3. Choose an Aurora MySQL version for the green cluster that's compatible with Aurora Serverless v2, for example 3.04.1.

For compatible versions, see [Aurora Serverless v2 with Aurora MySQL](#).

4. Modify the writer DB instance of the green cluster to use the **Serverless v2** (db.serverless) DB instance class.

For details, see [Converting a provisioned writer or reader to Aurora Serverless v2](#).

5. When your upgraded Aurora Serverless v2 DB cluster is available, switch over from the blue cluster to the green cluster.

## Migrating from an on-premises database to Aurora Serverless v2

You can migrate your on-premises databases to Aurora Serverless v2, just as with provisioned Aurora MySQL and Aurora PostgreSQL.

- For MySQL databases, you can use the `mysqldump` command. For more information, see [Importing data to an Amazon RDS for MySQL database with reduced downtime](#) in the *Amazon Relational Database Service User Guide*.
- For PostgreSQL databases, you can use the `pg_dump` and `pg_restore` commands. For more information, see the blog post [Best practices for migrating PostgreSQL databases to Amazon RDS and Amazon Aurora](#).

# Using Amazon Aurora Serverless v1

## Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

Amazon Aurora Serverless v1 (Amazon Aurora Serverless version 1) is an on-demand autoscaling configuration for Amazon Aurora. An *Aurora Serverless v1 DB cluster* is a DB cluster that scales compute capacity up and down based on your application's needs. This contrasts with Aurora *provisioned DB clusters*, for which you manually manage capacity. Aurora Serverless v1 provides a relatively simple, cost-effective option for infrequent, intermittent, or unpredictable workloads. It is cost-effective because it automatically starts up, scales compute capacity to match your application's usage, and shuts down when it's not in use.

To learn more about pricing, see [Serverless Pricing](#) under **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition** on the Amazon Aurora pricing page.

Aurora Serverless v1 clusters have the same kind of high-capacity, distributed, and highly available storage volume that is used by provisioned DB clusters.

For an Aurora Serverless v1 cluster, the cluster volume is always encrypted. You can choose the encryption key, but you can't disable encryption. That means that you can perform the same operations on an Aurora Serverless v1 that you can on encrypted snapshots. For more information, see [Aurora Serverless v1 and snapshots](#).

- [Viewing Aurora Serverless v1 DB clusters](#)
- [Deleting an Aurora Serverless v1 DB cluster](#)
- [Aurora Serverless v1 and Aurora database engine versions](#)

## Region and version availability for Aurora Serverless v1

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and Aurora Serverless v1, see [Aurora Serverless v1](#).

## Advantages of Aurora Serverless v1

Aurora Serverless v1 provides the following advantages:

- **Simpler than provisioned** – Aurora Serverless v1 removes much of the complexity of managing DB instances and capacity.
- **Scalable** – Aurora Serverless v1 seamlessly scales compute and memory capacity as needed, with no disruption to client connections.
- **Cost-effective** – When you use Aurora Serverless v1, you pay only for the database resources that you consume, on a per-second basis.
- **Highly available storage** – Aurora Serverless v1 uses the same fault-tolerant, distributed storage system with six-way replication as Aurora to protect against data loss.

## Use cases for Aurora Serverless v1

Aurora Serverless v1 is designed for the following use cases:

- **Infrequently used applications** – You have an application that is only used for a few minutes several times per day or week, such as a low-volume blog site. With Aurora Serverless v1, you pay for only the database resources that you consume on a per-second basis.
- **New applications** – You're deploying a new application and you're unsure about the instance size you need. By using Aurora Serverless v1, you can create a database endpoint and have the database autoscale to the capacity requirements of your application.
- **Variable workloads** – You're running a lightly used application, with peaks of 30 minutes to several hours a few times each day, or several times per year. Examples are applications for human resources, budgeting, and operational reporting applications. With Aurora Serverless v1, you no longer need to provision for peak or average capacity.
- **Unpredictable workloads** – You're running daily workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. With Aurora Serverless v1, your database autoscales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over.
- **Development and test databases** – Your developers use databases during work hours but don't need them on nights or weekends. With Aurora Serverless v1, your database automatically shuts down when it's not in use.
- **Multi-tenant applications** – With Aurora Serverless v1, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v1 manages individual database capacity for you.

## Limitations of Aurora Serverless v1

The following limitations apply to Aurora Serverless v1:

-  **Important**

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).
- Aurora Serverless v1 doesn't support the following features:

- Aurora global databases
- Aurora Replicas
- Amazon Identity and Access Management (IAM) database authentication
- Backtracking in Aurora
- Database activity streams
- Kerberos authentication
- Performance Insights
- RDS Proxy
- Viewing logs in the Amazon Web Services Management Console
- Connections to an Aurora Serverless v1 DB cluster are closed automatically if held open for longer than one day.
- All Aurora Serverless v1 DB clusters have the following limitations:
  - You can't export Aurora Serverless v1 snapshots to Amazon S3 buckets.
  - You can't use Amazon Database Migration Service and Change Data Capture (CDC) with Aurora Serverless v1 DB clusters. Only provisioned Aurora DB clusters support CDC with Amazon DMS as a source.
  - You can't save data to text files in Amazon S3 or load text file data to Aurora Serverless v1 from S3.
  - You can't attach an IAM role to an Aurora Serverless v1 DB cluster. However, you can load data to Aurora Serverless v1 from Amazon S3 by using the `aws_s3` extension with the `aws_s3.table_import_from_s3` function and the `credentials` parameter. For more information, see [Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster](#).
  - When using the query editor, a Secrets Manager secret is created for the DB credentials to access the database. If you delete the credentials from the query editor, the associated secret is also deleted from Secrets Manager. You can't recover this secret after it's deleted.
- Aurora MySQL–based DB clusters running Aurora Serverless v1 don't support the following:
  - Invoking Amazon Lambda functions from within your Aurora MySQL DB cluster. However, Amazon Lambda functions can make calls to your Aurora Serverless v1 DB cluster.
  - Restoring a snapshot from a DB instance that isn't Aurora MySQL or RDS for MySQL.
  - Replicating data using replication based on binary logs (binlogs). This limitation is true regardless of whether your Aurora MySQL–based DB cluster Aurora Serverless v1 is the source or the target of the replication. To replicate data into an Aurora Serverless v1 DB cluster

from a MySQL DB instance outside Aurora, such as one running on Amazon EC2, consider using Amazon Database Migration Service. For more information, see the [Amazon Database Migration Service User Guide](#).

- Creating users with host-based access (`'username'@'IP_address'`). This is because Aurora Serverless v1 uses a router fleet between the client and the database host for seamless scaling. The IP address that the Aurora Serverless DB cluster sees is that of the router host and not your client. For more information, see [Aurora Serverless v1 architecture](#).

Instead, use the wildcard (`'username'@'%'`).

- Aurora PostgreSQL–based DB clusters running Aurora Serverless v1 have the following limitations:
  - Aurora PostgreSQL query plan management (`apg_plan_management` extension) isn't supported.
  - The logical replication feature available in Amazon RDS PostgreSQL and Aurora PostgreSQL isn't supported.
  - Outbound communications such as those enabled by Amazon RDS for PostgreSQL extensions aren't supported. For example, you can't access external data with the `postgres_fdw/dblink` extension. For more information about RDS PostgreSQL extensions, see [PostgreSQL on Amazon RDS](#) in the *RDS User Guide*.
  - Currently, certain SQL queries and commands aren't recommended. These include session-level advisory locks, temporary relations, asynchronous notifications (`LISTEN`), and cursors with hold (`DECLARE name . . . CURSOR WITH HOLD FOR query`). Also, `NOTIFY` commands prevent scaling and aren't recommended.

For more information, see [Autoscaling for Aurora Serverless v1](#).

- You can't set the preferred automated backup window for an Aurora Serverless v1 DB cluster.
- You can set the maintenance window for an Aurora Serverless v1 DB cluster. For more information, see [Adjusting the preferred DB cluster maintenance window](#).

## Configuration requirements for Aurora Serverless v1

When you create an Aurora Serverless v1 DB cluster, pay attention to the following requirements:

- Use these specific port numbers for each DB engine:
  - Aurora MySQL – 3306

- Aurora PostgreSQL – 5432
- Create your Aurora Serverless v1 DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. When you create an Aurora Serverless v1 DB cluster in your VPC, you consume two (2) of the fifty (50) Interface and Gateway Load Balancer endpoints allotted to your VPC. These endpoints are created automatically for you. To increase your quota, you can contact Amazon Web Services Support. For more information, see [Amazon VPC quotas](#).
- You can't give an Aurora Serverless v1 DB cluster a public IP address. You can access an Aurora Serverless v1 DB cluster only from within a VPC.
- Create subnets in different Availability Zones for the DB subnet group that you use for your Aurora Serverless v1 DB cluster. In other words, you can't have more than one subnet in the same Availability Zone.
- Changes to a subnet group used by an Aurora Serverless v1 DB cluster aren't applied to the cluster.
- You can access an Aurora Serverless v1 DB cluster from Amazon Lambda. To do so, you must configure your Lambda function to run in the same VPC as your Aurora Serverless v1 DB cluster. For more information about working with Amazon Lambda, see [Configuring a Lambda function to access resources in an Amazon VPC](#) in the *Amazon Lambda Developer Guide*.

## Using TLS/SSL with Aurora Serverless v1

By default, Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v1 DB cluster. It supports TLS/SSL versions 1.0, 1.1, and 1.2. You don't need to configure your Aurora Serverless v1 DB cluster to use TLS/SSL.

However, the following limitations apply:

- TLS/SSL support for Aurora Serverless v1 DB clusters isn't currently available in the China (Beijing) Amazon Web Services Region.
- When you create database users for an Aurora MySQL–based Aurora Serverless v1 DB cluster, don't use the REQUIRE clause for SSL permissions. Doing so prevents users from connecting to the Aurora DB instance.
- For both MySQL Client and PostgreSQL Client utilities, session variables that you might use in other environments have no effect when using TLS/SSL between client and Aurora Serverless v1.

- For the MySQL Client, when connecting with TLS/SSL's VERIFY\_IDENTITY mode, currently you need to use the MySQL 8.0-compatible `mysql` command. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

Depending on the client that you use to connect to Aurora Serverless v1 DB cluster, you might not need to specify TLS/SSL to get an encrypted connection. For example, to use the PostgreSQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora PostgreSQL-Compatible Edition, connect as you normally do.

```
psql -h endpoint -U user
```

After you enter your password, the PostgreSQL Client shows you see the connection details, including the TLS/SSL version and cipher.

```
psql (12.5 (Ubuntu 12.5-0ubuntu0.20.04.1), server 10.12)
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256,
compression: off)
Type "help" for help.
```

### Important

Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt connections by default unless SSL/TLS is disabled by the client application. The TLS/SSL connection terminates at the router fleet. Communication between the router fleet and your Aurora Serverless v1 DB cluster occurs within the service's internal network boundary.

You can check the status of the client connection to examine whether the connection to Aurora Serverless v1 is TLS/SSL encrypted. The PostgreSQL `pg_stat_ssl` and `pg_stat_activity` tables and its `ssl_is_used` function don't show the TLS/SSL state for the communication between the client application and Aurora Serverless v1. Similarly, the TLS/SSL state can't be derived from the MySQL `status` statement.

The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL formerly weren't supported for Aurora Serverless v1. These parameters are available now for Aurora Serverless v1. For a complete list of parameters supported by Aurora Serverless v1, call the

[DescribeEngineDefaultClusterParameters](#) API operation. For more information on parameter groups and Aurora Serverless v1, see [Parameter groups for Aurora Serverless v1](#).

To use the MySQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora MySQL-Compatible Edition, you specify TLS/SSL in your request. The following example includes the [Amazon root CA 1 trust store](#) downloaded from Amazon Trust Services, which is necessary for this connection to succeed.

```
mysql -h endpoint -P 3306 -u user -p --ssl-ca=amazon-root-CA-1.pem --ssl-mode=REQUIRED
```

When prompted, enter your password. Soon, the MySQL monitor opens. You can confirm that the session is encrypted by using the `status` command.

```
mysql> status
-----
mysql Ver 14.14 Distrib 5.5.62, for Linux (x86_64) using readline 5.1
Connection id:          19
Current database:
Current user:           ***@*****
SSL:                    Cipher in use is ECDHE-RSA-AES256-SHA
...
```

To learn more about connecting to Aurora MySQL database with the MySQL Client, see [Connecting to a DB instance running the MySQL database engine](#).

