json
```

## 2. Modify your RDS Proxy to enable end-to-end IAM authentication

```
aws rds modify-db-proxy \  
    --db-proxy-name my-database-proxy \  
    --default-auth-scheme IAM_AUTH \  
    --region us-east-1
```

Verify that RDS Proxy status is **Available** and `DefaultAuthScheme` is `IAM_AUTH` before proceeding to ensure zero downtime during migration.

```
aws rds describe-db-proxies --db-proxy-name my-database-proxy --region us-east-1
```

Expected output:

```
{  
  "DBProxies": [  
    {  
      "DBProxyName": "my-database-proxy",  
      "DBProxyArn": "arn:aws-cn:rds:us-east-1:123456789012:db-  
proxy:prx-0123456789abcdef",  
      "Status": "available",  
      ...  
      "DefaultAuthScheme": "IAM_AUTH"  
    }  
  ]  
}
```

## 3. Enable IAM authentication on database

```
aws rds modify-db-cluster \  
    --db-cluster-identifier my-database-cluster \  
    --enable-iam-database-authentication \  
    --region us-east-1
```

## 4. Configure database user for IAM authentication

### For Aurora PostgreSQL:

```
GRANT rds_iam TO jane_doe;
```

### For Aurora MySQL:

```
ALTER USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';  
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

5. Your client application code doesn't need to change. The connection process remains the same:

### For Aurora PostgreSQL:

```
# Generate authentication token  
export PGPASSWORD=$(aws rds generate-db-auth-token \  
  --hostname my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com  
 \  
  --port 5432 \  
  --username jane_doe \  
  --region us-east-1)  
  
# Connect to database through proxy  
psql "host=my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com  
port=5432 user=jane_doe dbname=postgres password=$PGPASSWORD sslmode=require  
sslrootcert=us-east-1-bundle.pem"
```

### For Aurora MySQL:

```
# Generate authentication token  
export MYSQL_PWD=$(aws rds generate-db-auth-token \  
  --hostname my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com  
 \  
  --port 3306 \  
  --username jane_doe \  
  --region us-east-1)  
  
# Connect to database through proxy  
mysql -h my-database-proxy.proxy-ABCDEFGHIJKL01234.us-east-1.rds.amazonaws.com \  
  -P 3306 \  
  -u jane_doe \  
  --ssl-ca=us-east-1-bundle.pem \  
  --ssl-mode=REQUIRED
```

```
--enable-plaintext-plugin
```

## RDS Proxy connection considerations

### Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- [IdleClientTimeout](#)
- [MaxConnectionsPercent](#)
- [MaxIdleConnectionsPercent](#)
- [ConnectionBorrowTimeout](#)

#### IdleClientTimeout

You can specify how long a client connection can be idle before the proxy closes it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, then lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, then raise the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the Amazon CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see [Amazon Web Services Management Console](#). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command [modify-db-proxy](#) or the API operation [ModifyDBProxy](#).

#### MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the target database. You specify the limit as a percentage of the maximum connections available for your database. This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the Amazon CLI and the API.

The `MaxConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the Aurora DB cluster used by the target group. The proxy doesn't create all of these connections in advance. This setting allows the proxy to establish these connections as the workload needs them.

For example, for a registered database target with `max_connections` set to 1000, and `MaxConnectionsPercent` set to 95, RDS Proxy sets 950 connections as the upper limit for concurrent connections to that database target.

A common side-effect of your workload reaching the maximum number of allowed database connections is an increase in overall query latency, along with an increase in the `DatabaseConnectionsBorrowLatency` metric. You can monitor currently used and total allowed database connections by comparing the `DatabaseConnections` and `MaxDatabaseConnectionsAllowed` metrics.

When setting this parameter, note the following best practices:

- Allow sufficient connection headroom for changes in workload pattern. It is recommended to set the parameter at least 30% above your maximum recent monitored usage. As RDS Proxy redistributes database connection quotas across multiple nodes, internal capacity changes might require at least 30% headroom for additional connections to avoid increased borrow latencies.
- RDS Proxy reserves a certain number of connections for active monitoring to support fast failover, traffic routing and internal operations. The `MaxDatabaseConnectionsAllowed` metric does not include these reserved connections. It represents the number of connections available to serve the workload, and can be lower than the value derived from the `MaxConnectionsPercent` setting.

Minimal recommended `MaxConnectionsPercent` values are as follows:

- `db.t3.small`: 100
- `db.t3.medium`: 55
- `db.t3.large`: 35
- `db.r3.large` or above: 20

If multiple target instances are registered with RDS Proxy like an Aurora cluster with reader nodes, set the minimum value based on the smallest registered instance.

To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see [Amazon Web Services Management Console](#). To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

### Important

If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's `MaxConnectionsPercent` value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter `aurora_fwd_writer_max_connections_pct`. For information about write forwarding, see [Using write forwarding in an Amazon Aurora global database](#).

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

## MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. By default, RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

The `MaxIdleConnectionsPercent` value is expressed as a percentage of the `max_connections` setting for the RDS DB instance target group. The default value is 50 percent of `MaxConnectionsPercent`, and the upper limit is the value of `MaxConnectionsPercent`. For example, if `MaxConnectionsPercent` is 80, then the default value of `MaxIdleConnectionsPercent` is 40.

With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent`. Doing so means that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the Amazon CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

## ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies when no appropriate database instance is available to handle the request, such as when a failover operation is in process. Using this setting, you can set the best wait period for your application without changing the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the Amazon CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see [Amazon Web Services Management Console](#). To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

## Client and database connections

Connections from your application to RDS Proxy are known as client connections. Connections from a proxy to the database are database connections. When using RDS Proxy, client connections terminate at the proxy while database connections are managed within RDS Proxy.

Application-side connection pooling can provide the benefit of reducing recurring connection establishment between your application and RDS Proxy.

Consider the following configuration aspects before implementing an application-side connection pool:

- **Client connection max life:** RDS Proxy enforces a maximum life of client connections of 24 hours. This value is not configurable. Configure your pool with a maximum connection life less than 24 hours to avoid unexpected client connection drops.
- **Client connection idle timeout:** RDS Proxy enforces a maximum idle time for client connections. Configure your pool with an idle connection timeout of a value lower than your client connection idle timeout setting for RDS Proxy to avoid unexpected connection drops.

The maximum number of client connections configured in your application-side connection pool does not have to be limited to the **max\_connections** setting for RDS Proxy.

Client connection pooling results in a longer client connection life. If your connections experience pinning, then pooling client connections might reduce multiplexing efficiency. Client connections that are pinned but idle in the application-side connection pool continue to hold on to a database connection and prevent the database connection to be reused by other client connections. Review your proxy logs to check whether your connections experience pinning.

**Note**

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

## Avoiding pinning an RDS Proxy

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through SET or SELECT statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, your application changes a session variable or configuration parameter. In this case, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

For some database engines, this rule doesn't apply to all parameters that you can set. RDS Proxy tracks certain statements and variables. Thus, RDS Proxy doesn't pin the session when you modify them. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings. For the lists of tracked statements and variables for Aurora MySQL, see [What RDS Proxy tracks for Aurora MySQL databases](#).

## What RDS Proxy tracks for Aurora MySQL databases

RDS Proxy tracks the following MySQL statements:

- DROP DATABASE
- DROP SCHEMA
- USE

RDS Proxy tracks the following MySQL variables:

- AUTOCOMMIT
- AUTO\_INCREMENT\_INCREMENT
- CHARACTER SET (or CHAR SET)
- CHARACTER\_SET\_CLIENT
- CHARACTER\_SET\_DATABASE
- CHARACTER\_SET\_FILESYSTEM
- CHARACTER\_SET\_CONNECTION
- CHARACTER\_SET\_RESULTS
- CHARACTER\_SET\_SERVER
- COLLATION\_CONNECTION
- COLLATION\_DATABASE
- COLLATION\_SERVER
- INTERACTIVE\_TIMEOUT
- NAMES
- NET\_WRITE\_TIMEOUT
- QUERY\_CACHE\_TYPE
- SESSION\_TRACK\_SCHEMA
- SQL\_MODE

- TIME\_ZONE
- TRANSACTION\_ISOLATION (or TX\_ISOLATION)
- TRANSACTION\_READ\_ONLY (or TX\_READ\_ONLY)
- WAIT\_TIMEOUT

**Note**

RDS Proxy tracks changes to the TRANSACTION\_ISOLATION and TRANSACTION\_READ\_ONLY variables when you set them at the session scope. However, if you set them at the next transaction scope, RDS Proxy pins connections. This behavior applies whether you use a SET statement or a SET TRANSACTION statement to configure these values.

## Minimizing pinning

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning.

You can minimize pinning by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- For a MySQL engine family database, apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the Amazon CloudWatch metric DatabaseConnectionsCurrentlySessionPinned. For information about this and other CloudWatch metrics, see [Monitoring RDS Proxy metrics with Amazon CloudWatch](#).
- If you use SET statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding SET statements from your application code, so that they don't interfere with transaction-level multiplexing.

For metrics about how often pinning occurs for a proxy, see [Monitoring RDS Proxy metrics with Amazon CloudWatch](#).

## Conditions that cause pinning for all engine families

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.

## Conditions that cause pinning for Aurora MySQL

For MySQL, the following interactions also cause pinning:

- Explicit table lock statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Creating named locks by using `GET_LOCK` causes the proxy to pin the session.
- Setting a user or system variable (with some exceptions) pins the session to the proxy. If this significantly limits connection reuse, you can configure SET operations to avoid pinning. To do this, adjust the session pinning filters property. For more information, see [Creating a proxy for Amazon Aurora](#) and [Modifying an RDS Proxy](#).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the `ROW_COUNT` and `FOUND_ROWS` functions sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ among Aurora MySQL versions that are compatible with MySQL 5.7.

- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- RDS Proxy does not pin connections when you use `SET LOCAL`.

- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.
- Queries with executable comments for MySQL (syntax `/*! ... */`) or MariaDB (syntax `/*M! ... */`) cause pinning. RDS Proxy cannot parse SQL embedded in these comments to track session state changes.

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

## Conditions that cause pinning for Aurora PostgreSQL

For PostgreSQL, the following interactions also cause pinning:

- Using SET commands.
- Using PREPARE, DISCARD, DEALLOCATE, or EXECUTE commands to manage prepared statements.
- Creating temporary sequences, tables, or views.
- Declaring cursors.
- Discarding the session state.
- Listening on a notification channel.
- Loading a library module such as `auto_explain`.
- Manipulating sequences using functions such as `nextval` and `setval`.
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`.

### Note

RDS Proxy does not pin on transaction level advisory locks, specifically `pg_advisory_xact_lock`, `pg_advisory_xact_lock_shared`, `pg_try_advisory_xact_lock`, and `pg_try_advisory_xact_lock_shared`.

- Setting a parameter, or resetting a parameter to its default. Specifically, using SET and set\_config commands to assign default values to session variables.
- Calling stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Make sure that your application doesn't change session state inside stored routines if you rely on that session state to persist across transactions. For example, RDS Proxy isn't currently compatible with a stored procedure that creates a temporary table that persists across all transactions.
- Discarding session state. If you use connection pooling libraries with DISCARD ALL query configured as a reset query, RDS Proxy pins your client connection on release. This reduces the proxy's multiplexing efficiency and might lead to unexpected results because the DISCARD ALL command can interfere with session state management.

## Deleting an RDS Proxy

You can delete a proxy when you no longer need it. Or, you might delete a proxy if you take the DB instance or cluster associated with it out of service.

### Amazon Web Services Management Console

#### To delete a proxy

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

### Amazon CLI

To delete a DB proxy, use the Amazon CLI command [delete-db-proxy](#). To remove related associations, also use the [deregister-db-proxy-targets](#) command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets  
--db-proxy-name proxy_name
```

```
[--target-group-name target_group_name]  
[--target-ids comma_separated_list] # or  
[--db-instance-identifiers instance_id] # or  
[--db-cluster-identifiers cluster_id]
```

## RDS API

To delete a DB proxy, call the Amazon RDS API function [DeleteDBProxy](#). To delete related items and associations, you also call the functions [DeleteDBProxyTargetGroup](#) and [DeregisterDBProxyTargets](#).

## Working with Amazon RDS Proxy endpoints

RDS Proxy endpoints provide flexible and efficient ways to manage database connections, which improves scalability, availability, and security. With proxy endpoints, you can:

- **Simplify monitoring and troubleshooting** – Use multiple endpoints to track and manage connections from different applications independently.
- **Enhance read scalability** – Leverage reader endpoints with Aurora DB clusters to distribute read traffic efficiently, which optimizes performance for query-heavy workloads.
- **Enable cross-VPC access** – Connect databases across VPCs using cross-VPC endpoints, which allows resources like Amazon EC2 instances in one VPC to access databases in another.

### Topics

- [Overview of proxy endpoints](#)
- [Limitations for proxy endpoints](#)
- [Using reader endpoints with Aurora clusters](#)
- [Accessing Aurora databases across VPCs](#)
- [Creating a proxy endpoint](#)
- [Viewing proxy endpoints](#)
- [Modifying a proxy endpoint](#)
- [Deleting a proxy endpoint](#)

## Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints. If you aren't familiar with Aurora endpoints, find more information in [Amazon Aurora endpoint connections](#).

When you use RDS Proxy with an Aurora cluster, the default endpoint supports both read and write operations. This means it routes all requests to the cluster's writer instance, contributing to its `max_connections` limit. To better distribute traffic, you can create additional read/write or read-only endpoints for your proxy, which allows more efficient workload management and improved scalability.

Use a read-only endpoint with your proxy to handle read queries, just as you would with a reader endpoint for an Aurora provisioned cluster. This approach maximizes Aurora's read scalability by distributing queries across one or more reader DB instances. By using a read-only endpoint and adding more reader instances as needed, you can increase the number of simultaneous queries and connections that your cluster can handle.

### Tip

When you create a proxy for an Aurora cluster using the Amazon Web Services Management Console, you can have RDS Proxy automatically create a reader endpoint. For information about the benefits of a reader endpoint, see [Using reader endpoints with Aurora clusters](#).

When you create a proxy endpoint, you can associate it with a different virtual private cloud (VPC) than the proxy's VPC. This allows you to connect to the proxy from another VPC, such as one used by a different application within your organization.

For information about limits associated with proxy endpoints, see [Limitations for proxy endpoints](#).

RDS Proxy logs prefix each entry with the name of the associated proxy endpoint. This can be either the name that you specified for a user-defined endpoint, or the special name `default` for the proxy's default read/write endpoint.

Each proxy endpoint has its own set of CloudWatch metrics. Monitor metrics for all proxy endpoints, a specific endpoint, or all read/write or read-only endpoints of a proxy. For more information, see [Monitoring RDS Proxy metrics with Amazon CloudWatch](#).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

To learn how proxy endpoints work for DB clusters in an Aurora global database, see [How RDS Proxy endpoints work with global databases](#).

## Limitations for proxy endpoints

RDS Proxy endpoints have the following limitations:

- The RDS proxy default endpoint cannot be modified.
- The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.
- When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.
- For IPv6 or dual-stack endpoint network types, your VPC and subnets must be configured to support the selected network type.

When you create a proxy, RDS automatically creates a VPC endpoint for secure communication between applications and the database. The VPC endpoint is visible and can be accessed from the Amazon VPC Console.

Adding a new proxy endpoint provisions an Amazon PrivateLink interface endpoint. If you add one or more endpoints to your proxy, you incur additional charges. For more information, see [RDS Proxy Pricing](#).

## Using reader endpoints with Aurora clusters

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Aurora clusters. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

### Note

When you specify that a new endpoint is read-only, RDS Proxy requires that the Aurora cluster has one or more reader DB instances. In some cases, you might change the target

of the proxy to an Aurora cluster containing only a single writer. If you do, any requests to the reader endpoint fail with an error. Requests also fail if the target of the proxy is an RDS instance instead of an Aurora cluster.

If an Aurora cluster has reader instances but those instances aren't available, RDS Proxy waits to send the request instead of returning an error immediately. If no reader instance becomes available within the connection borrow timeout period, the request fails with an error.

## How reader endpoints help application availability

In some cases, one or more reader instances in your cluster might become unavailable. If so, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Aurora reader endpoint. RDS Proxy routes connections to only the available reader instances in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader DB instance without any interruption to your application. During the automatic switchover to a new reader instance, RDS Proxy checks the replication lag of the old and new reader instances. RDS Proxy makes sure that the new reader instance is up to date with the same changes as the previous reader instance. That way, your application never sees stale data when RDS Proxy switches from one reader DB instance to another.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same endpoint. RDS Proxy routes the connection to a different reader DB instance that's in available state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instances.

If your Aurora cluster doesn't have any available reader instances, RDS Proxy checks whether this condition is temporary or permanent. The behavior in each case is as follows:

- Suppose that your cluster has one or more reader DB instances, but none of them are in the Available state. For example, all reader instances might be rebooting or encountering problems. In that case, attempts to connect to a reader endpoint wait for a reader instance to become available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.

- Suppose that your cluster has no reader DB instances. In that case, RDS Proxy returns an error immediately if you try to connect to a reader endpoint. To resolve this problem, add one or more reader instances to your cluster before you connect to the reader endpoint.

## How reader endpoints help query scalability

Reader endpoints for a proxy help with Aurora query scalability in the following ways:

- As you add reader instances to your Aurora cluster, RDS Proxy can route new connections to any reader endpoints to the different reader instances. That way, queries performed using one reader endpoint connection don't slow down queries performed using another reader endpoint connection. The queries run on separate DB instances. Each DB instance has its own compute resources, buffer cache, and so on.
- Where practical, RDS Proxy uses the same reader DB instance for all the queries issue using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see [Overview of RDS Proxy concepts](#).
- The more reader DB instances that you have in the cluster, the more simultaneous connections you can make using reader endpoints. For example, suppose that your cluster has four reader DB instances, each configured to support 200 simultaneous connections. Suppose also that your proxy is configured to use 50% of the maximum connections. Here, the maximum number of connections that you can make through the reader endpoints in the proxy is 100 (50% of 200) for reader 1. It's also 100 for reader 2, and so on, for a total of 400. If you double the number of cluster reader DB instances to eight, then the maximum number of connections through the reader endpoints also doubles, to 800.

## Examples of using reader endpoints

The following Linux example shows how you can confirm that you're connected to an Aurora MySQL cluster through a reader endpoint. The `innodb_read_only` configuration setting is

enabled. Attempts to perform write operations such as `CREATE DATABASE` statements fail with an error. And you can confirm that you're connected to a reader DB instance by checking the DB instance name using the `aurora_server_id` variable.

### Tip

Don't rely only on checking the DB instance name to determine whether the connection is read/write or read-only. Remember that DB instances in an Aurora cluster can change roles between writer and reader when failovers happen.

```
$ mysql -h endpoint-demo-reader.endpoint.proxy-demo.us-east-1.rds.amazonaws.com -u
admin -p
...
mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
|                1 |
+-----+
mysql> create database shouldnt_work;
ERROR 1290 (HY000): The MySQL server is running with the --read-only option so it
cannot execute this statement

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| proxy-reader-endpoint-demo-instance-3 |
+-----+
```

The following example shows how your connection to a proxy reader endpoint can keep working even when the reader DB instance is deleted. In this example, the Aurora cluster has two reader instances, `instance-5507` and `instance-7448`. The connection to the reader endpoint begins using one of the reader instances. During the example, this reader instance is deleted by a `delete-db-instance` command. RDS Proxy switches to a different reader instance for subsequent queries.

```
$ mysql -h reader-demo.endpoint.proxy-demo.us-east-1.rds.amazonaws.com
-u my_user -p
```

```

...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-5507      |
+-----+

mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
|                    1 |
+-----+

mysql> select count(*) from information_schema.tables;
+-----+
| count(*) |
+-----+
|      328 |
+-----+

```

While the `mysql` session is still running, the following command deletes the reader instance that the reader endpoint is connected to.

```
aws rds delete-db-instance --db-instance-identifier instance-5507 --skip-final-snapshot
```

Queries in the `mysql` session continue working without the need to reconnect. RDS Proxy automatically switches to a different reader DB instance.

```

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-7448      |
+-----+

mysql> select count(*) from information_schema.TABLES;
+-----+
| count(*) |
+-----+
|      328 |
+-----+

```

+-----+

## Accessing Aurora databases across VPCs

By default, the components of your Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora DB cluster in one VPC from resources in another VPC, such as EC2 instances. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. The proxy itself resides in the same VPC as the Aurora DB cluster. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora work. Each VPC should have its own associated network resources such as an internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult [Getting started with Amazon Aurora](#) for the steps to set up another VPC to use Aurora successfully. You can also examine your existing VPC in the Amazon EC2 console to see the kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster that you want to connect to. Follow the procedure in [Creating a proxy for Amazon Aurora](#).
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in [Creating a proxy endpoint](#).
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Aurora DB cluster, choose a different VPC. This VPC must be in the same Amazon Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster, make new selections. Make these based on the subnets and security groups from the VPC that you chose.

7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in. Similarly, when using IAM authentication, your IAM configuration and permissions work consistently across all proxy endpoints, even when endpoints are in different VPCs. No additional IAM configuration is required per endpoint.
8. Wait for the new endpoint to reach the **Available** state.
9. Make a note of the full endpoint name. This is the value ending in *Region\_name*.rds.amazonaws.com that you supply as part of the connection string for your database application.
10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then, log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

## Creating a proxy endpoint

To create a proxy endpoint, follow these instructions:

### Console

#### To create a proxy endpoint

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

The **Create proxy endpoint** window appears.

5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use read/write endpoints can perform any kind of operations, such as data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint

in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default to access the endpoint from the same EC2 instances or other resources that normally use to access the proxy or its associated database. To set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora databases across VPCs](#).
8. For **Endpoint network type**, choose the IP version for the proxy endpoint. The available options are:
  - **IPv4** – The proxy endpoint uses IPv4 addresses only (default).
  - **IPv6** – The proxy endpoint uses IPv6 addresses only.
  - **Dual-stack** – The proxy endpoint supports both IPv4 and IPv6 addresses.

To use IPv6 or dual-stack, your VPC and subnets must be configured to support the selected network type.

9. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. To restrict access to the endpoint to only a portion of the VPC's address range being able to connect to it, remove one or more subnets.
10. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, then keep the default choice.

If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console later.

11. Choose **Create proxy endpoint**.

## Amazon CLI

To create a proxy endpoint, use the Amazon CLI [create-db-proxy-endpoint](#) command.

Include the following required parameters:

- `--db-proxy-name` *value*
- `--db-proxy-endpoint-name` *value*
- `--vpc-subnet-ids` *list\_of\_ids*. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role` { `READ_WRITE` | `READ_ONLY` }. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value affects only Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Aurora clusters, see [Using reader endpoints with Aurora clusters](#).
- `--vpc-security-group-ids` *value*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.
- `--endpoint-network-type` { `IPV4` | `IPV6` | `DUAL` }. This parameter specifies the IP version for the proxy endpoint. The default is `IPV4`. To use `IPV6` or `DUAL`, your VPC and subnets must be configured to support the selected network type.

## Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \  
  --db-proxy-name my-proxy \  
  --db-proxy-endpoint-name my-endpoint \  
  --vpc-subnet-ids subnet_id subnet_id subnet_id ... \  
  --target-role READ_ONLY \  
  --vpc-security-group-ids security_group_id \  
  --endpoint-network-type DUAL
```

## For Windows:

```
aws rds create-db-proxy-endpoint ^
  --db-proxy-name my-proxy ^
  --db-proxy-endpoint-name my-endpoint ^
  --vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
  --target-role READ_ONLY ^
  --vpc-security-group-ids security_group_id ^
  --endpoint-network-type DUAL
```

## RDS API

To create a proxy endpoint, use the RDS API [CreateDBProxyEndpoint](#) action.

## Viewing proxy endpoints

To view existing proxy endpoints, follow these instructions:

### Console

#### To view the details for a proxy endpoint

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
  - Whether the endpoint is read/write or read-only.
  - The endpoint address that you use in a database connection string.
  - The VPC, subnets, and security groups associated with the endpoint.

## Amazon CLI

To view one or more proxy endpoints, use the Amazon CLI [describe-db-proxy-endpoints](#) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

### Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \  
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^  
  --db-proxy-endpoint-name my-endpoint
```

### RDS API

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](#) operation.

## Modifying a proxy endpoint

To modify your proxy endpoints, follow these instructions:

### Console

#### To modify one or more proxy endpoints

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.

5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or, on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

## Amazon CLI

To modify a proxy endpoint, use the Amazon CLI [modify-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \  
  --db-proxy-endpoint-name my-endpoint \  
  --new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^  
  --db-proxy-endpoint-name my-endpoint ^  
  --new-db-proxy-endpoint-name new-endpoint-name
```

## RDS API

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](#) operation.

## Deleting a proxy endpoint

To delete an endpoint for your proxy, follow these instructions:

### Note

You can't delete the default proxy endpoint that RDS Proxy automatically creates for each proxy.

When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

### Console

#### To delete a proxy endpoint using the Amazon Web Services Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or, on the proxy endpoint details page, for **Actions**, choose **Delete**.

### Amazon CLI

To delete a proxy endpoint, run the [delete-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \  
  --db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^  
  --db-proxy-endpoint-name my-endpoint
```

## RDS API

To delete a proxy endpoint with the RDS API, run the [DeleteDBProxyEndpoint](#) operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

## Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see [Using Amazon CloudWatch metrics](#) in the Amazon CloudWatch User Guide.

### Note

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances. Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for the default endpoint of a proxy that performs read/write requests.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints](#).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular

proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: ProxyName
- Dimension set 2: ProxyName, EndpointName
- Dimension set 3: ProxyName, TargetGroup, Target
- Dimension set 4: ProxyName, TargetGroup, TargetRole

Metric	Description	Valid period	CloudWatch dimension set
AvailabilityPercentage	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 4</a>
ClientConnections	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
ClientConnectionsClosed	The number of client connections closed. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsInSetup	The current number of client connections open but have not completed setup. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
ClientConnectionsNoTLS	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
ClientConnectionsSetupFailedAuth	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsSetupSucceeded	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
DatabaseConnectionRequestsWithTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
DatabaseConnectionBorrowLatency	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
DatabaseConnectionCurrentlyBorrowed	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
DatabaseConnectionCurrentlyInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsCurrentlySessionPinned	The current number of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
DatabaseConnectionsSetupFailed	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
DatabaseConnectionsSetupSucceeded	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsWithTLS	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
MaxDatabaseConnectionsAllowed	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a> , <a href="#">Dimension set 3</a> , <a href="#">Dimension set 4</a>
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>

Metric	Description	Valid period	CloudWatch dimension set
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	<a href="#">Dimension set 1</a> , <a href="#">Dimension set 2</a>

You can find logs of RDS Proxy activity under CloudWatch in the Amazon Web Services Management Console. Each proxy has an entry in the **Log groups** page.

### Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

## Working with RDS Proxy events

An *event* indicates a change in an environment such as an Amazon environment or a service or application from a software as a service (SaaS) partner. Or, it can be one of your own custom applications or services. For example, Amazon Aurora generates an event when you create or modify an RDS Proxy. Amazon Aurora delivers events to Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the Amazon Web Services Management Console, Amazon CLI, or RDS API, see [Viewing Amazon RDS events](#).
- To learn how to configure Amazon Aurora to send events to EventBridge, see [Creating a rule that triggers on an Amazon Aurora event](#).

## RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0204	RDS modified DB proxy <i>name</i> .	None

Category	RDS event ID	Message	Notes
configuration change	RDS-EVENT-0207	RDS modified the end point of the DB proxy <i>name</i> .	None
configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy <i>name</i> .	None
configuration change	RDS-EVENT-0214	RDS detected deletion of DB instance <i>name</i> and automatically removed it from target group <i>name</i> of DB proxy <i>name</i> .	None
configuration change	RDS-EVENT-0215	RDS detected deletion of DB cluster <i>name</i> and automatically removed it from target group <i>name</i> of DB proxy <i>name</i> .	None
creation	RDS-EVENT-0203	RDS created DB proxy <i>name</i> .	None
creation	RDS-EVENT-0206	RDS created endpoint <i>name</i> for DB proxy <i>name</i> .	None
deletion	RDS-EVENT-0205	RDS deleted DB proxy <i>name</i> .	None
deletion	RDS-EVENT-0208	RDS deleted endpoint <i>name</i> for DB proxy <i>name</i> .	None

Category	RDS event ID	Message	Notes
failure	RDS-EVENT-0243	RDS failed to provision capacity for proxy <i>name</i> because there aren't enough IP addresses available in your subnets: <i>name</i> . To fix the issue, make sure that your subnets have the minimum number of unused IP addresses as recommended in the RDS Proxy documentation.	To determine the recommended number for your instance class, see <a href="#">Planning for IP address capacity</a> .
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy <i>name</i> . The number of simultaneous connection requests from the client to the proxy has exceeded the limit.	None

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

```

## RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

### Examples

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the max\\_connections Setting for an Aurora DB Cluster](#)

### Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover. An example is when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```

$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+

```

```

| instance-9814      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com
    -u admin_user -p
$ # Initially, instance-9814 is the writer.
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-8898      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com
    -u admin_user -p
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-9814 is the writer again.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)
+-----+-----+
| Variable_name | Value          |
+-----+-----+
| hostname      | ip-10-1-3-178 |

```

```
+-----+-----+
1 row in set (0.02 sec)
```

## Example Adjusting the max\_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the `max_connections` setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.7. You specify a value for the `max_connections` setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-57-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-57

aws rds create-db-parameter-group --region $REGION \
  --db-parameter-group-family aurora-mysql5.7 \
  --db-parameter-group-name $CLUSTER_PARAM_GROUP \
  --description "Aurora MySQL 5.7 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
  --db-cluster-identifier $CLUSTER_NAME \
  --query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep "^max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-
group-name $CLUSTER_PARAM_GROUP \
  --parameters "ParameterName=max_connections,ParameterValue=$
$answer,ApplyMethod=immediate"
```

```
echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
  --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
  --query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
  --output text | grep "^max_connections"
```

## Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint. Or, it can be the special name `default` for the default endpoint of a proxy that performs read/write requests. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints](#).

### Topics

- [Verifying connectivity for a proxy](#)
- [Common issues and solutions](#)
- [Troubleshooting RDS Proxy issues with RDS for MySQL](#)
- [Troubleshooting RDS Proxy issues with RDS for PostgreSQL](#)

## Verifying connectivity for a proxy

You can use the following commands to verify that all components such as the proxy, database, and compute instances in the connection can communicate with the each other.

Examine the proxy itself using the [describe-db-proxies](#) command. Also examine the associated target group using the [describe-db-proxy-target-groups](#) command. Check that the details of the targets match the Aurora cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the [describe-db-proxy-targets](#) command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the [describe-db-proxy-targets](#) command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306  
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance Aurora cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets  
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes the `username` and `password` fields. The following example shows the format of the `SecretString` field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreateDate": some_timestamp
}
```

When troubleshooting IAM authentication issues, verify the following:

- The database has IAM authentication enabled.
- The proxy is configured with the correct authentication scheme.
- The IAM policies in the IAM role provided to the proxy grant the necessary `rds-db:connect` permission to the appropriate database and its username.
- For end-to-end IAM authentication, database users exist that match the IAM user or role names.
- SSL/TLS is enabled for the connection.

## Common issues and solutions

This section describes some common issues and potential solutions when using RDS Proxy.

After running the `aws rds describe-db-proxy-targets` CLI command, if the `TargetHealth` description states Proxy does not have any registered credentials, verify the following:

- There are credentials registered for the user to access the proxy.
- The IAM role to access the Secrets Manager secret used by the proxy is valid.

You might encounter the following RDS events while creating or connecting to a DB proxy.

Category	RDS event ID	Description
failure	RDS-EVENT-0243	RDS couldn't provision capacity for the proxy because there aren't enough IP addresses available in your subnets. To fix the issue, make sure that your subnets have the minimum number of unused IP addresses. To determine the recommended number for your instance class, see <a href="#">Planning for IP address capacity</a> .
failure	RDS-EVENT-0275	RDS throttled some connections to DB proxy <i>name</i> . The number of simultaneous connection requests from the client to the proxy has exceeded the limit.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
403: The security token included in the request is invalid	Select an existing IAM role instead of choosing to create a new one.

## Troubleshooting RDS Proxy issues with RDS for MySQL

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
ERROR 1040 (HY000): Connections rate limit exceeded ( <i>limit_value</i> )	The rate of connection requests from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): IAM authentication rate limit exceeded	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): Number simultaneous connections exceeded ( <i>limit_value</i> )	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user ' <i>DB_USER</i> '@'%' (user password: YES)	The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
ERROR 1105 (HY000): Unknown error	An unknown error occurred.
ERROR 1231 (42000): Variable 'character_set_client	The value set for the <code>character_set_client</code> parameter is not valid. For example, the value <code>ucs2</code> is not valid because it can crash the MySQL server.

Error	Causes or workarounds
<p>ient'' can't be set to the value of <i>value</i></p>	
<p>ERROR 3159 (HY000): This RDS Proxy requires TLS connections.</p>	<p>You enabled the setting <b>Require Transport Layer Security</b> in the proxy but your connection included the parameter <code>ssl-mode=DISABLED</code> in the MySQL client. Do either of the following:</p> <ul style="list-style-type: none"> <li>• Disable the setting <b>Require Transport Layer Security</b> for the proxy.</li> <li>• Connect to the database using the minimum setting of <code>ssl-mode=REQUIRED</code> in the MySQL client.</li> </ul>
<p>ERROR 2026 (HY000): SSL connection error: Internal Server <i>Error</i></p>	<p>The TLS handshake to the proxy failed. Some possible reasons include the following:</p> <ul style="list-style-type: none"> <li>• SSL is required but the server doesn't support it.</li> <li>• An internal server error occurred.</li> <li>• A bad handshake occurred.</li> </ul>
<p>ERROR 9501 (HY000): Timed-out waiting to acquire database connection</p>	<p>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</p> <ul style="list-style-type: none"> <li>• The proxy is unable to establish a database connection because the maximum connections have been reached</li> <li>• The proxy is unable to establish a database connection because the database is unavailable.</li> </ul>

## Troubleshooting RDS Proxy issues with RDS for PostgreSQL

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
<p>ERROR 28000: IAM authentication is</p>	<p>The user tried to connect to the database using IAM</p>	<p>The user needs to connect to the database using</p>

Error	Cause	Solution
allowed only with SSL connections.	authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.	the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the <a href="#">PostgreSQL SSL support</a> documentation.
ERROR 28000: This RDS proxy has no credentials for the role <i>role_name</i> . Check the credentials for this role and try again.	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role. For more information, see <a href="#">Configuring IAM authentication for RDS Proxy</a> .
ERROR 28000: RDS supports only IAM, MD5, or SCRAM authentication.	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy.	If you're not using IAM authentication, use the MD5 or SCRAM password authentication.
ERROR 28000: A user name is missing from the connection startup packet. Provide a user name for this connection.	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
ERROR 28000: IAM is allowed only with SSL connections.	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.

Error	Cause	Solution

Error	Cause	Solution
<p>ERROR XX000: Request returned an error: <i>database_error</i> .</p>	<p>The database connection established from the proxy returned an error.</p>	<p>The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means that the specified database name doesn't exist on the database server. Or it means that the user name used as a database name (if a database name isn't specified) doesn't exist on the server.</p>
<p>ERROR 53300: The IAM authentication failed because of too many competing requests.</p>	<p>The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.</p>	<p>Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.</p>
<p>ERROR 28000: Enable IAM authentication for the client connection to the proxy and try again.</p>	<p>RDS Proxy can't connect to the database because IAM authentication isn't enabled for the client connection to the proxy. This occurs when the proxy's <code>DefaultAuthScheme</code> parameter is set to <code>IAM_AUTH</code> with a registered user, but the client is using password authentication instead of IAM authentication.</p>	<p>Enable IAM authentication for the client connection to the proxy and try again.</p>

Error	Cause	Solution
ERROR 28000: Configure IAM authentication as the DefaultAuthScheme in your proxy and try again.	RDS Proxy can't connect to the database because the DefaultAuthScheme isn't set to IAM_AUTH. The proxy's DefaultAuthScheme parameter is set to NONE, but the client is attempting to use IAM authentication.	Set DefaultAuthScheme to IAM_AUTH for your proxy and try again.

## Troubleshooting deleted postgres database

If you mistakenly delete the postgres database from your instance, you need to restore the database to restore connectivity to your instance. Run the following commands within your DB instance:

```
CREATE DATABASE postgres;  
GRANT CONNECT ON DATABASE postgres TO rdsproxyadmin;
```

## Using RDS Proxy with Amazon CloudFormation

You can use RDS Proxy with Amazon CloudFormation. This helps you to create groups of related resources. Such a group can include a proxy that can connect to a newly created Aurora DB cluster. RDS Proxy support in Amazon CloudFormation involves two new registry types: DBProxy and DBProxyTargetGroup.

The following listing shows a sample Amazon CloudFormation template for RDS Proxy.