Aurora Serverless v1 supports all TLS/SSL modes available to the MySQL Client (`mysql`) and PostgreSQL Client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	mysql	psql
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)

Description of TLS/SSL mode	mysql	psql
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the CA.	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v1 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the [Amazon root CA 1 trust store](#) from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL Client:

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem
      dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres Client, see [Connecting to a DB instance running the PostgreSQL database engine](#).

For more information about connecting to Aurora DB clusters in general, see [Connecting to an Amazon Aurora DB cluster](#).

## Supported cipher suites for connections to Aurora Serverless v1 DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora Serverless v1 DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see [Configuring cipher suites for connections to Aurora MySQL DB clusters](#).

Aurora Serverless v1 DB clusters that are based on Aurora PostgreSQL don't support cipher suites.

## How Aurora Serverless v1 works

### Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

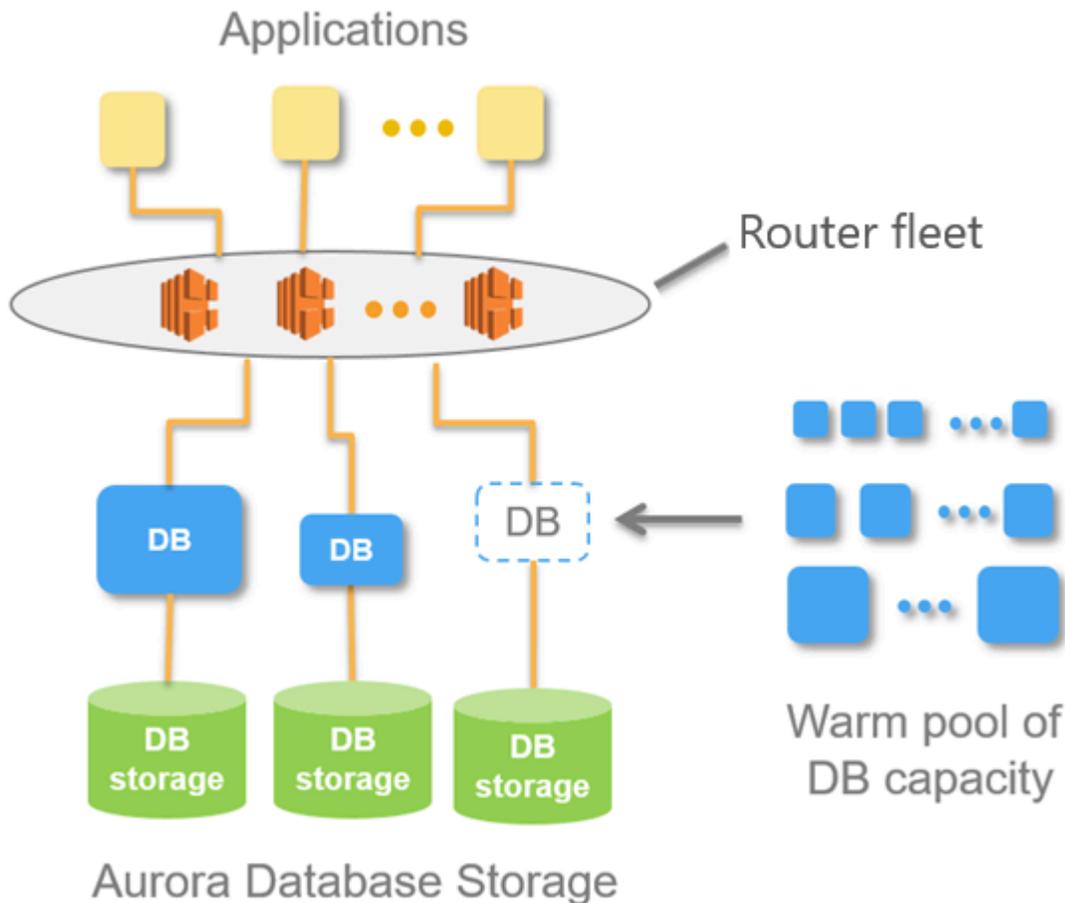

Following, you can learn how Aurora Serverless v1 works.

### Topics

- [Aurora Serverless v1 architecture](#)
- [Autoscaling for Aurora Serverless v1](#)
- [Timeout action for capacity changes](#)
- [Pause and resume for Aurora Serverless v1](#)
- [Determining the maximum number of database connections for Aurora Serverless v1](#)
- [Parameter groups for Aurora Serverless v1](#)
- [Logging for Aurora Serverless v1](#)
- [Aurora Serverless v1 and maintenance](#)
- [Aurora Serverless v1 and failover](#)
- [Aurora Serverless v1 and snapshots](#)

## Aurora Serverless v1 architecture

The following image shows an overview of the Aurora Serverless v1 architecture.

Instead of provisioning and managing database servers, you specify Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gigabytes (GB) of memory, corresponding CPU, and networking. Database storage automatically scales from 10 gibibytes (GiB) to 128 tebibytes (TiB), the same as storage in a standard Aurora DB cluster.

You can specify the minimum and maximum ACU. The *minimum Aurora capacity unit* is the lowest ACU to which the DB cluster can scale down. The *maximum Aurora capacity unit* is the highest ACU to which the DB cluster can scale up. Based on your settings, Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory.

Aurora Serverless v1 manages the warm pool of resources in an Amazon Web Services Region to minimize scaling time. When Aurora Serverless v1 adds new resources to the Aurora DB cluster, it uses the router fleet to switch active client connections to the new resources. At any specific time, you are charged only for the ACUs that are being actively used in your Aurora DB cluster.

## Autoscaling for Aurora Serverless v1

The capacity allocated to your Aurora Serverless v1 DB cluster seamlessly scales up and down based on the load generated by your client application. Here, load is CPU utilization and the number of connections. When capacity is constrained by either of these, Aurora Serverless v1 scales up. Aurora Serverless v1 also scales up when it detects performance issues that can be resolved by doing so.

You can view scaling events for your Aurora Serverless v1 cluster in the Amazon Web Services Management Console. During autoscaling, Aurora Serverless v1 resets the EngineUptime metric. The value of the reset metric value doesn't mean that seamless scaling had problems or that Aurora Serverless v1 dropped connections. It's simply the starting point for uptime at the new capacity. To learn more about metrics, see [Monitoring metrics in an Amazon Aurora cluster](#).

When your Aurora Serverless v1 DB cluster has no active connections, it can scale down to zero capacity (0 ACUs). To learn more, see [Pause and resume for Aurora Serverless v1](#).

When it does need to perform a scaling operation, Aurora Serverless v1 first tries to identify a *scaling point*, a moment when no queries are being processed. Aurora Serverless v1 might not be able to find a scaling point for the following reasons:

- Long-running queries
- In-progress transactions
- Temporary tables or table locks

To increase your Aurora Serverless v1 DB cluster's success rate when finding a scaling point, we recommend that you avoid long-running queries and long-running transactions. To learn more about operations that block scaling and how to avoid them, see [Best practices for working with Aurora Serverless v1](#).

By default, Aurora Serverless v1 tries to find a scaling point for 5 minutes (300 seconds). You can specify a different timeout period when you create or modify the cluster. The timeout period can be between 60 seconds and 10 minutes (600 seconds). If Aurora Serverless v1 can't find a scaling point within the specified period, the autoscaling operation times out.

By default, if autoscaling doesn't find a scaling point before timing out, Aurora Serverless v1 keeps the cluster at the current capacity. You can change this default behavior when you create or modify your Aurora Serverless v1 DB cluster by selecting the **Force the capacity change** option. For more information, see [Timeout action for capacity changes](#).

## Timeout action for capacity changes

If autoscaling times out without finding a scaling point, by default Aurora keeps the current capacity. You can choose to have Aurora force the change by selecting the **Force the capacity change** option. This option is available in the **Autoscaling timeout and action** section of the **Create database** page when you create the cluster.

By default, the **Force the capacity change** option isn't selected. Keep this option clear to have your Aurora Serverless v1 DB cluster's capacity remain unchanged if the scaling operation times out without finding a scaling point.

Selecting this option causes your Aurora Serverless v1 DB cluster to enforce the capacity change, even without a scaling point. Before selecting this option, be aware of the consequences of this selection:

- Any in-process transactions are interrupted, and the following error message appears.

Aurora MySQL version 2 – ERROR 1105 (HY000): The last transaction was aborted due to Seamless Scaling. Please retry.

You can resubmit the transactions as soon as your Aurora Serverless v1 DB cluster is available.

- Connections to temporary tables and locks are dropped.

We recommend that you select the **Force the capacity change** option only if your application can recover from dropped connections or incomplete transactions.

The choices that you make in the Amazon Web Services Management Console when you create an Aurora Serverless v1 DB cluster are stored in the `ScalingConfigurationInfo` object, in the `SecondsBeforeTimeout` and `TimeoutAction` properties. The value of the `TimeoutAction` property is set to one of the following values when you create your cluster:

- `RollbackCapacityChange` – This value is set when you select the **Roll back the capacity change** option. This is the default behavior.
- `ForceApplyCapacityChange` – This value is set when you select the **Force the capacity change** option.

You can get the value of this property on an existing Aurora Serverless v1 DB cluster by using the [describe-db-clusters](#) Amazon CLI command, as shown following.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters --region region \  
  --db-cluster-identifier your-cluster-name \  
  --query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'
```

For Windows:

```
aws rds describe-db-clusters --region region ^  
  --db-cluster-identifier your-cluster-name ^  
  --query "*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}"
```

As an example, the following shows the query and response for an Aurora Serverless v1 DB cluster named `west-coast-sles` in the US West (N. California) Region.

```
$ aws rds describe-db-clusters --region us-west-1 --db-cluster-identifier west-coast-  
sles  
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'  
  
[  
  {  
    "ScalingConfigurationInfo": {  
      "MinCapacity": 1,  
      "MaxCapacity": 64,  
      "AutoPause": false,  
      "SecondsBeforeTimeout": 300,  
      "SecondsUntilAutoPause": 300,  
      "TimeoutAction": "RollbackCapacityChange"  
    }  
  }  
]
```

As the response shows, this Aurora Serverless v1 DB cluster uses the default setting.

For more information, see [Creating an Aurora Serverless v1 DB cluster](#). After creating your Aurora Serverless v1, you can modify the timeout action and other capacity settings at any time. To learn how, see [Modifying an Aurora Serverless v1 DB cluster](#).

## Pause and resume for Aurora Serverless v1

You can choose to pause your Aurora Serverless v1 DB cluster after a given amount of time with no activity. You specify the amount of time with no activity before the DB cluster is paused. When you

select this option, the default inactivity time is five minutes, but you can change this value. This is an optional setting.

When the DB cluster is paused, no compute or memory activity occurs, and you are charged only for storage. If database connections are requested when an Aurora Serverless v1 DB cluster is paused, the DB cluster automatically resumes and services the connection requests.

When the DB cluster resumes activity, it has the same capacity as it had when Aurora paused the cluster. The number of ACUs depends on how much Aurora scaled the cluster up or down before pausing it.

### Note

If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, Aurora restores the DB cluster from the snapshot when there is a request to connect to it.

## Determining the maximum number of database connections for Aurora Serverless v1

The following examples are for an Aurora Serverless v1 DB cluster that's compatible with MySQL 5.7. You can use a MySQL client or the query editor, if you've configured access to it. For more information, see [Running queries in the query editor](#).

### To find the maximum number of database connections

1. Find the capacity range for your Aurora Serverless v1 DB cluster using the Amazon CLI.

```
aws rds describe-db-clusters \  
  --db-cluster-identifier my-serverless-57-cluster \  
  --query 'DBClusters[*].ScalingConfigurationInfo|[0]'
```

The result shows that its capacity range is 1–4 ACUs.

```
{  
  "MinCapacity": 1,  
  "AutoPause": true,  
  "MaxCapacity": 4,
```

```
"TimeoutAction": "RollbackCapacityChange",
"SecondsUntilAutoPause": 3600
}
```

2. Run the following SQL query to find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for the minimum capacity of the cluster, 1 ACU.

```
@@max_connections
90
```

3. Scale the cluster to 8–32 ACUs.

For more information on scaling, see [Modifying an Aurora Serverless v1 DB cluster](#).

4. Confirm the capacity range.

```
{
  "MinCapacity": 8,
  "AutoPause": true,
  "MaxCapacity": 32,
  "TimeoutAction": "RollbackCapacityChange",
  "SecondsUntilAutoPause": 3600
}
```

5. Find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for the minimum capacity of the cluster, 8 ACUs.

```
@@max_connections
1000
```

6. Scale the cluster to the maximum possible, 256–256 ACUs.
7. Confirm the capacity range.

```
{
  "MinCapacity": 256,
  "AutoPause": true,
```

```
"MaxCapacity": 256,  
"TimeoutAction": "RollbackCapacityChange",  
"SecondsUntilAutoPause": 3600  
}
```

- Find the maximum number of connections.

```
select @@max_connections;
```

The result shown is for 256 ACUs.

```
@@max_connections  
6000
```

 **Note**

The `max_connections` value doesn't scale linearly with the number of ACUs.

- Scale the cluster back down to 1–4 ACUs.

```
{  
  "MinCapacity": 1,  
  "AutoPause": true,  
  "MaxCapacity": 4,  
  "TimeoutAction": "RollbackCapacityChange",  
  "SecondsUntilAutoPause": 3600  
}
```

This time, the `max_connections` value is for 4 ACUs.

```
@@max_connections  
270
```

- Let the cluster scale down to 2 ACUs.

```
@@max_connections  
180
```

If you've configured the cluster to pause after a certain amount of time idle, it scales down to 0 ACUs. However, `max_connections` doesn't drop below the value for 1 ACU.

```
@max_connections  
90
```

## Parameter groups for Aurora Serverless v1

When you create your Aurora Serverless v1 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. Unlike provisioned Aurora DB clusters, an Aurora Serverless v1 DB cluster has a single read/write DB instance that's configured with a DB cluster parameter group only—it doesn't have a separate DB parameter group. During autoscaling, Aurora Serverless v1 needs to be able to change parameters for the cluster to work best for the increased or decreased capacity. Thus, with an Aurora Serverless v1 DB cluster, some of the changes that you might make to parameters for a particular DB engine type might not apply.

For example, an Aurora PostgreSQL-based Aurora Serverless v1 DB cluster can't use `apg_plan_mgmt.capture_plan_baselines` and other parameters that might be used on provisioned Aurora PostgreSQL DB clusters for query plan management.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the [describe-engine-default-cluster-parameters](#) CLI command and querying the Amazon Web Services Region. The following are values that you can use for the `--db-parameter-group-family` option.

Aurora MySQL version 2	<code>aurora-mysql5.7</code>
Aurora PostgreSQL version 11	<code>aurora-postgresql11</code>
Aurora PostgreSQL version 13	<code>aurora-postgresql13</code>

We recommend that you configure your Amazon CLI with your Amazon access key ID and Amazon secret access key, and that you set your Amazon Web Services Region before using Amazon CLI commands. Providing the Region to your CLI configuration saves you from entering the `--region` parameter when running commands. To learn more about configuring Amazon CLI, see [Configuration basics](#) in the *Amazon Command Line Interface User Guide*.

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 2.

## For Linux, macOS, or Unix:

```
aws rds describe-engine-default-cluster-parameters \  
  --db-parameter-group-family aurora-mysql5.7 --query \  
  'EngineDefaults.Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [  
contains(SupportedEngineModes, `serverless`) == `true`] | [*].{param:ParameterName}' \  
  --output text
```

## For Windows:

```
aws rds describe-engine-default-cluster-parameters ^  
  --db-parameter-group-family aurora-mysql5.7 --query ^  
  "EngineDefaults.Parameters[*].  
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [  
contains(SupportedEngineModes, 'serverless') == `true`] | [*].{param:ParameterName}" ^  
  --output text
```

## Modifying parameter values for Aurora Serverless v1

As explained in [Parameter groups for Amazon Aurora](#), you can't directly change values in a default parameter group, regardless of its type (DB cluster parameter group, DB parameter group). Instead, you create a custom parameter group based on the default DB cluster parameter group for your Aurora DB engine and change settings as needed on that parameter group. For example, you might want to change some of the settings for your Aurora Serverless v1 DB cluster to [log queries or to upload DB engine specific logs](#) to Amazon CloudWatch.

### To create a custom DB cluster parameter group

1. Sign in to the Amazon Web Services Management Console and then open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Parameter groups**.
3. Choose **Create parameter group** to open the Parameter group details pane.
4. Choose the appropriate default DB cluster group for the DB engine you want to use for your Aurora Serverless v1 DB cluster. Be sure that you choose the following options:
  - a. For **Parameter group family**, choose the appropriate family for your chosen DB engine. Be sure that your choice has the prefix `aurora-` in its name.
  - b. For **Type**, choose **DB Cluster Parameter Group**.

- c. For **Group name** and **Description**, enter meaningful names for you or others who might need to work with your Aurora Serverless v1 DB cluster and its parameters.
- d. Choose **Create**.

Your custom DB cluster parameter group is added to the list of parameter groups available in your Amazon Web Services Region. You can use your custom DB cluster parameter group when you create new Aurora Serverless v1 DB clusters. You can also modify an existing Aurora Serverless v1 DB cluster to use your custom DB cluster parameter group. After your Aurora Serverless v1 DB cluster starts using your custom DB cluster parameter group, you can change values for dynamic parameters using either the Amazon Web Services Management Console or the Amazon CLI.

You can also use the console to view a side-by-side comparison of the values in your custom DB cluster parameter group compared to the default DB cluster parameter group, as shown in the following screenshot.

RDS > Parameter groups > Parameters comparison

## Parameters comparison

Parameter	my-db-cluster-param-group-for-mysql-logs	default.aurora-mysql5.7
general_log	1	<engine-default>
log_queries_not_using_indexes	1	<engine-default>
long_query_time	60	<engine-default>
server_audit_events	CONNECT	<engine-default>
server_audit_logging	1	0
server_audit_logs_upload	1	0
slow_query_log	1	<engine-default>

[Close](#)

When you change parameter values on an active DB cluster, Aurora Serverless v1 starts a seamless scale in order to apply the parameter changes. If your Aurora Serverless v1 DB cluster is in a paused state, it resumes and starts scaling so that it can make the change. The scaling operation for a

parameter group change always [forces a capacity change](#), so be aware that modifying parameters might result in dropped connections if a scaling point can't be found during the scaling period.

## Logging for Aurora Serverless v1

By default, error logs for Aurora Serverless v1 are enabled and automatically uploaded to Amazon CloudWatch. You can also have your Aurora Serverless v1 DB cluster upload Aurora database-engine specific logs to CloudWatch. To do this, enable configuration parameters in your custom DB cluster parameter group. Your Aurora Serverless v1 DB cluster then uploads all available logs to Amazon CloudWatch. At this point, you can use CloudWatch to analyze log data, create alarms, and view metrics.

For Aurora MySQL, the following table shows the logs that you can enable. When enabled, they're automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch.

Aurora MySQL log	Description
general_log	Creates the general log. Set to 1 to turn on. Default is off (0).
log_queries_not_using_indexes	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
long_query_time	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 3,1536,000. Default is 0 (not active).
server_audit_events	The list of events to capture in the logs. Supported values are CONNECT, QUERY, QUERY_DCL , QUERY_DDL , QUERY_DML , and TABLE.
server_audit_logging	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.

Aurora MySQL log	Description
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

For Aurora PostgreSQL, the following table shows the logs that you can enable. When enabled, they're automatically uploaded from your Aurora Serverless v1 DB cluster to Amazon CloudWatch along with the regular error logs.

Aurora PostgreSQL log	Description
log_connections	Turned on by default and can't be changed. It logs details for all new client connections.
log_disconnections	Turned on by default and can't be changed. Logs all client disconnections.
log_hostname	Turned off by default and can't be changed. Hostnames aren't logged.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.  To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).

Aurora PostgreSQL log	Description
log_statement	Controls the specific SQL statements that get logged. Supported values are none, ddl, mod, and all. Default is none.

After you turn on logs for Aurora MySQL or Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can view the logs in CloudWatch.

## Viewing Aurora Serverless v1 logs with Amazon CloudWatch

Aurora Serverless v1 automatically uploads ("publishes") to Amazon CloudWatch all logs that are enabled in your custom DB cluster parameter group. You don't need to choose or specify the log types. Uploading logs starts as soon as you enable the log configuration parameter. If you later disable the log parameter, further uploads stop. However, all the logs that have already been published to CloudWatch remain until you delete them.

For more information on using CloudWatch with Aurora MySQL logs, see [Monitoring log events in Amazon CloudWatch](#).

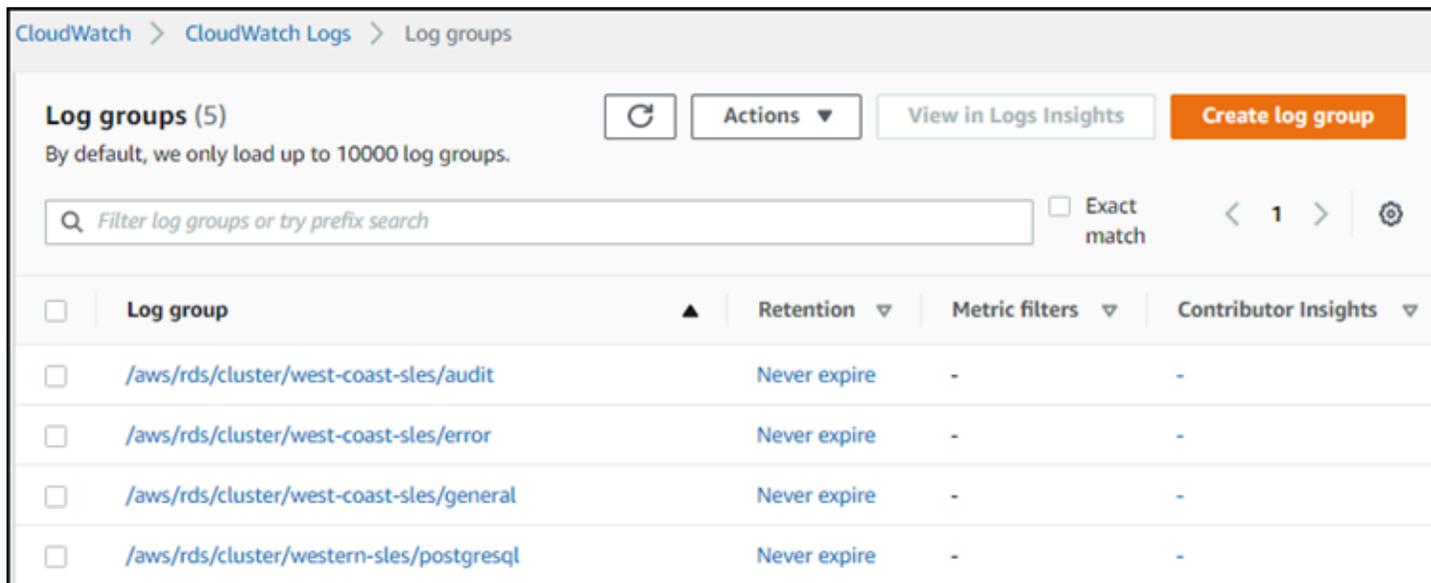

For more information about CloudWatch and Aurora PostgreSQL, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](#).

### To view logs for your Aurora Serverless v1 DB cluster

1. Open the CloudWatch console at <https://console.amazonaws.cn/cloudwatch/>.
2. Choose your Amazon Web Services Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v1 DB cluster log from the list. For error logs, the naming pattern is as follows.

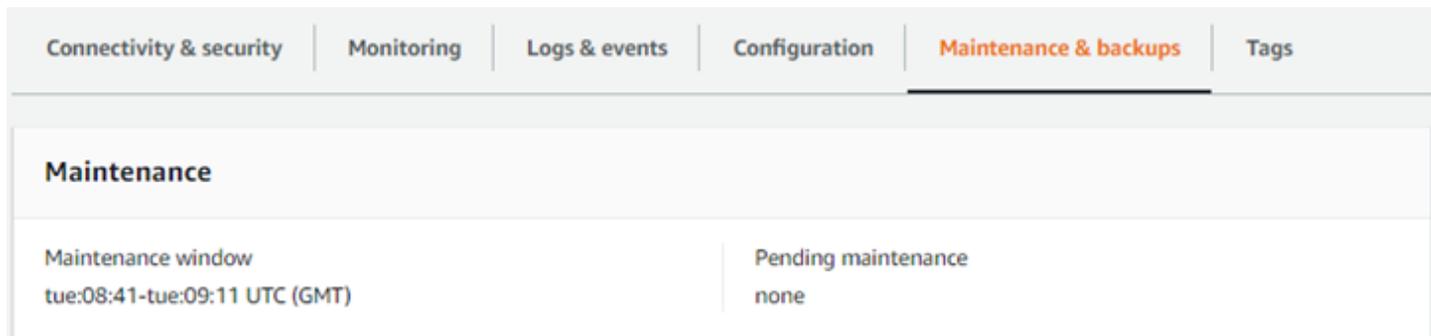