```
Resources:  
  DBProxy:  
    Type: Amazon::RDS::DBProxy  
    Properties:  
      DBProxyName: CanaryProxy  
      EngineFamily: MYSQL  
      RoleArn:  
        Fn::ImportValue: SecretReaderRoleArn
```

```
Auth:
  - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
VpcSubnetIds:
  Fn::Split: [",", "Fn::ImportValue": SubnetIds]
```

```
ProxyTargetGroup:
  Type: Amazon::RDS::DBProxyTargetGroup
  Properties:
    DBProxyName: CanaryProxy
    TargetGroupName: default
    DBInstanceIdentifiers:
      - Fn::ImportValue: DBInstanceName
  DependsOn: DBProxy
```

For more information about the resources in this sample, see [DBProxy](#) and [DBProxyTargetGroup](#).

For more information about resources that you can create using Amazon CloudFormation, see [RDS resource type reference](#).

## Using RDS Proxy with Aurora global databases

An *Aurora global database* is a single database that spans multiple Amazon Web Services Regions, allowing for low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single Amazon Web Services Region, but upon multiple Regions and different Availability Zones. For more information, see [Using Amazon Aurora Global Database](#).

You can use RDS Proxy with any DB cluster in an Aurora global database. Before you begin to use these features together, make sure that you familiarize yourself with the following information.

### Important

If the DB cluster is part of a global database with write forwarding turned on, reduce your proxy's `MaxConnectionsPercent` value by the quota that's allotted for write forwarding. The write forwarding quota is set in the DB cluster parameter `aurora_fwd_writer_max_connections_pct`. For information about write forwarding, see [Using write forwarding in an Amazon Aurora global database](#).

## Limitations for RDS Proxy with global databases

When the Aurora DB cluster has write forwarding turned on, RDS Proxy doesn't support the `SESSION` value for the `aurora_replica_read_consistency` variable. Setting this value can cause unexpected behavior.

## How RDS Proxy endpoints work with global databases

When you understand how RDS Proxy endpoints work with global databases, you can better manage your applications that use Aurora databases with both of these features.

For a proxy with a global database's primary cluster as the registered target, the proxy endpoints work the same way as with any Aurora DB cluster. The proxy's read/write endpoints send all requests to the writer instance of the cluster. The proxy's read-only endpoints send all requests to the reader instances. If a reader becomes unavailable while a connection is open, RDS Proxy redirects subsequent queries on the connection to another reader instance. For a proxy with a secondary cluster as the registered target, requests that are sent to the proxy's read-only endpoints are also sent to the reader instances. Because the cluster has no writer instances, requests that are sent to read/write endpoints fail with the error "The target group doesn't have any associated read/write instances".

Global database switchover and failover operations both involve a role switch between the primary and one of the secondary DB clusters. When the selected secondary cluster becomes the new primary, one of its reader instances is promoted to a writer. This DB instance is now the new writer instance for the global cluster. Make sure to redirect your application's write operations to the appropriate read/write endpoint of the proxy that's associated with the new primary cluster. This proxy endpoint might be the default endpoint or a custom read/write endpoint.

RDS Proxy queues all requests through read/write endpoints and sends them to the writer instance of the new primary cluster as soon as it's available. It does so regardless of whether the switchover or failover operation has completed. During switchover or failover, the default endpoint of the proxy for the old primary cluster still accepts write operations. However, as soon as that cluster becomes a secondary cluster, all of the write operations fail. To learn how and when to perform specific global switchover or failover tasks, see the following topics:

- Global database switchover – [Performing switchovers for Amazon Aurora global databases](#)
- Global database failover – [Recovering an Amazon Aurora global database from an unplanned outage](#)

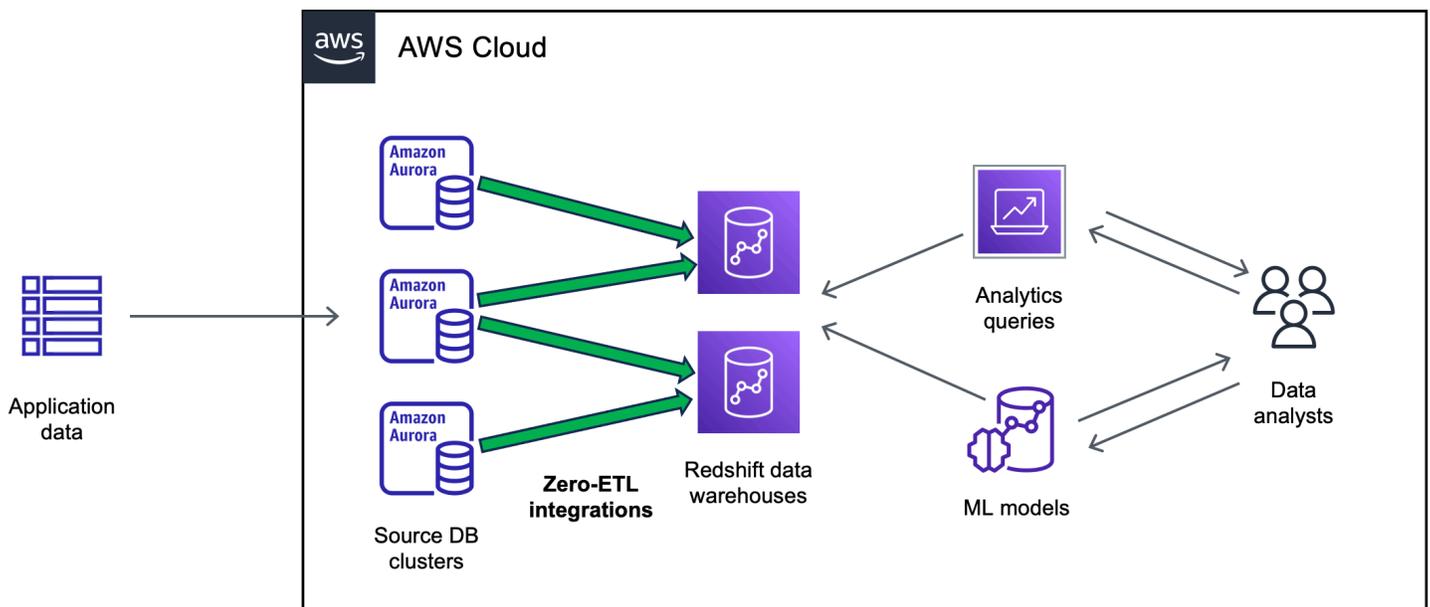

# Aurora zero-ETL integrations

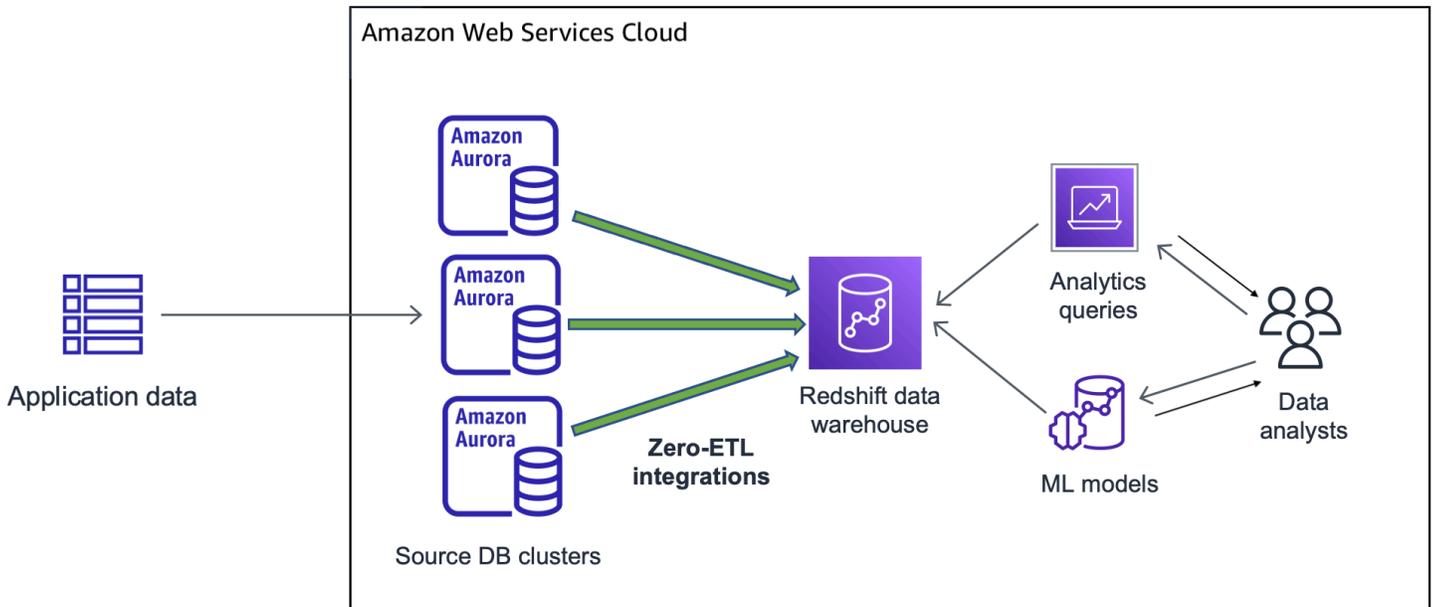

An Aurora zero-ETL integration with Amazon Redshift and Amazon SageMaker AI enables near real-time analytics and machine learning (ML) using data from Aurora. It's a fully managed solution for making transactional data available in your analytics destination after it is written to an Aurora DB cluster. *Extract, transform, and load* (ETL) is the process of combining data from multiple sources into a large, central data warehouse.

A zero-ETL integration makes the data in your Aurora DB cluster available in Amazon Redshift or an Amazon SageMaker AI lakehouse in near real-time. Once that data is in the target data warehouse or data lake, you can power your analytics, ML, and AI workloads using the built-in capabilities, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker AI, Quick Suite, and other Amazon Web Services services.

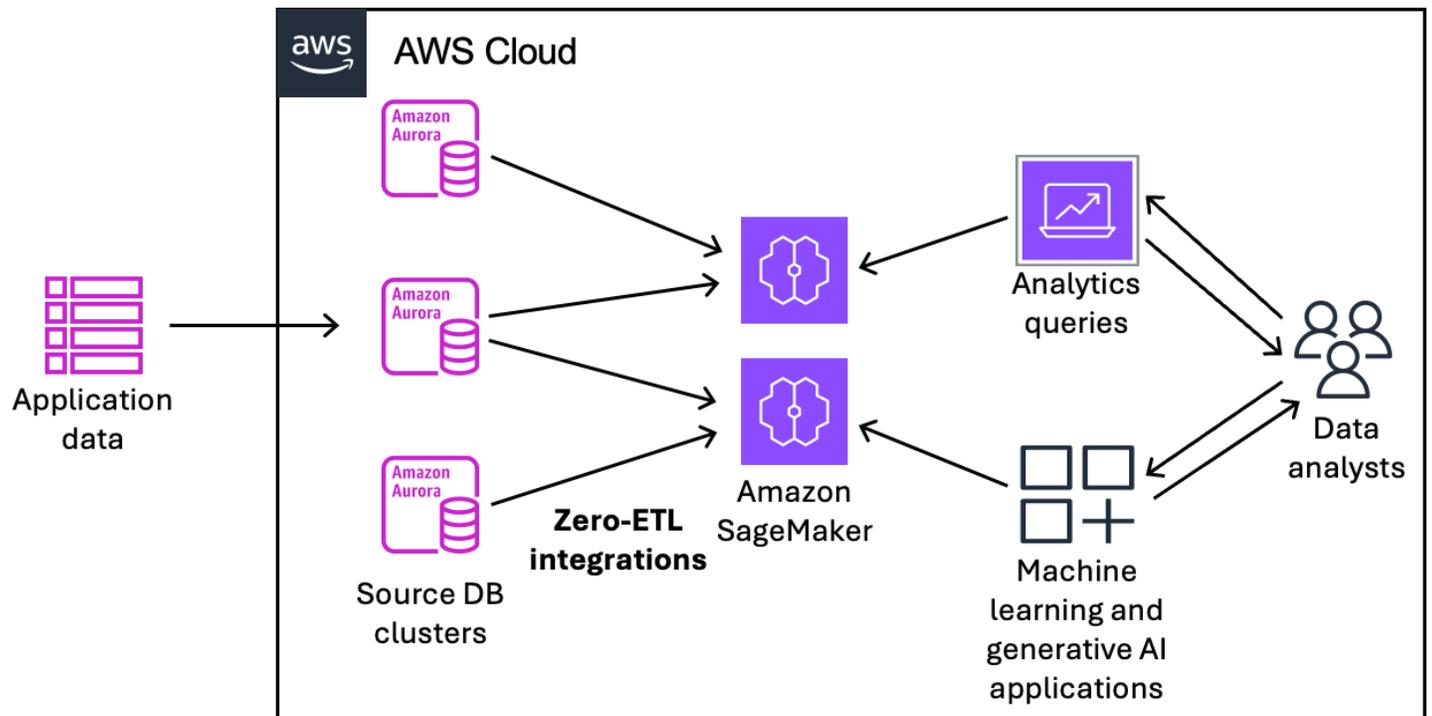

To create a zero-ETL integration, you specify an Aurora DB cluster as the *source*, and a supported data warehouse or lakehouse as the *target*. The integration replicates data from the source database into the target data warehouse or lakehouse.

The following diagram illustrates this functionality for zero-ETL integration with Amazon Redshift:

The following diagram illustrates this functionality for zero-ETL integration with an Amazon SageMaker AI lakehouse:

The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple Aurora DB clusters into a single target data warehouse or lakehouse enabling you to derive insights across multiple applications.

For information about pricing for zero-ETL integrations, see [Amazon Aurora pricing](#) and [Amazon Redshift pricing](#).

## Topics

- [Benefits](#)

- [Viewing and monitoring Aurora zero-ETL integrations](#)
- [Modifying Aurora zero-ETL integrations](#)
- [Deleting Aurora zero-ETL integrations](#)
- [Troubleshooting Aurora zero-ETL integrations](#)

## Benefits

Aurora zero-ETL integrations have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage the target destination's analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

# Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

## Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an Aurora DB cluster to a data warehouse or catalog.

## Source DB cluster

The Aurora DB cluster where data is replicated from. You can specify a DB cluster that uses provisioned DB instances or Aurora Serverless v2 DB instances as the source.

## Target

The data warehouse or lakehouse where the data is replicated to. There are two types of data warehouse: a [provisioned cluster](#) data warehouse and a [serverless](#) data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a *cluster*. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an analytics engine and contain one or more databases.

A target lakehouse consists of catalogs, databases, tables, and views. For more information about lakehouse architecture, see [SageMaker Lakehouse components](#) in the *Amazon SageMaker AI Unified Studio User Guide*.

Multiple source DB clusters can write to the same target.

For more information, see [Data warehouse system architecture](#) in the *Amazon Redshift Developer Guide*.

# Limitations

The following limitations apply to Aurora zero-ETL integrations.

## Topics

- [General limitations](#)
- [Aurora MySQL limitations](#)
- [Aurora PostgreSQL limitations](#)

- [Amazon Redshift limitations](#)
- [Amazon SageMaker AI lakehouse limitations](#)

## General limitations

- The source DB cluster must be in the same Region as the target.
- You can't rename a DB cluster or any of its instances if it has existing integrations.
- You can't create multiple integrations between the same source and target databases.
- You can't delete a DB cluster that has existing integrations. You must delete all associated integrations first.
- If you stop the source DB cluster, the last few transactions might not be replicated to the target until you resume the cluster.
- If your cluster is the source of a blue/green deployment, the blue and green environments can't have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.
- A DB cluster must contain at least one DB instance in order to be the source of an integration.
- You can't create an integration for a source DB cluster that is a cross-account clone, such as those shared using Amazon Resource Access Manager (Amazon RAM).
- If your source cluster is the primary DB cluster in an Aurora global database and it fails over to one of its secondary clusters, the integration becomes inactive. You must delete and recreate the integration.
- You can't create an integration for a source database that has another integration being actively created.
- When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag.
- Some data types aren't supported. For more information, see [the section called "Data type differences"](#).
- System tables, temporary tables, and views aren't replicated to target warehouses.
- Performing DDL commands (for example ALTER TABLE) on a source table can trigger a table resynchronization, making the table unavailable for querying while it's resynchronizing. For more information, see [the section called "One or more of my Amazon Redshift tables requires a resync"](#).

## Aurora MySQL limitations

- Your source DB cluster must be running a supported version of Aurora MySQL. For a list of supported versions, see [the section called “Zero-ETL integrations”](#).
- Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. Don't use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.
- Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.
- Foreign key references with predefined table updates aren't supported. Specifically, ON DELETE and ON UPDATE rules aren't supported with CASCADE, SET NULL, and SET DEFAULT actions. Attempting to create or update a table with such references to another table will put the table into a failed state.
- [XA transactions](#) performed on the source DB cluster cause the integration to enter a state of Syncing.

## Aurora PostgreSQL limitations

- Your source DB cluster must be running a supported version of Aurora PostgreSQL. For a list of supported versions, see [the section called “Zero-ETL integrations”](#).
- If you select an Aurora PostgreSQL source DB cluster, you must specify at least one data filter pattern. At minimum, the pattern must include a single database (*database-name*.\*.\*) for replication to the target warehouse. For more information, see [the section called “Data filtering for zero-ETL integrations”](#).
- All databases created within the source Aurora PostgreSQL DB cluster must use UTF-8 encoding.
- When using declarative partitioning, the table partitions will be replicated to Amazon Redshift. However, the partitioned table itself isn't replicated to Amazon Redshift.
- [Two-phase transactions](#) aren't supported.
- If you delete all DB instances from a DB cluster that is the source of an integration and then re-add a DB instance, replication breaks between the source and the target clusters.
- The source DB cluster can't use Aurora Limitless Database.
- Primary keys are required on all tables present in the data filter. Any tables without a primary key will be put into the failed state.

## Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see [Considerations when using zero-ETL integrations with Amazon Redshift](#) in the *Amazon Redshift Management Guide*.

## Amazon SageMaker AI lakehouse limitations

Following is a limitation for Amazon SageMaker AI lakehouse zero-ETL integrations.

- Catalog names are limited to 19 characters in length.

## Quotas

Your account has the following quotas related to Aurora zero-ETL integrations. Each quota is per-Region unless otherwise specified.

Name	Default	Description
Integrations	100	The total number of integrations within an Amazon Web Services account.
Integrations per target	50	The number of integrations sending data to a single target data warehouse or lakehouse.
Integrations per source cluster	5	The number of integrations sending data from a single source DB cluster.

In addition, the target warehouse places certain limits on the number of tables allowed in each DB instance or cluster node. For more information about Amazon Redshift quotas and limits, see [Quotas and limits in Amazon Redshift](#) in the *Amazon Redshift Management Guide*.

## Supported Regions

Aurora zero-ETL integrations are available in a subset of Amazon Web Services Regions. For a list of supported Regions, see [the section called "Zero-ETL integrations"](#).

# Getting started with Aurora zero-ETL integrations

Before you create a zero-ETL integration, configure your Aurora DB cluster and your data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. [Create a custom DB cluster parameter group](#).
2. [Create a source DB cluster](#).
3. [Create a target data warehouse for Amazon Redshift](#) or [Create a target Amazon SageMaker AI lakehouse](#).

After you complete these tasks, continue to [the section called "Creating zero-ETL integrations with Amazon Redshift"](#) or [the section called "Creating zero-ETL integrations with an Amazon SageMaker lakehouse"](#).

You can use the Amazon SDKs to automate the setup process for you. For more information, see [the section called "Set up an integration using the Amazon SDKs"](#).

## Tip

You can have RDS complete these setup steps for you while you're creating the integration, rather than performing them manually. To immediately start creating an integration, see [the section called "Creating zero-ETL integrations with Amazon Redshift"](#).

For Step 3, you can choose to create either a target data warehouse (Step 3a) or a target lakehouse (Step 3b) depending on your needs:

- Choose a data warehouse if you need traditional data warehousing capabilities with SQL-based analytics.
- Choose an Amazon SageMaker AI lakehouse if you need machine learning capabilities and want to use lakehouse features for data science and ML workflows.

## Step 1: Create a custom DB cluster parameter group

Aurora zero-ETL integrations require specific values for the DB cluster parameters that control replication. Specifically, Aurora MySQL requires *enhanced binlog*

(`aurora_enhanced_binlog`), and Aurora PostgreSQL requires *enhanced logical replication* (`aurora.enhanced_logical_replication`).

To configure binary logging or logical replication, you must first create a custom DB cluster parameter group, and then associate it with the source DB cluster.

#### **Aurora MySQL (aurora-mysql8.0 family):**

- `aurora_enhanced_binlog=1`
- `binlog_backup=0`
- `binlog_format=ROW`
- `binlog_replication_globaldb=0`
- `binlog_row_image=full`
- `binlog_row_metadata=full`

In addition, make sure that the `binlog_transaction_compression` parameter is *not* set to ON, and that the `binlog_row_value_options` parameter is *not* set to PARTIAL\_JSON.

For more information about Aurora MySQL enhanced binlog, see [the section called "Setting up enhanced binlog"](#).

#### **Aurora PostgreSQL (aurora-postgresql16 family):**

- `rds.logical_replication=1`
- `aurora.enhanced_logical_replication=1`
- `aurora.logical_replication_backup=0`
- `aurora.logical_replication_globaldb=0`

Enabling enhanced logical replication (`aurora.enhanced_logical_replication`) will always write all column values to the write ahead log (WAL) even if `REPLICA IDENTITY FULL` isn't enabled. This might increase the IOPS for your source DB cluster.

#### **Important**

If you enable or disable the `aurora.enhanced_logical_replication` DB cluster parameter, the primary DB instance invalidates all logical replication slots. This stops

replication from the source to the target, and you must recreate replication slots on the primary DB instance. To prevent interruptions, keep the parameter state consistent during replication.

## Step 2: Select or create a source DB cluster

After you create a custom DB cluster parameter group, choose or create an Aurora DB cluster. This cluster will be the source of data replication to the target data warehouse. You can specify a DB cluster that uses provisioned DB instances or Aurora Serverless v2 DB instances as the source. For instructions to create a DB cluster, see [the section called "Creating a DB cluster"](#) or [the section called "Creating an Aurora Serverless v2 DB cluster"](#).

The database must be running a supported DB engine version. For a list of supported versions, see [the section called "Zero-ETL integrations"](#).

When you create the database, under **Additional configuration**, change the default **DB cluster parameter group** to the custom parameter group that you created in the previous step.

### Note

If you associate the parameter group with the DB cluster *after* the cluster is already created, you must reboot the primary DB instance in the cluster to apply the changes before you can create a zero-ETL integration. For instructions, see [the section called "Rebooting an Aurora DB cluster or instance"](#).

## Step 3a: Create a target data warehouse

After you create your source DB cluster, you must create and configure a target data warehouse. The data warehouse must meet the following requirements:

- Using an RA3 node type with at least two nodes, or Redshift Serverless.
- Encrypted (if using a provisioned cluster). For more information, see [Amazon Redshift database encryption](#).

For instructions to create a data warehouse, see [Creating a cluster](#) for provisioned clusters, or [Creating a workgroup with a namespace](#) for Redshift Serverless.

## Enable case sensitivity on the data warehouse

For the integration to be successful, the case sensitivity parameter ([enable\\_case\\_sensitive\\_identifier](#)) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.

To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see [Managing parameter groups using the console](#) or [Configuring parameter values using the Amazon CLI](#).

### Note

Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the Amazon CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Send the following [update-workgroup](#) request:

```
aws redshift-serverless update-workgroup \  
  --workgroup-name target-workgroup \  
  --config-parameters  
  parameterKey=enable_case_sensitive_identifier,parameterValue=true
```

You don't need to reboot a workgroup after you modify its parameter values.

## Configure authorization for the data warehouse

After you create a data warehouse, you must configure the source Aurora DB cluster as an authorized integration source. For instructions, see [Configure authorization for your Amazon Redshift data warehouse](#).

## Set up an integration using the Amazon SDKs

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the [Amazon SDK for Python \(Boto3\)](#) to create a source Amazon Aurora DB cluster and target data warehouse, each with

the required parameter values. It then waits for the databases to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip install time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

## Python code example

### Aurora MySQL

```
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default Region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_cluster_name = 'my-source-cluster' # A name for the source cluster
source_param_group_name = 'my-source-param-group' # A name for the source parameter
group
target_cluster_name = 'my-target-cluster' # A name for the target cluster
target_param_group_name = 'my-target-param-group' # A name for the target parameter
group

def create_source_cluster(*args):
    """Creates a source Aurora MySQL DB cluster"""

    response = rds.create_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='aurora-mysql8.0',
        Description='For Aurora MySQL binary logging'
    )
```

```
print('Created source parameter group: ' + response['DBClusterParameterGroup']
      ['DBClusterParameterGroupName'])

response = rds.modify_db_cluster_parameter_group(
    DBClusterParameterGroupName=source_param_group_name,
    Parameters=[
        {
            'ParameterName': 'aurora_enhanced_binlog',
            'ParameterValue': '1',
            'ApplyMethod': 'pending-reboot'
        },
        {
            'ParameterName': 'binlog_backup',
            'ParameterValue': '0',
            'ApplyMethod': 'pending-reboot'
        },
        {
            'ParameterName': 'binlog_format',
            'ParameterValue': 'ROW',
            'ApplyMethod': 'pending-reboot'
        },
        {
            'ParameterName': 'binlog_replication_globaldb',
            'ParameterValue': '0',
            'ApplyMethod': 'pending-reboot'
        },
        {
            'ParameterName': 'binlog_row_image',
            'ParameterValue': 'full',
            'ApplyMethod': 'pending-reboot'
        },
        {
            'ParameterName': 'binlog_row_metadata',
            'ParameterValue': 'full',
            'ApplyMethod': 'pending-reboot'
        }
    ]
)
print('Modified source parameter group: ' +
      response['DBClusterParameterGroupName'])

response = rds.create_db_cluster(
    DBClusterIdentifier=source_cluster_name,

## Step 3b: Create an Amazon Glue catalog for Amazon SageMaker AI zero-ETL integration

When creating a zero-ETL integration with an Amazon SageMaker AI lakehouse, you must create an Amazon Glue managed catalog in Amazon Lake Formation. The target catalog must be an Amazon Redshift managed catalog. To create an Amazon Redshift managed catalog, first create

the `AWSServiceRoleForRedshift` service-linked role. In the Lake Formation console, add the `AWSServiceRoleForRedshift` as a read-only administrator.

For more information about the previous tasks, see the following topics.

- For information about creating an Amazon Redshift managed catalog, see [Creating an Amazon Redshift managed catalog in the Amazon Glue Data Catalog](#) in the *Amazon Lake Formation Developer Guide*.
- For information about the service-linked role for Amazon Redshift, see [Using service-linked roles for Amazon Redshift](#) in the *Amazon Redshift Management Guide*.
- For information about read-only administrator permissions for Lake Formation, see [Lake Formation personas and IAM permissions reference](#) in the *Amazon Lake Formation Developer Guide*.

## Configure permissions for the target Amazon Glue catalog

Before creating a target catalog for zero-ETL integration, you must create the Lake Formation target creation role and the Amazon Glue data transfer role. Use the Lake Formation target creation role to create the target catalog. When creating the target catalog, enter the Glue data transfer role in the **IAM role** field in the **Access from engines section**.

### Lake Formation target creation role

The target creation role must be a Lake Formation administrator and requires the following permissions.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "lakeformation:RegisterResource",
      "Resource": "*"
    },
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
```

```

    "Action": [
      "s3:PutEncryptionConfiguration",
      "iam:PassRole",
      "glue:CreateCatalog",
      "glue:GetCatalog",
      "s3:PutBucketTagging",
      "s3:PutLifecycleConfiguration",
      "s3:PutBucketPolicy",
      "s3:CreateBucket",
      "redshift-serverless:CreateNamespace",
      "s3>DeleteBucket",
      "s3:PutBucketVersioning",
      "redshift-serverless:CreateWorkgroup"
    ],
    "Resource": [
      "arn:aws:glue:*:111122223333:catalog",
      "arn:aws:glue:*:111122223333:catalog/*",
      "arn:aws:s3:::*",
      "arn:aws:redshift-serverless:*:111122223333:workgroup/*",
      "arn:aws:redshift-serverless:*:111122223333:namespace/*",
      "arn:aws:iam:*:111122223333:role/GlueDataCatalogDataTransferRole"
    ]
  }
]
}

```

The target creation role must have the following trust relationship.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Effect": "Allow",

```

```

    "Principal": {
      "AWS": "arn:aws:iam::111122223333:user/Username"
    },
    "Action": "sts:AssumeRole"
  }
]
}

```

## Glue data transfer role

The Glue data transfer role is required for MySQL catalog operations and must have the following permissions.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DataTransferRolePolicy",
      "Effect": "Allow",
      "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt",
        "glue:GetCatalog",
        "glue:GetDatabase"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}

```

The Glue data transfer role must have the following trust relationship.

JSON

```

{

```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": [
        "glue.amazonaws.com",
        "redshift.amazonaws.com"
      ]
    },
    "Action": "sts:AssumeRole"
  }
]
```

## Next steps

With a source Aurora DB cluster and either an Amazon Redshift target data warehouse or Amazon SageMaker AI lakehouse, you can create a zero-ETL integration and replicate data. For instructions, see [the section called “Creating zero-ETL integrations with Amazon Redshift”](#).

## Creating Aurora zero-ETL integrations with Amazon Redshift

When you create an Aurora zero-ETL integration, you specify the source Aurora DB cluster and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured Amazon Redshift target.

## Prerequisites

Before you create a zero-ETL integration, you must create a source DB cluster and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see [the section called “Getting started with zero-ETL integrations”](#).

## Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse.

The following sample policies demonstrate the [least privilege permissions](#) required to create and manage integrations. You might not need these exact permissions if your user or role has broader permissions, such as an AdministratorAccess managed policy.

### Note

Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (/) rather than a colon (:) before the serverless namespace UUID.

- Provisioned cluster – `arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid`
- Serverless – `arn:aws:redshift-serverless:{region}:{account-id}:namespace/namespace-uuid`

### Sample policy for Redshift target

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateIntegration",
      "Effect": "Allow",
      "Action": [
        "rds:CreateIntegration"
      ]
    }
  ],
}
```

```
"Resource": [
  "arn:aws-cn:rds:us-east-1:123456789012:db:source-db",
  "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
],
{
  "Sid": "DescribeIntegrationDetails",
  "Effect": "Allow",
  "Action": [
    "rds:DescribeIntegrations"
  ],
  "Resource": [
    "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
  ]
},
{
  "Sid": "ChangeIntegrationDetails",
  "Effect": "Allow",
  "Action": [
    "rds>DeleteIntegration",
    "rds:ModifyIntegration"
  ],
  "Resource": [
    "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
  ]
},
{
  "Sid": "AllowRedShiftIntegration",
  "Effect": "Allow",
  "Action": [
    "redshift>CreateInboundIntegration"
  ],
  "Resource": [
    "arn:aws-cn:redshift:us-east-1:123456789012:namespace:namespace-uuid"
  ]
}
]
```

## Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another Amazon Web Services account, you must create a role that allows users in the current account to access resources in the target account. For more information, see [Providing access to an IAM user in another Amazon Web Services account that you own](#).

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

### Required permissions and trust policy

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "redshift:DescribeClusters",
        "redshift-serverless:ListNamespaces"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
```

```
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For instructions to create the role, see [Creating a role using custom trust policies](#).

## Creating zero-ETL integrations

You can create a zero-ETL integration using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

### Important

zero-ETL integrations do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

## RDS console

### To create a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.

### Important

Catalog names are limited to 19 characters in length. Ensure your integration identifier meets this requirement if it will be used as a catalog name.

5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from.

**Note**

RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see [the section called "Step 1: Create a custom DB cluster parameter group"](#).

Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.

7. (Optional) Select **Customize data filtering options** and add data filters to your integration. You can use data filters to define the scope of replication to the target data warehouse. For more information, see [the section called "Data filtering for zero-ETL integrations"](#).
8. Once your source DB cluster is successfully configured, choose **Next**.
9. For **Target**, do the following:
  1. (Optional) To use a different Amazon Web Services account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data warehouses. For instructions to create the IAM role, see [the section called "Choosing a target data warehouse in a different account"](#).
  2. For **Amazon Redshift data warehouse**, select the target for replicated data from the source DB cluster. You can choose a provisioned Amazon Redshift *cluster* or a Redshift Serverless *namespace* as the target.

**Note**

RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see [Turn on case sensitivity for your data warehouse](#) and [Configure authorization for your data warehouse](#) in the *Amazon Redshift Management Guide*.

Modifying case sensitivity for a *provisioned* Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.

If your selected source and target are in different Amazon Web Services accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

10. Once your target data warehouse is configured correctly, choose **Next**.
11. (Optional) For **Tags**, add one or more tags to the integration. For more information, see [the section called "Tagging Aurora and RDS resources"](#).
12. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an Amazon owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see [the section called "Encrypting Amazon Aurora resources"](#).

Optionally, add an encryption context. For more information, see [Encryption context](#) in the *Amazon Key Management Service Developer Guide*.

 **Note**

Amazon RDS adds the following encryption context pairs in addition to any that you add:

- `aws:redshift:integration:arn` - IntegrationArn
- `aws:servicename:id` - Redshift

This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see [Using grant constraints](#) in the *Amazon Key Management Service Developer Guide*.

13. Choose **Next**.
14. Review your integration settings and choose **Create zero-ETL integration**.

If creation fails, see [the section called "I can't create a zero-ETL integration"](#) for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon Redshift data warehouse has a status of `Modifying`. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to `Active`.

## Amazon CLI

To create a zero-ETL integration using the Amazon CLI, use the [create-integration](#) command with the following options:

### Note

Remember that catalog names are limited to 19 characters. Choose your integration name accordingly if it will be used as a catalog name.

- `--integration-name` – Specify a name for the integration.
- `--source-arn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

## Example

For Linux, macOS, or Unix:

```
aws rds create-integration \  
  --integration-name my-integration \  
  --source-arn arn:aws:rds:{region}:{account-id}:my-db \  
  --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```
aws rds create-integration ^  
  --integration-name my-integration ^  
  --source-arn arn:aws:rds:{region}:{account-id}:my-db ^  
  --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

## RDS API

To create a zero-ETL integration by using the Amazon RDS API, use the [CreateIntegration](#) operation with the following parameters:

**Note**

Catalog names are limited to 19 characters. Ensure your `IntegrationName` parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

## Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an Amazon owned key when you create an integration, the key policy must provide the Amazon Redshift service principal access to the `CreateGrant` action. In addition, it must allow the current user to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

### Sample key policy

JSON

```
{
  "Version": "2012-10-17",
  "Id": "Key policy",
  "Statement": [
    {
      "Sid": "Enables IAM user permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
  ],
}
```

```

    {
      "Sid": "Allows the Redshift service principal to add a grant to a KMS
key",
      "Effect": "Allow",
      "Principal": {
        "Service": "redshift.amazonaws.com"
      },
      "Action": "kms:CreateGrant",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:{context-key}": "{context-value}"
        },
        "ForAllValues:StringEquals": {
          "kms:GrantOperations": [
            "Decrypt",
            "GenerateDataKey",
            "CreateGrant"
          ]
        }
      }
    },
    {
      "Sid": "Allows the current user or role to add a grant to a KMS key",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/{role-name}"
      },
      "Action": "kms:CreateGrant",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:{context-key}": "{context-value}",
          "kms:ViaService": "rds.us-east-1.amazonaws.com"
        },
        "ForAllValues:StringEquals": {
          "kms:GrantOperations": [
            "Decrypt",
            "GenerateDataKey",
            "CreateGrant"
          ]
        }
      }
    }
  ],

```

```
    {
      "Sid": "Allows the current user or role to retrieve information about
a KMS key",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/{role-name}"
      },
      "Action": "kms:DescribeKey",
      "Resource": "*"
    }
  ]
}
```

For more information, see [Creating a key policy](#) in the *Amazon Key Management Service Developer Guide*.

## Next steps

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source Aurora DB cluster and querying it in Amazon Redshift. For instructions, see [Creating destination databases in Amazon Redshift](#).

## Creating Aurora zero-ETL integrations with an Amazon SageMaker lakehouse

When you create an Aurora zero-ETL integration with an Amazon SageMaker lakehouse, you specify the source Aurora DB cluster and the target Amazon Glue managed catalog. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured target.

## Prerequisites

Before you create a zero-ETL integration with an Amazon SageMaker lakehouse, you must create a source DB cluster and a target Amazon Glue managed catalog. You also must allow replication into the catalog by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see [the section called “Getting started with zero-ETL integrations”](#).

## Required permissions

Certain IAM permissions are required to create a zero-ETL integration with an Amazon SageMaker lakehouse. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target Amazon Glue managed catalog.
- Access Amazon S3 buckets used by the Amazon Glue managed catalog.
- Use Amazon KMS keys for encryption if custom encryption is configured.
- Register resources with Lake Formation.
- Put resource policy on the Amazon Glue managed catalog to authorize inbound integrations.

The following sample policy demonstrates the [least privilege permissions](#) required to create and manage integrations with an Amazon SageMaker lakehouse. You might not need these exact permissions if your user or role has broader permissions, such as an AdministratorAccess managed policy.

Additionally, you must configure a resource policy on the target Amazon Glue managed catalog to authorize inbound integrations. Use the following Amazon CLI command to apply the resource policy.

### Sample Amazon CLI command to authorize inbound integrations on the target catalog

```
aws glue put-resource-policy \  
  --policy-in-json '{  
  "Version": "2012-10-17",  
  "Statement": [{  
    "Effect": "Allow",  
    "Principal": {  
      "Service": "glue.amazonaws.com"  
    },  
    "Action": [  
      "glue:AuthorizeInboundIntegration"  
    ],  
  },  
  ],  
}
```

```

    "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"],
    "Condition": {
      "StringEquals": {
        "aws:SourceArn": "arn:aws:rds:region:account_id:db:source_name"
      }
    }
  },
  {
    "Effect": "Allow",
    "Principal": {
      "AWS": "account_id"
    },
    "Action": ["glue:CreateInboundIntegration"],
    "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"]
  }
]
}' \
--region region

```

### Note

Glue catalog Amazon Resource Names (ARNs) have the following format:

- Glue catalog – `arn:aws:glue:{region}:{account-id}:catalog/catalog-name`

## Choosing a target Amazon Glue managed catalog in a different account

If you plan to specify a target Amazon Glue managed catalog that's in another Amazon Web Services account, you must create a role that allows users in the current account to access resources in the target account. For more information, see [Providing access to an IAM user in another Amazon Web Services account that you own](#).

The role must have the following permissions, which allow the user to view available Amazon Glue catalogs in the target account.

### Required permissions and trust policy

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement":[
  {
    "Effect":"Allow",
    "Action":[
      "glue:GetCatalog"
    ],
    "Resource":[
      "*"
    ]
  }
]
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Effect":"Allow",
      "Principal":{"
        "AWS": "arn:aws:iam::111122223333:root"
      }},
      "Action":"sts:AssumeRole"
    }
  ]
}
```

For instructions to create the role, see [Creating a role using custom trust policies](#).

## Creating zero-ETL integrations with an Amazon SageMaker lakehouse

You can create a zero-ETL integration with an Amazon SageMaker lakehouse using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

**⚠ Important**

Zero-ETL integrations with an Amazon SageMaker lakehouse do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

**RDS console****To create a zero-ETL integration with an Amazon SageMaker lakehouse**

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from.

**i Note**

RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see [the section called "Step 1: Create a custom DB cluster parameter group"](#).

Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.

7. (Optional) Select **Customize data filtering options** and add data filters to your integration. You can use data filters to define the scope of replication to the target Amazon SageMaker lakehouse. For more information, see [the section called "Data filtering for zero-ETL integrations"](#).
8. Once your source DB cluster is successfully configured, choose **Next**.
9. For **Target**, do the following:

1. (Optional) To use a different Amazon Web Services account for the Amazon SageMaker lakehouse target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your Amazon Glue catalogs. For instructions to create the IAM role, see [the section called "Choosing a target Amazon Glue managed catalog in a different account"](#).
2. For **Amazon Glue catalog**, select the target for replicated data from the source DB cluster. You can choose an existing Amazon Glue managed catalog as the target.
3. The target IAM role needs describe permissions on the target catalog and must have the following permissions:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "glue:GetCatalog",
      "Resource": [
        "arn:aws:glue:us-east-1:111122223333:catalog/*",
        "arn:aws:glue:us-east-1:111122223333:catalog"
      ]
    }
  ]
}
```

The target IAM role must have the following trust relationship:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

```
    }  
  ]  
}
```

4. You must grant the target IAM role describe permissions for the target Amazon Glue managed catalog with the Lake Formation administrator role created in [Step 3b: Create an Amazon Glue catalog for Amazon SageMaker AI zero-ETL integration](#).

#### Note

RDS notifies you if the resource policy or configuration settings for the specified Amazon Glue managed catalog aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. If your selected source and target are in different Amazon Web Services accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in SageMaker Unified Studio.

10. Once your target Amazon Glue managed catalog is configured correctly, choose **Next**.
11. (Optional) For **Tags**, add one or more tags to the integration. For more information, see [the section called "Tagging Aurora and RDS resources"](#).
12. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an Amazon owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see [the section called "Encrypting Amazon Aurora resources"](#).

Optionally, add an encryption context. For more information, see [Encryption context](#) in the *Amazon Key Management Service Developer Guide*.

#### Note

Amazon RDS adds the following encryption context pairs in addition to any that you add:

- `aws:glue:integration:arn` - IntegrationArn
- `aws:servicename:id` - glue

This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see [Using grant constraints](#) in the *Amazon Key Management Service Developer Guide*.

13. Choose **Next**.

14. Review your integration settings and choose **Create zero-ETL integration**.

If creation fails, see [the section called "Troubleshooting zero-ETL integrations"](#) for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon SageMaker lakehouse has a status of `Modifying`. During this time, you can't query the catalog or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon SageMaker lakehouse both change to `Active`.

## Amazon CLI

To prepare a target Amazon Glue managed catalog for zero-ETL integration using the Amazon CLI, you must first use the [create-integration-resource-property](#) command with the following options:

- `--resource-arn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.
- `--target-processing-properties` – Specify the ARN of the IAM role to access the target Amazon Glue managed catalog

```
aws glue create-integration-resource-property --region us-east-1
--resource-arn arn:aws:glue:region:account_id:catalog/catalog_name \
--target-processing-properties '{"RoleArn" : "arn:aws:iam::account_id:role/TargetIamRole"}'
```

To create a zero-ETL integration with an Amazon SageMaker lakehouse using the Amazon CLI, use the [create-integration](#) command with the following options:

- `--integration-name` – Specify a name for the integration.

- `--source-arn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.

## Example

For Linux, macOS, or Unix:

```
aws rds create-integration \  
  --integration-name my-sagemaker-integration \  
  --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db \  
  --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

For Windows:

```
aws rds create-integration ^  
  --integration-name my-sagemaker-integration ^  
  --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db ^  
  --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

## RDS API

To create a zero-ETL integration with Amazon SageMaker by using the Amazon RDS API, use the [CreateIntegration](#) operation with the following parameters:

### Note

Catalog names are limited to 19 characters. Ensure your `IntegrationName` parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.

## Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an Amazon owned key when you create an integration with Amazon SageMaker, the key policy must provide the SageMaker Unified Studio service principal access to the CreateGrant action. In addition, it must allow the current user to perform the DescribeKey and CreateGrant actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

### Sample key policy

JSON

```
{
  "Version": "2012-10-17",
  "Id": "Key policy",
  "Statement": [
    {
      "Sid": "EnablesIAMUserPermissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "kms:*",
      "Resource": "*"
    },
    {
      "Sid": "GlueServicePrincipalAddGrant",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "kms:CreateGrant",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:{context-key}": "{context-value}"
        },
        "ForAllValues:StringEquals": {
          "kms:GrantOperations": [
            "Decrypt",

```

```

        "GenerateDataKey",
        "CreateGrant"
    ]
}
},
{
    "Sid": "AllowsCurrentUserRoleAddGrantKMSKey",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/{role-name}"
    },
    "Action": "kms:CreateGrant",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "kms:EncryptionContext:{context-key}":"{context-value}",
            "kms:ViaService": "rds.us-east-1.amazonaws.com"
        },
        "ForAllValues:StringEquals": {
            "kms:GrantOperations": [
                "Decrypt",
                "GenerateDataKey",
                "CreateGrant"
            ]
        }
    }
},
{
    "Sid": "AllowsCurrentUserRoleRetrieveKMSKeyInformation",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/{role-name}"
    },
    "Action": "kms:DescribeKey",
    "Resource": "*"
}
]
}

```

For more information, see [Creating a key policy](#) in the *Amazon Key Management Service Developer Guide*.

## Next steps

After you successfully create a zero-ETL integration with Amazon SageMaker, you can start adding data to the source Aurora DB cluster and querying it in your Amazon SageMaker lakehouse. The data will be automatically replicated and made available for analytics and machine learning workloads.

## Data filtering for Aurora zero-ETL integrations

Aurora zero-ETL integrations support data filtering, which lets you control which data is replicated from your source Aurora DB cluster to your target data warehouse. Instead of replicating the entire database, you can apply one or more filters to selectively include or exclude specific tables. This helps you optimize storage and query performance by ensuring that only relevant data is transferred. Currently, filtering is limited to the database and table levels. Column- and row-level filtering are not supported.

Data filtering can be useful when you want to:

- Join certain tables from two or more different source clusters, and you don't need complete data from either cluster.
- Save costs by performing analytics using only a subset of tables rather than an entire fleet of databases.
- Filter out sensitive information—such as phone numbers, addresses, or credit card details—from certain tables.

You can add data filters to a zero-ETL integration using the Amazon Web Services Management Console, the Amazon Command Line Interface (Amazon CLI), or the Amazon RDS API.

If the integration has a provisioned cluster as its target, the cluster must be on [patch 180](#) or higher to use data filtering.

### Topics

- [Format of a data filter](#)
- [Filter logic](#)
- [Filter precedence](#)
- [Aurora MySQL examples](#)
- [Aurora PostgreSQL examples](#)

- [Adding data filters to an integration](#)
- [Removing data filters from an integration](#)

## Format of a data filter

You can define multiple filters for a single integration. Each filter either includes or excludes any existing and future database tables that match one of the patterns in the filter expression. Aurora zero-ETL integrations use [Maxwell filter syntax](#) for data filtering.

Each filter has the following elements:

Element	Description
Filter type	An Include filter type <i>includes</i> all tables that match one of the patterns in the filter expression. An Exclude filter type <i>excludes</i> all tables that match one of the patterns.
Filter expression	A comma-separated list of patterns. Expressions must use <a href="#">Maxwell filter syntax</a> .
Pattern	A filter pattern in the format <i>database.table</i> for Aurora MySQL, or <i>database.schema.table</i> for Aurora PostgreSQL. You can specify literal names, or define regular expressions. <div data-bbox="857 1409 1507 1862"><p><b>Note</b></p><p>For Aurora MySQL, regular expressions are supported in both the database and table name. For Aurora PostgreSQL, regular expressions are supported only in the schema and table name, not in the database name.</p></div>

Element	Description
	<p>You can't include column-level filters or denylists.</p> <p>A single integration can have a maximum of 99 total patterns. In the console, you can enter patterns within a single filter expression, or spread them out among multiple expressions. A single pattern can't exceed 256 characters in length.</p>

### Important

If you select an Aurora PostgreSQL source DB cluster, you must specify at least one data filter pattern. At minimum, the pattern must include a single database (*database-name*.\*.\*) for replication to the target data warehouse.

The following image shows the structure of Aurora MySQL data filters in the console:

**Data filtering options - optional** [Info](#)

Include or exclude any existing and future database table that matches your entered list of filter expressions. All tables are included by default.

Customize data filtering options

Choose filter type	Filter expression	
Include ▼	mydb.mytable, mydb./table_\d+/	Remove
Exclude ▼		Remove

**⚠ Important**

Do not include personally identifying, confidential, or sensitive information in your filter patterns.

## Data filters in the Amazon CLI

When using the Amazon CLI to add a data filter, the syntax differs slightly from the console. You must assign a filter type (Include or Exclude) to each pattern individually, so you can't group multiple patterns under one filter type.

For example, in the console you can group the following comma-separated patterns under a single Include statement:

### Aurora MySQL

```
mydb.mytable, mydb./table_\d+/
```

### Aurora PostgreSQL

```
mydb.myschema.mytable, mydb.myschema./table_\d+/
```

However, when using the Amazon CLI, the same data filter must be in the following format:

### Aurora MySQL

```
'include: mydb.mytable, include: mydb./table_\d+/'
```

### Aurora PostgreSQL

```
'include: mydb.myschema.mytable, include: mydb.myschema./table_\d+/'
```

## Filter logic

If you don't specify any data filters in your integration, Aurora assumes a default filter of `include: *.*`, which replicates all tables to the target data warehouse. However, if you add at least one filter, the default logic switches to `exclude: *.*`, which excludes all tables by default. This lets you explicitly define which databases and tables to include in replication.

For example, if you define the following filter:

```
'include: db.table1, include: db.table2'
```

Aurora evaluates the filter as follows:

```
'exclude: *.* , include: db.table1, include: db.table2'
```

Therefore, Aurora only replicates `table1` and `table2` from the database named `db` to the target data warehouse.

## Filter precedence

Aurora evaluates data filters in the order you specify. In the Amazon Web Services Management Console, it processes filter expressions from left to right and top to bottom. A second filter or an individual pattern that follows the first can override it.

For example, if the first filter is `Include books.stephenking`, it includes only the `stephenking` table from the `books` database. However, if you add a second filter, `Exclude books.*`, it overrides the first filter. This prevents any tables from the `books` index from being replicated to the target data warehouse.

When you specify at least one filter, the logic starts by assuming `exclude: *.*` by default, which automatically *excludes* all tables from replication. As a best practice, define filters from broadest to most specific. Start with one or more `Include` statements to specify the data to replicate, then add `Exclude` filters to selectively remove certain tables.

The same principle applies to filters that you define using the Amazon CLI. Aurora evaluates these filter patterns in the order that you specify them, so a pattern might override one that you specify before it.

## Aurora MySQL examples

The following examples demonstrate how data filtering works for Aurora MySQL examples zero-ETL integrations:

- Include all databases and all tables:

```
'include: *.*'
```

- Include all tables within the books database:

```
'include: books.*'
```

- Exclude any tables named mystery:

```
'include: *.* , exclude: *.mystery'
```

- Include two specific tables within the books database:

```
'include: books.stephen_king, include: books.carolyn_keene'
```

- Include all tables in the books database, except for those containing the substring mystery:

```
'include: books.* , exclude: books./.*mystery.*/'
```

- Include all tables in the books database, except those starting with mystery:

```
'include: books.* , exclude: books./mystery.*/'
```

- Include all tables in the books database, except those ending with mystery:

```
'include: books.* , exclude: books./.*mystery/'
```

- Include all tables in the books database that start with table\_, except for the one named table\_stephen\_king. For example, table\_movies or table\_books would be replicated, but not table\_stephen\_king.

```
'include: books./table_.*/, exclude: books.table_stephen_king'
```

## Aurora PostgreSQL examples

The following examples demonstrate how data filtering works for Aurora PostgreSQL zero-ETL integrations:

- Include all tables within the books database:

```
'include: books.*.*'
```

- Exclude any tables named mystery in the books database:

```
'include: books.*.*, exclude: books.*.mystery'
```

- Include one table within the books database in the mystery schema, and one table within employee database in the finance schema:

```
'include: books.mystery.stephen_king, include: employee.finance.benefits'
```

- Include all tables in the books database and science\_fiction schema, except for those containing the substring king:

```
'include: books.science_fiction.*, exclude: books.*./.*king.*/'
```

- Include all tables in the books database, except those with a schema name starting with sci:

```
'include: books.*.*, exclude: books./sci.*/*.'
```

- Include all tables in the books database, except those in the mystery schema ending with king:

```
'include: books.*.*, exclude: books.mystery./.*king/'
```

- Include all tables in the books database that start with table\_, except for the one named table\_stephen\_king. For example, table\_movies in the fiction schema and table\_books in the mystery schema are replicated, but not table\_stephen\_king in either schema:

```
'include: books.*./table_.*/, exclude: books.*.table_stephen_king'
```

## Adding data filters to an integration

You can configure data filtering using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API.

### Important

If you add a filter after you create an integration, Aurora treats it as if it always existed. It removes any data in the target data warehouse that doesn't match the new filtering criteria and resynchronizes all affected tables.

## RDS console

### To add data filters to a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Zero-ETL integrations**. Select the integration that you want to add data filters to, and then choose **Modify**.
3. Under **Source**, add one or more **Include** and **Exclude** statements.

The following image shows an example of data filters for a MySQL integration:

**Source**

**Source database**  
The source database where the data is replicated from. Only databases running the supported versions are available.

my-database

**Data filtering options - optional** [Info](#)  
Include or exclude any existing and future database table that matches your entered list of filter expressions. All tables are included by default.

Customize data filtering options

Choose filter type	Filter expression	
Include ▼	mydb.mytable, mydb./table_\d+/ <small>Each filter expression must be a comma-separated list of patterns. Each pattern can have a maximum of 256 characters. You can include a maximum of 100 total patterns. Filters are evaluated in the order they appear (left to right, top to bottom).</small>	<input type="button" value="Remove"/>
Exclude ▼	 <small>Each filter expression must be a comma-separated list of patterns. Each pattern can have a maximum of 256 characters. You can include a maximum of 100 total patterns. Filters are evaluated in the order they appear (left to right, top to bottom).</small>	<input type="button" value="Remove"/>

4. When you're satisfied with the changes, choose **Continue** and **Save changes**.

## Amazon CLI

To add data filters to a zero-ETL integration using the Amazon CLI, call the [modify-integration](#) command. In addition to the integration identifier, specify the `--data-filter` parameter with a comma-separated list of Include and Exclude Maxwell filters.

### Example

The following example adds filter patterns to `my-integration`.

For Linux, macOS, or Unix:

```
aws rds modify-integration \  
  --integration-identifier my-integration \  
  --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

For Windows:

```
aws rds modify-integration ^  
  --integration-identifier my-integration ^  
  --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

## RDS API

To modify a zero-ETL integration using the RDS API, call the [ModifyIntegration](#) operation. Specify the integration identifier and provide a comma-separated list of filter patterns.

## Removing data filters from an integration

When you remove a data filter from an integration, Aurora reevaluates the remaining filters as if the removed filter never existed. It then replicates any previously excluded data that now meets the criteria into the target data warehouse. This triggers a resynchronization of all affected tables.

## Adding data to a source Aurora DB cluster and querying it

To finish creating a zero-ETL integration that replicates data from Amazon Aurora into Amazon Redshift, you must create a database in the target destination.

For connections with Amazon Redshift, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source Aurora DB cluster and see it replicated in Amazon Redshift or Amazon SageMaker.

## Topics

- [Creating a target database](#)
- [Adding data to the source DB cluster](#)
- [Querying your Aurora data in Amazon Redshift](#)
- [Data type differences between Aurora and Amazon Redshift databases](#)
- [DDL operations for Aurora PostgreSQL](#)

## Creating a target database

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a database in your target data warehouse. This database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see [Create a destination database in Amazon Redshift](#).

## Adding data to the source DB cluster

After you configure your integration, you can populate the source Aurora DB cluster with data that you want to replicate into your data warehouse.

### Note

There are differences between data types in Amazon Aurora and the target analytics warehouse. For a table of data type mappings, see [the section called “Data type differences”](#).

First, connect to the source DB cluster using the MySQL or PostgreSQL client of your choice. For instructions, see [the section called “Connecting to a DB cluster”](#).

Then, create a table and insert a row of sample data.

### Important

Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

The `pg_dump` and `pg_restore` PostgreSQL utilities initially create tables without a primary key and then add it afterwards. If you're using one of these utilities, we recommend first creating a schema and then loading data in a separate command.

## MySQL

The following example uses the [MySQL Workbench utility](#).

```
CREATE DATABASE my_db;  
  
USE my_db;  
  
CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author  
  VARCHAR(50) NOT NULL,  
  Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));  
  
INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural  
  fiction');
```

## PostgreSQL

The following example uses the `psql` PostgreSQL interactive terminal. When connecting to the cluster, include the named database that you specified when creating the integration.

```
psql -h mycluster.cluster-123456789012.us-east-2.rds.amazonaws.com -p 5432 -U username  
  -d named_db;  
  
named_db=> CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL,  
  Author VARCHAR(50) NOT NULL,  
  Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));  
  
named_db=> INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977,  
  'Supernatural fiction');
```

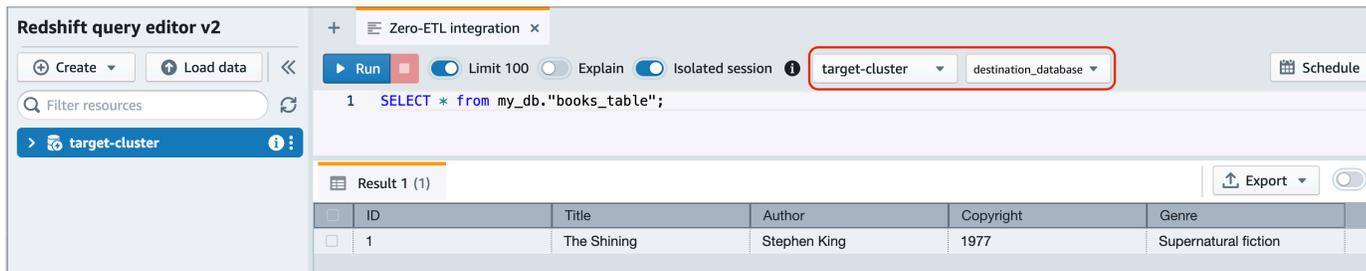

## Querying your Aurora data in Amazon Redshift

After you add data to the Aurora DB cluster, it's replicated into the destination database and is ready to be queried.

### To query the replicated data

1. Navigate to the Amazon Redshift console and choose **Query editor v2** from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (**destination\_database** in this example). For instructions to create a destination database, see [Create a destination database in Amazon Redshift](#).
3. Use a SELECT statement to query your data. In this example, you can run the following command to select all data from the table that you created in the source Aurora DB cluster:

```
SELECT * from my_db."books_table";
```

- *my\_db* is the Aurora database schema name. This option is only needed for MySQL databases.
- *books\_table* is the Aurora table name.

You can also query the data using the a command line client. For example:

```
destination_database=# select * from my_db."books_table";
```

```
ID | Title | Author | Copyright | Genre | txn_seq |
----+-----+-----+-----+-----+-----+
1 | The Shining | Stephen King | 1977 | Supernatural fiction |
```

1 | The Shining | Stephen King | 1977 | Supernatural fiction | 2 | 12192

### Note

For case-sensitivity, use double quotes (" ") for schema, table, and column names. For more information, see [enable\\_case\\_sensitive\\_identifier](#).

## Data type differences between Aurora and Amazon Redshift databases

The following tables show the mappings of Aurora MySQL and Aurora PostgreSQL data types to corresponding destination data types. *Amazon Aurora currently supports only these data types for zero-ETL integrations.*

If a table in your source DB cluster includes an unsupported data type, the table goes out of sync and isn't consumable by the destination target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in the target destination, you must manually revert the breaking change and then refresh the integration by running [ALTER DATABASE...INTEGRATION REFRESH](#).

### Note

You can't refresh zero-ETL integrations with an Amazon SageMaker lakehouse. Instead, delete and try to create the integration again.

## Aurora MySQL

Aurora MySQL data type	Target data type	Description	Limitations
INT	INTEGER	Signed four-byte integer	None

Aurora MySQL data type	Target data type	Description	Limitations
SMALLINT	SMALLINT	Signed two-byte integer	None
TINYINT	SMALLINT	Signed two-byte integer	None
MEDIUMINT	INTEGER	Signed four-byte integer	None
BIGINT	BIGINT	Signed eight-byte integer	None
INT UNSIGNED	BIGINT	Signed eight-byte integer	None
TINYINT UNSIGNED	SMALLINT	Signed two-byte integer	None
MEDIUMINT UNSIGNED	INTEGER	Signed four-byte integer	None
BIGINT UNSIGNED	DECIMAL(20,0)	Exact numeric of selectable precision	None
DECIMAL(p,s) = NUMERIC(p,s)	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported
DECIMAL(p,s) UNSIGNED = NUMERIC(p,s) UNSIGNED	DECIMAL(p,s)	Exact numeric of selectable precision	Precision greater than 38 and scale greater than 37 not supported

Aurora MySQL data type	Target data type	Description	Limitations
FLOAT4/REAL	REAL	Single precision floating-point number	None
FLOAT4/REAL UNSIGNED	REAL	Single precision floating-point number	None
DOUBLE/REAL/FLOAT8	DOUBLE PRECISION	Double precision floating-point number	None
DOUBLE/REAL/FLOAT8 UNSIGNED	DOUBLE PRECISION	Double precision floating-point number	None
BIT(n)	VARBYTE(8)	Variable-length binary value	None
BINARY(n)	VARBYTE(n)	Variable-length binary value	None
VARBINARY(n)	VARBYTE(n)	Variable-length binary value	None
CHAR(n)	VARCHAR(n)	Variable-length string value	None
VARCHAR(n)	VARCHAR(n)	Variable-length string value	None
TEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

Aurora MySQL data type	Target data type	Description	Limitations
TINYTEXT	VARCHAR(255)	Variable-length string value up to 255 characters	None
MEDIUMTEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
LONGTEXT	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
ENUM	VARCHAR(1020)	Variable-length string value up to 1,020 characters	None
SET	VARCHAR(1020)	Variable-length string value up to 1,020 characters	None
DATE	DATE	Calendar date (year, month, day)	None
DATETIME	TIMESTAMP	Date and time (without time zone)	None
TIMESTAMP(p)	TIMESTAMP	Date and time (without time zone)	None

Aurora MySQL data type	Target data type	Description	Limitations
TIME	VARCHAR(18)	Variable-length string value up to 18 characters	None
YEAR	VARCHAR(4)	Variable-length string value up to 4 characters	None
JSON	SUPER	Semistructured data or documents as values	None

## Aurora PostgreSQL

Zero-ETL integrations for Aurora PostgreSQL don't support custom data types or data types created by extensions.

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
array	SUPER	Semistructured data or documents as values	None
bigint	BIGINT	Signed eight-byte integer	None
bigserial	BIGINT	Signed eight-byte integer	None
bit varying(n)	VARBYTE(n)	Variable-length binary value up	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
		to 16,777,216 bytes	
bit(n)	VARBYTE(n)	Variable-length binary value up to 16,777,216 bytes	None
bit, bit varying	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
boolean	BOOLEAN	Logical boolean (true/false)	None
bytea	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
char(n)	CHAR(n)	Fixed-length character string value up to 65,535 bytes	None
char varying(n)	VARCHAR(65535)	Variable-length character string value up to 65,535 characters	None
cid	BIGINT	Signed eight-byte integer	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
cidr	VARCHAR(19)	Variable-length string value up to 19 characters	None
date	DATE	Calendar date (year, month, day)	Values greater than 294,276 A.D. not supported
double precision	DOUBLE PRECISION	Double precision floating-point numbers	Subnormal values not fully supported
gtsvector	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
inet	VARCHAR(19)	Variable-length string value up to 19 characters	None
integer	INTEGER	Signed four-byte integer	None
int2vector	SUPER	Semistructured data or documents as values.	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
interval	INTERVAL	Duration of time	Only INTERVAL types that specify either a year to month or a day to second qualifier are supported.
json	SUPER	Semistructured data or documents as values	None
jsonb	SUPER	Semistructured data or documents as values	None
jsonpath	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
macaddr	VARCHAR(17)	Variable-length string value up to 17 characters	None
macaddr8	VARCHAR(23)	Variable-length string value up to 23 characters	None
money	DECIMAL(20,3)	Currency amount	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
name	VARCHAR(64)	Variable-length string value up to 64 characters	None
numeric(p,s)	DECIMAL(p,s)	User-defined fixed precision value	<ul style="list-style-type: none"> <li>• NaN values not supported</li> <li>• Precision and scale must be explicitly defined and not greater than 38 (precision) and 37 (scale)</li> <li>• Negative scale not supported</li> </ul>
oid	BIGINT	Signed eight-byte integer	None
oidvector	SUPER	Semistructured data or documents as values.	None
pg_brin_bloom_summary	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_dependencies	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
pg_lsn	VARCHAR(17)	Variable-length string value up to 17 characters	None
pg_mcv_list	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_ndistinct	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_node_tree	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
pg_snapshot	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
real	REAL	Single precision floating-point number	Subnormal values not fully supported
refcursor	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
smallint	SMALLINT	Signed two-byte integer	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
smallserial	SMALLINT	Signed two-byte integer	None
serial	INTEGER	Signed four-byte integer	None
text	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
tid	VARCHAR(23)	Variable-length string value up to 23 characters	None
time [(p)] without time zone	VARCHAR(19)	Variable-length string value up to 19 characters	Infinity and -Infinity values not supported
time [(p)] with time zone	VARCHAR(22)	Variable-length string value up to 22 characters	Infinity and -Infinity values not supported

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
timestamp [(p)] without time zone	TIMESTAMP	Date and time (without time zone)	<ul style="list-style-type: none"> <li>• Infinity and -Infinity values not supported</li> <li>• Values greater than 9999-12-31 not supported</li> <li>• B.C. values not supported</li> </ul>
timestamp [(p)] with time zone	TIMESTAMPTZ	Date and time (with time zone)	<ul style="list-style-type: none"> <li>• Infinity and -Infinity values not supported</li> <li>• Values greater than 9999-12-31 not supported</li> <li>• B.C. values not supported</li> </ul>
tsquery	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
tsvector	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
txid_snapshot	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None
uuid	VARCHAR(36)	Variable-length 36 character string	None
xid	BIGINT	Signed eight-byte integer	None
xid8	DECIMAL(20, 0)	Fixed precision decimal	None
xml	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

## DDL operations for Aurora PostgreSQL

Amazon Redshift is derived from PostgreSQL, so it shares several features with Aurora PostgreSQL due to their common PostgreSQL architecture. Zero-ETL integrations leverage these similarities to streamline data replication from Aurora PostgreSQL to Amazon Redshift, mapping databases by name and utilizing the shared database, schema, and table structure.

Consider the following points when managing Aurora PostgreSQL zero-ETL integrations:

- Isolation is managed at the database level.
- Replication occurs at the database level.
- Aurora PostgreSQL databases are mapped to Amazon Redshift databases by name, with data flowing to the corresponding renamed Redshift database if the original is renamed.

Despite their similarities, Amazon Redshift and Aurora PostgreSQL have important differences. The following sections outline Amazon Redshift system responses for common DDL operations.

## Topics

- [Database operations](#)
- [Schema operations](#)
- [Table operations](#)

## Database operations

The following table shows the system responses for database DDL operations.

DDL operation	Redshift system response
CREATE DATABASE	No operation
DROP DATABASE	Amazon Redshift drops all the data in the target Redshift database.
RENAME DATABASE	Amazon Redshift drops all the data in the original target database and resynchronizes the data in the new target database. If the new database doesn't exist, you must manually create it. For instructions, see <a href="#">Create a destination database in Amazon Redshift</a> .

## Schema operations

The following table shows the system responses for schema DDL operations.

DDL operation	Redshift system response
CREATE SCHEMA	No operation
DROP SCHEMA	Amazon Redshift drops the original schema.

DDL operation	Redshift system response
RENAME SCHEMA	Amazon Redshift drops the original schema then resynchronizes the data in the new schema.

## Table operations

The following table shows the system responses for table DDL operations.

DDL operation	Redshift system response
CREATE TABLE	Amazon Redshift creates the table.  Some operations cause table creation to fail, such as creating a table without a primary key or performing declarative partitioning. For more information, see <a href="#">the section called “Limitations”</a> and <a href="#">the section called “Troubleshooting zero-ETL integrations”</a> .
DROP TABLE	Amazon Redshift drops the table.
TRUNCATE TABLE	Amazon Redshift truncates the table.
ALTER TABLE (RENAME . . . )	Amazon Redshift renames the table or column.
ALTER TABLE (SET SCHEMA)	Amazon Redshift drops the table in the original schema and resynchronizes the table in the new schema.
ALTER TABLE (ADD PRIMARY KEY)	Amazon Redshift adds a primary key and resynchronizes the table.
ALTER TABLE (ADD COLUMN)	Amazon Redshift adds a column to the table.

DDL operation	Redshift system response
ALTER TABLE (DROP COLUMN)	Amazon Redshift drops the column if it's not a primary key column. Otherwise, it resynchronizes the table.
ALTER TABLE (SET LOGGED/UNLOGGED )	If you change the table to logged, Amazon Redshift resynchronizes the table. If you change the table to unlogged, Amazon Redshift drops the table.

## Viewing and monitoring Aurora zero-ETL integrations

You can view the details of an Amazon Aurora zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

### Topics

- [Viewing integrations](#)
- [Monitoring integrations using system tables for Amazon Redshift](#)
- [Monitoring integrations with Amazon EventBridge for Amazon Redshift](#)

## Viewing integrations

You can view Aurora zero-ETL integrations using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

### Console

#### To view the details of a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. From the left navigation pane, choose **Zero-ETL integrations**.

3. Select an integration to view more details about it, such as its source DB cluster and target data warehouse.

The screenshot shows the AWS console interface for a Zero-ETL integration. The breadcrumb navigation is 'RDS > Zero-ETL integrations > my-integration'. The main heading is 'my-integration' with a 'Delete' button in the top right corner. Below the heading is a section titled 'Zero-ETL integration details' which is divided into three columns: 'General settings', 'Source', and 'Destination'.

General settings	Source	Destination
<b>Integration name</b> my-integration	<b>Source type</b> Aurora MySQL	<b>Destination type</b> Redshift provisioned cluster
<b>Date created</b> May 31, 2023, 17:06:08 (UTC-07:00)	<b>DB cluster name</b> database-1 <a href="#">↗</a>	<b>Data warehouse</b> a7b90fa8-fa4e-4006-a46d-d2d5b6f80f35
<b>Integration ARN</b> arn:aws:rds:sus-east-1:123456789012:integration:a472a2b6-6d73-4978-af3f-77381e5a4698	<b>Source ARN</b> arn:aws:rds:sus-east-1:123456789012:cluster:database-1	<b>Destination ARN</b> arn:aws:redshift:us-east-1:123456789012:namespace:a7b90fa8-fa4e-4006-a46d-d2d5b6f80f35
<b>Status</b> <span style="color: green;">✔ Active</span>		

An integration can have the following statuses:

- **Creating** – The integration is being created.
- **Active** – The integration is sending transactional data to the target data warehouse.
- **Syncing** – The integration has encountered a recoverable error and is reseeding data. Affected tables aren't available for querying until they finish resyncing.
- **Needs attention** – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- **Failed** – The integration encountered an unrecoverable event or error that can't be fixed. You must delete and recreate the integration.
- **Deleting** – The integration is being deleted.