```
/aws/rds/cluster/cluster-name/error
```

For example, in the following screenshot you can find listings for logs published for an Aurora PostgreSQL Aurora Serverless v1 DB cluster named `western-s1es`. You can also find several listings for Aurora MySQL Aurora Serverless v1 DB cluster, `west-coast-s1es`. Choose the log that you're interested in to start exploring its content.

## Aurora Serverless v1 and maintenance

Maintenance for Aurora Serverless v1 DB cluster, such as applying the latest features, fixes, and security updates, is performed automatically for you. Aurora Serverless v1 has a maintenance window that you can view in the Amazon Web Services Management Console in **Maintenance & backups** for your Aurora Serverless v1 DB cluster. You can find the date and time that maintenance might be performed and if any maintenance is pending for your Aurora Serverless v1 DB cluster, as shown in the following figure.

You can set the maintenance window when you create the Aurora Serverless v1 DB cluster, and you can modify the window later. For more information, see [Adjusting the preferred DB cluster maintenance window](#).

Maintenance windows are used for scheduled major version upgrades. Minor version upgrades and patches are applied immediately during scaling. Scaling happens according to your setting for `TimeoutAction`:

- `ForceApplyCapacityChange` – The change is applied immediately.
- `RollbackCapacityChange` – Aurora forcibly updates the cluster after 3 days from the first patch attempt.

As with any change that's forced without an appropriate scaling point, this might interrupt your workload.

Whenever possible, Aurora Serverless v1 performs maintenance in a nondisruptive manner. When maintenance is required, your Aurora Serverless v1 DB cluster scales its capacity to handle the necessary operations. Before scaling, Aurora Serverless v1 looks for a scaling point. It does so for up to three days if necessary.

At the end of each day that Aurora Serverless v1 can't find a scaling point, it creates a cluster event. This event notifies you of the pending maintenance and the need to scale to perform maintenance. The notification includes the date when Aurora Serverless v1 can force the DB cluster to scale.

For more information, see [Timeout action for capacity changes](#).

## Aurora Serverless v1 and failover

If the DB instance for an Aurora Serverless v1 DB cluster becomes unavailable or the Availability Zone (AZ) it's in fails, Aurora recreates the DB instance in a different AZ. However, the Aurora Serverless v1 cluster isn't a Multi-AZ cluster. That's because it consists of a single DB instance in a single AZ. Thus, this failover mechanism takes longer than for an Aurora cluster with provisioned or Aurora Serverless v2 instances. The Aurora Serverless v1 failover time is undefined because it depends on demand and capacity availability in other AZs within the given Amazon Web Services Region.

Because Aurora separates computation capacity and storage, the storage volume for the cluster is spread across multiple AZs. Your data remains available even if outages affect the DB instance or the associated AZ.

## Aurora Serverless v1 and snapshots

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. To copy or share a snapshot of an Aurora Serverless v1 cluster, encrypt the snapshot using your own Amazon KMS key. For more information, see [DB cluster snapshot copying](#). To learn more about encryption and Amazon Aurora, see [Encrypting an Amazon Aurora DB cluster](#)

# Creating an Aurora Serverless v1 DB cluster

## Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

The following procedure creates an Aurora Serverless v1 cluster without any of your schema objects or data. If you want to create an Aurora Serverless v1 cluster that's a duplicate of an existing provisioned or Aurora Serverless v1 cluster, you can perform a snapshot restore or cloning operation instead. For those details, see [Restoring from a DB cluster snapshot](#) and [Cloning a volume for an Amazon Aurora DB cluster](#). You can't convert an existing provisioned cluster to Aurora Serverless v1. You also can't convert an existing Aurora Serverless v1 cluster back to a provisioned cluster.

When you create an Aurora Serverless v1 DB cluster, you can set the minimum and maximum capacity for the cluster. A capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless v1 creates scaling rules for thresholds for CPU utilization, connections, and available memory and seamlessly scales to a range of capacity units as needed for your applications. For more information see [Aurora Serverless v1 architecture](#).

You can set the following specific values for your Aurora Serverless v1 DB cluster:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.

You can also choose the following optional scaling configuration options:

- **Force scaling the capacity to the specified values when the timeout is reached** – You can choose this setting if you want Aurora Serverless v1 to force Aurora Serverless v1 to scale even

if it can't find a scaling point before it times out. If you want Aurora Serverless v1 to cancel capacity changes if it can't find a scaling point, don't choose this setting. For more information, see [Timeout action for capacity changes](#).

- **Pause compute capacity after consecutive minutes of inactivity** – You can choose this setting if you want Aurora Serverless v1 to scale to zero when there's no activity on your DB cluster for an amount of time you specify. With this setting enabled, your Aurora Serverless v1 DB cluster automatically resumes processing and scales to the necessary capacity to handle the workload when database traffic resumes. To learn more, see [Pause and resume for Aurora Serverless v1](#).

Before you can create an Aurora Serverless v1 DB cluster, you need an Amazon account. You also need to have completed the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster](#).

Aurora Serverless v1 is available in certain Amazon Web Services Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora Serverless v1](#).

#### Note

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. When you create your Aurora Serverless v1 DB cluster, you can't turn off encryption, but you can choose to use your own encryption key. With Aurora Serverless v2, you can choose whether to encrypt the cluster volume.

You can create an Aurora Serverless v1 DB cluster with the Amazon CLI or the RDS API.

#### Note

If you receive the following error message when trying to create your cluster, your account needs additional permissions.

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

See [Using service-linked roles for Amazon Aurora](#) for more information.

You can't directly connect to the DB instance on your Aurora Serverless v1 DB cluster. To connect to your Aurora Serverless v1 DB cluster, you use the database endpoint. You can find the endpoint

for your Aurora Serverless v1 DB cluster on the **Connectivity & security** tab for your cluster in the Amazon Web Services Management Console. For more information, see [Connecting to an Amazon Aurora DB cluster](#).

## Amazon CLI

To create a new Aurora Serverless v1 DB cluster with the Amazon CLI, run the [create-db-cluster](#) command and specify `serverless` for the `--engine-mode` option.

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections.

The following command examples create a new Serverless DB cluster by setting the `--engine-mode` option to `serverless`. The examples also specify values for the `--scaling-configuration` option.

### Example for Aurora MySQL

The following command creates a new Aurora MySQL-compatible Serverless DB cluster. Valid capacity values for Aurora MySQL are 1, 2, 4, 8, 16, 32, 64, 128, and 256.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.4 \  
  --engine-mode serverless \  
  --scaling-configuration  
  MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \  
  --master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster ^  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.4 ^  
  --engine-mode serverless ^  
  --scaling-configuration  
  MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^  
  --master-username username --master-user-password password
```

## Example for Aurora PostgreSQL

The following command creates a new PostgreSQL 13.9-compatible Serverless DB cluster. Valid capacity values for Aurora PostgreSQL are 2, 4, 8, 16, 32, 64, 192, and 384.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster \  
  --engine aurora-postgresql --engine-version 13.9 \  
  --engine-mode serverless \  
  --scaling-configuration  
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true \  
  --master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster ^  
  --engine aurora-postgresql --engine-version 13.9 ^  
  --engine-mode serverless ^  
  --scaling-configuration  
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true ^  
  --master-username username --master-user-password password
```

## RDS API

To create a new Aurora Serverless v1 DB cluster with the RDS API, run the [CreateDBCluster](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

# Restoring an Aurora Serverless v1 DB cluster

## Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

You can configure an Aurora Serverless v1 DB cluster when you restore a provisioned DB cluster snapshot with the the Amazon CLI or the RDS API.

When you restore a snapshot to an Aurora Serverless v1 DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see [Timeout action for capacity changes](#).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

For general information about restoring a DB cluster from a snapshot, see [Restoring from a DB cluster snapshot](#).

## Amazon CLI

You can configure an Aurora Serverless DB cluster when you restore a provisioned DB cluster snapshot with the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see [Timeout action for capacity changes](#).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

### Note

The version of the DB cluster snapshot must be compatible with Aurora Serverless v1. For the list of supported versions, see [Aurora Serverless v1](#).

To restore a snapshot to an Aurora Serverless v1 cluster with MySQL 5.7 compatibility, include the following additional parameters:

- `--engine aurora-mysql`
- `--engine-version 5.7`

The `--engine` and `--engine-version` parameters let you create a MySQL 5.7-compatible Aurora Serverless v1 cluster from a MySQL 5.6-compatible Aurora or Aurora Serverless v1 snapshot. The following example restores a snapshot from a MySQL 5.6-compatible cluster

named *mydbclustersnapshot* to a MySQL 5.7-compatible Aurora Serverless v1 cluster named *mynewdbcluster*.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier mynewdbcluster \  
  --snapshot-identifier mydbclustersnapshot \  
  --engine-mode serverless \  
  --engine aurora-mysql \  
  --engine-version 5.7
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^  
  --db-instance-identifier mynewdbcluster ^  
  --db-snapshot-identifier mydbclustersnapshot ^  
  --engine aurora-mysql ^  
  --engine-version 5.7
```

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In the following example, you restore from a previously created DB cluster snapshot named *mydbclustersnapshot* to a new DB cluster named *mynewdbcluster*. You set the `--scaling-configuration` so that the new Aurora Serverless v1 DB cluster can scale from 8 ACUs to 64 ACUs (Aurora capacity units) as needed to process the workload. After processing completes and after 1000 seconds with no connections to support, the cluster shuts down until connection requests prompt it to restart.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier mynewdbcluster \  
  --snapshot-identifier mydbclustersnapshot \  
  --scaling-configuration {  
    "MinCapacity": 8,  
    "MaxCapacity": 64,  
    "AutoPause": true,  
    "AutoPauseTimeout": 1000  
  }
```

```
--engine-mode serverless --scaling-configuration  
MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=10
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^  
  --db-instance-identifier mynewdbcluster ^  
  --db-snapshot-identifier mydbclustersnapshot ^  
  --engine-mode serverless --scaling-configuration  
  MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=10
```

## RDS API

To configure an Aurora Serverless v1 DB cluster when you restore from a DB cluster using the RDS API, run the [RestoreDBClusterFromSnapshot](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

## Modifying an Aurora Serverless v1 DB cluster

### Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

After you configure an Aurora Serverless v1 DB cluster, you can modify certain properties with the Amazon Web Services Management Console, the Amazon CLI, or the RDS API. Most of the properties you can modify are the same as for other kinds of Aurora clusters.

The most relevant changes for Aurora Serverless v1 are the following:

- [Modifying the scaling configuration](#)
- [Converting from Aurora Serverless v1 to provisioned](#)

## Modifying the scaling configuration of an Aurora Serverless v1 DB cluster

You can set the minimum and maximum capacity for the DB cluster. Each capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory. You can also set whether Aurora Serverless pauses the database when there's no activity and then resumes when activity begins again.

You can set the following specific values for the scaling configuration:

- **Minimum Aurora capacity unit** – Aurora Serverless can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless can increase capacity up to this capacity unit.
- **Autoscaling timeout and action** – This section specifies how long Aurora Serverless waits to find a scaling point before timing out. It also specifies the action to take when a capacity modification times out because it can't find a scaling point. Aurora can force the capacity change to set the capacity to the specified value as soon as possible. Or, it can roll back the capacity change to cancel it. For more information, see [Timeout action for capacity changes](#).
- **Pause after inactivity** – Use the optional **Scale the capacity to 0 ACUs when cluster is idle** setting to scale the database to zero processing capacity while it's inactive. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

**Note**

When you modify the capacity range for an Aurora Serverless DB cluster, the change takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

**Console**

You can modify the scaling configuration of an Aurora DB cluster with the Amazon Web Services Management Console.

**To modify an Aurora Serverless v1 DB cluster**

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Modify cluster**.
5. In the **Capacity settings** section, modify the scaling configuration.
6. Choose **Continue**.
7. On the **Modify DB cluster** page, review your modifications, then choose when to apply them.
8. Choose **Modify cluster**.

**Amazon CLI**

To modify the scaling configuration of an Aurora Serverless v1 DB cluster using the Amazon CLI, run the [modify-db-cluster](#) Amazon CLI command. Specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you modify the scaling configuration of an Aurora Serverless v1 DB cluster named *sample-cluster*.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --scaling-configuration  
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --scaling-configuration  
  MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange
```

## RDS API

You can modify the scaling configuration of an Aurora DB cluster with the [ModifyDBCluster](#) API operation. Specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

## Converting an Aurora Serverless v1 DB cluster to provisioned

You can convert an Aurora Serverless v1 DB cluster to a provisioned DB cluster. To perform the conversion, use the Amazon CLI or Amazon RDS API to change the DB instance class to **Provisioned**. Use the steps below to modify your DB instance class.