## Amazon CLI

To view all zero-ETL integrations in the current account using the Amazon CLI, use the [describe-integrations](#) command and specify the `--integration-identifier` option.

## Example

For Linux, macOS, or Unix:

```
aws rds describe-integrations \  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds describe-integrations ^  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

## RDS API

To view zero-ETL integration using the Amazon RDS API, use the [DescribeIntegrations](#) operation with the `IntegrationIdentifier` parameter.

## Monitoring integrations using system tables for Amazon Redshift

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any other database table. For more information about system tables and views in Amazon Redshift, see [System tables and views reference](#) in the *Amazon Redshift Database Developer Guide*.

You can query the following system views and tables to get information about your Aurora zero-ETL integrations:

- [SVV\\_INTEGRATION](#) – Provides configuration details for your integrations.
- [SVV\\_INTEGRATION\\_TABLE\\_STATE](#) – Describes the state of each table within an integration.
- [SYS\\_INTEGRATION\\_TABLE\\_STATE\\_CHANGE](#) – Displays table state change logs for an integration.
- [SYS\\_INTEGRATION\\_ACTIVITY](#) – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see [Metrics for zero-ETL integrations](#) in the *Amazon Redshift Management Guide*. Currently, Amazon Aurora doesn't publish any integration metrics to CloudWatch.

## Monitoring integrations with Amazon EventBridge for Amazon Redshift

Amazon Redshift send integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see [Zero-ETL integration event notifications with Amazon EventBridge](#) in the *Amazon Redshift Management Guide*.

# Modifying Aurora zero-ETL integrations

You can modify only the name, description, and data filtering options for a zero-ETL integration in a supported data warehouse. You can't modify the Amazon KMS key used to encrypt the integration, or the source or target databases.

If you add a data filter to an existing integration, Aurora reevaluates the filter as if it always existed. It removes any data that is currently in the target data warehouse that doesn't match the new filtering criteria. If you *remove* a data filter from an integration, it replicates any data that previously didn't match the filtering criteria (but now does) into the target data warehouse. For more information, see [the section called "Data filtering for zero-ETL integrations"](#).

You can modify a zero-ETL integration using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API.

## RDS console

### To modify a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Zero-ETL integrations**, and then choose the integration that you want to modify.
3. Choose **Modify** and make modifications to any available settings.
4. When all the changes are as you want them, choose **Modify**.

## Amazon CLI

To modify a zero-ETL integration using the Amazon CLI, call the [modify-integration](#) command. Along with the `--integration-identifier`, specify any of the following options:

- `--integration-name` – Specify a new name for the integration.
- `--description` – Specify a new description for the integration.
- `--data-filter` – Specify data filtering options for the integration. For more information, see [the section called "Data filtering for zero-ETL integrations"](#).

## Example

The following request modifies an existing integration.

For Linux, macOS, or Unix:

```
aws rds modify-integration \  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 \  
  --integration-name my-renamed-integration
```

For Windows:

```
aws rds modify-integration ^  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 ^  
  --integration-name my-renamed-integration
```

## RDS API

To modify a zero-ETL integration using the RDS API, call the [ModifyIntegration](#) operation. Specify the integration identifier, and the parameters that you want to modify.

## Deleting Aurora zero-ETL integrations

When you delete a zero-ETL integration, Amazon Aurora removes it from the source Aurora DB cluster. Your transactional data isn't deleted from Amazon Aurora or the analytics destination, but Aurora doesn't send new data to Amazon Redshift or Amazon SageMaker.

You can only delete an integration when it has a status of Active, Failed, Syncing, or Needs attention.

You can delete zero-ETL integrations using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

### To delete a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select the zero-ETL integration that you want to delete.

#### 4. Choose **Actions, Delete**, and confirm deletion.

## Amazon CLI

To delete a zero-ETL integration, use the [delete-integration](#) command and specify the `--integration-identifier` option.

### Example

For Linux, macOS, or Unix:

```
aws rds delete-integration \  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds delete-integration ^  
  --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

## RDS API

To delete a zero-ETL integration using the Amazon RDS API, use the [DeleteIntegration](#) operation with the `IntegrationIdentifier` parameter.

## Troubleshooting Aurora zero-ETL integrations

You can check the state of a zero-ETL integration by querying the [SVV\\_INTEGRATION](#) system table in the analytics destination. If the `state` column has a value of `ERRORState`, it means something's wrong. For more information, see [the section called "Monitoring using system tables"](#).

Use the following information to troubleshoot common issues with Aurora zero-ETL integrations.

### Important

Resync and refresh operations are not available for zero-ETL integrations with an Amazon SageMaker AI lakehouse. If there are issues with an integration, you must delete the integration and create a new integration. You can't refresh or resync an existing integration.

## Topics

- [I can't create a zero-ETL integration](#)
- [My integration is stuck in a state of Syncing](#)
- [My tables aren't replicating to Amazon Redshift](#)
- [One or more of my Amazon Redshift tables requires a resync](#)
- [Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations](#)
- [DDL changes are in Amazon Redshift before the DDL transaction is complete for Aurora PostgreSQL](#)

## I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source database:

- Your source database must be running a supported DB engine version. For a list of supported versions, see [the section called "Zero-ETL integrations"](#).
- You correctly configured DB parameters. If the required parameters are set incorrectly or not associated with the database, creation fails. See [the section called "Step 1: Create a custom DB cluster parameter group"](#).

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See [Turn on case sensitivity for your data warehouse](#).
- You added the correct authorized principal and integration source. See [Configure authorization for your Amazon Redshift data warehouse](#).
- The data warehouse is encrypted (if it's a provisioned cluster). See [Amazon Redshift database encryption](#).

## My integration is stuck in a state of Syncing

Your integration might consistently show a status of Syncing if you change the value of one of the required DB parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source DB cluster, and make sure that they match the required values. For more information, see [the section called "Step 1: Create a custom DB cluster parameter group"](#).

If you modify any parameters, make sure to reboot the DB cluster to apply the changes.

## My tables aren't replicating to Amazon Redshift

If you don't see one or more tables reflected in Amazon Redshift, you can run the following command to resynchronize them:

```
ALTER DATABASE dbname INTEGRATION REFRESH TABLES table1, table2;
```

For more information, see [ALTER DATABASE](#) in the Amazon Redshift SQL reference.

Your data might not be replicating because one or more of your source tables doesn't have a primary key. The monitoring dashboard in Amazon Redshift displays the status of these tables as `Failed`, and the status of the overall zero-ETL integration changes to `Needs attention`. To resolve this issue, you can identify an existing key in your table that can become a primary key, or you can add a synthetic primary key. For detailed solutions, see the following resources:

- [Handle tables without primary keys while creating Amazon Aurora MySQL or Amazon RDS for MySQL zero-ETL integrations with Amazon Redshift](#)
- [Handle tables without primary keys while creating Amazon Aurora PostgreSQL zero-ETL integrations with Amazon Redshift](#)

## One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source database might require your tables to be resynchronized. In these cases, the [SVV\\_INTEGRATION\\_TABLE\\_STATE](#) system view shows a `table_state` of `ResyncRequired`, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of `Syncing`. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you can't access it in Amazon Redshift.

The following are some example operations that can put a table into a `ResyncRequired` state, and possible alternatives to consider.

Operation	Example	Alternative
Adding a column into a specific position	<pre>ALTER TABLE <i>table_name</i>   ADD COLUMN <i>column_name</i> INTEGER   NOT NULL first;</pre>	<p>Amazon Redshift doesn't support adding columns into specific positions using <code>first</code> or <code>after</code> keywords. If the order of columns in the target table isn't critical, add the column to the end of the table using a simpler command:</p> <pre>ALTER   TABLE <i>table_name</i>   ADD   COLUMN <i>column_name</i> <i>column_type</i> ;</pre>
Adding a timestamp column with the default	<pre>ALTER TABLE <i>table_name</i>   ADD COLUMN <i>column_name</i> TIMESTAMP   NOT NULL DEFAULT CURRENT_TIMESTAMP;</pre>	The <code>CURRENT_TIMESTAMP</code> value for

Operation	Example	Alternative
CURRENT_TIMESTAMP		<p>existing table rows is calculated by Aurora MySQL and can't be simulated in Amazon Redshift without full table data resynchronization.</p> <p>If possible, switch the default value to a literal constant like <code>2023-01-01 00:00:15</code> to avoid latency in table availability.</p>

Operation	Example	Alternative
Performing multiple column operations within a single command	<pre>ALTER TABLE <i>table_name</i>   ADD COLUMN <i>column_1</i>,   RENAME COLUMN <i>column_2</i> TO <i>column_3</i>;</pre>	Consider splitting the command into two separate operations, ADD and RENAME, which won't require resynchronization.

## Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations

If you encounter issues with an existing zero-ETL integration with an Amazon SageMaker AI lakehouse, the only resolution is to delete the integration and create a new one. Unlike other Amazon services, zero-ETL integrations do not support refresh or resync operations.

To resolve integration issues:

1. Delete the problematic zero-ETL integration using the console, CLI, or API.
2. Verify that the source database and target data warehouse configurations are correct.
3. Create a new zero-ETL integration with the same or updated configuration.

This process will result in a complete re-initialization of the data pipeline, which may take time depending on the size of your source database.

## DDL changes are in Amazon Redshift before the DDL transaction is complete for Aurora PostgreSQL

DDL changes can appear in Amazon Redshift before a DDL operation finishes in Aurora PostgreSQL zero-ETL integrations. For more information, see [DDL operations for Aurora PostgreSQL](#).

# Using Aurora Serverless v2

Aurora Serverless v2 is an on-demand, autoscaling configuration for Amazon Aurora. Aurora Serverless v2 helps to automate the processes of monitoring the workload and adjusting the capacity for your databases. Capacity is adjusted automatically based on application demand. You're charged only for the resources that your DB clusters consume. Thus, Aurora Serverless v2 can help you to stay within budget and avoid paying for computer resources that you don't use.

This type of automation is especially valuable for multitenant databases, distributed databases, development and test systems, and other environments with highly variable and unpredictable workloads.

## Topics

- [Aurora Serverless v2 use cases](#)

- [Performance and scaling for Aurora Serverless v2](#)
- [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#)
- [Migrating to Aurora Serverless v2](#)

## Aurora Serverless v2 use cases

Aurora Serverless v2 supports many types of database workloads. These range from development and testing environments, to websites and applications that have unpredictable workloads, to the most demanding, business-critical applications that require high scale and availability.

Aurora Serverless v2 is especially useful for the following use cases:

- **Variable workloads** – You're running workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. Another is an e-commerce site with increased traffic when you offer sales or special promotions. With Aurora Serverless v2, your database automatically scales capacity to meet the needs of the

application's peak load and scales back down when the surge of activity is over. With Aurora Serverless v2, you no longer need to provision for peak or average capacity. You can specify an upper capacity limit to handle the worst-case situation, and that capacity isn't used unless it's needed.

The granularity of scaling in Aurora Serverless v2 helps you to match capacity closely to your database's needs. For a provisioned cluster, scaling up requires adding a whole new DB instance. For an Aurora Serverless v1 cluster, scaling up requires doubling the number of Aurora capacity units (ACUs) for the cluster, such as from 16 to 32 or 32 to 64. In contrast, Aurora Serverless v2 can add half an ACU when only a little more capacity is needed. It can add 0.5, 1, 1.5, 2, or additional half-ACUs based on the additional capacity needed to handle an increase in workload. And it can remove 0.5, 1, 1.5, 2, or additional half-ACUs when the workload decreases and that capacity is no longer needed.

- **Multi-tenant applications** – With Aurora Serverless v2, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v2 manages individual database capacity for you.

You can create a cluster for each tenant. That way, you can use features such as cloning, snapshot restore, and Aurora global databases to enhance high availability and disaster recovery as appropriate for each tenant.

Each tenant might have specific busy and idle periods depending on the time of day, time of year, promotional events, and so on. Each cluster can have a wide capacity range. That way, clusters with low activity incur minimal DB instance charges. Any cluster can quickly scale up to handle periods of high activity.

- **New applications** – You're deploying a new application and you're unsure about the DB instance size you need. By using Aurora Serverless v2, you can set up a cluster with one or many DB instances and have the database autoscale to the capacity requirements of your application.
- **Mixed-use applications** – Suppose that you have an online transaction processing (OLTP) application, but you periodically experience spikes in query traffic. By specifying promotion tiers for the Aurora Serverless v2 DB instances in a cluster, you can configure your cluster so that the reader DB instances can scale independently of the writer DB instance to handle the additional load. When the usage spike subsides, the reader DB instances scale back down to match the capacity of the writer DB instance.
- **Capacity planning** – Suppose that you usually adjust your database capacity, or verify the optimal database capacity for your workload, by modifying the DB instance classes of all the DB instances in a cluster. With Aurora Serverless v2, you can avoid this administrative overhead. You

can determine the appropriate minimum and maximum capacity by running the workload and checking how much the DB instances actually scale.

You can modify existing DB instances from provisioned to Aurora Serverless v2 or from Aurora Serverless v2 to provisioned. You don't need to create a new cluster or a new DB instance in such cases.

With an Aurora global database, you might not need as much capacity for the secondary clusters as in the primary cluster. You can use Aurora Serverless v2 DB instances in the secondary clusters. That way, the cluster capacity can scale up if a secondary region is promoted and takes over your application's workload.

- **Development and testing** – In addition to running your most demanding applications, you can also use Aurora Serverless v2 for development and testing environments. With Aurora Serverless v2, you can create DB instances with a low minimum capacity instead of using burstable db.t\* DB instance classes. You can set the maximum capacity high enough that those DB instances can still run substantial workloads without running low on memory. When the database isn't in use, all of the DB instances scale down to avoid unnecessary charges.

#### Tip

To make it convenient to use Aurora Serverless v2 in development and test environments, the Amazon Web Services Management Console provides the **Easy create** shortcut when you create a new cluster. If you choose the **Dev/Test** option, Aurora creates a cluster with an Aurora Serverless v2 DB instance and a capacity range that's typical for a development and test system.

## Using Aurora Serverless v2 for existing provisioned workloads

Suppose that you already have an Aurora application running on a provisioned cluster. You can check how the application would work with Aurora Serverless v2 by adding one or more Aurora Serverless v2 DB instances to the existing cluster as reader DB instances. You can check how often the reader DB instances scale up and down. You can use the Aurora failover mechanism to promote an Aurora Serverless v2 DB instance to be the writer and check how it handles the read/write workload. That way, you can switch over with minimal downtime and without changing the endpoint that your client applications use. For details on the procedure to convert existing clusters to Aurora Serverless v2, see [Migrating to Aurora Serverless v2](#).

## Advantages of Aurora Serverless v2

Aurora Serverless v2 is intended for variable or "spiky" workloads. With such unpredictable workloads, you might have difficulty planning when to change your database capacity. You might also have trouble making capacity changes quickly enough using the familiar mechanisms such as adding DB instances or changing DB instance classes. Aurora Serverless v2 provides the following advantages to help with such use cases:

- **Simpler capacity management than provisioned** – Aurora Serverless v2 reduces the effort for planning DB instance sizes and resizing DB instances as the workload changes. It also reduces the effort for maintaining consistent capacity for all the DB instances in a cluster.
- **Faster and easier scaling during periods of high activity** – Aurora Serverless v2 scales compute and memory capacity as needed, with no disruption to client transactions or your overall workload. The ability to use reader DB instances with Aurora Serverless v2 helps you to take advantage of horizontal scaling in addition to vertical scaling. The ability to use Aurora global databases means that you can spread your Aurora Serverless v2 read workload across multiple Amazon Web Services Regions. This capability is more convenient than the scaling mechanisms for provisioned clusters. It's also faster and more granular than the scaling capabilities in Aurora Serverless v1.
- **Cost-effective during periods of low activity** – Aurora Serverless v2 helps you to avoid overprovisioning your DB instances. Aurora Serverless v2 adds resources in granular increments when DB instances scale up. You pay only for the database resources that you consume. Aurora Serverless v2 resource usage is measured on a per-second basis. That way, when a DB instance scales down, the reduced resource usage is registered right away.
- **Greater feature parity with provisioned** – You can use many Aurora features with Aurora Serverless v2 that aren't available for Aurora Serverless v1. For example, with Aurora Serverless v2 you can use reader DB instances, global databases, Amazon Identity and Access Management (IAM) database authentication, and Performance Insights. You can also use many more configuration parameters than with Aurora Serverless v1.

In particular, with Aurora Serverless v2 you can take advantage of the following features from provisioned clusters:

- **Reader DB instances** – Aurora Serverless v2 can take advantage of reader DB instances to scale horizontally. When a cluster contains one or more reader DB instances, the cluster can fail over immediately in case of problems with the writer DB instance. This is a capability that isn't available with Aurora Serverless v1.

- **Multi-AZ clusters** – You can distribute the Aurora Serverless v2 DB instances of a cluster across multiple Availability Zones (AZs). Setting up a Multi-AZ cluster helps to ensure business continuity even in the rare case of issues that affect an entire AZ. This is a capability that isn't available with Aurora Serverless v1.
- **Global databases** – You can use Aurora Serverless v2 in combination with Aurora global databases to create additional read-only copies of your cluster in other Amazon Web Services Regions for disaster recovery purposes.
- **RDS Proxy** – You can use Amazon RDS Proxy to allow your applications to pool and share database connections to improve their ability to scale.
- **Faster, more granular, less disruptive scaling than Aurora Serverless v1** – Aurora Serverless v2 can scale up and down faster. Scaling can change capacity by as little as 0.5 ACUs, instead of doubling or halving the number of ACUs. Scaling typically happens with no pause in processing at all. Scaling doesn't involve an event that you have to be aware of, as with Aurora Serverless v1. Scaling can happen while SQL statements are running and transactions are open, without the need to wait for a quiet point.

## How Aurora Serverless v2 works

The following overview describes how Aurora Serverless v2 works.

### Topics

- [Aurora Serverless v2 overview](#)
- [Configurations for Aurora DB clusters](#)
- [Aurora Serverless v2 capacity](#)
- [Aurora Serverless v2 scaling](#)
- [Aurora Serverless v2 and high availability](#)
- [Aurora Serverless v2 and storage](#)
- [Configuration parameters for Aurora clusters](#)

## Aurora Serverless v2 overview

*Amazon Aurora Serverless v2* is suitable for the most demanding, highly variable workloads. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail, gaming, or sports websites

with periodic promotional events, and databases that produce reports when needed. Others are development and testing environments, and new applications where usage might ramp up quickly. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

In contrast, *Aurora provisioned clusters* are suitable for steady workloads. With provisioned clusters, you choose a DB instance class that has a predefined amount of memory, CPU power, I/O bandwidth, and so on. If your workload changes, you manually modify the instance class of your writer and readers. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns and it's acceptable to have brief outages while you change the instance class of the writer and readers in your cluster.

Aurora Serverless v2 is architected from the ground up to support serverless DB clusters that are instantly scalable. Aurora Serverless v2 is engineered to provide the same degree of security and isolation as with provisioned writers and readers. These aspects are crucial in multitenant serverless cloud environments. The dynamic scaling mechanism has very little overhead so that it can respond quickly to changes in the database workload. It's also powerful enough to meet dramatic increases in processing demand.

By using Aurora Serverless v2, you can create an Aurora DB cluster without being locked into a specific database capacity for each writer and reader. You specify the minimum and maximum capacity range. Aurora scales each Aurora Serverless v2 writer or reader in the cluster within that capacity range. By using a Multi-AZ cluster where each writer or reader can scale dynamically, you can take advantage of dynamic scaling and high availability.

Aurora Serverless v2 scales the database resources automatically based on your minimum and maximum capacity specifications. Scaling is fast because most scaling events operations keep the writer or reader on the same host. In the rare cases that an Aurora Serverless v2 writer or reader is moved from one host to another, Aurora Serverless v2 manages the connections automatically. You don't need to change your database client application code or your database connection strings.

With Aurora Serverless v2, as with provisioned clusters, storage capacity and compute capacity are separate. When we refer to Aurora Serverless v2 capacity and scaling, it's always compute capacity that's increasing or decreasing. Thus, your cluster can contain many terabytes of data even when the CPU and memory capacity scale down to low levels.

Instead of provisioning and managing database servers, you specify database capacity. For details about Aurora Serverless v2 capacity, see [Aurora Serverless v2 capacity](#). The actual capacity of each

Aurora Serverless v2 writer or reader varies over time, depending on your workload. For details about that mechanism, see [Aurora Serverless v2 scaling](#).

### Important

With Aurora Serverless v1, your cluster has a single measure of compute capacity that can scale between the minimum and maximum capacity values. With Aurora Serverless v2, your cluster can contain readers in addition to the writer. Each Aurora Serverless v2 writer and reader can scale between the minimum and maximum capacity values. Thus, the total capacity of your Aurora Serverless v2 cluster depends on both the capacity range that you define for your DB cluster and the number of writers and readers in the cluster. At any specific time, you are only charged for the Aurora Serverless v2 capacity that is being actively used in your Aurora DB cluster.

## Configurations for Aurora DB clusters

For each of your Aurora DB clusters, you can choose any combination of Aurora Serverless v2 capacity, provisioned capacity, or both.

You can set up a cluster that contains both Aurora Serverless v2 and provisioned capacity, called a *mixed-configuration cluster*. For example, suppose that you need more read/write capacity than is available for an Aurora Serverless v2 writer. In this case, you can set up the cluster with a very large provisioned writer. In that case, you can still use Aurora Serverless v2 for the readers. Or suppose that the write workload for your cluster varies but the read workload is steady. In this case, you can set up your cluster with an Aurora Serverless v2 writer and one or more provisioned readers.

You can also set up a DB cluster where all the capacity is managed by Aurora Serverless v2. To do this, you can create a new cluster and use Aurora Serverless v2 from the start. Or you can replace all the provisioned capacity in an existing cluster with Aurora Serverless v2. For example, some of the upgrade paths from older engine versions require starting with a provisioned writer and replacing it with a Aurora Serverless v2 writer. For the procedures to create a new DB cluster with Aurora Serverless v2 or to switch an existing DB cluster to Aurora Serverless v2, see [Creating an Aurora Serverless v2 DB cluster](#) and [Switching from a provisioned cluster to Aurora Serverless v2](#).

If you don't use Aurora Serverless v2 at all in a DB cluster, all the writers and readers in the DB cluster are *provisioned*. This is the oldest and most common kind of DB cluster that most users are familiar with. In fact, before Aurora Serverless, there wasn't a special name for this kind of Aurora DB cluster. Provisioned capacity is constant. The charges are relatively easy to forecast. However,

you have to predict in advance how much capacity you need. In some cases, your predictions might be inaccurate or your capacity needs might change. In these cases, your DB cluster can become underprovisioned (slower than you want) or overprovisioned (more expensive than you want).

## Aurora Serverless v2 capacity

The unit of measure for Aurora Serverless v2 is the *Aurora capacity unit (ACU)*. Aurora Serverless v2 capacity isn't tied to the DB instance classes that you use for provisioned clusters.

Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. You specify the database capacity range using this unit of measure. The `ServerlessDatabaseCapacity` and `ACUUtilization` metrics help you to determine how much capacity your database is actually using and where that capacity falls within the specified range.

At any moment in time, each Aurora Serverless v2 DB writer or reader has a *capacity*. The capacity is represented as a floating-point number representing ACUs. The capacity increases or decreases whenever the writer or reader scales. This value is measured every second. For each DB cluster where you intend to use Aurora Serverless v2, you define a *capacity range*: the minimum and maximum capacity values that each Aurora Serverless v2 writer or reader can scale between. The capacity range is the same for each Aurora Serverless v2 writer or reader in a DB cluster. Each Aurora Serverless v2 writer or reader has its own capacity, falling somewhere in that range.

The following table shows the Aurora Serverless v2 capacity ranges and engine version support for Aurora MySQL and Aurora PostgreSQL.

Capacity range (ACUs)	Aurora MySQL supported versions	Aurora PostgreSQL supported versions
0.5–128	3.02.0 and higher	13.6 and higher, 14.3 and higher, 15.2 and higher, 16.1 and higher
0.5–256	3.06.0 and higher	13.13 and higher, 14.10 and higher, 15.5 and higher, 16.1 and higher
0–256	3.08.0 and higher	13.15 and higher, 14.12 and higher, 15.7 and higher, 16.3 and higher

The following table shows the Aurora Serverless v2 platform versions with their ACU ranges and performance characteristics.

Aurora Serverless v2 platform version	ACU range	Performance
1	0–128	Baseline performance
2	0–256	Baseline performance
3	0–256	Up to 30% improved performance compared to platform version 2

**Note**

The available scaling range for a given cluster is determined by both engine version and platform version. It is possible to have a more capable engine version running on a less capable platform version and vice-versa. The scaling range is determined by the lowest capable engine or platform version.

You can determine what platform version your cluster is running on in the Instance Configuration section of the Amazon Web Services Management Console or through the API by viewing the `ServerlessV2PlatformVersion` for a [DBCluster](#).

The smallest Aurora Serverless v2 capacity that you can define is 0 ACUs, for Aurora Serverless v2 versions that support the auto-pause feature. You can specify a higher number if it's less than or equal to the maximum capacity value. Setting the minimum capacity to a small number lets lightly loaded DB clusters consume minimal compute resources. At the same time, they stay ready to accept connections immediately and scale up when they become busy.

We recommend setting the minimum to a value that allows each DB writer or reader to hold the working set of the application in the buffer pool. That way, the contents of the buffer pool aren't discarded during idle periods. For all the considerations when choosing the minimum capacity value, see [Choosing the minimum Aurora Serverless v2 capacity setting for a cluster](#). For all the considerations when choosing the maximum capacity value, see [Choosing the maximum Aurora Serverless v2 capacity setting for a cluster](#).

Depending on how you configure the readers in a Multi-AZ deployment, their capacities can be tied to the capacity of the writer or independently. For details about how to do that, see [Aurora Serverless v2 scaling](#).

Monitoring Aurora Serverless v2 involves measuring the capacity values for the writer and readers in your DB cluster over time. If your database doesn't scale down to the minimum capacity, you can take actions such as adjusting the minimum and optimizing your database application. If your database consistently reaches its maximum capacity, you can take actions such as increasing the maximum. You can also optimize your database application and spread the query load across more readers.

The charges for Aurora Serverless v2 capacity are measured in terms of ACU-hours. For information about how Aurora Serverless v2 charges are calculated, see the [Aurora pricing page](#).

Suppose that the total number of writers and readers in your cluster is  $n$ . In that case, the cluster consumes approximately  $n \times \textit{minimum ACUs}$  when you aren't running any database operations. Aurora itself might run monitoring or maintenance operations that cause some small amount of load. That cluster consumes no more than  $n \times \textit{maximum ACUs}$  when the database is running at full capacity.

For more details about choosing appropriate minimum and maximum ACU values, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster](#). The minimum and maximum ACU values that you specify also affect the way some of the Aurora configuration parameters work for Aurora Serverless v2. For details about the interaction between the capacity range and configuration parameters, see [Working with parameter groups for Aurora Serverless v2](#).

## Aurora Serverless v2 scaling

For each Aurora Serverless v2 writer or reader, Aurora continuously tracks utilization of resources such as CPU, memory, and network. These measurements collectively are called the *load*. The load includes the database operations performed by your application. It also includes background processing for the database server and Aurora administrative tasks. When capacity is constrained by any of these, Aurora Serverless v2 scales up. Aurora Serverless v2 also scales up when it detects performance issues that it can resolve by doing so. You can monitor resource utilization and how it affects Aurora Serverless v2 scaling by using the procedures in [Important Amazon CloudWatch metrics for Aurora Serverless v2](#) and [Monitoring Aurora Serverless v2 performance with Performance Insights](#).

The load can vary across the writer and readers in your DB cluster. The writer handles all data definition language (DDL) statements, such as `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`. The writer also handles all data manipulation language (DML) statements, such as `INSERT` and `UPDATE`. Readers can process read-only statements, such as `SELECT` queries.

*Scaling* is the operation that increases or decreases Aurora Serverless v2 capacity for your database. With Aurora Serverless v2, each writer and reader has its own current capacity value, measured in ACUs. Aurora Serverless v2 scales a writer or reader up to a higher capacity when its current capacity is too low to handle the load. It scales the writer or reader down to a lower capacity when its current capacity is higher than needed.

Unlike Aurora Serverless v1, which scales by doubling the capacity each time the DB cluster reaches a threshold, Aurora Serverless v2 can increase capacity incrementally. When your workload demand begins to reach the current database capacity of a writer or reader, Aurora Serverless v2 increases the number of ACUs for that writer or reader. Aurora Serverless v2 scales capacity in the increments required to provide the best performance for the resources consumed. Scaling happens in increments as small as 0.5 ACUs. The larger the current capacity, the larger the scaling increment and thus the faster scaling can happen.

Because Aurora Serverless v2 scaling is so frequent, granular, and nondisruptive, it doesn't cause discrete events in the Amazon Web Services Management Console the way that Aurora Serverless v1 does. Instead, you can measure the Amazon CloudWatch metrics such as `ServerlessDatabaseCapacity` and `ACUUtilization` and track their minimum, maximum, and average values over time. To learn more about Aurora metrics, see [Monitoring metrics in an Amazon Aurora cluster](#). For tips about monitoring Aurora Serverless v2, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#).

You can choose to make a reader scale at the same time as the associated writer, or independently from the writer. You do so by specifying the promotion tier for that reader.

- Readers in promotion tiers 0 and 1 scale at the same time as the writer. That scaling behavior makes readers in priority tiers 0 and 1 ideal for availability. That's because they are always sized to the right capacity to take over the workload from the writer in case of failover.
- Readers in promotion tiers 2–15 scale independently from the writer. Each reader remains within the minimum and maximum ACU values that you specified for your cluster. When a reader scales independently of the associated writer DB, it can become idle and scale down while the writer continues to process a high volume of transactions. It's still available as a failover target, if no

other readers are available in lower promotion tiers. However, if it's promoted to be the writer, it might need to scale up to handle the full workload of the writer.

For details about promotion tiers, see [Choosing the promotion tier for an Aurora Serverless v2 reader](#).

The notions of scaling points and associated timeout periods from Aurora Serverless v1 don't apply in Aurora Serverless v2. Aurora Serverless v2 scaling can happen while database connections are open, while SQL transactions are in process, while tables are locked, and while temporary tables are in use. Aurora Serverless v2 doesn't wait for a quiet point to begin scaling. Scaling doesn't disrupt any database operations that are underway.

If your workload requires more read capacity than is available with a single writer and a single reader, you can add multiple Aurora Serverless v2 readers to the cluster. Each Aurora Serverless v2 reader can scale within the range of minimum and maximum capacity values that you specified for your DB cluster. You can use the cluster's reader endpoint to direct read-only sessions to the readers and reduce the load on the writer.

Whether Aurora Serverless v2 performs scaling, and how fast scaling occurs once it starts, also depends on the minimum and maximum ACU settings for the cluster. In addition, it depends on whether a reader is configured to scale along with the writer or independently from it. For details about the factors that affect Aurora Serverless v2 scaling, see [Performance and scaling for Aurora Serverless v2](#).

## Scaling to Zero

In recent Aurora MySQL and Aurora PostgreSQL versions, Aurora Serverless v2 writers and readers can scale all the way down to zero ACUs. We refer to this capability as automatic pause and resume, or auto-pause. You can choose whether to allow this behavior by specifying a zero or nonzero value for the minimum capacity. You can also choose how long to wait before an Aurora Serverless v2 instance pauses. For information about which versions have this capability, see [Aurora Serverless v2 capacity](#). For information about how to use it effectively, see [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#).

In older Aurora MySQL and Aurora PostgreSQL versions, idle Aurora Serverless v2 writers and readers can scale down to the minimum ACU value that you specified for the cluster, but not all the way to zero ACUs. In that case, zero ACUs isn't available as a choice when you set the capacity range. That behavior is different than Aurora Serverless v1, which can pause after a period of idleness, but then takes some time to resume when you open a new connection.

When your DB cluster with Aurora Serverless v2 capacity isn't needed for some time, you can also stop and start the entire cluster, the same as with provisioned DB clusters. This technique is most appropriate for development and test systems, where they might not be needed for many hours at a time, and the speed of resuming the cluster isn't crucial. The stop/start cluster feature is available for all Aurora Serverless v2 versions. For more information about that feature, see [Stopping and starting an Amazon Aurora DB cluster](#).

## Aurora Serverless v2 and high availability

The way to establish high availability for an Aurora DB cluster is to make it a Multi-AZ DB cluster. A *Multi-AZ Aurora DB cluster* has compute capacity available at all times in more than one Availability Zone (AZ). That configuration keeps your database up and running even in case of a significant outage. Aurora performs an automatic failover in case of an issue that affects the writer or even the entire AZ. With Aurora Serverless v2, you can choose for the standby compute capacity to scale up and down along with the capacity of the writer. That way, the compute capacity in the second AZ is ready to take over the current workload at any time. At the same time, the compute capacity in all AZs can scale down when the database is idle. For details about how Aurora works with Amazon Web Services Regions and Availability Zones, see [High availability for Aurora DB instances](#).

The Aurora Serverless v2 Multi-AZ capability uses *readers* in addition to the writer. Support for readers is new for Aurora Serverless v2 compared to Aurora Serverless v1. You can add up to 15 Aurora Serverless v2 readers spread across 3 AZs to an Aurora DB cluster.

For business-critical applications that must remain available even in case of an issue that affects your entire cluster or the whole Amazon Region, you can set up an Aurora global database. You can use Aurora Serverless v2 capacity in the secondary clusters so they're ready to take over during disaster recovery. They can also scale down when the database isn't busy. For details about Aurora global databases, see [Using Amazon Aurora Global Database](#).

Aurora Serverless v2 works like provisioned for failover and other high availability features. For more information, see [High availability for Amazon Aurora](#).

Suppose that you want to ensure maximum availability for your Aurora Serverless v2 cluster. You can create a reader in addition to the writer. If you assign the reader to promotion tier 0 or 1, whatever scaling happens for the writer also happens for the reader. That way, a reader with identical capacity is always ready to take over for the writer in case of a failover.

Suppose that you want to run quarterly reports for your business at the same time as your cluster continues to process transactions. If you add an Aurora Serverless v2 reader to the cluster and assign it to a promotion tier from 2 through 15, you can connect directly to that reader to run the reports. Depending on how memory-intensive and CPU-intensive the reporting queries are, that reader can scale up to accommodate the workload. It can then scale down again when the reports are finished.

## Aurora Serverless v2 and storage

The storage for each Aurora DB cluster consists of six copies of all your data, spread across three AZs. This built-in data replication applies regardless of whether your DB cluster includes any readers in addition to the writer. That way, your data is safe, even from issues that affect the compute capacity of the cluster.

Aurora Serverless v2 storage has the same reliability and durability characteristics as described in [Amazon Aurora storage](#). That's because the storage for Aurora DB clusters works the same whether the compute capacity uses Aurora Serverless v2 or provisioned.

## Configuration parameters for Aurora clusters

You can adjust all the same cluster and database configuration parameters for clusters with Aurora Serverless v2 capacity as for provisioned DB clusters. However, some capacity-related parameters are handled differently for Aurora Serverless v2. In a mixed-configuration cluster, the parameter values that you specify for those capacity-related parameters still apply to any provisioned writers and readers.

Almost all of the parameters work the same way for Aurora Serverless v2 writers and readers as for provisioned ones. The exceptions are some parameters that Aurora automatically adjusts during scaling, and some parameters that Aurora keeps at fixed values that depend on the maximum capacity setting.

For example, the amount of memory reserved for the buffer cache increases as a writer or reader scales up, and decreases as it scales down. That way, memory can be released when your database isn't busy. Conversely, Aurora automatically sets the maximum number of connections to a value that's appropriate based on the maximum capacity setting. That way, active connections aren't dropped if the load drops and Aurora Serverless v2 scales down. For information about how Aurora Serverless v2 handles specific parameters, see [Working with parameter groups for Aurora Serverless v2](#).

# Requirements and limitations for Aurora Serverless v2

When you create a cluster where you intend to use Aurora Serverless v2 DB instances, pay attention to the following requirements and limitations.

## Topics

- [Region and version availability](#)
- [Clusters that use Aurora Serverless v2 must have a capacity range specified](#)
- [Some provisioned features aren't supported in Aurora Serverless v2](#)
- [Some Aurora Serverless v2 aspects are different from Aurora Serverless v1](#)

## Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and Aurora Serverless v2, see [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).

The following example shows the Amazon CLI commands to confirm the exact DB engine values you can use with Aurora Serverless v2 for a specific Amazon Web Services Region. The `--db-instance-class` parameter for Aurora Serverless v2 is always `db.serverless`. The `--engine` parameter can be `aurora-mysql` or `aurora-postgresql`. Substitute the appropriate `--region` and `--engine` values to confirm the `--engine-version` values that you can use. If the command doesn't produce any output, Aurora Serverless v2 isn't available for that combination of Amazon Web Services Region and DB engine.

```
aws rds describe-orderable-db-instance-options --engine aurora-mysql --db-instance-class db.serverless \  
  --region my_region --query 'OrderableDBInstanceOptions[][EngineVersion]' --output text
```

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.serverless \  
  --region my_region --query 'OrderableDBInstanceOptions[][EngineVersion]' --output text
```

## Clusters that use Aurora Serverless v2 must have a capacity range specified

An Aurora cluster must have a `ServerlessV2ScalingConfiguration` attribute before you can add any DB instances that use the `db.serverless` DB instance class. This attribute specifies the capacity range. Aurora Serverless v2 capacity ranges from a minimum of 0 Aurora capacity units (ACU) to a maximum of 256 ACUs, in increments of 0.5 ACU. The allowed minimum value depends on the Aurora version. Each ACU provides the equivalent of approximately 2 gibibytes (GiB) of RAM and associated CPU and networking. For details about how Aurora Serverless v2 uses the capacity range settings, see [How Aurora Serverless v2 works](#).

For the allowed capacity ranges for various DB engine versions and platform versions, see [Aurora Serverless v2 capacity](#). The available scaling range for a given cluster is influenced by both engine version and hardware (platform version).

You can specify the minimum and maximum ACU values in the Amazon Web Services Management Console when you create a cluster and associated Aurora Serverless v2 DB instance. You can also specify the `--serverless-v2-scaling-configuration` option in the Amazon CLI. Or you can specify the `ServerlessV2ScalingConfiguration` parameter with the Amazon RDS API. You can specify this attribute when you create a cluster or modify an existing cluster. For the procedures to set the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster](#). For a detailed discussion of how to pick minimum and maximum capacity values and how those settings affect some database parameters, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster](#).

## Some provisioned features aren't supported in Aurora Serverless v2

The following features from Aurora provisioned DB instances currently aren't available for Amazon Aurora Serverless v2:

- Database activity streams (DAS).
- Cluster cache management for Aurora PostgreSQL. The `apg_ccm_enabled` configuration parameter doesn't apply to Aurora Serverless v2 DB instances.

Some Aurora features work with Aurora Serverless v2, but might cause issues if your capacity range is lower than needed for the memory requirements for those features with your specific workload. In that case, your database might not perform as well as usual, or might encounter out-of-memory

errors. For recommendations about setting the appropriate capacity range, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster](#). For troubleshooting information if your database encounters out-of-memory errors due to a misconfigured capacity range, see [Avoiding out-of-memory errors](#).

Aurora Auto Scaling isn't supported. This type of scaling adds new readers to handle additional read-intensive workload, based on CPU usage. However, scaling based on CPU usage isn't meaningful for Aurora Serverless v2. As an alternative, you can create Aurora Serverless v2 reader DB instances in advance and leave them scaled down to low capacity. That's a faster and less disruptive way to scale a cluster's read capacity than adding new DB instances dynamically.

## Some Aurora Serverless v2 aspects are different from Aurora Serverless v1

If you are an Aurora Serverless v1 user and this is your first time using Aurora Serverless v2, consult the [differences between Aurora Serverless v2 and Aurora Serverless v1 requirements](#) to understand how requirements are different between Aurora Serverless v1 and Aurora Serverless v2.

## Creating a DB cluster that uses Aurora Serverless v2

To create an Aurora cluster where you can add Aurora Serverless v2 DB instances, you follow the same procedure as in [Creating an Amazon Aurora DB cluster](#). With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. You can have clusters where some DB instances use Aurora Serverless v2 and some DB instances are provisioned.

### Topics

- [Settings for Aurora Serverless v2 DB clusters](#)
- [Creating an Aurora Serverless v2 DB cluster](#)
- [Creating an Aurora Serverless v2 writer DB instance](#)

## Settings for Aurora Serverless v2 DB clusters

Make sure that the cluster's initial settings meet the requirements listed in [Requirements and limitations for Aurora Serverless v2](#). Specify the following settings to make sure that you can add Aurora Serverless v2 DB instances to the cluster:

## Amazon Web Services Region

Create the cluster in an Amazon Web Services Region where Aurora Serverless v2 DB instances are available. For details about available Regions, see [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).

## DB engine version

Choose an engine version that's compatible with Aurora Serverless v2. For information about the Aurora Serverless v2 version requirements, see [Requirements and limitations for Aurora Serverless v2](#).

## DB instance class

If you create a cluster using the Amazon Web Services Management Console, you choose the DB instance class for the writer DB instance at the same time. Choose the **Serverless** DB instance class. When you choose that DB instance class, you also specify the capacity range for the writer DB instance. That same capacity range applies to all other Aurora Serverless v2 DB instances that you add to that cluster.

If you don't see the **Serverless** choice for the DB instance class, make sure that you chose a DB engine version that's supported for [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).

When you use the Amazon CLI or the Amazon RDS API, the parameter that you specify for the DB instance class is `db.serverless`.

## Capacity range

Fill in the minimum and maximum Aurora capacity unit (ACU) values that apply to all the DB instances in the cluster. This option is available on both the **Create cluster** and **Add reader** console pages when you choose **Serverless** for the DB instance class.

For the allowed capacity ranges for various DB engine versions, see [Aurora Serverless v2 capacity](#).

If you don't see the minimum and maximum ACU fields, make sure that you chose the **Serverless** DB instance class for the writer DB instance.

If you initially create the cluster with a provisioned DB instance, you don't specify the minimum and maximum ACUs. In that case you can modify the cluster afterward to add that setting. You can also

add an Aurora Serverless v2 reader DB instance to the cluster. You specify the capacity range as part of that process.

Until you specify the capacity range for your cluster, you can't add any Aurora Serverless v2 DB instances to the cluster using the Amazon CLI or RDS API. If you try to add a Aurora Serverless v2 DB instance, you get an error. In the Amazon CLI or the RDS API procedures, the capacity range is represented by the `ServerlessV2ScalingConfiguration` attribute.

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second or later reader DB instance to your cluster. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader](#).

## Creating an Aurora Serverless v2 DB cluster

You can use the Amazon Web Services Management Console, Amazon CLI, or RDS API to create an Aurora Serverless v2 DB cluster.

### Console

#### To create a cluster with an Aurora Serverless v2 writer

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**. On the page that appears, choose the following options:
  - For **Engine type**, choose **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.
  - For **Version**, choose one of the supported versions for [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).
4. For **DB instance class**, select **Serverless v2**.
5. For **Capacity range**, you can accept the default range. Or you can choose other values for minimum and maximum capacity units. You can choose from 0 ACUs minimum through 256 ACUs maximum, in increments of 0.5 ACU.

For more information about Aurora Serverless v2 capacity units, see [Aurora Serverless v2 capacity](#) and [Performance and scaling for Aurora Serverless v2](#).

Depending on the engine and version that you choose, the upper limit might be 128 ACUs, the lower limit might be 0.5 ACUs, or both. For details about the limit for each combination of Aurora engine and version, see [Aurora Serverless v2 capacity](#).

### Serverless v2 capacity settings

**Capacity range** | [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

<b>Minimum capacity (ACUs)</b>	<b>Maximum capacity (ACUs)</b>
<input type="text" value="2"/> (4 GiB)	<input type="text" value="4"/> (8 GiB)
0 to 256 in increments of 0.5	1 to 256 in increments of 0.5

**Pause after inactivity** | [Info](#)  
Clusters with a minimum capacity setting of 0 ACUs can be paused during inactivity. Specify the amount of time the DB instance can be idle before pausing. For more information, see [Pause Aurora Serverless DB Instances](#).

Enter a time from 5 minutes to 24 hours

**i** Clusters with a minimum capacity setting of 0.5 ACUs or greater don't support pausing after inactivity.

Choosing a minimum capacity of 0 ACUs enables the Aurora Serverless v2 automatic pause and resume capability. In that case, you can make an additional choice of how long the Aurora Serverless v2 DB instances wait with no database connections before automatically pausing. For information about the automatic pause and resume capability, see [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#).

## Instance configuration

The DB instance configuration options below are limited to those supported by the engine that you selected above.

**DB instance class** | [Info](#)

### ▼ Hide filters

- Include previous generation classes
- Serverless v2
- Memory optimized classes (includes r classes)
- Burstable classes (includes t classes)
- Optimized Reads classes - *new*

Serverless v2  
Instant scaling for even the most demanding workloads.

**Capacity range** | [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum capacity (ACUs)

0 (0 GiB)

0 to 256 in increments of 0.5

Maximum capacity (ACUs)

4 (8 GiB)

1 to 256 in increments of 0.5

**Pause after inactivity** | [Info](#)

Clusters with a minimum capacity setting of 0 ACUs can be paused during inactivity. Specify the amount of time the DB instance can be idle before pausing. For more information, see [Pause Aurora Serverless DB Instances](#)

00:05:00

Enter a time from 5 minutes to 24 hours

- Choose any other DB cluster settings, as described in [Settings for Aurora DB clusters](#).
- Choose **Create database** to create your Aurora DB cluster with an Aurora Serverless v2 DB instance as the writer instance, also known as the primary DB instance.

## CLI

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the Amazon CLI, you follow the CLI procedure in [Creating an Amazon Aurora DB cluster](#). Include the following parameters in your `create-db-cluster` command:

- `--region` *AWS\_Region\_where\_Aurora\_Serverless\_v2\_instances\_are\_available*
- `--engine-version` *serverless\_v2\_compatible\_engine\_version*
- `--serverless-v2-scaling-configuration`  
MinCapacity=*minimum\_capacity*,MaxCapacity=*maximum\_capacity*

The following example shows the creation of an Aurora Serverless v2 DB cluster.

```
aws rds create-db-cluster \  
  --db-cluster-identifier my-serverless-v2-cluster \  
  --region eu-central-1 \  
  --engine aurora-mysql \  
  --engine-version 8.0.mysql_aurora.3.04.1 \  
  --serverless-v2-scaling-configuration MinCapacity=1,MaxCapacity=4 \  
  --master-username myuser \  
  --manage-master-user-password
```

### Note

When you create an Aurora Serverless v2 DB cluster using the Amazon CLI, the engine mode appears in the output as `provisioned` rather than `serverless`. The `serverless` engine mode refers to Aurora Serverless v1.

This example specifies the `--manage-master-user-password` option to generate the administrative password and manage it in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For information about the Aurora Serverless v2 version requirements, see [Requirements and limitations for Aurora Serverless v2](#). For information about the allowed numbers for the capacity range and what those numbers represent, see [Aurora Serverless v2 capacity](#) and [Performance and scaling for Aurora Serverless v2](#).

To verify whether an existing cluster has the capacity settings specified, check the output of the `describe-db-clusters` command for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {  
  "MinCapacity": 1.5,  
  "MaxCapacity": 24.0  
}
```

**Tip**

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `modify-db-cluster` command afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

**API**

To create a DB cluster that's compatible with Aurora Serverless v2 DB instances using the RDS API, you follow the API procedure in [Creating an Amazon Aurora DB cluster](#). Choose the following settings. Make sure that your `CreateDBCluster` operation includes the following parameters:

```
EngineVersion serverless_v2_compatible_engine_version
ServerlessV2ScalingConfiguration with MinCapacity=minimum_capacity and
MaxCapacity=maximum_capacity
```

For information about the Aurora Serverless v2 version requirements, see [Requirements and limitations for Aurora Serverless v2](#). For information about the allowed numbers for the capacity range and what those numbers represent, see [Aurora Serverless v2 capacity](#) and [Performance and scaling for Aurora Serverless v2](#).

To check if an existing cluster has the capacity settings specified, check the output of the `DescribeDBClusters` operation for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
  "MinCapacity": 1.5,
  "MaxCapacity": 24.0
}
```

**Tip**

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `ModifyDBCluster` operation afterward to add that setting. Until you do, you can't add any Aurora Serverless v2 DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

## Creating an Aurora Serverless v2 writer DB instance

Although you specify the Aurora Serverless v2 capacity range when you create an Aurora cluster, you can choose whether to use Aurora Serverless v2 or provisioned for each DB instance in the cluster. To begin using Aurora Serverless v2 immediately in your DB cluster, add a writer DB instance that uses the `db.serverless` instance class. In the console, you typically make this choice as part of the workflow to create the DB cluster. Therefore, this procedure applies mostly when you do the setup through the CLI.

### Console

When you create a DB cluster using the Amazon Web Services Management Console, you specify the properties of the writer DB instance at the same time. To make the writer DB instance use Aurora Serverless v2, choose the **Serverless** DB instance class.

Then you set the capacity range for the cluster by specifying the minimum and maximum Aurora capacity unit (ACU) values. These minimum and maximum values apply to each Aurora Serverless v2 DB instance in the cluster. For that procedure and the significance of the minimum and maximum capacity settings, see [Creating an Aurora Serverless v2 DB cluster](#).

If you don't create an Aurora Serverless v2 DB instance when you first create the cluster, you can add one or more Aurora Serverless v2 DB instances later. To do so, follow the procedures in [Adding an Aurora Serverless v2 reader](#) and [Converting a provisioned writer or reader to Aurora Serverless v2](#). You specify the capacity range at the time that you add the first Aurora Serverless v2 DB instance to the cluster. You can change the capacity range later by following the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#).

### CLI

When you create a Aurora Serverless v2 DB cluster using the Amazon CLI, you explicitly add the writer DB instance using the [create-db-instance](#) command. Include the following parameter:

- `--db-instance-class db.serverless`

The following example shows the creation of an Aurora Serverless v2 writer DB instance.

```
aws rds create-db-instance \  
  --db-cluster-identifier my-serverless-v2-cluster \  
  --db-instance-identifier my-serverless-v2-instance \  
  --db-instance-class db.serverless
```

```
--db-instance-class db.serverless \  
--engine aurora-mysql
```

## Managing Aurora Serverless v2 DB clusters

With Aurora Serverless v2, your clusters are interchangeable with provisioned clusters. The Aurora Serverless v2 properties apply to one or more DB instances within a DB cluster. Thus, the procedures for creating clusters, modifying clusters, creating and restoring snapshots, and so on, are basically the same as for other kinds of Aurora clusters. For general procedures for managing Aurora clusters and DB instances, see [Managing an Amazon Aurora DB cluster](#).

In the following topics, you can learn about management considerations for clusters that contain Aurora Serverless v2 DB instances.

### Topics

- [Setting the Aurora Serverless v2 capacity range for a cluster](#)
- [Checking the capacity range for Aurora Serverless v2](#)

## Setting the Aurora Serverless v2 capacity range for a cluster

To modify configuration parameters or other settings for clusters containing Aurora Serverless v2 DB instances, or the DB instances themselves, follow the same general procedures as for provisioned clusters. For details, see [Modifying an Amazon Aurora DB cluster](#).

The most important setting that's unique to Aurora Serverless v2 is the capacity range. After you set the minimum and maximum Aurora capacity unit (ACU) values for an Aurora cluster, you don't need to actively adjust the capacity of the Aurora Serverless v2 DB instances in the cluster. Aurora

does that for you. This setting is managed at the cluster level. The same minimum and maximum ACU values apply to each Aurora Serverless v2 DB instance in the cluster.

You can set the following specific values:

- **Minimum ACUs** – The Aurora Serverless v2 DB instance can reduce capacity down to this number of ACUs.
- **Maximum ACUs** – The Aurora Serverless v2 DB instance can increase capacity up to this number of ACUs.

The available capacity range for Aurora Serverless v2 is a function of both the DB engine version and the platform version. Newer DB engine versions allow a maximum capacity of 256 ACUs, a minimum capacity of 0 ACUs, or both. For the capacity ranges for various DB engine versions, see [Aurora Serverless v2 capacity](#).

For the auto-pause and resume capability that's enabled by setting the minimum capacity to 0 ACUs, see [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#).

For more information on making sure that your Aurora Serverless v2 DB clusters can scale up to 256 ACUs, see [Upgrading your Aurora Serverless v2 DB cluster to allow scaling to 256 ACUs](#).

 **Note**

When you modify the capacity range for an Aurora Serverless v2 DB cluster, the change takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

In Aurora Serverless v2, you can't directly set the current capacity without modifying the capacity range, as capacity dynamically adjusts based on the workload within the specified range. However, you can influence the capacity indirectly in the following ways:

- **Adjust the minimum capacity** – Temporarily lower the minimum capacity to reduce the baseline capacity when workloads are light.
- **Pause scaling temporarily** – To fix the capacity at a specific value, set the minimum and maximum capacity to the same level.
- **Scale proactive for bursting usage** – If you anticipate bursting workloads, increase the minimum capacity beforehand to maintain a higher baseline during periods of high activity.

For details about the effects of the capacity range and how to monitor and fine-tune it, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#) and [Performance and scaling for Aurora Serverless v2](#). Your goal is to make sure that the maximum capacity for the cluster is high enough to handle spikes in workload, and the minimum is low enough to minimize costs when the cluster isn't busy.

Suppose that you determine based on your monitoring that the ACU range for the cluster should be higher, lower, wider, or narrower. You can set the capacity of an Aurora cluster to a specific range of ACUs with the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API. This capacity range applies to every Aurora Serverless v2 DB instance in the cluster.

For example, suppose that your cluster has a capacity range of 1–16 ACUs and contains two Aurora Serverless v2 DB instances. Then the cluster as a whole consumes somewhere between 2 ACUs (when idle) and 32 ACUs (when fully utilized). If you change the capacity range from 8 to 40.5 ACUs, now the entire cluster consumes 16 ACUs when idle, and up to 81 ACUs when fully utilized.

Aurora automatically sets certain parameters for Aurora Serverless v2 DB instances to values that depend on the maximum ACU value in the capacity range. For the list of such parameters, see [Maximum connections for Aurora Serverless v2](#). For static parameters that rely on this type of calculation, the value is evaluated again when you reboot the DB instance. Thus, you can update the value of such parameters by rebooting the DB instance after changing the capacity range. To check whether you need to reboot your DB instance to pick up such parameter changes, check the `ParameterApplyStatus` attribute of the DB instance. A value of `pending-reboot` indicates that rebooting will apply changes to some parameter values.

## Console

You can set the capacity range of a cluster that contains Aurora Serverless v2 DB instances with the Amazon Web Services Management Console.

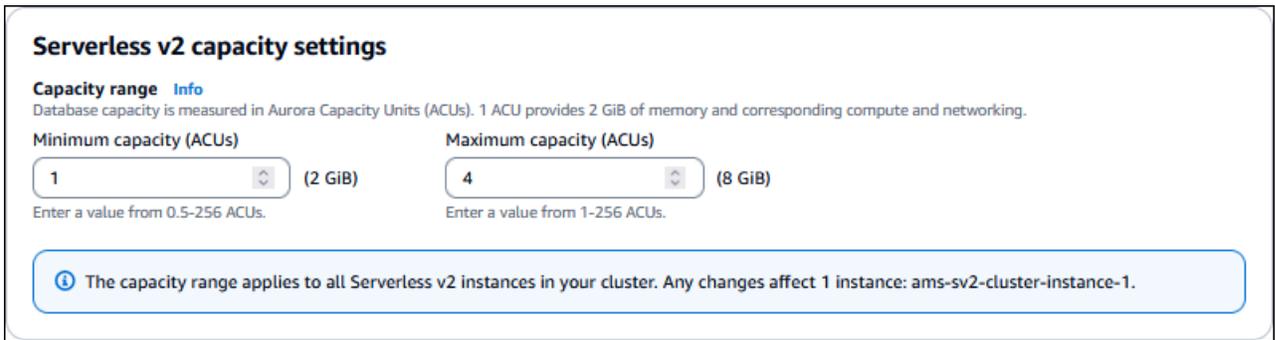

When you use the console, you set the capacity range for the cluster at the time that you add the first Aurora Serverless v2 DB instance to that cluster. You might do so when you choose the **Serverless v2** DB instance class for the writer DB instance when you create the cluster. Or you might do so when you choose the **Serverless** DB instance class when you add an Aurora Serverless v2 reader DB instance to the cluster. Or you might do so when you convert an existing provisioned DB instance in the cluster to the **Serverless** DB instance class. For the full versions of those procedures, see [Creating an Aurora Serverless v2 writer DB instance](#), [Adding an Aurora Serverless v2 reader](#), and [Converting a provisioned writer or reader to Aurora Serverless v2](#).

Whatever capacity range that you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 reader DB instances. Each has an identical capacity range of 2–64 ACUs.

Databases						
<input type="text" value="Filter by databases"/>						
DB identifier	Role	Engine	Engine version	Region & AZ	Size	
serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	3 instances	
serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	
serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	
serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	

## To modify the capacity range of an Aurora Serverless v2 cluster

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the cluster containing your Aurora Serverless v2 DB instances from the list. The cluster must already contain at least one Aurora Serverless v2 DB instance. Otherwise, Aurora doesn't show the **Capacity range** section.
4. For **Actions**, choose **Modify**.
5. In the **Capacity range** section, choose the following:
  - a. Enter a value for **Minimum ACUs**. The console shows the allowed range of values. You can choose a minimum capacity from 0 to 256 ACUs. You can choose a maximum capacity from 1 to 256 ACUs. You can adjust the capacity values in increments of 0.5 ACU. The available capacity range depends on both your DB engine version and the platform version.
  - b. Enter a value for **Maximum ACUs**. This value must be greater than or equal to **Minimum ACUs**. The console shows the allowed range of values. The following figure shows that choice.

**Serverless v2 capacity settings**

**Capacity range** [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum capacity (ACUs)  (2 GiB)  (8 GiB)  
Maximum capacity (ACUs)

Enter a value from 0.5-256 ACUs. Enter a value from 1-256 ACUs.

**i** The capacity range applies to all Serverless v2 instances in your cluster. Any changes affect 1 instance: ams-sv2-cluster-instance-1.

6. Choose **Continue**. The **Summary of modifications** page appears.
7. Choose **Apply immediately**.

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

8. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

## Amazon CLI

To set the capacity of a cluster where you intend to use Aurora Serverless v2 DB instances using the Amazon CLI, run the [modify-db-cluster](#) Amazon CLI command. Specify the `--serverless-v2-scaling-configuration` option. The cluster might already contain one or more Aurora Serverless v2 DB instances, or you can add the DB instances later. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- 0, 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 256. The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

The maximum available capacity depends on both your DB engine version and the platform version.

In this example, you set the ACU range of an Aurora DB cluster named `sample-cluster` to a minimum of 48.5 and a maximum of 64.

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
  --serverless-v2-scaling-configuration MinCapacity=48.5,MaxCapacity=64
```

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

After doing so, you can add Aurora Serverless v2 DB instances to the cluster and each new DB instance can scale between 48.5 and 64 ACUs. The new capacity range also applies to any Aurora Serverless v2 DB instances that were already in the cluster. The DB instances scale up or down if necessary to fall within the new capacity range.

For additional examples of setting the capacity range using the CLI, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster](#).

To modify the scaling configuration of an Aurora Serverless DB cluster using the Amazon CLI, run the [modify-db-cluster](#) Amazon CLI command. Specify the `--serverless-v2-scaling-configuration` option to configure the minimum capacity and maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0, 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- Aurora PostgreSQL: 0, 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

In the following example, you modify the scaling configuration of an Aurora Serverless v2 DB instance named `sample-instance` that's part of a cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \  
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster ^  
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

## RDS API

You can set the capacity of an Aurora DB instance with the [ModifyDBCluster](#) API operation. Specify the `ServerlessV2ScalingConfiguration` parameter. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- 0, 0.5, 1, 1.5, 2, and so on, in steps of 0.5, up to a maximum of 256. The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

You can modify the scaling configuration of a cluster containing Aurora Serverless v2 DB instances with the [ModifyDBCluster](#) API operation. Specify the `ServerlessV2ScalingConfiguration` parameter to configure the minimum capacity and the maximum capacity. Valid capacity values include the following:

- Aurora MySQL: 0, 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- Aurora PostgreSQL: 0, 0.5, 1, 1.5, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

The maximum available capacity depends on both your DB engine version and the platform version.

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

## Upgrading your Aurora Serverless v2 DB cluster to allow scaling to 256 ACUs

In some cases, when you try to scale your Aurora Serverless v2 DB cluster to capacities greater than 128 ACUs, you receive an error message. The error message tells you which instances are incompatible with the new scaling range. This highlights the important relationship between your capacity range, DB engine version, and platform version.

The inability to scale greater than 128 ACUs can happen for one of two reasons:

- Older DB engine version – Upgrade the DB engine version to one that supports 256 ACUs. For more information, see [Aurora Serverless v2 capacity](#).
- Older platform version – Upgrade the platform for your Aurora Serverless v2 DB cluster. You can do this in one of the following ways:
  - Stop and restart the DB cluster. When the cluster restarts, it will be on the latest platform version capable which may be capable of a higher ACU maximum.

However, stopping and starting a DB cluster incurs some downtime, usually several minutes. For more information, see [Stopping and starting an Amazon Aurora DB cluster](#).

- Use a blue/green deployment. For more information, see [Overview of Amazon Aurora Blue/Green Deployments](#).
  1. Create a blue/green deployment. For more information, see [Creating a blue/green deployment in Amazon Aurora](#).
  2. Confirm that you can set the maximum capacity for the staging (green) environment to 256 ACUs.
  3. Switch over to the green environment. For more information, see [Switching a blue/green deployment in Amazon Aurora](#).
  4. Delete the original DB cluster.

### Note

If you maintain your database credentials in Amazon Secrets Manager, you can't use blue/green deployments.  
Aurora Global Database doesn't support blue/green deployments.

## Checking the capacity range for Aurora Serverless v2

The procedure to check the capacity range for your Aurora Serverless v2 cluster requires that you first set a capacity range. If you haven't done so, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#).

Whatever capacity range you set at the cluster level applies to all Aurora Serverless v2 DB instances in your cluster. The following image shows a cluster with multiple Aurora Serverless v2 DB instances. Each has an identical capacity range.

Databases							
<input type="text" value="Filter by databases"/>							
<input type="checkbox"/>	DB Identifier	Role	Engine	Engine version	Region & AZ	Size	
<input type="checkbox"/>	serverless-v2-cluster	Regional cluster	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1	3 instances	
<input type="checkbox"/>	serverless-v2-cluster-reader-1	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	
<input type="checkbox"/>	serverless-v2-cluster-reader-2	Reader instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	
<input type="checkbox"/>	serverless-v2-cluster-instance-1	Writer instance	Aurora MySQL	8.0.mysql_aurora.3.02.0	eu-central-1c	Serverless v2 (2 - 64 ACUs)	

You can also view the details page for any Aurora Serverless v2 DB instance in the cluster. DB instances' capacity range appears on the **Configuration** tab.

### Instance configuration

Instance type

Serverless v2

Minimum capacity

2 ACUs (4 GiB)

Maximum capacity

64 ACUs (128 GiB)

You can also see the current capacity range for the cluster on the **Modify** page for the cluster. At that point, you can change the capacity range. For all the ways that you can set or change the capacity range, see [Setting the Aurora Serverless v2 capacity range for a cluster](#).

## Checking the current capacity range for an Aurora cluster

You can check the capacity range that's configured for Aurora Serverless v2 DB instances in a cluster by examining the `ServerlessV2ScalingConfiguration` attribute for the cluster. The following Amazon CLI example shows a cluster with a minimum capacity of 0.5 Aurora capacity units (ACUs) and a maximum capacity of 16 ACUs.

```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-64-acu-cluster \
  --query 'DBClusters[*].[ServerlessV2ScalingConfiguration]'
[
  [
    {
      "MinCapacity": 0.5,
      "MaxCapacity": 16.0
    }
  ]
]
```

## Adding an Aurora Serverless v2 reader

To add an Aurora Serverless v2 reader DB instance to your cluster, you follow the same general procedure as in [Adding Aurora Replicas to a DB cluster](#). Choose the **Serverless v2** instance class for the new DB instance.

If the reader DB instance is the first Aurora Serverless v2 DB instance in the cluster, you also choose the capacity range. This setting applies to this reader DB instance and to any other Aurora

Serverless v2 DB instances that you add to the cluster. Each Aurora Serverless v2 DB instance can scale between the minimum and maximum ACU values.

If any other Aurora Serverless v2 instances already exist in the cluster, the **Add reader** dialog shows the current capacity range for the cluster. In that case, you can't change the capacity. The following image shows the report of the current cluster capacity.

**Instance configuration**  
The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Serverless v2

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

Optimized Reads classes - new

Capacity range [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

If you already added any Aurora Serverless v2 DB instances to the cluster, adding another Aurora Serverless v2 reader DB instance shows you the current capacity range. The following image shows those read-only controls.

**Instance configuration**  
The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Serverless v2

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

Capacity range [Info](#)  
Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
2 ACUs (4 GiB)	64 ACUs (128 GiB)

If you want to change the capacity range for the cluster, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#).

For clusters containing more than one reader DB instance, the failover priority of each Aurora Serverless v2 reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second reader or later DB instance to your cluster. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader](#).

For other ways that you can see the current capacity range for a cluster, see [Checking the capacity range for Aurora Serverless v2](#).

## Converting a provisioned writer or reader to Aurora Serverless v2

You can convert a provisioned DB instance to use Aurora Serverless v2. To do so, you follow the procedure in [Modifying a DB instance in a DB cluster](#). The cluster must meet the requirements in [Requirements and limitations for Aurora Serverless v2](#). For example, Aurora Serverless v2 DB instances require that the cluster be running certain minimum engine versions.

Suppose that you are converting a running provisioned cluster to take advantage of Aurora Serverless v2. In that case, you can minimize downtime by converting a DB instance to Aurora Serverless v2 as the first step in the switchover process. For the full procedure, see [Switching from a provisioned cluster to Aurora Serverless v2](#).

If the DB instance that you convert is the first Aurora Serverless v2 DB instance in the cluster, you choose the capacity range for the cluster as part of the **Modify** operation. This capacity range applies to each Aurora Serverless v2 DB instance that you add to the cluster. The following image shows the page where you specify the minimum and maximum Aurora capacity units (ACUs).

**Instance configuration**

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Serverless v2

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

Optimized Reads classes - new

Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
0.5 ACUs (1 GiB)	16 ACUs (32 GiB)

For details about the significance of the capacity range, see [Aurora Serverless v2 capacity](#).

If the cluster already contains one or more Aurora Serverless v2 DB instances, you see the existing capacity range during the **Modify** operation. The following image shows an example of that information panel.

**Instance configuration**

The DB instance configuration options below are limited to those supported by the engine that you selected above.

DB instance class [Info](#)

Serverless v2

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

Capacity range [Info](#)

Database capacity is measured in Aurora Capacity Units (ACUs). 1 ACU provides 2 GiB of memory and corresponding compute and networking.

Minimum ACUs	Maximum ACUs
2 ACUs (4 GiB)	64 ACUs (128 GiB)

If you want to change the capacity range for the cluster after you add more Aurora Serverless v2 DB instances, follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#).

## Converting an Aurora Serverless v2 writer or reader to provisioned

You can convert an Aurora Serverless v2 DB instance to a provisioned DB instance. To do so, you follow the procedure in [Modifying a DB instance in a DB cluster](#). Choose a DB instance class other than **Serverless**.

You might convert an Aurora Serverless v2 DB instance to provisioned if it needs a larger capacity than is available with the maximum Aurora capacity units (ACUs) of an Aurora Serverless v2 DB instance. For example, the largest db.r5 and db.r6g DB instance classes have a larger memory capacity than an Aurora Serverless v2 DB instance can scale to.

### Tip

Some of the older DB instance classes such as db.r3 and db.t2 aren't available for the Aurora versions that you use with Aurora Serverless v2. To see which DB instance classes you can use when converting an Aurora Serverless v2 DB instance to a provisioned one, see [Supported DB engines for DB instance classes](#).

If you are converting the writer DB instance of your cluster from Aurora Serverless v2 to provisioned, you can follow the procedure in [Switching from a provisioned cluster to Aurora Serverless v2](#) but in reverse. Switch one of the reader DB instances in the cluster from Aurora Serverless v2 to provisioned. Then perform a failover to make that provisioned DB instance into the writer.

Any capacity range that you previously specified for the cluster remains in place, even if all Aurora Serverless v2 DB instances are removed from the cluster. If you want to change the capacity range, you can modify the cluster, as explained in [Setting the Aurora Serverless v2 capacity range for a cluster](#).

## Pausing Aurora Serverless v2 DB instances

You can configure Aurora clusters to automatically pause and resume their Aurora Serverless v2 DB instances. For more information, see [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#).

## Choosing the promotion tier for an Aurora Serverless v2 reader

For clusters containing multiple Aurora Serverless v2 DB instances or a mixture of provisioned and Aurora Serverless v2 DB instances, pay attention to the promotion tier setting for each Aurora Serverless v2 DB instance. This setting controls more behavior for Aurora Serverless v2 DB instances than for provisioned DB instances.

In the Amazon Web Services Management Console, you specify this setting using the **Failover priority** choice under **Additional configuration** for the **Create database**, **Modify instance**, and **Add reader** pages. You see this property for existing DB instances in the optional **Priority tier** column on the **Databases** page. You can also see this property on the details page for a DB cluster or DB instance.

For provisioned DB instances, the choice of tier 0–15 determines only the order in which Aurora chooses which reader DB instance to promote to the writer during a failover operation. For Aurora Serverless v2 reader DB instances, the tier number also determines whether the DB instance scales up to match the capacity of the writer DB instance or scales independently based on its own workload. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. That way, they are ready to take over from the writer DB instance in case of a failover. If the writer DB instance is a provisioned DB instance, Aurora estimates the equivalent Aurora Serverless v2 capacity. It uses that estimate as the minimum capacity for the Aurora Serverless v2 reader DB instance.

Aurora Serverless v2 reader DB instances in tiers 2–15 don't have the same constraint on their minimum capacity. When they are idle, they can scale down to the minimum Aurora capacity unit (ACU) value specified in the cluster's capacity range.

The following Linux Amazon CLI example shows how to examine the promotion tiers of all the DB instances in your cluster. The final field includes a value of `True` for the writer DB instance and `False` for all the reader DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier promotion-tier-demo \  
  --query 'DBClusters[*].DBClusterMembers[*].  
[PromotionTier,DBInstanceIdentifier,IsClusterWriter]' \  
  --output text  
  
1   instance-192   True  
1   tier-01-4840   False  
10  tier-10-7425     False  
15  tier-15-6694     False
```

The following Linux Amazon CLI example shows how to change the promotion tier of a specific DB instance in your cluster. The commands first modify the DB instance with a new promotion tier. Then they wait for the DB instance to become available again and confirm the new promotion tier for the DB instance.