The following example demonstrates how to use the Amazon CLI to convert an Aurora Serverless v1 DB cluster to a provisioned cluster.

### Amazon CLI

To convert an Aurora Serverless v1 DB cluster to a provisioned cluster, run the [modify-db-cluster](#) Amazon CLI command.

The following parameters are required:

- `--db-cluster-identifier` – The Aurora Serverless v1 DB cluster that you're converting to provisioned.

- `--engine-mode` – Use the value provisioned.
- `--allow-engine-mode-change`
- `--db-cluster-instance-class` – Choose the DB instance class for the provisioned DB cluster based on the capacity of the Aurora Serverless v1 DB cluster.

In this example, you convert an Aurora Serverless v1 DB cluster named `sample-cluster` and use the `db.r5.xlarge` DB instance class.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
--db-cluster-identifier sample-cluster \  
--engine-mode provisioned \  
--allow-engine-mode-change \  
--db-cluster-instance-class db.r5.xlarge
```

For Windows:

```
aws rds modify-db-cluster ^  
--db-cluster-identifier sample-cluster ^  
--engine-mode provisioned ^  
--allow-engine-mode-change ^  
--db-cluster-instance-class db.r5.xlarge
```

The following example demonstrates how to use the Amazon RDS API to convert an Aurora Serverless v1 DB cluster to a provisioned cluster.

## RDS API

To convert an Aurora Serverless v1 DB cluster to a provisioned cluster, use the [ModifyDBCluster](#) API operation.

The following parameters are required:

- `DBClusterIdentifier` – The Aurora Serverless v1 DB cluster that you're converting to provisioned.
- `EngineMode` – Use the value provisioned.
- `AllowEngineModeChange`

- `DBClusterInstanceClass` – Choose the DB instance class for the provisioned DB cluster based on the capacity of the Aurora Serverless v1 DB cluster.

## Considerations when converting from an Aurora Serverless v1 DB cluster to a provisioned cluster

The following considerations apply when an Aurora Serverless v1 DB cluster is converted to a provisioned cluster:

- You can use this conversion as part of upgrading your DB cluster from Aurora Serverless v1 to Aurora Serverless v2. For more information, see [Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2](#).
- The conversion process creates a reader DB instance in the DB cluster, promotes the reader instance to a writer instance, and then deletes the original Aurora Serverless v1 instance. When you convert the DB cluster, you can't perform any other modifications at the same time, such as changing the DB engine version or DB cluster parameter group. The conversion operation is applied immediately, and can't be undone.
- During the conversion, a backup DB cluster snapshot is taken of the DB cluster in case an error occurs. The identifier for the DB cluster snapshot has the form `pre-modify-engine-mode-DB_cluster_identifier-timestamp`.
- Aurora uses the current default DB minor engine version for the provisioned DB cluster.
- If you don't provide a DB instance class for your converted DB cluster, Aurora recommends one based on the maximum capacity of the original Aurora Serverless v1 DB cluster. The recommended capacity to instance class mappings are shown in the following table.

Serverless maximum capacity (ACUs)	Provisioned DB instance class
1	db.t3.small
2	db.t3.medium
4	db.t3.large
8	db.r5.large
16	db.r5.xlarge

Serverless maximum capacity (ACUs)	Provisioned DB instance class
32	db.r5.2xlarge
64	db.r5.4xlarge
128	db.r5.8xlarge
192	db.r5.12xlarge
256	db.r5.16xlarge
384	db.r5.24xlarge

**Note**

Depending on the DB instance class you choose, and your database usage, you might see different costs for a provisioned DB cluster compared to Aurora Serverless v1. If you convert your Aurora Serverless v1 DB cluster to a burstable (db.t\*) DB instance class, you might incur additional costs for using the DB cluster. For more information, see [DB instance class types](#).

## Scaling Aurora Serverless v1 DB cluster capacity manually

**Important**

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

Typically, Aurora Serverless v1 DB clusters scale seamlessly based on the workload. However, capacity might not always scale fast enough to meet sudden extremes, such as an exponential

increase in transactions. In such cases you can initiate the scaling operation manually by setting a new capacity value. After you set the capacity explicitly, Aurora Serverless v1 automatically scales the DB cluster. It does so based on the cooldown period for scaling down.

You can explicitly set the capacity of an Aurora Serverless v1 DB cluster to a specific value with the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

You can set the capacity of an Aurora DB cluster with the Amazon Web Services Management Console.

### To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Set capacity**.
5. In the **Scale database capacity** window, choose the following:
  - a. For the **Scale DB cluster to** drop-down selector, choose the new capacity that you want for your DB cluster.
  - b. For the **If a seamless scaling point cannot be found** check box, choose the behavior that you want for your Aurora Serverless v1 DB cluster's TimeoutAction setting, as follows:
    - Clear this option if you want your capacity to remain unchanged if Aurora Serverless v1 can't find a scaling point before timing out.
    - Select this option if you want to force your Aurora Serverless v1 DB cluster change its capacity even if it can't find a scaling point before timing out. This option can result Aurora Serverless v1 dropping connections that prevent it from finding a scaling point.
  - c. For **seconds**, enter the amount of time you want to allow your Aurora Serverless v1 DB cluster to look for a scaling point before timing out. You can specify anywhere from 10 seconds to 600 seconds (10 minutes). The default is five minutes (300 seconds). This following example forces the Aurora Serverless v1 DB cluster to scale down to 2 ACUs even if it can't find a scaling point within five minutes.

**Scale database capacity** ✕

The new capacity unit for the Aurora Serverless DB cluster *my-database-1* takes effect immediately. Aurora can scale from 2 to 64 Aurora capacity units (minimum and maximum capacity for the DB cluster)

Scale DB cluster to

2  
4GB RAM

If a seamless scaling point cannot be found with the specified seconds, forcibly scale capacity by closing client connections.  
Otherwise, capacity will remain at the current capacity after specified number of seconds

300 seconds  
Min: 10, Max: 600

Cancel **Apply**

6. Choose **Apply**.

To learn more about scaling points, TimeoutAction, and cooldown periods, see [Autoscaling for Aurora Serverless v1](#).

## Amazon CLI

To set the capacity of an Aurora Serverless v1 DB cluster using the Amazon CLI, run the [modify-current-db-cluster-capacity](#) Amazon CLI command, and specify the `--capacity` option. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you set the capacity of an Aurora Serverless v1 DB cluster named *sample-cluster* to *64*.

```
aws rds modify-current-db-cluster-capacity --db-cluster-identifier sample-cluster --capacity 64
```

## RDS API

You can set the capacity of an Aurora DB cluster with the [ModifyCurrentDBClusterCapacity](#) API operation. Specify the `Capacity` parameter. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

## Viewing Aurora Serverless v1 DB clusters

### Important

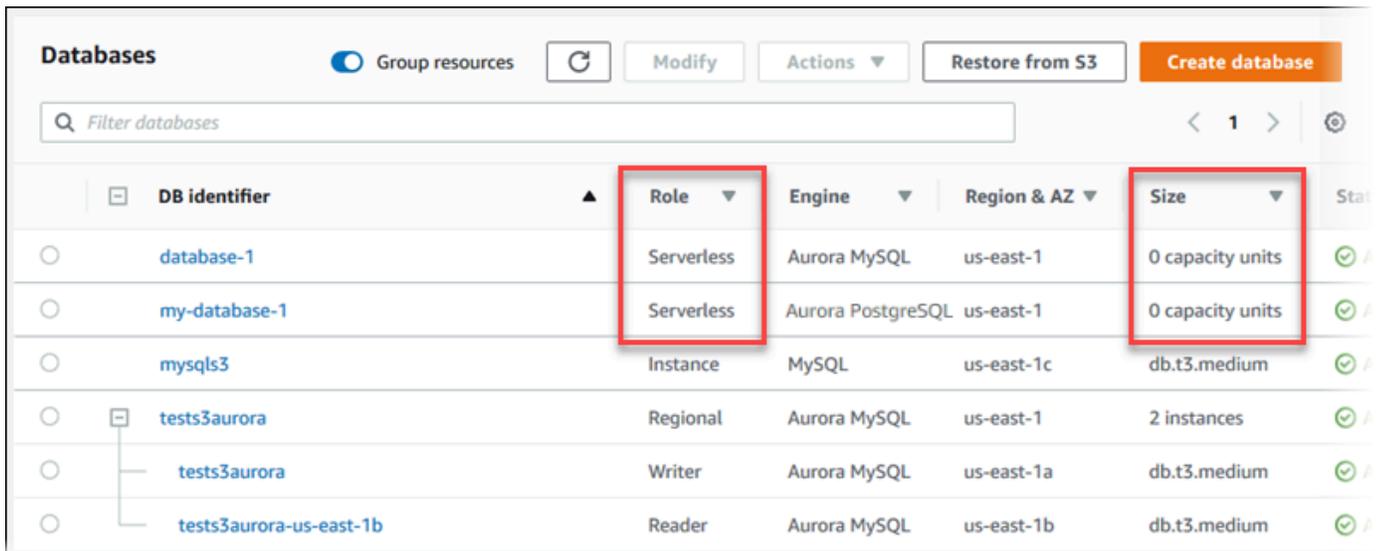

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

After you create one or more Aurora Serverless v1 DB clusters, you can view which DB clusters are type **Serverless** and which are type **Instance**. You can also view the current number of Aurora capacity units (ACUs) each Aurora Serverless v1 DB cluster is using. Each ACU is a combination of processing (CPU) and memory (RAM) capacity.

### To view your Aurora Serverless v1 DB clusters

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the upper-right corner of the Amazon Web Services Management Console, choose the Amazon Web Services Region in which you created the Aurora Serverless v1 DB clusters.
3. In the navigation pane, choose **Databases**.

For each DB cluster, the DB cluster type is shown under **Role**. The Aurora Serverless v1 DB clusters show **Serverless** for the type. You can view an Aurora Serverless v1 DB cluster's current capacity under **Size**.

DB identifier	Role	Engine	Region & AZ	Size	Status
database-1	Serverless	Aurora MySQL	us-east-1	0 capacity units	✓
my-database-1	Serverless	Aurora PostgreSQL	us-east-1	0 capacity units	✓
mysqls3	Instance	MySQL	us-east-1c	db.t3.medium	✓
tests3aurora	Regional	Aurora MySQL	us-east-1	2 instances	✓
tests3aurora	Writer	Aurora MySQL	us-east-1a	db.t3.medium	✓
tests3aurora-us-east-1b	Reader	Aurora MySQL	us-east-1b	db.t3.medium	✓

4. Choose the name of an Aurora Serverless v1 DB cluster to display its details.

On the **Connectivity & security** tab, note the database endpoint. Use this endpoint to connect to your Aurora Serverless v1 DB cluster.

### database-1

**Summary**

DB cluster id database-1	CPU
Role Serverless	Current activity

**Connectivity & security** | Monitoring | Logs & events | Configuration

#### Connectivity & security

<b>Endpoint &amp; port</b>	<b>Network</b>
Endpoint database-1. [redacted] .us-east-1.rds.amazonaws.com	VPC vpc-6
Port 3306	Subnet defau
	Subnet subne

Choose the **Configuration** tab to view the capacity settings.

The screenshot shows the Amazon Aurora console interface. At the top, there are tabs for Connectivity & security, Monitoring, Logs & events, Configuration (selected), Maintenance & backups, and Tags. Below the tabs, the 'Database' section is visible. On the left, the 'Configuration' section lists details for a DB cluster, including Resource id, ARN, DB cluster parameter group, and Deletion protection. On the right, the 'Capacity settings' section is highlighted with a red box and contains the following information:

- Minimum Aurora capacity unit: 2 capacity units
- Maximum Aurora capacity unit: 16 capacity units
- Pause compute capacity after consecutive minutes of inactivity: 5 minutes
- Force scaling the capacity to the specified values when the timeout is reached: Enabled

A *scaling event* is generated when the DB cluster scales up, scales down, pauses, or resumes. Choose the **Logs & events** tab to see recent events. The following image shows examples of these events.

The screenshot shows the Amazon Aurora console interface with the 'Logs & events' tab selected. Below the tabs, the 'Recent events (2)' section is visible. A search bar is present with the placeholder text 'Filter db events'. Below the search bar, there is a table with two columns: 'Time' and 'System notes'. The table contains two rows of events:

Time	System notes
Mon Aug 06 17:04:15 GMT-700 2018	The DB cluster has scaled from 8 capacity units to 4 capacity units.
Mon Aug 06 17:04:09 GMT-700 2018	Scaling DB cluster from 8 capacity units to 4 capacity units for this

## Monitoring capacity and scaling events for your Aurora Serverless v1 DB cluster

You can view your Aurora Serverless v1 DB cluster in CloudWatch to monitor the capacity allocated to the DB cluster with the `ServerlessDatabaseCapacity` metric. You can also monitor all of

the standard Aurora CloudWatch metrics, such as `CPUUtilization`, `DatabaseConnections`, `Queries`, and so on.

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by enabling the [configuration parameters such as `general\_log` and `slow\_query\_log` in the DB cluster parameter group](#) associated with the Aurora Serverless v1 cluster. Unlike provisioned clusters, Aurora Serverless v1 clusters don't require you to specify in the DB cluster settings which log types to upload to CloudWatch. Aurora Serverless v1 clusters automatically upload all the available logs. When you disable a log configuration parameter, publishing of the log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

To get started with Amazon CloudWatch for your Aurora Serverless v1 DB cluster, see [Viewing Aurora Serverless v1 logs with Amazon CloudWatch](#). To learn more about how to monitor Aurora DB clusters through CloudWatch, see [Monitoring log events in Amazon CloudWatch](#).

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For more information, see [Connecting to an Amazon Aurora DB cluster](#).

#### Note

You can't connect directly to specific DB instances in your Aurora Serverless v1 DB clusters.

## Deleting an Aurora Serverless v1 DB cluster

#### Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

Depending on how you create an Aurora Serverless v1 DB cluster, deletion protection might be turned on by default. You can't immediately delete an Aurora Serverless v1 DB cluster that has **Deletion protection** enabled. To delete Aurora Serverless v1 DB clusters that have deletion

protection by using the Amazon Web Services Management Console, you first modify the cluster to remove this protection. For information about using the Amazon CLI for this task, see [Amazon CLI](#).

### To disable deletion protection using the Amazon Web Services Management Console

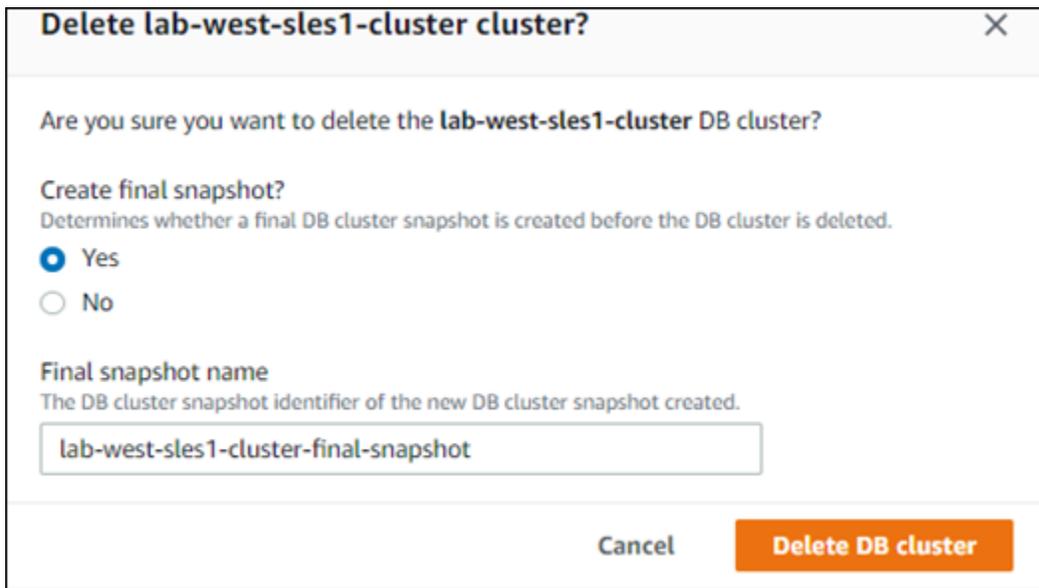

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **DB clusters**.
3. Choose your Aurora Serverless v1 DB cluster from the list.
4. Choose **Modify** to open your DB cluster's configuration. The Modify DB cluster page opens the Settings, Capacity settings, and other configuration details for your Aurora Serverless v1 DB cluster. Deletion protection is in the **Additional configuration** section.
5. Clear the **Enable deletion protection** check box in the **Additional configuration** properties card.
6. Choose **Continue**. The **Summary of modifications** appears.
7. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

After deletion protection is no longer active, you can delete your Aurora Serverless v1 DB cluster by using the Amazon Web Services Management Console.

## Console

### To delete an Aurora Serverless v1 DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the **Resources** section, choose **DB Clusters**.
3. Choose the Aurora Serverless v1 DB cluster that you want to delete.
4. For **Actions**, choose **Delete**. You're prompted to confirm that you want to delete your Aurora Serverless v1 DB cluster.
5. We recommend that you keep the preselected options:
  - **Yes** for **Create final snapshot?**
  - Your Aurora Serverless v1 DB cluster name plus `-final-snapshot` for **Final snapshot name**. However, you can change the name for your final snapshot in this field.

**Delete lab-west-sles1-cluster cluster?**

Are you sure you want to delete the **lab-west-sles1-cluster** DB cluster?

**Create final snapshot?**  
Determines whether a final DB cluster snapshot is created before the DB cluster is deleted.

Yes  
 No

**Final snapshot name**  
The DB cluster snapshot identifier of the new DB cluster snapshot created.

lab-west-sles1-cluster-final-snapshot

Cancel Delete DB cluster

If you choose **No** for **Create final snapshot?** you can't restore your DB cluster using snapshots or point-in-time recovery.

6. Choose **Delete DB cluster**.

Aurora Serverless v1 deletes your DB cluster. If you chose to have a final snapshot, you see your Aurora Serverless v1 DB cluster's status change to "Backing-up" before it's deleted and no longer appears in the list.

## Amazon CLI

Before you begin, configure your Amazon CLI with your Amazon Access Key ID, Amazon Secret Access Key, and the Amazon Web Services Region where your Aurora Serverless v1 DB cluster is. For more information, see [Configuration basics](#) in the Amazon Command Line Interface User Guide.

You can't delete an Aurora Serverless v1 DB cluster until after you first disable deletion protection for clusters configured with this option. If you try to delete a cluster that has this protection option enabled, you see the following error message.