```
$ aws rds modify-db-instance --db-instance-identifier instance-192 --promotion-tier 0
$ aws rds wait db-instance-available --db-instance-identifier instance-192
$ aws rds describe-db-instances --db-instance-identifier instance-192 \
  --query '*[].[PromotionTier]' --output text
0
```

For more guidance about specifying promotion tiers for different use cases, see [Aurora Serverless v2 scaling](#).

## Using TLS/SSL with Aurora Serverless v2

Aurora Serverless v2 can use the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v2 DB instances. It supports TLS/SSL versions 1.0, 1.1, and 1.2. For general information about using TLS/SSL with Aurora, see [TLS connections to Aurora MySQL DB clusters](#).

To learn more about connecting to Aurora MySQL database with the MySQL client, see [Connecting to a DB instance running the MySQL database engine](#).

Aurora Serverless v2 supports all TLS/SSL modes available to the MySQL client (`mysql`) and PostgreSQL client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	mysql	psql
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require

Description of TLS/SSL mode	mysql	psql
Enforce TLS/SSL and verify the certificate authority (CA).	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v2 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the [Amazon root CA 1 trust store](#) from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL client, do the following.

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem
dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres client, see [Connecting to a DB instance running the PostgreSQL database engine](#).

For more information about connecting to Aurora DB clusters in general, see [Connecting to an Amazon Aurora DB cluster](#).

## Supported cipher suites for connections to Aurora Serverless v2 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v2 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora MySQL DB clusters](#).

Aurora Serverless v2 DB clusters that are based on Aurora PostgreSQL support the same cipher suites as Aurora PostgreSQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters](#).

## Viewing Aurora Serverless v2 writers and readers

You can view the details of Aurora Serverless v2 DB instances in the same way that you do for provisioned DB instances. To do so, follow the general procedure from [Viewing an Amazon Aurora DB cluster](#). A cluster might contain all Aurora Serverless v2 DB instances, all provisioned DB instances, or some of each.

After you create one or more Aurora Serverless v2 DB instances, you can view which DB instances are type **Serverless** and which are type **Instance**. You can also view the minimum and maximum Aurora capacity units (ACUs) that the Aurora Serverless v2 DB instance can use. Each ACU is a combination of processing (CPU) and memory (RAM) capacity. This capacity range applies to each Aurora Serverless v2 DB instance in the cluster. For the procedure to check the capacity range of a cluster or any Aurora Serverless v2 DB instance in the cluster, see [Checking the capacity range for Aurora Serverless v2](#).

In the Amazon Web Services Management Console, Aurora Serverless v2 DB instances are marked under the **Size** column in the **Databases** page. Provisioned DB instances show the name of a DB instance class such as r6g.xlarge. The Aurora Serverless DB instances show **Serverless** for the DB instance class, along with the DB instance's minimum and maximum capacity. For example, you might see **Serverless v2 (4–64 ACUs)** or **Serverless v2 (1–40 ACUs)**.

You can find the same information on the **Configuration** tab for each Aurora Serverless v2 DB instance in the console. For example, you might see an **Instance type** section such as the following. Here, the **Instance type** value is **Serverless v2**, the **Minimum capacity** value is **2 ACUs (4 GiB)**, and the **Maximum capacity** value is **64 ACUs (128 GiB)**.

### Instance configuration

Instance type

Serverless v2

Minimum capacity

2 ACUs (4 GiB)

Maximum capacity

64 ACUs (128 GiB)

You can monitor the capacity of each Aurora Serverless v2 DB instance over time. That way, you can check the minimum, maximum, and average ACUs consumed by each DB instance. You can also check how close the DB instance came to its minimum or maximum capacity. To see such details in the Amazon Web Services Management Console, examine the graphs of Amazon CloudWatch metrics on the **Monitoring** tab for the DB instance. For information about the metrics to watch and how to interpret them, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#).

## Logging for Aurora Serverless v2

To turn on database logging, you specify the logs to enable using configuration parameters in your custom parameter group.

For Aurora MySQL, you can enable the following logs.

Aurora MySQL	Description
<code>general_log</code>	Creates the general log. Set to 1 to turn on. Default is off (0).
<code>log_queries_not_using_indexes</code>	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
<code>long_query_time</code>	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).
<code>server_audit_events</code>	The list of events to capture in the logs. Supported values are CONNECT, QUERY, QUERY_DCL , QUERY_DDL , QUERY_DML , and TABLE.
<code>server_audit_logging</code>	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the <code>server_audit_events</code> parameter.

Aurora MySQL	Description
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless v2 DB instances.

Aurora PostgreSQL	Description
log_connections	Logs each successful connection.
log_disconnections	Logs end of a session including duration.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).
log_statement	Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.

## Topics

- [Logging with Amazon CloudWatch](#)

- [Viewing Aurora Serverless v2 logs in Amazon CloudWatch](#)
- [Monitoring capacity with Amazon CloudWatch](#)
- [Monitoring Aurora Serverless v2 pause and resume activity](#)

## Logging with Amazon CloudWatch

After you use the procedure in [Logging for Aurora Serverless v2](#) to choose which database logs to turn on, you can choose which logs to upload ("publish") to Amazon CloudWatch.

You can use Amazon CloudWatch to analyze log data, create alarms, and view metrics. By default, error logs for Aurora Serverless v2 are enabled and automatically uploaded to CloudWatch. You can also upload other logs from Aurora Serverless v2 DB instances to CloudWatch.

Then you choose which of those logs to upload to CloudWatch, by using the **Log exports** settings in the Amazon Web Services Management Console or the `--enable-cloudwatch-logs-exports` option in the Amazon CLI.

You can choose which of your Aurora Serverless v2 logs to upload to CloudWatch. For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. We recommend that you create your custom DB cluster parameter group before creating your Aurora Serverless v2 DB cluster, so that it's available to choose when you create a database on the console.

### Note

For Aurora Serverless v2, you can create both DB cluster and DB parameter groups. This contrasts with Aurora Serverless v1, where you can only create DB cluster parameter groups.

## Viewing Aurora Serverless v2 logs in Amazon CloudWatch

After you use the procedure in [Logging with Amazon CloudWatch](#) to choose which database logs to turn on, you can view the contents of the logs.

For more information on using CloudWatch with Aurora MySQL and Aurora PostgreSQL logs, see [Monitoring log events in Amazon CloudWatch](#) and [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](#).

### To view logs for your Aurora Serverless v2 DB cluster

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. Choose your Amazon Web Services Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v2 DB cluster log from the list. The log naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/log_type
```

#### Note

For Aurora MySQL-compatible Aurora Serverless v2 DB clusters, the error log includes buffer pool scaling events even when there are no errors.

## Monitoring capacity with Amazon CloudWatch

With Aurora Serverless v2, you can use CloudWatch to monitor the capacity and utilization of all the Aurora Serverless v2 DB instances in your cluster. You can view instance-level metrics to check the capacity of each Aurora Serverless v2 DB instance as it scales up and down. You can also compare the capacity-related metrics to other metrics to see how changes in workloads affect resource consumption. For example, you can compare `ServerlessDatabaseCapacity` to `DatabaseUsedMemory`, `DatabaseConnections`, and `DMLThroughput` to assess how your DB cluster is responding during operations. For details about the capacity-related metrics that apply to Aurora Serverless v2, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#).

### To monitor your Aurora Serverless v2 DB cluster's capacity

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. Choose **Metrics**. All available metrics appear as cards in the console, grouped by service name.
3. Choose **RDS**.

4. (Optional) Use the **Search** box to find the metrics that are especially important for Aurora Serverless v2: `ServerlessDatabaseCapacity`, `ACUUtilization`, `CPUUtilization`, and `FreeableMemory`.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora Serverless v2 DB cluster capacity using the capacity-related metrics. To learn how, see [Building dashboards with CloudWatch](#).

To learn more about using Amazon CloudWatch with Amazon Aurora, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](#).

## Monitoring Aurora Serverless v2 pause and resume activity

Aurora writes a separate log file for Aurora Serverless v2 DB instances with auto-pause enabled. Aurora writes to the log for each 10-minute interval that the instance isn't paused. Aurora retains up to seven of these logs, rotated daily. The current log file is named `instance.log`, and older logs are named using the pattern `instance.YYYY-MM-DD.N.log`.

This log is enabled by default for Aurora Serverless v2 DB instances with auto-pause enabled. You can view the contents of this log in the Amazon Web Services Management Console or by using the Amazon CLI or RDSP API. Currently, you can't upload this log to CloudWatch.

The events listed in [DB instance events](#) provide a high-level overview of pause and resume activity, such as the following:

- When the instance begins to pause, and when it finishes pausing.
- When the instance begins to resume, and when it finishes resuming.
- Cases where the instance attempted to pause, but some condition prevented it from pausing.

The `instance.log` provides more granular detail about the reasons why an Aurora Serverless v2 instance might or might not be able to pause.

The log might indicate that an instance resumed for different reasons:

- **user activity:** A database connection request. This could be from an interactive client session, an RDS Data API call, or a request to download logs from the instance.
- **background activity:** A broad category that includes all the reasons why Aurora resumes an instance. For example, when a connection request to a reader instance causes the writer instance

to resume, the log for the reader indicates user activity, while the log for the writer classifies that resume request as background activity. For the reasons why Aurora might resume an instance other than a user connection request, see [Resuming an auto-paused Aurora Serverless v2 instance](#).

When Aurora isn't aware of any conditions that would prevent the instance from pausing when the auto-pause interval expires, it periodically writes an informational message to the log. For clusters with only a single DB instance, the log contains this message:

```
[INFO] No auto-pause blockers registered since time
```

For clusters with multiple DB instances, the message is slightly different. That's because a writer might be unable to pause due to activity on any of the reader instances. If the activity on the reader finishes before the auto-pause interval expires on the writer, the writer is able to pause at the expected time.

```
[INFO] No auto-pause blockers registered since time.  
Database might be required to maintain compute capacity for high availability.
```

If a pause operation starts, but a new database connection request arrives before the instance finishes pausing, the log contains this message:

```
[INFO] Unable to pause database due to a new database activity
```

If Aurora becomes aware of any conditions that definitely prevent the instance from pausing, the log contains this message that lists all such conditions:

```
[INFO] Auto-pause blockers registered since time: list_of_conditions
```

That way, Aurora doesn't prevent you from turning on replication, zero-ETL integration, Aurora Global Database, and so on in combination with the auto-pause feature. The log informs you when the use of such features might prevent auto-pause from taking effect.

The following are reasons why an Aurora Serverless v2 instance might exceed the auto-pause timeout interval, but be prevented from pausing:

- **database activity before auto-pause timeout:** The DB instance received a connection request before the timeout interval expired.

- **member of global database:** If the DB cluster is part of an Aurora global database, the Aurora Serverless v2 instances in the cluster don't pause. A cluster can change from a standalone cluster to a global database cluster. Thus, instances that formerly auto-paused might stop pausing, and report this reason in the log. Once a cluster becomes a member of a global database, it doesn't revert to a standalone cluster until you explicitly detach it. The primary cluster is still considered part of the global database even if you detach all of the secondary clusters.
- **replication capability configured:** The writer DB instance has engine-specific replication enabled, either binlog replication for MySQL or logical replication for PostgreSQL. This condition could also be caused by using another Aurora feature that requires turning on replication, such as zero-ETL integrations or Database Activity Streams (DAS).
- **continuous backup lag:** If the Aurora storage system hasn't finished applying the storage changes up to the current point in time, the writer instance doesn't pause until it catches up. This condition only affects the writer instance, and is expected to be relatively brief.
- **service or customer maintenance action:** If a maintenance operation starts, the DB instance won't pause again until that operation finishes. This condition includes a wide variety of operations that might be started by you or by Aurora, such as upgrades, cloning, changing configuration settings, upgrades, downloading log files, and so on. This event also happens when you request to delete an instance, and Aurora briefly resumes the instance as part of the deletion mechanism.
- **transient communication issue:** If Aurora can't determine whether the scaling configuration currently has a minimum capacity setting of zero ACUs, it doesn't pause the instance. This is expected to be a very rare occurrence.

## Performance and scaling for Aurora Serverless v2

The following procedures and examples show how you can set the capacity range for Aurora Serverless v2 clusters and their associated DB instances. You can also use procedures following to monitor how busy your DB instances are. Then you can use your findings to determine if you need to adjust the capacity range upward or downward.

Before you use these procedures, make sure that you are familiar with how Aurora Serverless v2 scaling works. The scaling mechanism is different than in Aurora Serverless v1. For details, see [Aurora Serverless v2 scaling](#).

## Choosing the Aurora Serverless v2 capacity range for an Aurora cluster

With Aurora Serverless v2 DB instances, you set the capacity range that applies to all the DB instances in your DB cluster at the same time that you add the first Aurora Serverless v2 DB instance to the DB cluster. For the procedure to do so, see [Setting the Aurora Serverless v2 capacity range for a cluster](#).

You can also change the capacity range for an existing cluster. The following sections discuss in more detail how to choose appropriate minimum and maximum values and what happens when you make a change to the capacity range. For example, changing the capacity range can modify the default values of some configuration parameters. Applying all the parameter changes can require rebooting each Aurora Serverless v2 DB instance.

## Choosing the minimum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose 0.5 for the minimum Aurora Serverless v2 capacity setting. That value allows the DB instance to scale down to the smallest capacity when it's completely idle, while remaining active. You can also enable automatic pause behavior by specifying a minimum capacity of 0 ACUs, as explained in [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#). However, depending on how you use that cluster and the other settings that you configure, a different minimum capacity might be the most effective. Consider the following factors when choosing the minimum capacity setting:

- The scaling rate for an Aurora Serverless v2 DB instance depends on its current capacity. The higher the current capacity, the faster it can scale up. If you need the DB instance to quickly scale up to a very high capacity, consider setting the minimum capacity to a value where the scaling rate meets your requirement.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to make a rough estimate of the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of low traffic, consult [Hardware specifications for DB instance classes for Aurora](#).

For example, suppose that you use the db.r6g.xlarge DB instance class when your cluster has a low workload. That DB instance class has 32 GiB of memory. Thus, you can specify a minimum Aurora capacity unit (ACU) setting of 16 to set up an Aurora Serverless v2 DB instance that can scale down to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat lower value to let the DB instance scale down further in case your db.r6g.xlarge DB instance was sometimes underutilized.

- If your application works most efficiently when the DB instances have a certain amount of data in the buffer cache, consider specifying a minimum ACU setting where the memory is large enough to hold the frequently accessed data. Otherwise, some data is evicted from the buffer cache when the Aurora Serverless v2 DB instances scale down to a lower memory size. Then when the DB instances scale back up, the information is read back into the buffer cache over time. If the amount of I/O to bring the data back into the buffer cache is substantial, it might be more effective to choose a higher minimum ACU value.
- If your Aurora Serverless v2 DB instances run most of the time at a particular capacity, consider specifying a minimum capacity setting that's lower than that baseline, but not too much lower.

Aurora Serverless v2 DB instances can most effectively estimate how much and how fast to scale up when the current capacity isn't drastically lower than the required capacity.

- If your provisioned workload has memory requirements that are too high for small DB instance classes such as T3 or T4g, choose a minimum ACU setting that provides memory comparable to an R5 or R6g DB instance.

In particular, we recommend the following minimum capacity for use with the specified features (these recommendations are subject to change):

- Performance Insights – 2 ACUs
- Aurora global databases – 8 ACUs (applies only to the primary Amazon Web Services Region)
- In Aurora, replication occurs at the storage layer, so reader capacity doesn't directly affect replication. However, for Aurora Serverless v2 reader DB instances that scale independently, make sure that the minimum capacity is sufficient to handle workloads during write-intensive periods to avoid query latency. If reader DB instances in promotion tiers 2–15 experience performance issues, consider increasing the cluster's minimum capacity. For details on choosing whether reader DB instances scale along with the writer or independently, see [Choosing the promotion tier for an Aurora Serverless v2 reader](#).
- If you have a DB cluster with Aurora Serverless v2 reader DB instances, the readers don't scale along with the writer DB instance when the promotion tier of the readers isn't 0 or 1. In that case, setting a low minimum capacity can result in excessive replication lag. That's because the readers might not have enough capacity to apply changes from the writer when the database is busy. We recommend that you set the minimum capacity to a value that represents a comparable amount of memory and CPU to the writer DB instance.
- The value of the `max_connections` parameter for Aurora Serverless v2DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

If you intend to use the Aurora PostgreSQL cluster for a high-connection workload, consider using a minimum ACU setting of 1 or higher. For details about how Aurora Serverless v2 handles the `max_connections` configuration parameter, see [Maximum connections for Aurora Serverless v2](#).

- The time it takes for an Aurora Serverless v2 DB instance to scale from its minimum capacity to its maximum capacity depends on the difference between its minimum and maximum ACU values. When the current capacity of the DB instance is large, Aurora Serverless v2 scales up in larger increments than when the DB instance starts from a small capacity. Thus, if you specify

a relatively large maximum capacity and the DB instance spends most of its time near that capacity, consider increasing the minimum ACU setting. That way, an idle DB instance can scale back up to maximum capacity more quickly.

## Choosing the maximum Aurora Serverless v2 capacity setting for a cluster

It's tempting to always choose some high value for the maximum Aurora Serverless v2 capacity setting. A large maximum capacity allows the DB instance to scale up the most when it's running an intensive workload. A low value avoids the possibility of unexpected charges. Depending on how you use that cluster and the other settings that you configure, the most effective value might be higher or lower than you originally thought. Consider the following factors when choosing the maximum capacity setting:

- The maximum capacity must be at least as high as the minimum capacity. You can set the minimum and maximum capacity to be identical. However, in that case the capacity never scales up or down. Thus, using identical values for minimum and maximum capacity isn't appropriate outside of testing situations.
- The maximum capacity must be higher than 0.5 ACUs. You can set the minimum and maximum capacity to be the same in most cases. However, you can't specify 0.5 for both the minimum and maximum. Use a value of 1 or higher for the maximum capacity.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to estimate the equivalent Aurora Serverless v2 capacity range. To determine the memory size to use in times of high traffic, consult [Hardware specifications for DB instance classes for Aurora](#).

For example, suppose that you use the `db.r6g.4xlarge` DB instance class when your cluster has a high workload. That DB instance class has 128 GiB of memory. Thus, you can specify a maximum ACU setting of 64 to set up an Aurora Serverless v2 DB instance that can scale up to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat higher value to let the DB instance scale up farther in case your `db.r6g.4xlarge` DB instance sometimes doesn't have enough capacity to handle the workload effectively.

- If you have a budgetary cap on your database usage, choose a value that stays within that cap even if all your Aurora Serverless v2 DB instances run at maximum capacity all the time. Remember that when you have  $n$  Aurora Serverless v2 DB instances in your cluster, the theoretical maximum Aurora Serverless v2 capacity that the cluster can consume at any moment

is  $n$  times the maximum ACU setting for the cluster. (The actual amount consumed might be less, for example if some readers scale independently from the writer.)

- If you make use of Aurora Serverless v2 reader DB instances to offload some of the read-only workload from the writer DB instance, you might be able to choose a lower maximum capacity setting. You do this to reflect that each reader DB instance doesn't need to scale as high as if the cluster contains only a single DB instance.
- Suppose that you want to protect against excessive usage due to misconfigured database parameters or inefficient queries in your application. In that case, you might avoid accidental overuse by choosing a maximum capacity setting that's lower than the absolute highest that you could set.
- If spikes due to real user activity are rare but do happen, you can take those occasions into account when choosing the maximum capacity setting. If the priority is for the application to keep running with full performance and scalability, you can specify a maximum capacity setting that's higher than you observe in normal usage. If it's OK for the application to run with reduced throughput during very extreme spikes in activity, you can choose a slightly lower maximum capacity setting. Make sure that you choose a setting that still has enough memory and CPU resources to keep the application running.
- If you turn on settings in your cluster that increase the memory usage for each DB instance, take that memory into account when deciding on the maximum ACU value. Such settings include those for Performance Insights, Aurora MySQL parallel queries, Aurora MySQL performance schema, and Aurora MySQL binary log replication. Make sure that the maximum ACU value allows the Aurora Serverless v2 DB instances to scale up enough to handle the workload when those feature are being used. For information about troubleshooting problems caused by the combination of a low maximum ACU setting and Aurora features that impose memory overhead, see [Avoiding out-of-memory errors](#).

## Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster

The following Amazon CLI example shows how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora MySQL cluster. Initially, the capacity range for the cluster is 8–32 ACUs.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \  
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'  
{
```

```

    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
  }

```

The DB instance is idle and scaled down to 8 ACUs. The following capacity-related settings apply to the DB instance at this point. To represent the size of the buffer pool in easily readable units, we divide it by 2 to the power of 30, yielding a measurement in gibibytes (GiB). That's because memory-related measurements for Aurora use units based on powers of 2, not powers of 10.

```

mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
|           3000 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|          9294577664 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes |
+-----+
|    8.65625 |
+-----+
1 row in set (0.00 sec)

```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```

aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{

```

```

    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
  }

```

Changing the capacity range caused changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that a reboot is needed to apply some parameter changes.

```

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].[DBClusterMembers:DBClusterMembers[*]'.
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroup
[0]'
{
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "DBClusterParameterGroupStatus": "pending-reboot"
    }
  ]
}

```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `innodb_buffer_pool_size` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

### Note

If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```

mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
|           3000 |
+-----+
1 row in set (0.00 sec)

```

```
mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|          15572402176 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes      |
+-----+
| 14.5029296875 |
+-----+
1 row in set (0.00 sec)
```

Now we reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

The pending-reboot status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].[DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroup
[0]}'
{
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "DBClusterParameterGroupStatus": "in-sync"
    }
  ]
}
```

The `innodb_buffer_pool_size` parameter has increased to its final size for an idle DB instance. The `max_connections` parameter has increased to reflect a value derived from the maximum ACU value. The formula that Aurora uses for `max_connections` causes an increase of 1,000 when the memory size doubles.

```
mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|          16139681792 |
+-----+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----+
| gibibytes |
+-----+
|   15.03125 |
+-----+
1 row in set (0.00 sec)

mysql> select @@max_connections;
+-----+
| @@max_connections |
+-----+
|           4000 |
+-----+
1 row in set (0.00 sec)
```

We set the capacity range to 0.5–128 ACUs, and reboot the DB instance. Now the idle DB instance has a buffer cache size that's less than 1 GiB, so we measure it in mebibytes (MiB). The `max_connections` value of 5000 is derived from the memory size of the maximum capacity setting.

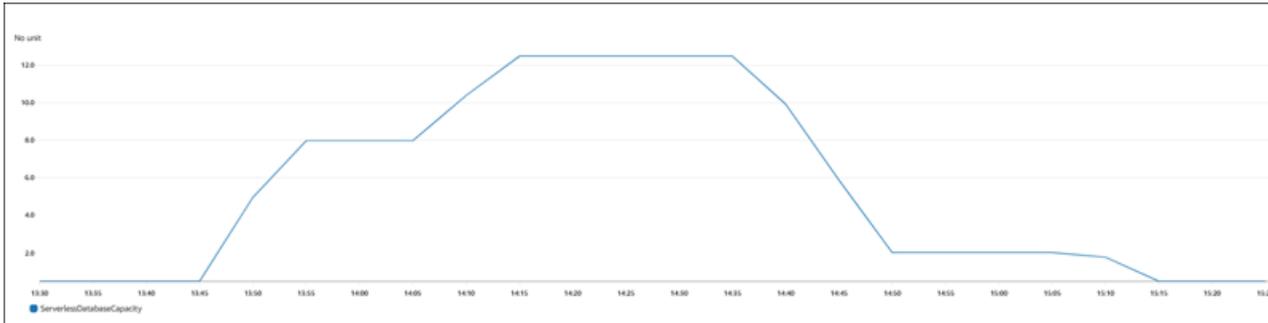

```
mysql> select @@innodb_buffer_pool_size / pow(2,20) as mebibytes, @@max_connections;
+-----+-----+
| mebibytes | @@max_connections |
+-----+-----+
|        672 |           5000 |
+-----+-----+
1 row in set (0.00 sec)
```

## Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster

The following CLI examples show how to update the ACU range for Aurora Serverless v2 DB instances in an existing Aurora PostgreSQL cluster.

1. The capacity range for the cluster starts at 0.5–1 ACU.
2. Change the capacity range to 8–32 ACUs.
3. Change the capacity range to 12.5–80 ACUs.
4. Change the capacity range to 0.5–128 ACUs.
5. Return the capacity to its initial range of 0.5–1 ACU.

The following figure shows the capacity changes in Amazon CloudWatch.

The DB instance is idle and scaled down to 0.5 ACUs. The following capacity-related settings apply to the DB instance at this point.

```
postgres=> show max_connections;
max_connections
-----
189
(1 row)

postgres=> show shared_buffers;
shared_buffers
-----
16384
(1 row)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 8.0–32.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
  "MinCapacity": 8.0,
  "MaxCapacity": 32.0
}
```

Changing the capacity range causes changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that you need a reboot to apply some parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[0].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroup
[0]}'
{
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "DBClusterParameterGroupStatus": "pending-reboot"
    }
  ]
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 8.0 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

### Note

If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```
postgres=> show max_connections;
max_connections
-----
189
```

```
(1 row)

postgres=> show shared_buffers;
 shared_buffers
-----
 1425408
(1 row)
```

We reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the pending-reboot status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].[DBClusterMembers:DBClusterMembers[*]'.
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGroup
[0]}'
{
  "DBClusterMembers": [
    {
      "DBInstanceIdentifier": "serverless-v2-instance-1",
      "DBClusterParameterGroupStatus": "in-sync"
    }
  ]
}
```

After rebooting, `max_connections` shows the value from the new maximum capacity.

```
postgres=> show max_connections;
 max_connections
-----
 5000
(1 row)
```

```
postgres=> show shared_buffers;
shared_buffers
-----
1425408
(1 row)
```

Next, we change the capacity range for the cluster to 12.5–80 ACUs.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
```

```
{
  "MinCapacity": 12.5,
  "MaxCapacity": 80.0
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` value is still 5000.

```
postgres=> show max_connections;
max_connections
-----
5000
(1 row)

postgres=> show shared_buffers;
shared_buffers
-----
2211840
(1 row)
```

We reboot again, but the parameter values stay the same. This is because `max_connections` has a maximum value of 5000 for an Aurora Serverless v2 DB cluster running Aurora PostgreSQL.

```
postgres=> show max_connections;
max_connections
-----
5000
(1 row)
```

```
postgres=> show shared_buffers;
shared_buffers
-----
2211840
(1 row)
```

Now we set the capacity range from 0.5 to 128 ACUs. The DB cluster scales down to 10 ACUs, then to 2. We reboot the DB instance.

```
postgres=> show max_connections;
max_connections
-----
2000
(1 row)

postgres=> show shared_buffers;
shared_buffers
-----
16384
(1 row)
```

The `max_connections` value for Aurora Serverless v2 DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

Now we return the capacity to its initial range of 0.5–1 ACU and reboot the DB instance. The `max_connections` parameter has returned to its original value.

```
postgres=> show max_connections;
max_connections
-----
189

postgres=> show shared_buffers;
shared_buffers
-----
16384
(1 row)
```

## Working with parameter groups for Aurora Serverless v2

When you create your Aurora Serverless v2 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. If you aren't familiar with how Aurora uses parameter groups to apply configuration settings consistently across clusters, see [Parameter groups for Amazon Aurora](#). All of those procedures for creating, modifying, applying, and other actions for parameter groups apply to Aurora Serverless v2.

The parameter group feature works generally the same between provisioned clusters and clusters containing Aurora Serverless v2 DB instances:

- The default parameter values for all DB instances in the cluster are defined by the cluster parameter group.
- You can override some parameters for specific DB instances by specifying a custom DB parameter group for those DB instances. You might do so during debugging or performance tuning for specific DB instances. For example, suppose that you have a cluster containing some Aurora Serverless v2 DB instances and some provisioned DB instances. In this case, you might specify some different parameters for the provisioned DB instances by using a custom DB parameter group.
- For Aurora Serverless v2, you can use all the parameters that have the value `provisioned` in the `SupportedEngineModes` attribute in the parameter group. In Aurora Serverless v1, you can only use the subset of parameters that have `serverless` in the `SupportedEngineModes` attribute.

### Topics

- [Default parameter values](#)
- [Maximum connections for Aurora Serverless v2](#)
- [Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down](#)
- [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity](#)

### Default parameter values

The crucial difference between provisioned DB instances and Aurora Serverless v2 DB instances is that Aurora overrides any custom parameter values for certain parameters that are related to DB instance capacity. The custom parameter values still apply to any provisioned DB instances in your cluster. For more details about how Aurora Serverless v2 DB instances interpret the

parameters from Aurora parameter groups, see [Configuration parameters for Aurora clusters](#). For the specific parameters that Aurora Serverless v2 overrides, see [Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down](#) and [Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity](#).

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the [describe-db-cluster-parameters](#) CLI command and querying the Amazon Web Services Region. The following are values that you can use for the `--db-parameter-group-family` and `-db-parameter-group-name` options for engine versions that are compatible with Aurora Serverless v2.

Database engine and version	Parameter group family	Default parameter group name
Aurora MySQL version 3	aurora-mysql8.0	default.aurora-mysql8.0
Aurora PostgreSQL version 13.x	aurora-postgresql13	default.aurora-postgresql13
Aurora PostgreSQL version 14.x	aurora-postgresql14	default.aurora-postgresql14
Aurora PostgreSQL version 15.x	aurora-postgresql15	default.aurora-postgresql15
Aurora PostgreSQL version 16.x	aurora-postgresql16	default.aurora-postgresql16
Aurora PostgreSQL version 17.x	aurora-postgresql17	default.aurora-postgresql17

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 3 and Aurora PostgreSQL 13. Those are the Aurora MySQL and Aurora PostgreSQL versions that you use with Aurora Serverless v2.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
```

```
--db-cluster-parameter-group-name default.aurora-mysql8.0 \  
--query 'Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |  
  [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \  
--output text  
  
aws rds describe-db-cluster-parameters \  
--db-cluster-parameter-group-name default.aurora-postgresql13 \  
--query 'Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |  
  [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \  
--output text
```

### For Windows:

```
aws rds describe-db-cluster-parameters ^  
--db-cluster-parameter-group-name default.aurora-mysql8.0 ^  
--query 'Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |  
  [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^  
--output text  
  
aws rds describe-db-cluster-parameters ^  
--db-cluster-parameter-group-name default.aurora-postgresql13 ^  
--query 'Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |  
  [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^  
--output text
```

## Maximum connections for Aurora Serverless v2

For both Aurora MySQL and Aurora PostgreSQL, Aurora Serverless v2 DB instances hold the `max_connections` parameter constant so that connections aren't dropped when the DB instance scales down. The default value for this parameter is derived from a formula based on the memory size of the DB instance. For details about the formula and the default values for provisioned DB instance classes, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

When Aurora Serverless v2 evaluates the formula, it uses the memory size based on the maximum Aurora capacity units (ACUs) for the DB instance, not the current ACU value. If you change the default value, we recommend using a variation of the formula instead of specifying a constant

value. That way, Aurora Serverless v2 can use an appropriate setting based on the maximum capacity.

When you change the maximum capacity of an Aurora Serverless v2 DB cluster, you have to reboot the Aurora Serverless v2 DB instances to update the `max_connections` value. This is because `max_connections` is a static parameter for Aurora Serverless v2.

The following table shows the default values for `max_connections` for Aurora Serverless v2 based on the maximum ACU value.

Maximum ACUs	Default maximum connections on Aurora MySQL	Default maximum connections on Aurora PostgreSQL
1	90	189
4	135	823
8	1,000	1,669
16	2,000	3,360
32	3,000	5,000
64	4,000	5,000
128	5,000	5,000
192	6,000	5,000
256	6,000	5,000

 **Note**

The `max_connections` value for Aurora Serverless v2DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

For specific examples showing how `max_connections` changes with the maximum ACU value, see [Example: Change the Aurora Serverless v2 capacity range of an Aurora MySQL cluster](#) and [Example: Change the Aurora Serverless v2 capacity range of an Aurora PostgreSQL cluster](#).

## Parameters that Aurora adjusts as Aurora Serverless v2 scales up and down

During autoscaling, Aurora Serverless v2 needs to be able to change parameters for each DB instance to work best for the increased or decreased capacity. Thus, you can't override some parameters related to capacity. For some parameters that you can override, avoid hardcoding fixed values. The following considerations apply to these settings that are related to capacity.

For Aurora MySQL, Aurora Serverless v2 resizes some parameters dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `innodb_buffer_pool_size`
- `innodb_purge_threads`
- `table_definition_cache`
- `table_open_cache`

For Aurora PostgreSQL, Aurora Serverless v2 resizes the following parameter dynamically during scaling. For the following parameters, Aurora Serverless v2 doesn't use any custom parameter values that you specify:

- `shared_buffers`

For all parameters other than those listed here, Aurora Serverless v2 DB instances work the same as provisioned DB instances. The default parameter value is inherited from the cluster parameter group. You can modify the default for the whole cluster by using a custom cluster parameter group. Or you can modify the default for certain DB instances by using a custom DB parameter group. Dynamic parameters are updated immediately. Changes to static parameters only take effect after you reboot the DB instance.

## Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity

For the following parameters, Aurora PostgreSQL uses default values that are derived from the memory size based on the maximum ACU setting, the same as with `max_connections`:

- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `effective_cache_size`
- `maintenance_work_mem`

## Avoiding out-of-memory errors

If one of your Aurora Serverless v2 DB instances consistently reaches the limit of its maximum capacity, Aurora indicates this condition by setting the DB instance to a status of `incompatible-parameters`. While the DB instance has the `incompatible-parameters` status, some operations are blocked. For example, you can't upgrade the engine version.

Typically, your DB instance goes into this status when it restarts frequently due to out-of-memory errors. Aurora records an event when this type of restart happens. You can view the event by following the procedure in [Viewing Amazon RDS events](#). Unusually high memory usage can happen because of overhead from turning on settings such as Performance Insights and IAM authentication. It can also come from a heavy workload on your DB instance or from managing the metadata associated with a large number of schema objects.

If the memory pressure becomes lower so that the DB instance doesn't reach its maximum capacity very often, Aurora automatically changes the DB instance status back to `available`.

To recover from this condition, you can take some or all of the following actions:

- Increase the lower limit on capacity for Aurora Serverless v2 DB instances by changing the minimum Aurora capacity unit (ACU) value for the cluster. Doing so avoids issues where an idle database scales down to a capacity with less memory than is needed for the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Increase the upper limit on capacity for Aurora Serverless v2 DB instances by changing the maximum ACU value for the cluster. Doing so avoids issues where a busy database can't scale up to a capacity with enough memory for the features that are turned on in your cluster and the database workload. After changing the ACU settings for the cluster, reboot the Aurora Serverless v2 DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.

- Turn off configuration settings that require memory overhead. For example, suppose that you have features such as Amazon Identity and Access Management (IAM), Performance Insights, or Aurora MySQL binary log replication turned on but don't use them. If so, you can turn them off. Or you can adjust the minimum and maximum capacity values for the cluster higher to account for the memory used by those features. For guidelines about choosing minimum and maximum capacity settings, see [Choosing the Aurora Serverless v2 capacity range for an Aurora cluster](#).
- Reduce the workload on the DB instance. For example, you can add reader DB instances to the cluster to spread the load from read-only queries across more DB instances.
- Tune the SQL code used by your application to use fewer resources. For example, you can examine your query plans, check the slow query log, or adjust the indexes on your tables. You can also perform other traditional kinds of SQL tuning.

## Important Amazon CloudWatch metrics for Aurora Serverless v2

To get started with Amazon CloudWatch for your Aurora Serverless v2 DB instance, see [Viewing Aurora Serverless v2 logs in Amazon CloudWatch](#). To learn more about how to monitor Aurora DB clusters through CloudWatch, see [Monitoring log events in Amazon CloudWatch](#).

You can view your Aurora Serverless v2 DB instances in CloudWatch to monitor the capacity consumed by each DB instance with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `DatabaseConnections` and `Queries`. For the full list of CloudWatch metrics that you can monitor for Aurora, see [Amazon CloudWatch metrics for Amazon Aurora](#). The metrics are divided into cluster-level and instance-level metrics, in [Cluster-level metrics for Amazon Aurora](#) and [Instance-level metrics for Amazon Aurora](#).

The following CloudWatch instance-level metrics are important to monitor for you to understand how your Aurora Serverless v2 DB instances are scaling up and down. All of these metrics are calculated every second. That way, you can monitor the current status of your Aurora Serverless v2 DB instances. You can set alarms to notify you if any Aurora Serverless v2 DB instance approaches a threshold for metrics related to capacity. You can determine if the minimum and maximum capacity settings are appropriate, or if you need to adjust them. You can determine where to focus your efforts for optimizing the efficiency of your database.

- `ServerlessDatabaseCapacity`. As an instance-level metric, it reports the number of ACUs represented by the current DB instance capacity. As a cluster-level metric, it represents the average of the `ServerlessDatabaseCapacity` values of all the Aurora Serverless v2 DB

instances in the cluster. This metric is only a cluster-level metric in Aurora Serverless v1. In Aurora Serverless v2, it's available at the DB instance level and at the cluster level.

- **ACUUtilization.** This metric is new in Aurora Serverless v2. This value is represented as a percentage. It's calculated as the value of the `ServerlessDatabaseCapacity` metric divided by the maximum ACU value of the DB cluster. Consider the following guidelines to interpret this metric and take action:
  - If this metric approaches a value of `100.0`, the DB instance has scaled up as high as it can. Consider increasing the maximum ACU setting for the cluster. That way, both writer and reader DB instances can scale to a higher capacity.
  - Suppose that a read-only workload causes a reader DB instance to approach an `ACUUtilization` of `100.0`, while the writer DB instance isn't close to its maximum capacity. In that case, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
  - Suppose that you are running a production application, where performance and scalability are the primary considerations. In that case, you can set the maximum ACU value for the cluster to a high number. Your goal is for the `ACUUtilization` metric to always be below `100.0`. With a high maximum ACU value, you can be confident that there's enough room in case there are unexpected spikes in database activity. You are only charged for the database capacity that's actually consumed.
- **CPUUtilization.** This metric is interpreted differently in Aurora Serverless v2 than in provisioned DB instances. For Aurora Serverless v2, this value is a percentage that's calculated as the amount of CPU currently being used divided by the CPU capacity that's available under the maximum ACU value of the DB cluster. Aurora monitors this value automatically and scales up your Aurora Serverless v2 DB instance when the DB instance consistently uses a high proportion of its CPU capacity.

If this metric approaches a value of `100.0`, the DB instance has reached its maximum CPU capacity. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `100.0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.

- **FreeableMemory.** This value represents the amount of unused memory that is available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. For every ACU that the

current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance.

- `TempStorageIOPS`. The number of IOPS done on local storage attached to the DB instance. It includes the IOPS for both reads and writes. This metric represents a count and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see [Instance-level metrics for Amazon Aurora](#).
- `TempStorageThroughput`. The amount of data transferred to and from local storage associated with the DB instance. This metric represents bytes and is measured once per second. This is a new metric for Aurora Serverless v2. For details, see [Instance-level metrics for Amazon Aurora](#).

Typically, most scaling up for Aurora Serverless v2 DB instances is caused by memory usage and CPU activity. The `TempStorageIOPS` and `TempStorageThroughput` metrics can help you to diagnose the rare cases where network activity for transfers between your DB instance and local storage devices is responsible for unexpected capacity increases. To monitor other network activity, you can use these existing metrics:

- `NetworkReceiveThroughput`
- `NetworkThroughput`
- `NetworkTransmitThroughput`
- `StorageNetworkReceiveThroughput`
- `StorageNetworkThroughput`
- `StorageNetworkTransmitThroughput`

You can have Aurora publish some or all database logs to Amazon CloudWatch Logs. For instructions, see the following depending on your database engine:

- [the section called "Publishing Aurora PostgreSQL logs to CloudWatch Logs"](#)
- [the section called "Publishing Aurora MySQL logs to CloudWatch Logs"](#)

## How Aurora Serverless v2 metrics apply to your Amazon bill

The Aurora Serverless v2 charges on your Amazon bill are calculated based on the same `ServerlessDatabaseCapacity` metric that you can monitor. The billing mechanism can differ from the computed CloudWatch average for this metric in cases where you use Aurora Serverless v2 capacity for only part of an hour. It can also differ if system issues make the CloudWatch metric unavailable for brief periods. Thus, you might see a slightly different value of ACU-hours on your bill than if you compute the number yourself from the `ServerlessDatabaseCapacity` average value.

## Examples of CloudWatch commands for Aurora Serverless v2 metrics

The following Amazon CLI examples demonstrate how you can monitor the most important CloudWatch metrics related to Aurora Serverless v2. In each case, replace the `Value=` string for the `--dimensions` parameter with the identifier of your own Aurora Serverless v2 DB instance.

The following Linux example displays the minimum, maximum, and average capacity values for a DB instance, measured every 10 minutes over one hour. The Linux `date` command specifies the start and end times relative to the current date and time. The `sort_by` function in the `--query` parameter sorts the results chronologically based on the `Timestamp` field.

```
aws cloudwatch get-metric-statistics --metric-name "ServerlessDatabaseCapacity" \  
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \  
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \  
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \  
  --query 'sort_by(Datapoints[*].  
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux examples demonstrate monitoring the capacity of each DB instance in a cluster. They measure the minimum, maximum, and average capacity utilization of each DB instance. The measurements are taken once each hour over a three-hour period. These examples use the `ACUUtilization` metric representing a percentage of the upper limit on ACUs, instead of `ServerlessDatabaseCapacity` representing a fixed number of ACUs. That way, you don't need to know the actual numbers for the minimum and maximum ACU values in the capacity range. You can see percentages ranging from 0 to 100.

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \  
  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \  
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \  

```

```
--dimensions Name=DBInstanceIdentifier,Value=my_writer_instance \
--query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table

aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
--start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_reader_instance \
--query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the CPUUtilization metric. The measurements are taken every 10 minutes over a 1-hour period. The numbers represent the percentage of available CPU used, based on the CPU resources available to the maximum capacity setting for the DB instance.

```
aws cloudwatch get-metric-statistics --metric-name "CPUUtilization" \
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_instance \
--query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the FreeableMemory metric. The measurements are taken every 10 minutes over a 1-hour period.

```
aws cloudwatch get-metric-statistics --metric-name "FreeableMemory" \
--start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
--namespace "AWS/RDS" --statistics Minimum Maximum Average \
--dimensions Name=DBInstanceIdentifier,Value=my_instance \
--query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

## Monitoring Aurora Serverless v2 performance with Performance Insights

You can use Performance Insights to monitor the performance of Aurora Serverless v2 DB instances. For Performance Insights procedures, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

The following new Performance Insights counters apply to Aurora Serverless v2 DB instances:

- `os.general.serverlessDatabaseCapacity` – The current capacity of the DB instance in ACUs. The value corresponds to the `ServerlessDatabaseCapacity` CloudWatch metric for the DB instance.
- `os.general.acuUtilization` – The percentage of current capacity out of the maximum configured capacity. The value corresponds to the `ACUUtilization` CloudWatch metric for the DB instance.
- `os.general.maxConfiguredAcu` – The maximum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs.
- `os.general.minConfiguredAcu` – The minimum capacity that you configured for this Aurora Serverless v2 DB instance. It's measured in ACUs

For the full list of Performance Insights counters, see [Performance Insights counter metrics](#).

When vCPU values are shown for an Aurora Serverless v2 DB instance in Performance Insights, those values represent estimates based on the ACU value for the DB instance. At the default interval of one minute, any fractional vCPU values are rounded up to the nearest whole number. For longer intervals, the vCPU value shown is the average of the integer vCPU values for each minute.

## Troubleshooting Aurora Serverless v2 capacity issues

In some cases, Aurora Serverless v2 doesn't scale down to the minimum capacity, even with no load on the database. This can happen for the following reasons:

- Certain features can increase resource usage and prevent the database from scaling down to minimum capacity. These features include the following:
  - Aurora global databases
  - Exporting CloudWatch Logs
  - Enabling `pg_audit` on Aurora PostgreSQL-compatible DB clusters
  - Enhanced Monitoring
  - Performance Insights

For more information, see [Choosing the minimum Aurora Serverless v2 capacity setting for a cluster](#).

- If a reader instance isn't scaling down to the minimum and stays at the same or higher capacity than the writer instance, then check the priority tier of the reader instance. Aurora Serverless v2 reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. Change the priority tier of the reader to 2 or higher so that it scales up and down independently of the writer. For more information, see [Choosing the promotion tier for an Aurora Serverless v2 reader](#).
- Set any database parameters that impact the size of shared memory to their default values. Setting a value higher than the default increases the shared memory requirement and prevents the database from scaling down to the minimum capacity. Examples are `max_connections` and `max_locks_per_transaction`.

 **Note**

Updating shared memory parameters requires a database restart for the changes to take effect.

- Heavy database workloads can increase resource usage.
- Large database volumes can increase resource usage.

Amazon Aurora uses memory and CPU resources for DB cluster management. Aurora requires more CPU and memory to manage DB clusters with larger database volumes. If your cluster's minimum capacity is less than the minimum required for cluster management, your cluster won't scale down to the minimum capacity.

- Background processes, such as purge, can also increase resource usage.
- Platform version limitations can affect scaling capabilities. The available scaling range for a given cluster is influenced by both engine version and hardware (platform version). It is possible to have a more capable engine version running on a less capable platform version and vice-versa.

If the database still doesn't scale down to the minimum capacity configured, then stop and restart the database to reclaim any memory fragments that might have built up over time. Stopping and starting a database results in downtime, so we recommend doing this sparingly.

# Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2

You can specify that Aurora Serverless v2 DB instances scale down to zero ACUs and automatically pause, if they don't have any connections initiated by user activity within a specified time period. You do so by specifying a minimum ACU value of zero for your DB cluster. You aren't charged for instance capacity while an instance is in the paused state. Enabling the automatic pause and resume feature (auto-pause) for Aurora clusters that are lightly used or have extended periods of inactivity can help you to manage costs for your database fleet.

## Note

The auto-pause feature is available for Aurora Serverless v2 with both Aurora PostgreSQL and Aurora MySQL. You might need to upgrade your Aurora database engine version to take advantage of this feature. For the engine versions where a minimum capacity of 0 ACUs is available, see [Aurora Serverless v2 capacity](#).

## Topics

- [Overview of the Aurora Serverless v2 auto-pause feature](#)
- [Prerequisites and Limitations for the Aurora Serverless v2 auto-pause feature](#)
- [Turning the auto-pause feature on and off](#)
- [How the Aurora Serverless v2 auto-pause feature works](#)
- [How Aurora Serverless v2 auto-pause works for different types of Aurora clusters](#)
- [Monitoring Aurora clusters that use auto-pause](#)
- [Troubleshooting for Aurora Serverless v2 auto-pause](#)
- [Application design considerations for the Aurora Serverless v2 auto-pause feature](#)

## Overview of the Aurora Serverless v2 auto-pause feature

Aurora Serverless v2 DB instances can automatically pause after a period with no user connections, and automatically resume when a connection request arrives. The Aurora Serverless v2 automatic pause/resume feature helps to manage costs for systems that don't have a stringent service level objective (SLO). For example, you might enable this feature for clusters used for development and

testing, or for internal applications where a brief pause is acceptable while the database resumes. If your workload has periods of inactivity and can tolerate slight delays in connecting while the instance resumes, consider using auto-pause with your Aurora Serverless v2 instances to reduce costs.

You control this behavior by specifying whether the Aurora Serverless v2 DB instances in a cluster can automatically pause or not, and how long each instance must be idle before it pauses. To enable the auto-pause behavior for all the Aurora Serverless v2 DB instances in an Aurora cluster, you set the minimum capacity value for the cluster to zero ACUs.

If you formerly took advantage of the Aurora Serverless v1 feature that scaled to zero ACUs after a period of inactivity, you can upgrade to Aurora Serverless v2 and use its corresponding auto-pause feature.

The cost-savings benefits of the auto-pause feature are similar to using the stop/start cluster feature. Auto-pause for Aurora Serverless v2 has the additional benefits of a faster resume than starting a stopped cluster, and automating the process of determining when to pause and resume each DB instance.

The auto-pause feature also provides additional granularity in controlling costs for compute resources within your cluster. You can enable some reader instances to pause even while the writer instance and other readers in the cluster remain active at all times. You do so by assigning the reader instances that can pause independently of other instances a failover priority in the range 2-15.

The writer instances and all reader instances with failover priority 0 and 1 always pause and resume at the same time. Thus, the instances in this group pause after none of them have any connections for the specified time interval.

Aurora DB clusters can contain a combination of writer and reader DB instances and provisioned and Aurora Serverless v2 DB instances. Therefore, to use this feature effectively, it's helpful to understand the following aspects of the auto-pause mechanism:

- The circumstances when a DB instance might automatically pause.
- When a DB instance might be prevented from pausing. For example, enabling some Aurora features or performing certain kinds of operations on the cluster might prevent instances from pausing, even without any connections to those instances.
- The consequences for monitoring and billing while an instance is paused.
- What actions cause a DB instance to resume processing.

- How the capacity of a DB instance changes around the time of the pause and resume events.
- How to control the idle interval before a DB instance pauses.
- How to code application logic to handle the period while a DB instance is resuming processing.

## Prerequisites and Limitations for the Aurora Serverless v2 auto-pause feature

Before using the auto-pause feature, check which engine versions to use. Also, check whether auto-pause works in combination with the other Aurora features you intend to use. You can't turn on auto-pause if you're using an engine version that doesn't support it. For incompatible features, you won't get any error if you use them in combination with auto-pause. If the cluster is using any incompatible features or settings, the Aurora Serverless v2 instances won't automatically pause.

- If you're using Aurora PostgreSQL, the database engine must be running at least version 16.3, 15.7, 14.12, or 13.15.
- If you're using Aurora MySQL, the database engine must be running version 3.08.0 or higher.
- For the full list of engine versions and Amazon Regions where this feature is available, see [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).
- When an Aurora Serverless v2 instance resumes, its capacity might be lower than it was when the instance was paused. For details, see [Differences in auto-pause behavior between Aurora Serverless v2 and Aurora Serverless v1](#).

Certain conditions or settings prevent Aurora Serverless v2 instances from automatically pausing. For more information, see [Situations where Aurora Serverless v2 doesn't auto-pause](#).

## Turning the auto-pause feature on and off

You can turn the auto-pause feature on and off at the cluster level. To do so, you use the same procedures as when you adjust the minimum and maximum capacity for the cluster. The auto-pause feature is represented by a minimum capacity of 0 ACUs.

### Topics

- [Turning on auto-pause for Aurora Serverless v2 instances in a cluster](#)
- [Configurable Aurora Serverless v2 auto-pause timeout interval](#)
- [Resuming an auto-paused Aurora Serverless v2 instance](#)

- [Turning off auto-pause for Aurora Serverless v2 instances in a cluster](#)

## Turning on auto-pause for Aurora Serverless v2 instances in a cluster

Follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#). For the minimum capacity, choose 0 ACUs. When you choose a minimum capacity of 0 ACUs, you can also specify the length of time for the instance to be idle before it's automatically paused.

The following CLI example shows how you might create an Aurora cluster with the auto-pause feature enabled and the auto-pause interval set to ten minutes (600 seconds).

```
aws rds create-db-cluster \  
  --db-cluster-identifier my-serverless-v2-cluster \  
  --region eu-central-1 \  
  --engine aurora-mysql \  
  --engine-version 8.0 \  
  --serverless-v2-scaling-configuration  
MinCapacity=0,MaxCapacity=4,SecondsUntilAutoPause=600 \  
  --master-username myuser \  
  --manage-master-user-password
```

The following CLI example shows how you might turn on the auto-pause feature for an existing Aurora cluster. This example sets the auto-pause interval to one hour (3600 seconds).

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \  
  --serverless-v2-scaling-configuration  
MinCapacity=0,MaxCapacity=80,SecondsUntilAutoPause=3600  
  
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \  
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'  
{  
  "MinCapacity": 0,  
  "MaxCapacity": 80.0,  
  "SecondsUntilAutoPause": 3600  
}
```

## Configurable Aurora Serverless v2 auto-pause timeout interval

The timeout interval is represented in the `ServerlessV2ScalingConfiguration` attribute of your Aurora cluster. You can specify this interval in the Amazon Web Services Management Console when creating or modifying an Aurora cluster, if the minimum capacity is set to zero ACUs. You

can specify it in the Amazon CLI by using the `--serverless-v2-scaling-configuration` parameter when creating or modifying an Aurora cluster. You can specify it in the RDS API by using the `ServerlessV2ScalingConfiguration` parameter when creating or modifying an Aurora cluster.

The minimum interval that you can set is 300 seconds (five minutes). That's the default if you don't specify an interval. The maximum interval that you can set is 86,400 seconds (one day).

Suppose that you turn off the auto-pause feature for a cluster by changing the cluster's minimum capacity to a nonzero value. In that case, the interval property is removed from the `ServerlessV2ScalingConfiguration` attribute. The absence of that property provides an extra confirmation that the auto-pause feature is turned off for that cluster. If you later turn auto-pause back on, you can specify any custom interval again at that time.

## Resuming an auto-paused Aurora Serverless v2 instance

- When you connect to a paused Aurora Serverless v2 instance, it automatically resumes and accepts the connection.
- A connection attempt that doesn't include valid credentials still causes the DB instance to resume.
- If you connect through the writer endpoint, Aurora resumes the writer DB instance if it's auto-paused. At the same time, Aurora resumes any auto-paused reader instances that have failover priority 0 or 1, meaning their capacity is tied to the capacity of the writer instance.
- If you connect through the reader endpoint, Aurora chooses a reader instance randomly. If that reader instance is paused, Aurora resumes it. Aurora also resumes the writer instance first, because the writer instance must always be active if any reader instances are active. When Aurora resumes that writer instance, that also causes any reader instances in failover promotion tiers zero and one to resume.
- If you send a request to your cluster through the RDS Data API, Aurora resumes the writer instance if it's paused. Then Aurora processes the Data API request.
- When you change the value of a configuration parameter in a DB cluster parameter group, Aurora automatically resumes any paused Aurora Serverless v2 instances in all clusters that use that cluster parameter group. Similarly, when you change a parameter value in a DB parameter group, Aurora automatically resumes any paused Aurora Serverless v2 instances that use that DB parameter group. The same automatic resume behavior applies when you modify a cluster to assign a different cluster parameter group, or when you modify an instance to assign a different DB parameter group.

- Performing a backtrack request automatically resumes the Aurora Serverless v2 writer instance if it's paused. Aurora processes the backtrack request after the writer instance resumes. You can backtrack to a time during which an Aurora Serverless v2 instance was paused.
- Taking a cluster snapshot or deleting a snapshot doesn't cause any Aurora Serverless v2 instances to resume.
- Creating an Aurora clone causes Aurora to resume the writer instance of the cluster that's being cloned.
- If a paused instance receives a large number of connection requests before it finishes resuming, some sessions might be unable to connect. We recommend implementing retry logic for connections to Aurora clusters that have some Aurora Serverless v2 instances with auto-pause enabled. For example, you might retry any failed connection three times.
- Aurora can perform some types of minor internal maintenance without waking up an instance. However, some types of maintenance that happen during the cluster's maintenance window do require Aurora to resume the instance. When the maintenance is finished, the instance is automatically paused again if there's no more activity after the specified interval.

 **Note**

Aurora doesn't automatically resume a paused instance for engine-specific scheduled jobs, such as those in the PostgreSQL `pg_cron` extension or the MySQL event scheduler. To ensure that such jobs run, initiate a connection manually to the instance before the scheduled time. Aurora doesn't queue any jobs where the scheduled time occurs while the DB instance is paused. Such jobs are skipped when the instance resumes later.

- If the Aurora cluster undergoes a failover while an Aurora Serverless v2 instance is auto-paused, Aurora might resume an instance and then promote that instance to be the writer. The same might happen if one or more DB instances are removed from the cluster while an instance is paused. In this case, the instance becomes the writer immediately when it's resumed.
- Operations that change properties of the cluster also cause any auto-paused Aurora Serverless v2 instances to resume. For example, an auto-paused instance resumes for operations such as the following:
  - Changing the scaling range of the cluster.
  - Upgrading the engine version of the cluster.

- Describing or downloading log files from a paused instance. You can examine historical log data from paused instances by enabling log uploads to CloudWatch and analyzing the logs through CloudWatch.

## Turning off auto-pause for Aurora Serverless v2 instances in a cluster

Follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#). For the minimum capacity, choose a value of 0.5 or greater. When you turn off the auto-pause feature, the interval for the instance to be idle is reset. If you turn auto-pause on again, you specify a new timeout interval.

The following CLI example shows how you might turn off the auto-pause feature for an existing Aurora cluster. The `describe-db-clusters` output shows that the `SecondsUntilAutoPause` attribute is removed when the minimum capacity is set to a nonzero value.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \  
  --serverless-v2-scaling-configuration MinCapacity=2,MaxCapacity=80  
  
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \  
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'  
{  
  "MinCapacity": 2,  
  "MaxCapacity": 80.0  
}
```

## How the Aurora Serverless v2 auto-pause feature works

You can use the following information to plan your usage of the auto-pause feature. Understanding the circumstances where instances pause, resume, or stay active can help you balance the tradeoffs between availability, responsiveness, and cost savings.

### Topics

- [How maintenance and upgrades work for auto-paused Aurora Serverless v2 clusters](#)

- [Differences in auto-pause behavior between Aurora Serverless v2 and Aurora Serverless v1](#)

## What happens when Aurora Serverless v2 instances pause

When an Aurora Serverless v2 DB instance pauses after a period with no connections:

- Aurora begins pausing the instance after the specified interval elapses with no connections to the instance, regardless of how many ACUs the instance has at the time.
- The pause mechanism isn't instantaneous. An Aurora Serverless v2 instance that's about to be auto-paused might wait briefly to catch up with all the changes to Aurora storage.
- The instance charges for that instance are put on hold. The `ServerlessV2Usage` metric has a value of 0 while the instance is paused.
- The status value for the instance doesn't change. The status is still shown as "available".
- The instance stops writing to the database log files. It stops sending metrics to CloudWatch, other than registering zero percent for `CPUUtilization` and `ACUUtilization`, and zero for `ServerlessDatabaseCapacity`.
- Aurora emits events when an Aurora Serverless v2 DB instance begins pausing, finishes pausing, and if the pause mechanism is interrupted or is unsuccessful. For details about these events, see [DB instance events](#).

## What happens when auto-paused Aurora Serverless v2 instances resume

When an Aurora Serverless v2 DB instance resumes after being automatically paused, the following conditions apply:

- Any parameter changes that are in `pending-reboot` changes are applied when the instance resumes.
- Aurora emits instance-level events when each Aurora Serverless v2 DB instance begins resuming, finishes resuming, and if the instance can't resume for some reason. For details about these events, see [DB instance events](#).
- Any requested connections are established after the DB instance finishes resuming. Because the typical time to resume might be approximately 15 seconds, we recommend that you adjust any client timeout settings to be longer than 15 seconds. For example, in your JDBC driver settings you might adjust the values for the `connectTimeout` and `sslResponseTimeout` settings to be longer than 15 seconds.

**Note**

If an Aurora Serverless v2 instance remains paused more than 24 hours, Aurora can put the instance into a deeper sleep that takes longer to resume. In that case, the resume time can be 30 seconds or longer, roughly equivalent to doing a reboot of the instance. If your database has periods of inactivity that last longer than a day, we recommend setting connection timeouts to 30 seconds or more.

## How instance billing works for auto-paused Aurora Serverless v2 clusters

While an Aurora Serverless v2 instance is auto-paused, its instance charge is zero. The `ServerlessV2Usage` metric is zero during that period. Amazon still charges for Aurora storage and other aspects of the cluster that aren't tied to that specific DB instance.

## Situations where Aurora Serverless v2 doesn't auto-pause

- If the minimum capacity value for your DB cluster is higher than zero ACUs, the Aurora Serverless v2 instances in the cluster don't automatically pause. If you have existing clusters with Aurora Serverless v2 instances from before the auto-pause feature was available, the lowest minimum capacity setting was 0.5 ACUs. To use the auto-pause feature with such clusters, modify the minimum capacity setting to zero ACUs.
- If any user-initiated connections are open to an Aurora Serverless v2 instance, the instance won't pause. The instance also won't pause while activities such as patching and upgrades are in progress. Administrative connections that Aurora uses for health checks aren't counted as activity and don't prevent the instance from pausing.
- In an Aurora PostgreSQL cluster has logical replication enabled, or an Aurora MySQL cluster that has binlog replication enabled, the writer instance and any reader instances in failover promotion tiers zero and one don't automatically pause. Aurora performs a constant minimal amount of activity for checking the health of the replication connection.

For clusters with replication enabled, you can still have Aurora reader instances in the source cluster that auto-pause. To do so, set their failover priority to a value other than zero or one. That way, they can be paused independently of the writer instance.

- If your Aurora cluster has an associated RDS Proxy, the proxy maintains an open connection to each DB instance in the cluster. Thus, any Aurora Serverless v2 instances in such a cluster won't automatically pause.

- If your cluster is the primary cluster in an Aurora global database, Aurora doesn't automatically pause the Aurora Serverless v2 writer instance. That's because a constant level of activity is needed on the writer instance to manage the other clusters in the global database. Because the writer instance remains active, any Aurora Serverless v2 reader instances with failover priority zero or one also don't auto-pause.
- Aurora Serverless v2 instances in the secondary clusters of an Aurora Global Database don't automatically pause. If a DB cluster is promoted to a standalone cluster, then the auto-pause feature becomes effective if all the other conditions are met.
- In a cluster with an associated zero-ETL integration to Redshift, the writer instance and any reader instances in failover promotion tiers zero and one don't automatically pause.
- In addition to activity on the main database port for the instance, if an Aurora PostgreSQL instance has the Babelfish feature enabled, any connections and activity on the T-SQL port prevent the instance from being auto-paused.

## How auto-pause works with the cluster stop/start feature

You can stop and start an Aurora cluster when the auto-pause feature is enabled. It doesn't matter if some instances are paused. When you start the cluster again, any paused Aurora Serverless v2 instances are automatically resumed.

While an Aurora cluster is stopped, any paused Aurora Serverless v2 instances don't automatically resume based on attempts to connect. Once the cluster is started again, the usual mechanisms for pausing and resuming Aurora Serverless v2 instances apply.

## How maintenance and upgrades work for auto-paused Aurora Serverless v2 clusters

- While an Aurora Serverless v2 instance is auto-paused, if you attempt to upgrade the Aurora cluster, Aurora resumes the instance and upgrades it.
- Aurora periodically resumes any auto-paused Aurora Serverless v2 instances to perform maintenance such as minor version upgrades and changes to properties such as parameter groups.
- After an Aurora Serverless v2 instance wakes up for an administrative operation such as an upgrade or applying maintenance, Aurora waits at least 20 minutes before pausing that instance again. That's to allow any background operations to finish. The twenty-minute period also

avoids pausing and resuming the instance multiple times if the instance undergoes multiple administrative operations in succession.

## Differences in auto-pause behavior between Aurora Serverless v2 and Aurora Serverless v1

- The resumption time is improved in Aurora Serverless v2 compared with Aurora Serverless v1. The time to resume is typically approximately 15 seconds if the instance was paused for less than 24 hours. If the instance is paused for longer than 24 hours, the resume time might be longer.
- The way that Aurora Serverless v2 applies to multi-AZ clusters means that some DB instances in the cluster might be paused while others are active. The writer instance resumes whenever any reader is running, because the writer is needed to coordinate certain activities within the cluster. Because Aurora Serverless v1 doesn't use reader instances, the entire cluster would always be paused or be active.
- When the reader endpoint randomly picks a reader instance to connect to, that reader instance might already be active or might be auto-paused. Thus, the time to access the reader instance might vary and be harder to predict. Multi-AZ clusters that use Aurora Serverless v2 and auto-pause therefore might benefit from setting up custom endpoints for specific read-only use cases, instead of directing all read-only sessions to the reader endpoint.
- Aurora Serverless v2 instances undergo maintenance operations with the same frequency as provisioned instances do. Because Aurora automatically resumes instances when such maintenance is needed, you might find that Aurora Serverless v2 instances resume more frequently than Aurora Serverless v1 clusters did.

## How Aurora Serverless v2 auto-pause works for different types of Aurora clusters

The considerations for the auto-pause feature depend on how many instances are in your Aurora cluster, the failover promotion tiers of the reader instances, and whether all the instances are Aurora Serverless v2 or a combination of Aurora Serverless v2 and provisioned.

### Topics

- [Recommended Aurora cluster layouts when using auto-pause](#)
- [How Aurora Serverless v2 auto-pause works for the writer instance in a DB cluster](#)
- [How Aurora Serverless v2 auto-pause works for multi-AZ clusters](#)

- [How Aurora Serverless v2 auto-pause works for clusters with provisioned instances](#)

## Recommended Aurora cluster layouts when using auto-pause

When the auto-pause feature is enabled, you can arrange your Aurora cluster for the right balance of high availability, fast response, and scalability to suit your use case. You do so by choosing the combination of Aurora Serverless v2 instances, provisioned instances, and failover promotion tiers for the DB instances in your cluster.

The following types of configurations demonstrate different tradeoffs between high availability and cost optimization for your cluster:

- For a development and test system, you can set up a single-AZ DB cluster with an Aurora Serverless v2 DB instance. The single instance serves all read and write requests. When the cluster isn't used for significant intervals of time, the DB instance pauses. At that point, the DB compute costs for your cluster are also paused.
- For a system running an application where high availability is a priority, but the cluster still has periods where it's entirely idle, you can set up a multi-AZ cluster where both the writer and reader DB instances are Aurora Serverless v2. Set the reader instance to failover priority zero or one, so that the writer and reader instance both pause and resume at the same time. Now you get the benefit of fast failover while the cluster is active. When the cluster remains idle for longer than the auto-pause threshold, the DB instance charges for both of the instances are paused. When the cluster resumes processing, the first database session takes a brief time to connect.
- Suppose your cluster is constantly active with some minimal amount of activity, and requires fast response for any connection. In that case, you can create a cluster with more than one Aurora Serverless v2 reader instance, and decouple the capacities of some reader instances from the writer. Specify failover priority zero or one for the writer instance and one reader instance. Specify a priority greater than one for the other reader instances. That way, the reader instances in the higher priority tiers can auto-pause, even while the writer and one of the readers remain active.

In this case, you can employ some other techniques to ensure that the cluster stays continuously available while still scaling down to a low capacity during idle periods:

- You can use provisioned instances for the writer and the priority 0 or 1 reader. That way, two DB instances never auto-pause and are always available to serve database traffic and to perform failovers.

- You can set up a custom endpoint that includes the Aurora Serverless v2 instances in the higher priority tiers, but not the writer or the promotion tier 0 or 1 readers. That way, you can direct read-only sessions that aren't sensitive to latency to the readers that might be auto-paused. You can avoid using the reader endpoint for such requests, because Aurora might direct reader endpoint connections to the always-awake reader instance, or to one of the auto-paused instances. Using the custom endpoint lets you direct connections to different groups of instances based on your preference for fast response or extra scaling capacity.

## How Aurora Serverless v2 auto-pause works for the writer instance in a DB cluster

When an Aurora DB cluster contains only a single DB instance, the mechanism for auto-pausing and resuming the DB instance is straightforward. It depends only on activity on the writer instance. You might have such a configuration for clusters used for development and testing, or for running applications where high availability isn't crucial. Note that in a single-instance cluster, Aurora directs connections through the reader endpoint to the writer DB instance. Thus, for a single-instance DB cluster, attempting to connect to the reader endpoint causes the auto-paused writer DB instance to resume.

The following additional factors apply to Aurora clusters with multiple DB instances:

- Within an Aurora DB cluster, the writer DB instance is typically accessed frequently. Therefore, you might find that the writer DB instance remains active even while one or more of the reader DB instances automatically pauses.
- Certain activities on the reader DB instances require that writer DB instance to be available. Therefore, the writer DB instances can't be paused until all the reader instances are also paused. Resuming any reader instance automatically resumes the writer instance, even if your application isn't accessing the writer instance directly.
- Aurora Serverless v2 reader instances in failover promotion tiers zero and one scale to keep their capacity in synch with the writer instance. Thus, when an Aurora Serverless v2 writer instance resumes, so do any Aurora Serverless v2 reader instances that are in promotion tiers zero or one.

## How Aurora Serverless v2 auto-pause works for multi-AZ clusters

Within an Aurora DB cluster containing both a writer and one or more reader DB instances, some Aurora Serverless v2 DB instances might be paused while other DB instances are active. The writer instance and any reader instances with failover priority 0 and 1 always pause and resume all at the

same time. Reader instances with priority other than 0 or 1 can pause and resume independently of the other instances.

When you use this feature for clusters with multiple reader instances, you can manage costs without sacrificing high availability. The writer instance and another one or two reader instances can remain active at all times, while additional reader instances can pause when they're not needed to handle high-volume read traffic.

Whether a reader instance can automatically pause depends on whether its capacity can scale independently, or whether the capacity is tied to that of the writer DB instance. That scaling property depends on the failover priority of the reader DB instance. When the priority of the reader is zero or one, the capacity of the reader tracks the capacity of the writer DB instance. Therefore, to allow reader DB instances to automatically pause in the broadest range of situations, set their priority to a value higher than one.

The time to resume a reader instance might be slightly longer than to resume a writer instance. For the fastest response if instances might be paused, connect to the cluster endpoint.

## How Aurora Serverless v2 auto-pause works for clusters with provisioned instances

Any provisioned DB instances in your Aurora DB cluster won't automatically pause. Only Aurora Serverless v2 DB instances, with the `db.serverless` instance class, can use the auto-pause feature.

When your Aurora cluster contains any provisioned DB instances, any Aurora Serverless v2 writer instance doesn't automatically pause. That's because of the requirement that the writer instance remains available while any reader instances are active. The fact that the Aurora Serverless v2 writer remains active also means that any Aurora Serverless v2 reader instances with failover priority 0 and 1 won't auto-pause in a hybrid cluster containing any provisioned instances.

## Monitoring Aurora clusters that use auto-pause

To monitor Aurora, you should already be familiar with the monitoring procedures in [Monitoring Amazon Aurora metrics with Amazon CloudWatch](#) and the CloudWatch metrics listed in [Metrics reference for Amazon Aurora](#). Be aware that there are some special considerations when you monitor Aurora clusters that use the auto-pause feature:

- There can be periods of time when Aurora Serverless v2 instances aren't recording log data and most metrics because the instances are paused. The only metrics sent to CloudWatch while an

instance is paused are zero percent for CPUUtilization and ACUUtilization, and zero for ServerlessDatabaseCapacity.

- You can check whether Aurora Serverless v2 instances are pausing more or less frequently than you expect. To do so, check how often the ServerlessDatabaseCapacity metric changes from a nonzero value to zero, and how long it stays zero. If the instances don't remain paused as long as you expect, you don't save as much as you could on costs. If the instances pause and resume more frequently than you intend, your cluster might have unnecessary latency when responding to connection requests. For information about the factors that affect whether and how often Aurora Serverless v2 instances can pause, see [Prerequisites and Limitations for the Aurora Serverless v2 auto-pause feature](#), [Situations where Aurora Serverless v2 doesn't auto-pause](#), and [Troubleshooting for Aurora Serverless v2 auto-pause](#).
- You can also examine a log file that records automatic pause and resume operations for an Aurora Serverless v2 instance. If an instance didn't pause after the timeout interval expired, this log file also includes the reason why auto-pause didn't happen. For more information, see [Monitoring Aurora Serverless v2 pause and resume activity](#).

## Topics

- [Checking if an Aurora Serverless v2 instance is paused](#)
- [Events for auto-pause and auto-resume operations](#)
- [How auto-pause works with Performance Insights and Enhanced Monitoring](#)
- [How the Aurora Serverless v2 auto-pause feature interacts with Aurora metrics](#)

## Checking if an Aurora Serverless v2 instance is paused

To determine whether an Aurora Serverless v2 instance is in the paused state, you can observe the ACUUtilization metric for the instance. That metric has a value of zero while the instance is paused.

While an Aurora Serverless v2 instance is paused, its status value is still listed as **Available**. The same applies while a paused Aurora Serverless v2 instance is in the process of resuming. That's because you can successfully connect to such an instance, even if the connection experiences a slight delay.

Any metrics related to the availability of Aurora instances consider the period while the instance is paused as time that the instance was available.