```
An error occurred (InvalidParameterCombination) when calling the DeleteDBCluster operation: Cannot delete protected Cluster, please disable deletion protection and try again.
```

You can change your Aurora Serverless v1 DB cluster's deletion-protection setting by using the [modify-db-cluster](#) Amazon CLI command as shown in the following:

```
aws rds modify-db-cluster --db-cluster-identifier your-cluster-name --no-deletion-protection
```

This command returns the revised properties for the specified DB cluster. You can now delete your Aurora Serverless v1 DB cluster.

We recommend that you always create a final snapshot whenever you delete an Aurora Serverless v1 DB cluster. The following example of using the Amazon CLI [delete-db-cluster](#) shows you how. You provide the name of your DB cluster and a name for the snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster --db-cluster-identifier \  
your-cluster-name --no-skip-final-snapshot \  
--final-db-snapshot-identifier name-your-snapshot
```

For Windows:

```
aws rds delete-db-cluster --db-cluster-identifier ^  
your-cluster-name --no-skip-final-snapshot ^  
--final-db-snapshot-identifier name-your-snapshot
```

## Aurora Serverless v1 and Aurora database engine versions

### Important

Amazon has [announced the end-of-life date for Aurora Serverless v1: March 31st, 2025](#). All Aurora Serverless v1 clusters that are not migrated by March 31, 2025 will be migrated to Aurora Serverless v2 during the maintenance window. If the upgrade fails, Amazon Aurora converts the Serverless v1 cluster to a provisioned cluster with the equivalent engine version during the maintenance window. If applicable, Amazon Aurora will enroll the converted provisioned cluster in Amazon RDS Extended Support. For more information, see [RDS Extended Support](#).

Aurora Serverless v1 is available in certain Amazon Web Services Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For the current list of Amazon Web Services Regions that support Aurora Serverless v1 and the specific Aurora MySQL and Aurora PostgreSQL versions available in each Region, see [Aurora Serverless v1](#).

Aurora Serverless v1 uses its associated Aurora database engine to identify specific supported releases for each database engine supported, as follows:

- Aurora MySQL Serverless
- Aurora PostgreSQL Serverless

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various Amazon Web Services Regions where Aurora Serverless v1 is available. In other words, you don't need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster's DB engine when it's available for Aurora Serverless v1.

## Aurora MySQL Serverless

Aurora Serverless v1 is available in certain Amazon Web Services Regions and for specific Aurora MySQL versions only. For the current list of Amazon Web Services Regions that support Aurora Serverless v1 and the specific Aurora MySQL versions available in each Region, see [Aurora Serverless v1 with Aurora MySQL](#).

To learn about enhancements and bug fixes for Aurora MySQL version 2, see [Database engine updates for Amazon Aurora MySQL version 2](#) in the *Release Notes for Aurora MySQL*.

To use a more recent version of Aurora MySQL, you can use Aurora Serverless v2. For the Amazon Web Services Regions and Aurora MySQL versions that you can use with Aurora Serverless v2, see [Aurora Serverless v2 with Aurora MySQL](#). For usage information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

## Aurora PostgreSQL Serverless

Aurora Serverless v1 is available in certain Amazon Web Services Regions and for specific Aurora PostgreSQL versions only. For the current list of Amazon Web Services Regions that support Aurora Serverless v1 and the specific Aurora PostgreSQL versions available in each Region, see [Aurora Serverless v1 with Aurora PostgreSQL](#).

If you want to use Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you can use the Aurora PostgreSQL 13-compatible versions. Minor releases for Aurora PostgreSQL-Compatible Edition include only changes that are backward-compatible. Your Aurora Serverless v1 DB cluster is transparently upgraded when an Aurora PostgreSQL minor release becomes available for Aurora Serverless v1 in your Amazon Web Services Region.

To use a more recent version of Aurora PostgreSQL, you can use Aurora Serverless v2. For the Amazon Web Services Regions and Aurora PostgreSQL versions that you can use with Aurora Serverless v2, see [Aurora Serverless v2 with Aurora PostgreSQL](#). For usage information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

## **Automatic minor version upgrades for Aurora Serverless v1**

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various Amazon Web Services Regions where Aurora Serverless v1 is available. In other words, you don't need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster's DB engine when it's available for Aurora Serverless v1.

# Using the Amazon RDS Data API

By using RDS Data API (Data API), you can work with a web-services interface to your Aurora DB cluster. Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with Amazon SDKs. You can use the endpoint to run SQL statements without managing connections.

Users don't need to pass credentials with calls to Data API, because Data API uses database credentials stored in Amazon Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also Data API. For more information about authorizing users, see [Authorizing access to the Amazon RDS Data API](#).

You can also use Data API to integrate Amazon Aurora with other Amazon applications such as Amazon Lambda, Amazon AppSync, and Amazon Cloud9. Data API provides a more secure way to use Amazon Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see [Amazon Lambda](#), [Amazon AppSync](#), and [Amazon Cloud9](#).

You can enable Data API when you create the Aurora DB cluster. You can also modify the configuration later. For more information, see [Enabling the Amazon RDS Data API](#).

After you enable Data API, you can also use the query editor to run ad hoc queries without configuring a query tool to access Aurora in a VPC. For more information, see [Using the Aurora query editor](#).

## Topics

- [Region and version availability for the Amazon RDS Data API](#)
- [Using IPv6 with Amazon RDS Data API](#)
- [Limitations for the Amazon RDS Data API](#)
- [Comparing Amazon RDS Data API behaviors for Aurora Serverless v2 and provisioned clusters with Aurora Serverless v1 clusters](#)
- [Authorizing access to the Amazon RDS Data API](#)
- [Enabling the Amazon RDS Data API](#)
- [Creating an Amazon VPC endpoint for the Amazon RDS Data API \(Amazon PrivateLink\)](#)
- [Calling the Amazon RDS Data API](#)
- [Using the Java client library for RDS Data API](#)

- [Logging Amazon RDS Data API calls with Amazon CloudTrail](#)
- [Monitoring RDS Data API queries with Performance Insights](#)

## Region and version availability for the Amazon RDS Data API

For information about the Regions and engine versions available for Data API, see the following sections.