## Events for auto-pause and auto-resume operations

Aurora emits events for Aurora Serverless v2 instances when auto-pause and auto-resume operations start, finish, or are cancelled. The events related to the auto-pause feature are RDS-EVENT-0370 through RDS-EVENT-0374. For details about these events, see [DB instance events](#).

## How auto-pause works with Performance Insights and Enhanced Monitoring

While an Aurora Serverless v2 instance is paused, Aurora doesn't collect monitoring information for that instance through either Performance Insights or Enhanced Monitoring. When the instance is resumed, there might be a brief delay before Aurora resumes collecting such monitoring information.

## How the Aurora Serverless v2 auto-pause feature interacts with Aurora metrics

While an Aurora Serverless v2 instance is paused, it doesn't emit most CloudWatch metrics or write any information to its database logs. The only metrics sent to CloudWatch while an instance is paused are zero percent for `CPUUtilization` and `ACUUtilization`, and zero for `ServerlessDatabaseCapacity`.

When CloudWatch is computing statistics related to instance or cluster availability and uptime, Aurora Serverless v2 instances are considered to be available during the time that they're paused.

When you initiate an Amazon CLI or RDS API action to describe or download the logs for a paused Aurora Serverless v2 instance, the instance resumes automatically to make the log information available.

### Example of CloudWatch metrics

The following Amazon CLI examples show how you might observe the capacity of an instance changing over time. During the time period, the instance auto-pauses and then resumes. While it's paused, the `ServerlessDatabaseCapacity` metric reports a value of zero. To determine whether the instance was paused at any point during the time period, we check if the minimum capacity during that time period was zero.

The following Linux example represents an Aurora Serverless v2 instance that has been automatically paused for some time. We sample the `ServerlessDatabaseCapacity` each minute, over a period of three minutes. The minimum ACU value of 0.0 confirms that the instance was paused at some point during each minute.

```
$ aws cloudwatch get-metric-statistics \
  --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '3 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
  --statistics Minimum \
  --namespace "AWS/RDS" --dimensions Name=DBInstanceIdentifier,Value=my-autopause-
instance \
  --output text | sort -k 3

ServerlessDatabaseCapacity
DATAPOINTS 0.0 2024-08-02T22:11:00+00:00 None
DATAPOINTS 0.0 2024-08-02T22:12:00+00:00 None
DATAPOINTS 0.0 2024-08-02T22:13:00+00:00 None
```

Next, we attempt to make a connection to the paused Aurora Serverless v2 instance. In this example, we intentionally use an incorrect password so that the connection attempt doesn't succeed. Despite the failure, the connection attempt causes Aurora to resume the paused instance.

```
$ mysql -h my_cluster_endpoint.rds.amazonaws.com -u admin -pwrong-password

ERROR 1045 (28000): Access denied for user 'admin'@'ip_address' (using password: YES)
```

The following Linux example demonstrates that the paused instance resumed, remained idle for approximately five minutes, and then went back into its paused state. The instance resumed at a capacity of 2.0 ACUs. Then it scaled up slightly, for example to perform some internal cleanup. Because it didn't receive any user connection attempts within the five-minute timeout period, it went from 4.0 ACUs directly into the paused state.

```
$ aws cloudwatch get-metric-statistics \
  --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '8 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
  --statistics Minimum \
  --namespace "AWS/RDS" --dimensions Name=DBInstanceIdentifier,Value=my-autopause-
instance \
  --output text | sort -k 3

ServerlessDatabaseCapacity
DATAPOINTS 0.0 2024-08-02T22:13:00+00:00 None
DATAPOINTS 2.0 2024-08-02T22:14:00+00:00 None
DATAPOINTS 3.0 2024-08-02T22:15:00+00:00 None
DATAPOINTS 3.0 2024-08-02T22:16:00+00:00 None
```

```
DATAPPOINTS 4.0 2024-08-02T22:17:00+00:00 None
DATAPPOINTS 4.0 2024-08-02T22:18:00+00:00 None
DATAPPOINTS 4.0 2024-08-02T22:19:00+00:00 None
DATAPPOINTS 0.0 2024-08-02T22:20:00+00:00 None
```

If the report was intended to show how quickly the instance scaled up to handle the workload, we might specify `Maximum` for the statistic instead of `Minimum`. For capacity planning and cost estimation, we might specify a longer time period and use the `Average` statistic. That way, we could determine typical capacity values during periods of high activity, low activity, and paused state. To examine behavior during the precise times around pausing and resuming, we might specify a period of one second and examine a shorter time interval. The timestamp values in the output, such as `2024-08-02T22:13:00+00:00`, demonstrate the format to specify precise parameters for the `--start-time` and `--end-time` options.

## Troubleshooting for Aurora Serverless v2 auto-pause

If you find that Aurora Serverless v2 instances aren't pausing as often as you expect, check for the following possible causes:

- Confirm that the Aurora version you're running does support a minimum capacity of zero ACUs. For the capacity ranges of different Aurora versions, see [Aurora Serverless v2 capacity](#).
- Confirm that the minimum capacity value for the cluster is set to zero ACUs.
- Confirm that the instance in question is actually using the Aurora Serverless v2 instance class `db.serverless`, not one of the provisioned instance classes.
- Confirm that the cluster isn't using any of the incompatible features or settings from [Prerequisites and Limitations for the Aurora Serverless v2 auto-pause feature](#).
- Examine the log file showing when Aurora Serverless v2 instances were paused, resumed, or Aurora wasn't able to pause or resume an instance for some reason. For more information, see [Monitoring Aurora Serverless v2 pause and resume activity](#).
- Check if any clients or applications are keeping connections open for long periods of time. Conversely, check if any applications that use RDS Data API or Lambda functions are sending frequent requests so that the instance is never idle long enough to pause. You can examine the CloudWatch metrics such as `ConnectionAttempts` and `DatabaseConnections`. For more information, see [Instance-level metrics for Amazon Aurora](#).
- If a reader instance rarely if ever pauses, check its failover priority. If the reader is used for read scaling and not as a standby in case of failover, set it to a priority in the range 2-15.

- If the writer instance rarely if ever pauses, check your usage of the reader instances. The writer can only pause if the entire cluster is idle. That's because a connection to any reader instance causes the writer to resume.
- If your application receives timeouts during connection requests while Aurora Serverless v2 instances are resuming, consider lengthening the timeout interval used by your application code or the underlying database framework. Longer connection timeouts reduce the possibility of failed connections while Aurora Serverless v2 instances are resuming. However, the longer timeouts can also make your application slower to detect availability issues in your cluster.

Conversely, consider lengthening the auto-pause interval so that applications don't encounter paused instances as often.

If there isn't a logical balance between the auto-pause behavior and cluster responsiveness for your application, that cluster might not be a good candidate for using the auto-pause feature.

- If you estimate how long your Aurora Serverless v2 instances will be paused, be aware that there are factors that make it impractical to make precise predictions.
  - Instances might resume periodically to perform maintenance, minor version upgrades, or apply changes to parameter groups.
  - For multi-AZ clusters, there are situations where resuming one instance causes other instances to resume also. Resuming any reader always causes the writer to resume. Resuming the writer always causes any readers with failover priority 0 and 1 to resume.

We recommend measuring the actual paused time over a period of several days, with a realistic workload. Then use those measurements to set a baseline for what proportion of time you can expect an instance to be paused.

- You might find that internal operations such as MySQL purge, MySQL event scheduler, PostgreSQL autovacuum, or PostgreSQL jobs scheduled through the `pg_cron` extension aren't running or aren't completing. The instance doesn't automatically resume to perform such operations that don't involve a user connection to the database. If such internal operations are underway when the auto-pause timeout expires, maintenance tasks such as MySQL purge and PostgreSQL autovacuum are canceled. Scheduled jobs from the MySQL event scheduler or the PostgreSQL `pg_cron` extension are also canceled if they're in progress when Aurora initiates the pause operation.

If you need to ensure that the instance is periodically awake to perform scheduled operations, you can initiate a connection to resume the instance before the start time of the job. You can also increase the auto-pause timeout interval so that operations such as autovacuum can run for

longer after user activity is finished. You can also use mechanisms such as Lambda functions to perform database operations on a schedule, in a way that automatically resumes the instance if necessary.

## Application design considerations for the Aurora Serverless v2 auto-pause feature

When an Aurora Serverless v2 DB instance resumes after being automatically paused, it begins with a relatively small capacity and scales up from there. This starting capacity applies even if the DB instance had some higher capacity immediately before it was automatically paused.

Use this feature with applications that can tolerate an interval of approximately 15 seconds while establishing a connection. That accounts for the typical case where an Aurora Serverless v2 instance resumes due to one or a small number of incoming connections. If the instance is paused for longer than 24 hours, the time to resume might be longer.

If your application was already using Aurora Serverless v1 and its automatic pause feature, you might already have such timeout intervals in place for connection attempts. If you are already using Aurora Serverless v2 in combination with the Aurora stop/start cluster feature, the resumption time for auto-paused Aurora Serverless v2 instances is typically much shorter than the time to start a cluster that's stopped.

When coding connection logic in your application, retry the connection if the first attempt return an error that has a transient cause. (If the error is due to authentication failure, correct the credentials before retrying.) An error that happens immediately after resuming might be a timeout, or some error related to database limits. Retrying can handle issues in the rarer case where an Aurora Serverless v2 instance is resumed due to a high number of simultaneous connection requests. In that case, some connections might take longer than usual to be processed, or might exceed the limit of simultaneous connections on the first attempt.

During application development and debugging, don't leave client sessions or programming tools with connections open to the database. Aurora won't pause an instance if there are any user-initiated connections open, regardless of whether the connections aren't running any SQL statements or transactions. When one Aurora Serverless v2 instance in an Aurora cluster can't pause, other instances in the cluster might also be prevented from pausing. For more information, see [Situations where Aurora Serverless v2 doesn't auto-pause](#).

Aurora emits events when an Aurora Serverless v2 DB instance begins resuming, finishes resuming, and if the instance can't resume for some reason. For details about these events, see [DB instance events](#).

## Migrating to Aurora Serverless v2

To convert an existing DB cluster to use Aurora Serverless v2, you can do the following:

- Upgrade from a provisioned Aurora DB cluster.
- Upgrade from an Aurora Serverless v1 cluster.
- Migrate from an on-premises database to an Aurora Serverless v2 cluster.

When your upgraded cluster is running the appropriate engine version as listed in [Requirements and limitations for Aurora Serverless v2](#), you can begin adding Aurora Serverless v2 DB instances to it. The first DB instance that you add to the upgraded cluster must be a provisioned DB instance. Then you can switch over the processing for the write workload, the read workload, or both to the Aurora Serverless v2 DB instances.

- [Migrating from an on-premises database to Aurora Serverless v2](#)

**Note**

These topics describe how to convert an existing DB cluster. For information on creating a new Aurora Serverless v2 DB cluster, see [Creating a DB cluster that uses Aurora Serverless v2](#).

## Upgrading or switching existing clusters to use Aurora Serverless v2

If your provisioned cluster has an engine version that supports Aurora Serverless v2, switching to Aurora Serverless v2 doesn't require an upgrade. In that case, you can add Aurora Serverless v2 DB instances to your original cluster. You can switch the cluster to use all Aurora Serverless v2 DB instances. You can also use a combination of Aurora Serverless v2 and provisioned DB instances in the same DB cluster. For the Aurora engine versions that support Aurora Serverless v2, see [Supported Regions and Aurora DB engines for Aurora Serverless v2](#).

If you're running a lower engine version that doesn't support Aurora Serverless v2, you take these general steps:

1. Upgrade the cluster.
2. Create a provisioned writer DB instance for the upgraded cluster.
3. Modify the cluster to use Aurora Serverless v2 DB instances.

**Important**

When you perform a major version upgrade to an Aurora Serverless v2-compatible version by using snapshot restore or cloning, the first DB instance that you add to the new cluster must be a provisioned DB instance. This addition starts the final stage of the upgrade process.

Until that final stage happens, the cluster doesn't have the infrastructure that's required for Aurora Serverless v2 support. Thus, these upgraded clusters always start with a provisioned writer DB instance. Then you can convert or fail over the provisioned DB instance to an Aurora Serverless v2 one.

Upgrading from Aurora Serverless v1 to Aurora Serverless v2 involves creating a provisioned cluster as an intermediate step. Then you perform the same upgrade steps as when you start with a provisioned cluster.

## Upgrade paths for MySQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora MySQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora MySQL version 3, compatible with MySQL 8.0	<p>This is the final stage for all conversions from existing Aurora MySQL clusters.</p> <p>If necessary, perform a minor version upgrade to version 3.02.0 or higher. Use a provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that the writer DB instance.</p> <p>(Optional) Convert other provisioned DB instances in the cluster to Aurora Serverless v2. Or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances.</p> <p>For the full procedure and examples, see <a href="#">Switching from a provisioned cluster to Aurora Serverless v2</a>.</p>
Provisioned cluster running Aurora MySQL version 2, compatible with MySQL 5.7	Perform a major version upgrade to Aurora MySQL version 3.02.0 or higher. Then follow the procedure for Aurora MySQL version 3 to switch the cluster to use Aurora Serverless v2 DB instances.

If your original Aurora MySQL cluster is this	Do this to switch to Aurora Serverless v2
Aurora Serverless v1 cluster running Aurora MySQL version 2, compatible with MySQL 5.7	<p>To help plan your conversion from Aurora Serverless v1, consult <a href="#">Comparison of Aurora Serverless v2 and Aurora Serverless v1</a> first.</p> <p>Then follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2</a>.</p>

## Upgrade paths for PostgreSQL-compatible clusters to use Aurora Serverless v2

If your original cluster is running Aurora PostgreSQL, choose the appropriate procedure depending on the engine version and engine mode of your cluster.

If your original Aurora PostgreSQL cluster is this	Do this to switch to Aurora Serverless v2
Provisioned cluster running Aurora PostgreSQL version 13	<p>This is the final stage for all conversions from existing Aurora PostgreSQL clusters.</p> <p>If necessary, perform a minor version upgrade to version 13.6 or higher. Add one provisioned DB instance for the writer DB instance. Add one Aurora Serverless v2 reader DB instance. Perform a failover to make that Aurora Serverless v2 instance the writer DB instance.</p> <p>(Optional) Convert other provisioned DB instances in the cluster to Aurora Serverless v2. Or add new Aurora Serverless v2 DB instances and remove the provisioned DB instances.</p>

If your original Aurora PostgreSQL cluster is this	Do this to switch to Aurora Serverless v2
	For the full procedure and examples, see <a href="#">Switching from a provisioned cluster to Aurora Serverless v2</a> .
Provisioned cluster running Aurora PostgreSQL version 11 or 12	Perform a major version upgrade to Aurora PostgreSQL version 13.6 or higher. Then follow the procedure for Aurora PostgreSQL version 13 to switch the cluster to use Aurora Serverless v2 DB instances.
Aurora Serverless v1 cluster running Aurora PostgreSQL version 11 or 13	To help plan your conversion from Aurora Serverless v1, consult <a href="#">Comparison of Aurora Serverless v2 and Aurora Serverless v1</a> first.  Then follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2</a> .

## Switching from a provisioned cluster to Aurora Serverless v2

To switch a provisioned cluster to use Aurora Serverless v2, follow these steps:

1. Check if the provisioned cluster needs to be upgraded to be used with Aurora Serverless v2 DB instances. For the Aurora versions that are compatible with Aurora Serverless v2, see [Requirements and limitations for Aurora Serverless v2](#).

If the provisioned cluster is running an engine version that isn't available for Aurora Serverless v2, upgrade the engine version of the cluster:

- If you have a MySQL 5.7–compatible provisioned cluster, follow the upgrade instructions for Aurora MySQL version 3. Use the procedures in [How to perform an in-place upgrade](#).
- If you have a PostgreSQL-compatible provisioned cluster running PostgreSQL version 11 or 12, follow the upgrade instructions for Aurora PostgreSQL version 13. Use the procedures in [Performing a major version upgrade](#).

2. Configure any other cluster properties to match the Aurora Serverless v2 requirements from [Requirements and limitations for Aurora Serverless v2](#).
3. Configure the scaling configuration for the cluster. Follow the procedure in [Setting the Aurora Serverless v2 capacity range for a cluster](#).
4. Add one or more Aurora Serverless v2 DB instances to the cluster. Follow the general procedure in [Adding Aurora Replicas to a DB cluster](#). For each new DB instance, specify the special DB instance class name **Serverless** in the Amazon Web Services Management Console, or `db.serverless` in the Amazon CLI or Amazon RDS API.

In some cases, you might already have one or more provisioned reader DB instances in the cluster. If so, you can convert one of the readers to an Aurora Serverless v2 DB instance instead of creating a new DB instance. To do so, follow the procedure in [Converting a provisioned writer or reader to Aurora Serverless v2](#).

5. Perform a failover operation to make one of the Aurora Serverless v2 DB instances the writer DB instance for the cluster.
6. (Optional) Convert any provisioned DB instances to Aurora Serverless v2, or remove them from the cluster. Follow the general procedure in [Converting a provisioned writer or reader to Aurora Serverless v2](#) or [Deleting a DB instance from an Aurora DB cluster](#).

### Tip

Removing the provisioned DB instances isn't mandatory. You can set up a cluster containing both Aurora Serverless v2 and provisioned DB instances. However, until you are familiar with the performance and scaling characteristics of Aurora Serverless v2 DB instances, we recommend that you configure your clusters with DB instances all of the same type.

The following Amazon CLI example shows the switchover process using a provisioned cluster that's running Aurora MySQL version 3.02.0. The cluster is named `mysql-80`. The cluster starts with two provisioned DB instances named `provisioned-instance-1` and `provisioned-instance-2`, a writer and a reader. They both use the `db.r6g.large` DB instance class.

```
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \  
  --query '*[].[DBClusterIdentifier,DBClusterMembers[*].  
  [DBInstanceIdentifier,IsClusterWriter]]' --output text  
mysql-80
```

```

provisioned-instance-2    False
provisioned-instance-1    True

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-1 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-1    db.r6g.large

$ aws rds describe-db-instances --db-instance-identifier provisioned-instance-2 \
  --output text --query '*[].[DBInstanceIdentifier,DBInstanceClass]'
provisioned-instance-2    db.r6g.large

```

We create a table with some data. That way, we can confirm that the data and operation of the cluster are the same before and after the switchover.

```

mysql> create database serverless_v2_demo;
mysql> create table serverless_v2_demo.demo (s varchar(128));
mysql> insert into serverless_v2_demo.demo values ('This cluster started with a
  provisioned writer. ');
Query OK, 1 row affected (0.02 sec)

```

First, we add a capacity range to the cluster. Otherwise, we get an error when adding any Aurora Serverless v2 DB instances to the cluster. If we use the Amazon Web Services Management Console for this procedure, that step is automatic when we add the first Aurora Serverless v2 DB instance.

```

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 \
  --db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-
mysql

An error occurred (InvalidDBClusterStateFault) when calling the CreateDBInstance
operation:
Set the Serverless v2 scaling configuration on the parent DB cluster before creating a
Serverless v2 DB instance.

$ # The blank ServerlessV2ScalingConfiguration attribute confirms that the cluster
doesn't have a capacity range set yet.
$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 --query
'DBClusters[*].ServerlessV2ScalingConfiguration'
[]

$ aws rds modify-db-cluster --db-cluster-identifier mysql-80 \
  --serverless-v2-scaling-configuration MinCapacity=0.5,MaxCapacity=16
{

```

```

"DBClusterIdentifier": "mysql-80",
"ServerlessV2ScalingConfiguration": {
  "MinCapacity": 0.5,
  "MaxCapacity": 16
}
}

```

We create two Aurora Serverless v2 readers to take the place of the original DB instances. We do so by specifying the `db.serverless` DB instance class for the new DB instances.

```

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-1 --db-
cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceStatus": "creating"
}

$ aws rds create-db-instance --db-instance-identifier serverless-v2-instance-2 \
--db-cluster-identifier mysql-80 --db-instance-class db.serverless --engine aurora-
mysql
{
  "DBInstanceIdentifier": "serverless-v2-instance-2",
  "DBClusterIdentifier": "mysql-80",
  "DBInstanceClass": "db.serverless",
  "DBInstanceStatus": "creating"
}

$ # Wait for both DB instances to finish being created before proceeding.
$ aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
&& \
aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-2

```

We perform a failover to make one of the Aurora Serverless v2 DB instances the new writer for the cluster.

```

$ aws rds failover-db-cluster --db-cluster-identifier mysql-80 \
--target-db-instance-identifier serverless-v2-instance-1
{
  "DBClusterIdentifier": "mysql-80",
  "DBClusterMembers": [

```

```

{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "IsClusterWriter": false,
  "DBClusterParameterGroupStatus": "in-sync",
  "PromotionTier": 1
},
{
  "DBInstanceIdentifier": "serverless-v2-instance-2",
  "IsClusterWriter": false,
  "DBClusterParameterGroupStatus": "in-sync",
  "PromotionTier": 1
},
{
  "DBInstanceIdentifier": "provisioned-instance-2",
  "IsClusterWriter": false,
  "DBClusterParameterGroupStatus": "in-sync",
  "PromotionTier": 1
},
{
  "DBInstanceIdentifier": "provisioned-instance-1",
  "IsClusterWriter": true,
  "DBClusterParameterGroupStatus": "in-sync",
  "PromotionTier": 1
}
],
"Status": "available"
}

```

It takes a few seconds for that change to take effect. At that point, we have an Aurora Serverless v2 writer and an Aurora Serverless v2 reader. Thus, we don't need either of the original provisioned DB instances.

```

$ aws rds describe-db-clusters --db-cluster-identifier mysql-80 \
  --query '*[].[DBClusterIdentifier,DBClusterMembers[*].
  [DBInstanceIdentifier,IsClusterWriter]]' \
  --output text
mysql-80
serverless-v2-instance-1      True
serverless-v2-instance-2     False
provisioned-instance-2       False
provisioned-instance-1       False

```

The last step in the switchover procedure is to delete both of the provisioned DB instances.

```

$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-2 --skip-
final-snapshot
{
  "DBInstanceIdentifier": "provisioned-instance-2",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceClass": "db.r6g.large"
}

$ aws rds delete-db-instance --db-instance-identifier provisioned-instance-1 --skip-
final-snapshot
{
  "DBInstanceIdentifier": "provisioned-instance-1",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceClass": "db.r6g.large"
}

```

As a final check, we confirm that the original table is accessible and writeable from the Aurora Serverless v2 writer DB instance.

```

mysql> select * from serverless_v2_demo.demo;
+-----+
| s                |
+-----+
| This cluster started with a provisioned writer. |
+-----+
1 row in set (0.00 sec)

mysql> insert into serverless_v2_demo.demo values ('And it finished with a Serverless
v2 writer. ');
Query OK, 1 row affected (0.01 sec)

mysql> select * from serverless_v2_demo.demo;
+-----+
| s                |
+-----+
| This cluster started with a provisioned writer. |
| And it finished with a Serverless v2 writer.   |
+-----+

```

```
2 rows in set (0.01 sec)
```

We also connect to the Aurora Serverless v2 reader DB instance and confirm that the newly written data is available there too.

```
mysql> select * from serverless_v2_demo.demo;
+-----+
| s      |
+-----+
| This cluster started with a provisioned writer. |
| And it finished with a Serverless v2 writer.   |
+-----+
2 rows in set (0.01 sec)
```

## Comparison of Aurora Serverless v2 and Aurora Serverless v1

If you are already using Aurora Serverless v1, you can learn the major differences between Aurora Serverless v1 and Aurora Serverless v2. The architectural differences, such as support for reader DB instances, open up new types of use cases.

You can use the following tables to help understand the most important differences between Aurora Serverless v2 and Aurora Serverless v1.

### Topics

- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements](#)
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability](#)
- [Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support](#)
- [Adapting Aurora Serverless v1 use cases to Aurora Serverless v2](#)

## Comparison of Aurora Serverless v2 and Aurora Serverless v1 requirements

The following table summarizes the different requirements to run your database using Aurora Serverless v2 or Aurora Serverless v1. Aurora Serverless v2 offers higher versions of the Aurora MySQL and Aurora PostgreSQL DB engines than Aurora Serverless v1 does.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
DB engines	Aurora MySQL, Aurora PostgreSQL	Aurora MySQL, Aurora PostgreSQL
Supported Aurora MySQL versions	See <a href="#">Aurora Serverless v2 with Aurora MySQL</a> .	See <a href="#">Aurora Serverless v1 with Aurora MySQL</a> .
Supported Aurora PostgreSQL versions	See <a href="#">Aurora Serverless v2 with Aurora PostgreSQL</a> .	See <a href="#">Aurora Serverless v1 with Aurora PostgreSQL</a> .
Upgrading a DB cluster	<p>Similarly to provisioned DB clusters, you can perform upgrades manually without waiting for Aurora to upgrade the DB cluster for you. For more information, see <a href="#">Modifying an Amazon Aurora DB cluster</a>.</p> <div data-bbox="594 1094 1029 1654" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #E6F2FF;"> <p><b>Note</b></p> <p>To perform a major version upgrade from 13.x to 14.x or 15.x for an Aurora PostgreSQL-compatible DB cluster, the maximum capacity of your cluster must be at least 2 ACUs.</p> </div>	<p>Minor version upgrades are applied automatically as they become available. For more information, see <a href="#">Aurora Serverless v1 and Aurora database engine versions</a>.</p> <p>You can perform major version upgrades manually. For more information, see <a href="#">Modifying an Aurora Serverless v1 DB cluster</a>.</p>
Converting from provisioned DB cluster	You can use the following methods:	Restore snapshot of provisioned cluster to create new Aurora Serverless v1 cluster.

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
	<ul style="list-style-type: none"> <li>• Add one or more Aurora Serverless v2 reader DB instances to an existing provisioned cluster. To use Aurora Serverless v2 for the writer, perform a failover to one of the Aurora Serverless v2 DB instances. For the entire cluster to use Aurora Serverless v2 DB instances, remove any provisioned writer DB instances after promoting the Aurora Serverless v2 DB instance to the writer.</li> <li>• Create a new cluster with the appropriate DB engine and engine version. Use any of the standard methods. For example, restore a cluster snapshot or create a clone of an existing cluster. Choose Aurora Serverless v2 for some or all of the DB instances in the new cluster.</li> </ul> <p>If you create the new cluster through cloning, you can't upgrade the engine version at the same time. Make sure that the original cluster is already running an engine version</p>	

Feature	Aurora Serverless v2 requirement	Aurora Serverless v1 requirement
	that's compatible with Aurora Serverless v2.	
Converting from Aurora Serverless v1 cluster	Follow the procedure in <a href="#">Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2</a> .	Not applicable
Available DB instance classes	The special DB instance class <code>db.serverless</code> . In the Amazon Web Services Management Console, it's labeled as <b>Serverless</b> .	Not applicable. Aurora Serverless v1 uses the <code>serverless</code> engine mode.
Port	Any port that's compatible with MySQL or PostgreSQL	Default MySQL or PostgreSQL port only
Public IP address allowed?	Yes	No
Virtual private cloud (VPC) required?	Yes	Yes. Each Aurora Serverless v1 cluster consumes 2 interface and Gateway Load Balancer endpoints allocated to your VPC.

## Comparison of Aurora Serverless v2 and Aurora Serverless v1 scaling and availability

The following table summarizes differences between Aurora Serverless v2 and Aurora Serverless v1 for scalability and availability.

Aurora Serverless v2 scaling is more responsive, more granular, and less disruptive than the scaling in Aurora Serverless v1. Aurora Serverless v2 can scale both by changing the size of the DB instance and by adding more DB instances to the DB cluster. It can also scale by adding clusters in other Amazon Web Services Regions to an Aurora global database. In contrast, Aurora Serverless v1

only scales by increasing or decreasing the capacity of the writer. All the compute for an Aurora Serverless v1 cluster runs in a single Availability Zone and a single Amazon Web Services Region.

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Minimum Aurora capacity units (ACUs) (Aurora MySQL)	0.5 when the cluster is running, 0 when the cluster is paused.	1 when the cluster is running, 0 when the cluster is paused.
Minimum ACUs (Aurora PostgreSQL)	0.5 when the cluster is running, 0 when the cluster is paused.	2 when the cluster is running, 0 when the cluster is paused.
Maximum ACUs (Aurora MySQL)	256	256
Maximum ACUs (Aurora PostgreSQL)	256	384
Stopping a cluster	You can manually stop and start the cluster by using <a href="#">the same cluster stop and start feature</a> as provisioned clusters.	The cluster pauses automatically after a timeout. It takes some time to become available when activity resumes.
Scaling for DB instances	Scale up and down with minimum increment of 0.5 ACUs.	Scale up and down by doubling or halving the ACUs.
Number of DB instances	Same as a provisioned cluster: 1 writer DB instance, up to 15 reader DB instances.	1 DB instance handling both reads and writes.
Scaling can happen while SQL statements are running?	Yes. Aurora Serverless v2 doesn't require waiting for a quiet point.	No. For example, scaling waits for completion of long-running transactions, temporary tables, and table locks.

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Reader DB instances scale along with writer	Optional	Not applicable
Maximum storage	128 TiB	128 TiB
Buffer cache preserved when scaling	Yes. Buffer cache is resized dynamically.	No. Buffer cache is rewarmed after scaling.
Failover	Yes, same as for provisioned clusters.	Best effort only, subject to capacity availability. Slower than in Aurora Serverless v2.
Multi-AZ capability	Yes, same as for provisioned. A Multi-AZ cluster requires a reader DB instance in a second Availability Zone (AZ). For a Multi-AZ cluster, Aurora performs Multi-AZ failover in case of an AZ failure.	Aurora Serverless v1 clusters run all their compute in a single AZ. Recovery in case of AZ failure is best effort only and subject to capacity availability.
Aurora global databases	Yes	No
Scaling based on memory pressure	Yes	No
Scaling based on CPU load	Yes	Yes
Scaling based on network traffic	Yes, based on memory and CPU overhead of network traffic. The <code>max_connections</code> parameter remains constant to avoid dropping connections when scaling down.	Yes, based on number of connections.

Scaling and high availability feature	Aurora Serverless v2 behavior	Aurora Serverless v1 behavior
Timeout action for scaling events	No	Yes
Adding new DB instances to cluster through Amazon Auto Scaling	Not applicable. You can create Aurora Serverless v2 reader DB instances in promotion tiers 2–15 and leave them scaled down to low capacity.	No. Reader DB instances aren't available.

## Comparison of Aurora Serverless v2 and Aurora Serverless v1 feature support

The following table summarizes these:

- Features that are available in Aurora Serverless v2 but not Aurora Serverless v1
- Features that work differently between Aurora Serverless v1 and Aurora Serverless v2
- Features that aren't currently available in Aurora Serverless v2

Aurora Serverless v2 includes many features from provisioned clusters that aren't available for Aurora Serverless v1.

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
Cluster topology	Aurora Serverless v2 is a property of individual DB instances. A cluster can contain multiple Aurora Serverless v2 DB instances, or a combination of Aurora Serverless v2 and provisioned DB instances.	Aurora Serverless v1 clusters don't use the notion of DB instances. You can't change the Aurora Serverless v1 property after you create the cluster.
Configuration parameters	Almost all the same parameters can be modified	Only a subset of parameters can be modified.

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
	as in provisioned clusters. For details, see <a href="#">Working with parameter groups for Aurora Serverless v2</a> .	
Parameter groups	Cluster parameter group and DB parameter groups. Parameters with provisioned value in Supported EngineModes attribute are available. That's many more parameters than in Aurora Serverless v1.	Cluster parameter group only. Parameters with serverless value in Supported EngineModes attribute are available.
Encryption for cluster volume	Optional	Required. The limitations in <a href="#">Limitations of Amazon Aurora encrypted DB clusters</a> apply to all Aurora Serverless v1 clusters.
Cross-Region snapshots	Yes	Snapshot must be encrypted with your own Amazon Key Management Service (Amazon KMS) key.
Automated backups retained after DB cluster deletion	Yes	No
TLS/SSL	Yes. The support is the same as for provisioned clusters. For usage information, see <a href="#">Using TLS/SSL with Aurora Serverless v2</a> .	Yes. There are some differences from TLS support for provisioned clusters. For usage information, see <a href="#">Using TLS/SSL with Aurora Serverless v1</a> .

Feature	Aurora Serverless v2 support	Aurora Serverless v1 support
Cloning	Only from and to DB engine versions that are compatible with Aurora Serverless v2. You can't use cloning to upgrade from Aurora Serverless v1 or from an earlier version of a provisioned cluster.	Only from and to DB engine versions that are compatible with Aurora Serverless v1.
Integration with Amazon S3	Yes	Yes
Integration with Amazon Secrets Manager	Yes	No
Exporting DB cluster snapshots to S3	Yes	No
Associating an IAM role	Yes	No
Uploading logs to Amazon CloudWatch	Optional. You choose which logs to turn on and which logs to upload to CloudWatch.	All logs that are turned on are uploaded to CloudWatch automatically.
Data API available	Yes	Yes
Query editor available	Yes	Yes
Performance Insights	Yes	No
Amazon RDS Proxy available	Yes	No
Babelfish for Aurora PostgreSQL available	Yes. Supported for Aurora PostgreSQL versions that are compatible with both Babelfish and Aurora Serverless v2.	No

## Adapting Aurora Serverless v1 use cases to Aurora Serverless v2

Depending on your use case for Aurora Serverless v1, you might adapt that approach to take advantage of Aurora Serverless v2 features as follows.

Suppose that you have an Aurora Serverless v1 cluster that is lightly loaded and your priority is maintaining continuous availability while minimizing costs. With Aurora Serverless v2, you can configure a smaller minimum ACU setting of 0.5, compared with a minimum of 1 ACU for Aurora Serverless v1. You can increase availability by creating a Multi-AZ configuration, with the reader DB instance also having a minimum of 0.5 ACUs.

Suppose that you have an Aurora Serverless v1 cluster that you use in a development and test scenario. In this case, cost is also a high priority but the cluster doesn't need to be available at all times. Aurora Serverless v2 can automatically pause each instance when it's completely idle. You do so by specifying a minimum capacity of 0 ACUs for the cluster, as explained in [Scaling to Zero ACUs with automatic pause and resume for Aurora Serverless v2](#). You can also manually stop the cluster when it's not needed, and start it when it's time for the next test or development cycle.

Suppose that you have an Aurora Serverless v1 cluster with a heavy workload. An equivalent cluster using Aurora Serverless v2 can scale with more granularity. For example, Aurora Serverless v1 scales by doubling the capacity, for example from 64 to 128 ACUs. In contrast, your Aurora Serverless v2 DB instance can scale in 0.5-ACU increments.

Suppose that your workload requires a higher total capacity than is available in Aurora Serverless v1. You can use multiple Aurora Serverless v2 reader DB instances to offload the read-intensive parts of the workload from the writer DB instance. You can also divide the read-intensive workload among multiple reader DB instances.

For a write-intensive workload, you might configure the cluster with a large provisioned DB instance as the writer. You might do so alongside one or more Aurora Serverless v2 reader DB instances.

## Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2

### Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon

Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

The process of upgrading a DB cluster from Aurora Serverless v1 to Aurora Serverless v2 has multiple steps. That's because you can't convert directly from Aurora Serverless v1 to Aurora Serverless v2. There's always an intermediate step that involves converting the Aurora Serverless v1 DB cluster to a provisioned cluster.

## Aurora MySQL-compatible DB clusters

You can convert your Aurora Serverless v1 DB cluster to a provisioned DB cluster, then use a blue/green deployment to upgrade it and convert it to an Aurora Serverless v2 DB cluster. We recommend this procedure for production environments. For more information, see [Using Amazon Aurora Blue/Green Deployments for database updates](#).

### To use a blue/green deployment to upgrade an Aurora Serverless v1 cluster running Aurora MySQL version 2 (MySQL 5.7-compatible)

1. Convert the Aurora Serverless v1 DB cluster to a provisioned Aurora MySQL version 2 cluster. Follow the procedure in [Converting from Aurora Serverless v1 to provisioned](#).
2. Create a blue/green deployment. Follow the procedure in [Creating a blue/green deployment in Amazon Aurora](#).