Cluster type	Region and version availability
Aurora PostgreSQL provisioned and Serverless v2	<a href="#">Data API with Aurora PostgreSQL Serverless v2 and provisioned</a>
Aurora MySQL provisioned and Serverless v2	<a href="#">Data API with Aurora MySQL Serverless v2 and provisioned</a>
Aurora PostgreSQL Serverless v1	<a href="#">Data API with Aurora PostgreSQL Serverless v1</a>
Aurora MySQL Serverless v1	<a href="#">Data API with Aurora MySQL Serverless v1</a>

If you require cryptographic modules validated by FIPS 140-2 when accessing Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

## Using IPv6 with Amazon RDS Data API

Amazon RDS Data API supports IPv6 connectivity through dual-stack endpoints. This allows you to connect to Data API using IPv6 addresses while maintaining backward compatibility with IPv4.

### IPv6 endpoint support

Data API provides dual-stack endpoints that support both IPv4 and IPv6 connections. These endpoints use the `.aws` domain instead of the traditional `.amazonaws.com` domain.

## Available endpoint types

### Public dual-stack endpoints

Format: `rds-data.region.api.aws`

Example: `rds-data.us-east-1.api.aws`

### FIPS dual-stack endpoints

Format: `rds-data-fips.region.api.aws`

Example: `rds-data-fips.us-east-1.api.aws`

### PrivateLink IPv6 endpoints

Available through VPC endpoints with IPv6 support

Allows private IPv6 connectivity within your VPC

## Legacy IPv4-only endpoints

The existing `.amazonaws.com` endpoints continue to support IPv4-only connections:

- `rds-data.region.amazonaws.com`
- `rds-data-fips.region.amazonaws.com`

### Note

Legacy endpoints remain unchanged to ensure backward compatibility with existing applications.

## Using IPv6 endpoints

To use IPv6 with Data API, update your application to use the new dual-stack endpoints. Your application will automatically use IPv6 if available, or fall back to IPv4.

For general guidance on setting up IPv6 in your VPC, see [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

You can configure IPv6 endpoints in two ways:

- **Using environment variable:** Set `AWS_USE_DUALSTACK_ENDPOINT=true` in your IPv6 environment. The Amazon CLI and Amazon SDKs will automatically construct the appropriate `api.aws` endpoints without requiring you to specify endpoint URLs manually.
- **Using explicit endpoint URLs:** Specify the dual-stack endpoint URL directly in your Amazon CLI commands or SDK configuration as shown in the examples below.

## Amazon CLI configuration

Configure the Amazon CLI to use IPv6 endpoints by specifying the endpoint URL:

For Linux, macOS, or Unix:

```
aws rds-data execute-statement \  
  --endpoint-url https://rds-data.us-east-1.api.aws \  
  --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster" \  
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret" \  
  --database "mydb" \  
  --sql "SELECT * FROM users LIMIT 10"
```

For Windows:

```
aws rds-data execute-statement ^  
  --endpoint-url https://rds-data.us-east-1.api.aws ^  
  --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster" ^  
  --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret" ^  
  --database "mydb" ^  
  --sql "SELECT * FROM users LIMIT 10"
```

## Amazon SDK configuration

Configure Amazon SDKs to use dual-stack endpoints:

Python

```
import boto3  
  
# Create RDS Data API client with IPv6 dual-stack endpoint  
client = boto3.client(  
    'rds-data',  
    endpoint_url='https://rds-data.us-east-1.api.aws'  
)
```

```
# Execute a SQL statement
response = client.execute_statement(
    resourceArn='arn:aws:rds:us-east-1:123456789012:cluster:my-cluster',
    secretArn='arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret',
    database='mydb',
    sql='SELECT * FROM users LIMIT 10'
)

print(response['records'])
```

## Java

```
import software.amazon.awssdk.services.rdsdata.RdsDataClient;
import software.amazon.awssdk.services.rdsdata.model.ExecuteStatementRequest;
import software.amazon.awssdk.services.rdsdata.model.ExecuteStatementResponse;
import java.net.URI;

// Create RDS Data API client with IPv6 dual-stack endpoint
RdsDataClient client = RdsDataClient.builder()
    .endpointOverride(URI.create("https://rds-data.us-east-1.api.aws"))
    .build();

// Execute a SQL statement
ExecuteStatementRequest request = ExecuteStatementRequest.builder()
    .resourceArn("arn:aws:rds:us-east-1:123456789012:cluster:my-cluster")
    .secretArn("arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret")
    .database("mydb")
    .sql("SELECT * FROM users LIMIT 10")
    .build();

ExecuteStatementResponse response = client.executeStatement(request);
System.out.println(response.records());
```

## JavaScript

```
const { RDSDataClient, ExecuteStatementCommand } = require("@aws-sdk/client-rds-data");

// Create RDS Data API client with IPv6 dual-stack endpoint
const client = new RDSDataClient({
    endpoint: "https://rds-data.us-east-1.api.aws"
});
```

```
// Execute a SQL statement
const command = new ExecuteStatementCommand({
  resourceArn: "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster",
  secretArn: "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret",
  database: "mydb",
  sql: "SELECT * FROM users LIMIT 10"
});

const response = await client.send(command);
console.log(response.records);
```

## Using Amazon PrivateLink with IPv6

You can create VPC endpoints for Data API that support IPv6 connectivity within your VPC. For detailed instructions on creating VPC endpoints for Data API, see [Creating an Amazon VPC endpoint for the Amazon RDS Data API \(Amazon PrivateLink\)](#).

When creating a VPC endpoint for IPv6 support, ensure that:

- Your VPC and subnets are configured to support IPv6
- Security groups allow IPv6 traffic on the required ports (typically 443 for HTTPS)
- Network ACLs are configured to allow IPv6 traffic

## Migration considerations

When migrating to IPv6 endpoints, consider the following:

- **Gradual migration:** You can migrate applications gradually by updating endpoint URLs one application at a time.
- **Network compatibility:** Ensure your network infrastructure supports IPv6 before migrating.
- **Security policies:** Update security group rules and network ACLs to allow IPv6 traffic if needed.
- **Monitoring:** Update monitoring and logging configurations to handle IPv6 addresses.

**Note**

**Database connection addresses:** When using IPv6 endpoints for Data API, the underlying database connections and database logs will still show IPv4 addresses. This is expected behavior and does not affect the functionality of your IPv6-enabled applications.

## Troubleshooting IPv6 connectivity

If you experience issues with IPv6 connectivity, check the following:

### Network configuration

Verify that your network supports IPv6 and that IPv6 routing is configured correctly.

### DNS resolution

Ensure that your DNS resolver can resolve AAAA records for the dual-stack endpoints.

### Security groups

Update security group rules to allow IPv6 traffic on the required ports (typically 443 for HTTPS).

### Client libraries

Verify that your HTTP client libraries support IPv6 and dual-stack connectivity.

## Limitations for the Amazon RDS Data API

RDS Data API has the following limitations:

- You can only execute Data API queries on writer instances in a DB cluster. However, writer instances can accept both write and read queries.
- With Aurora global databases, you can enable Data API on both the primary and secondary DB clusters. However, a secondary cluster doesn't have a writer instance until it's promoted to be the primary. Data API requires access to the writer instance for query processing, even for read queries. As a result, read and write queries sent to the secondary cluster fail while it lacks a writer instance. Once a secondary cluster is promoted and has a writer instance available, Data API queries on that DB instance succeed.
- Data API isn't supported on T DB instance classes.

- For Aurora Serverless v2 and provisioned DB clusters, RDS Data API doesn't support some data types. For the list of supported types, see [the section called “Data API with Aurora Serverless v2 compared with Aurora Serverless v1”](#).
- For Aurora PostgreSQL version 14 and higher databases, Data API only supports `scram-sha-256` for password encryption.
- The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.
- For Aurora Serverless v1, the maximum number of requests per second is 1,000. For all other supported databases, there is no limit.
- The Data API size limit is 64 KB per row in the result set returned by the database. Make sure that each row in a result set is 64 KB or less.

## Comparing Amazon RDS Data API behaviors for Aurora Serverless v2 and provisioned clusters with Aurora Serverless v1 clusters

The most recent enhancements to the Amazon RDS Data APIs make Data APIs available for clusters that use recent versions of PostgreSQL or MySQL engines. These clusters can be configured to use Aurora Serverless v2 or provisioned instance classes such as `db.r6g` or `db.r6i`.

The following sections describe Amazon RDS Data API differences between Aurora Serverless v2 and provisioned DB clusters, and Aurora Serverless v1 DB clusters. Aurora Serverless v1 DB clusters use the `serverless` engine mode. Provisioned DB clusters use the `provisioned` engine mode. An Aurora Serverless v2 DB cluster also uses the `provisioned` engine mode, and contains one or more Aurora Serverless v2 DB instances with the `db.serverless` instance class.

### Maximum number of requests per second

#### Aurora Serverless v1

Data APIs can make up to 1,000 requests per second.

#### Aurora Serverless v2

Data APIs can make an unlimited number of requests per second.

# Enabling or disabling the Amazon RDS Data API on an existing database

## Aurora Serverless v1

- **With the Amazon RDS API**– Use the `ModifyCluster` operation and specify `True` or `False`, as applicable, for the `EnableHttpEndpoint` parameter.
- **With the Amazon CLI**– Use the `modify-db-cluster` operation with the `--enable-http-endpoint` or `--no-enable-http-endpoint` option, as applicable.

## Aurora Serverless v2

- **With the Amazon RDS API**– Use the `EnableHttpEndpoint` and `DisableHttpEndpoint` operations.
- **With the Amazon CLI**: Use the `enable-http-endpoint` and `disable-http-endpoint` operations.

## CloudTrail events

### Aurora Serverless v1

Events from Data API calls are management events. These events are automatically included in a trail by default. For more information, see [the section called “Excluding Data API events from a CloudTrail trail \(Aurora Serverless v1 only\)”](#).

### Aurora Serverless v2

Events from Data API calls are data events. These events are automatically excluded in a trail by default. For more information, see [the section called “Including Data API events in an CloudTrail trail”](#).

## Multistatement support

### Aurora Serverless v1

- For Aurora MySQL, multistatements aren't supported.
- For Aurora PostgreSQL, multistatements return only the first query response.

## Aurora Serverless v2

Multistatements aren't supported. Attempting to execute multiple statements in a single API call returns "An error occurred (ValidationException) when calling the ExecuteStatement operation: Multistatements aren't supported.". To execute multiple statements, make separate ExecuteStatement API calls or use the BatchExecuteStatement for batch processing.

The following example shows the resulting error message from an API call that attempts to execute a multistatement.

```
aws rds-data execute-statement \  
  --resource-arn "arn:aws:rds:region:account:cluster:cluster-name" \  
  --secret-arn "arn:aws:secretsmanager:region:account:secret:secret-name" \  
  --database "your_database" \  
  --sql "SELECT * FROM your_table; Select * FROM next_table;  
  
          "An error occurred (ValidationException) when calling  
the ExecuteStatement operation: Multistatements aren't supported.
```

The following example executes multiple statements with separate ExecuteStatement API calls.

```
aws rds-data execute-statement \  
  --resource-arn "arn:aws:rds:region:account:cluster:cluster-name" \  
  --secret-arn "arn:aws:secretsmanager:region:account:secret:secret-name" \  
  --database "your_database" \  
  --sql "SELECT * FROM your_table;"  
  
aws rds-data execute-statement \  
  --resource-arn "arn:aws:rds:region:account:cluster:cluster-name" \  
  --secret-arn "arn:aws:secretsmanager:region:account:secret:secret-name" \  
  --database "your_database" \  
  --sql "SELECT * FROM next_table;"
```

## Concurrent requests for the same transaction ID

### Aurora Serverless v1

Subsequent requests wait until the current request finishes. Your application needs to handle timeout errors if the waiting period is too long.

## Aurora Serverless v2

When the Data API receives multiple requests with the same transaction ID, it immediately returns this error:

```
DatabaseErrorException: Transaction is still running a query
```

This error occurs in two situations:

- Your application makes asynchronous requests (like JavaScript promises) using the same transaction ID.
- A previous request with that transaction ID is still processing.

The following example shows all requests executed in parallel with `promise.all()`.

```
const api_calls = [];  
for (let i = 0; i < 10; i++) {  
  api_calls.push(  
    client.send(  
      new ExecuteStatementCommand({  
        ...params,  
        sql: `insert into table_name values (i);`,  
        transactionId  
      })  
    )  
  );  
}  
await Promise.all(api_calls);
```

To resolve this error, wait for the current request to finish before sending another request with the same transaction ID or remove the transaction ID to allow parallel requests.

The following example shows an API call that uses sequential execution with the same transaction ID.

```
for (let i = 0; i < 10; i++) {  
  await client.send(  
    new ExecuteStatementCommand({  
      ...params,  
      sql: `insert into table_name values (i);`,  
      transactionId
```

```
    })  
    ).promise()  
);  
}
```

## BatchExecuteStatement behavior

For more information about BatchExecuteStatement, see [BatchExecuteStatement](#).

### Aurora Serverless v1

The generated fields object in the update result includes inserted values.

### Aurora Serverless v2

- For Aurora MySQL, the generated fields object in the update result includes inserted values.
- For Aurora PostgreSQL, the generated fields object is empty.

## ExecuteSQL behavior

For more information about ExecuteSQL, see [ExecuteSQL](#).

### Aurora Serverless v1

The ExecuteSQL operation is deprecated.

### Aurora Serverless v2

The ExecuteSQL operation isn't supported.

## ExecuteStatement behavior

For more information about ExecuteStatement, see [ExecuteStatement](#).

### Aurora Serverless v1

The ExecuteStatement parameter supports the retrieval of multidimensional array columns and all advanced data types.

### Aurora Serverless v2

The `ExecuteStatement` parameter doesn't support multidimensional array columns. It also doesn't support certain PostgreSQL data types, including geometric and monetary types. When a Data API encounters an unsupported data type, it returns this error—`UnsupportedResultException: The result contains the unsupported data type data_type`.

To work around this issue, cast the unsupported data type to `TEXT`. The following example casts an unsupported data type to `TEXT`.

```
SELECT custom_type::TEXT FROM my_table;--
ORSELECT CAST(custom_type AS TEXT) FROM my_table;
```

For a list of supported data types for each Aurora database engine, see [Data API operations reference](#).

## Schema parameter behavior

### Aurora Serverless v1

The Schema parameter isn't supported. When you include the Schema parameter in an API call, the Data API ignores the parameter.

### Aurora Serverless v2

The Schema parameter is deprecated. When you include the Schema parameter in an API call, the Data API returns this error—`ValidationException: The schema parameter isn't supported`. The following example shows a Data API call that returns the `ValidationException` error.

```
aws rds-data execute-statement \  
--resource-arn "arn:aws:rds:region:account:cluster:cluster-name" \  
--secret-arn "arn:aws:secretsmanager:region:account:secret:secret-name" \  
--database "your_database" \  
--schema "your_schema" \  
--sql "SELECT * FROM your_table LIMIT 10"
```

To solve this issue, remove the Schema parameter from your API call.

The following example shows a Data API call with the Schema parameter removed.

```
aws rds-data execute-statement \  
--resource-arn "arn:aws:rds:region:account:cluster:cluster-name" \  
--secret-arn "arn:aws:secretsmanager:region:account:secret:secret-name" \  
--database "your_database" \  
--sql "SELECT * FROM your_table LIMIT 10"
```

## Authorizing access to the Amazon RDS Data API

Users can invoke Amazon RDS Data API (Data API) operations only if they are authorized to do so. You can give a user permission to use Data API by attaching an Amazon Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An Amazon managed policy, `AmazonRDSDataFullAccess`, includes permissions for Data API.

The `AmazonRDSDataFullAccess` policy also includes permissions for the user to get the value of a secret from Amazon Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to Data API. Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with Data API, see [Storing database credentials in Amazon Secrets Manager](#).

The `AmazonRDSDataFullAccess` policy provides complete access (through Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

JSON

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "SecretsManagerDbCredentialsAccess",  
      "Effect": "Allow",
```

```

    "Action": [
      "secretsmanager:GetSecretValue"
    ],
    "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/*"
  },
  {
    "Sid": "RDSDataServiceAccess",
    "Effect": "Allow",
    "Action": [
      "rds-data:BatchExecuteStatement",
      "rds-data:BeginTransaction",
      "rds-data:CommitTransaction",
      "rds-data:ExecuteStatement",
      "rds-data:RollbackTransaction"
    ],
    "Resource": "arn:aws-cn:rds:us-east-2:111122223333:cluster:prod"
  }
]
}

```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (\*).

## Working with tag-based authorization

RDS Data API (Data API) and Secrets Manager both support tag-based authorization. *Tags* are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:

- `environment:production`
- `environment:development`

You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. (If you don't already have tags on your resources and you want to apply them, you can learn more at [Tagging Amazon RDS resources](#).) You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an `environment:production` tag.

Here's how the policy is applied: When a user makes a call using Data API, the request is sent to the service. Data API first verifies that the cluster ARN passed in the request is tagged with `environment:production`. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with `environment:production`. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SecretsManagerDbCredentialsAccess",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
      "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/environment": [
            "production"
          ]
        }
      }
    },
    {
      "Sid": "RDSDataServiceAccess",
      "Effect": "Allow",
      "Action": [
        "rds-data:*"
      ],
      "Resource": "arn:aws-cn:rds:us-east-2:111122223333:cluster:*",
      "Condition": {
        "StringEquals": {
```

```
        "aws:ResourceTag/environment": [
            "production"
        ]
    }
}
}
```

The example shows separate actions for `rds-data` and `secretsmanager` for Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see [Using identity-based policies \(IAM policies\) for Secrets Manager](#).

In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see [Controlling access to Amazon resources using resource tags](#).

#### Note

Both Data API and Amazon Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

## Storing database credentials in Amazon Secrets Manager

When you call the Amazon RDS Data API (Data API), you pass credentials for the Aurora DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

### To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.

For instructions, see [Create a database secret](#) in the *Amazon Secrets Manager User Guide*.

2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` Amazon CLI command.

Note the name and ARN of the secret. You can use them in calls to Data API.

For more information about using Secrets Manager, see the [Amazon Secrets Manager User Guide](#).

To understand how Amazon Aurora manages identity and access management, see [How Amazon Aurora works with IAM](#).

For more information about creating an IAM policy, see [Creating IAM Policies](#) in the *IAM User Guide*. For information about adding an IAM policy to a user, see [Adding and Removing IAM Identity Permissions](#) in the *IAM User Guide*.

## Enabling the Amazon RDS Data API

To use the Amazon RDS Data API (Data API), enable it for your Aurora DB cluster. You can enable Data API when you create or modify the DB cluster.

### Note

Whether Data API is available for your cluster depends on your Aurora version, database engine, and Amazon Region. For older Aurora versions, Data API only works with Aurora Serverless v1 clusters. For newer Aurora versions, Data API works with clusters that use both provisioned and Aurora Serverless v2 instances. To check whether your cluster can use Data API, see [Supported Regions and Aurora DB engines for RDS Data API](#).

### Topics

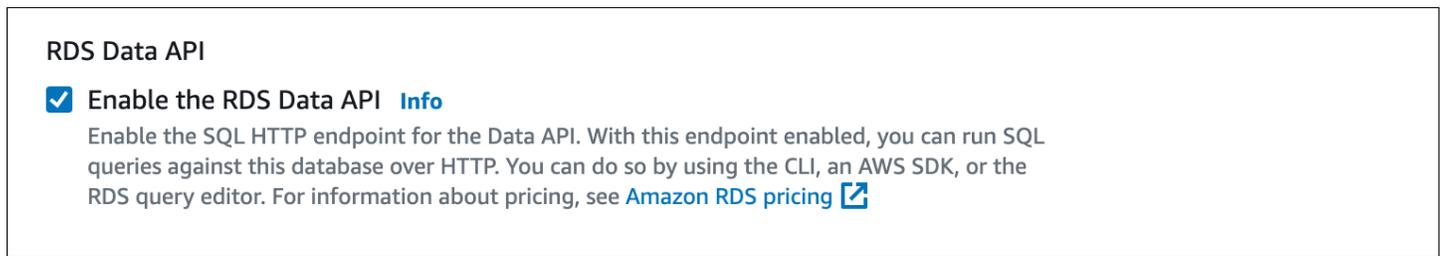

- [Enabling RDS Data API when you create a database](#)
- [Enabling RDS Data API on an existing database](#)

## Enabling RDS Data API when you create a database

While you are creating a database that supports RDS Data API (Data API), you can enable this feature. The following procedures describe how to do so when you use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

## Console

To enable Data API when you create a DB cluster, select the **Enable the RDS Data API** checkbox in the **Connectivity** section of the **Create database** page, as in the following screenshot.

For instructions on how to create an Aurora DB cluster that can use the RDS Data API, see the following:

- For Aurora Serverless v2 and provisioned clusters – [Creating an Amazon Aurora DB cluster](#)
- For Aurora Serverless v1 – [Creating an Aurora Serverless v1 DB cluster](#)

## Amazon CLI

To enable Data API while you're creating an Aurora DB cluster, run the [create-db-cluster](#) Amazon CLI command with the `--enable-http-endpoint` option.

The following example creates an Aurora PostgreSQL DB cluster with Data API enabled.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier my_pg_cluster \  
  --engine aurora-postgresql \  
  --enable-http-endpoint
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier my_pg_cluster ^  
  --engine aurora-postgresql ^  
  --enable-http-endpoint
```

## RDS API

To enable Data API while you're creating an Aurora DB cluster, use the [CreateDBCluster](#) operation with the value of the `EnableHttpEndpoint` parameter set to `true`.

## Enabling RDS Data API on an existing database

You can modify a DB cluster that supports RDS Data API (Data API) to enable or disable this feature.

### Topics

- [Enabling or disabling Data API \(Aurora Serverless v2 and provisioned\)](#)
- [Enabling or disabling Data API \(Aurora Serverless v1 only\)](#)

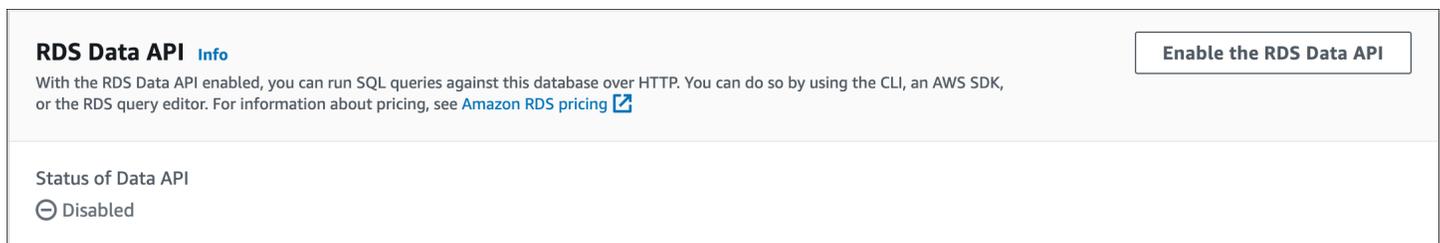

## Enabling or disabling Data API (Aurora Serverless v2 and provisioned)

Use the following procedures to enable or disable Data API on Aurora Serverless v2 and provisioned databases. To enable or disable Data API on Aurora Serverless v1 databases, use the procedures in [the section called “Enabling or disabling Data API \(Aurora Serverless v1 only\)”](#).

### Console

You can enable or disable Data API by using the RDS console for a DB cluster that supports this feature. To do so, open the cluster details page of the database on which you want to enable or disable Data API, and on the **Connectivity & security** tab, go to the **RDS Data API** section. This section displays the status of Data API, and allows you to enable or disable it.

The following screenshot shows that the **RDS Data API** isn't enabled.

### Amazon CLI

To enable or disable Data API on an existing database, run the [enable-http-endpoint](#) or [disable-http-endpoint](#) Amazon CLI command, and specify the ARN of your DB cluster.

The following example enables Data API.

For Linux, macOS, or Unix:

```
aws rds enable-http-endpoint \  
  --resource-arn cluster_arn
```

For Windows:

```
aws rds enable-http-endpoint ^  
  --resource-arn cluster_arn
```

## RDS API

To enable or disable Data API on an existing database, use the [EnableHttpEndpoint](#) and [DisableHttpEndpoint](#) operations.

## Enabling or disabling Data API (Aurora Serverless v1 only)

Use the following procedures to enable or disable Data API on existing Aurora Serverless v1 databases. To enable or disable Data API on Aurora Serverless v2 and provisioned databases, use the procedures in [the section called “Enabling or disabling Data API”](#).

### Console

When you modify an Aurora Serverless v1 DB cluster, you enable Data API in the RDS console's **Connectivity** section.

The following screenshot shows the enabled **Data API** when modifying an Aurora DB cluster.

## Connectivity

**VPC security group (firewall)**  
Choose one or more VPC security groups to allow access to your database. Make sure that the security group rules allow the appropriate incoming traffic.

Choose VPC security groups ▼

default ✕

**Web Service Data API**

**Data API** [Info](#)

Enable the SQL HTTP endpoint, a connectionless Web Service API for running SQL queries against this database. When the SQL HTTP endpoint is enabled, you can also query your database from inside the RDS console (these features are free to use).

For instructions on how to modify an Aurora Serverless v1 DB cluster, see [Modifying an Aurora Serverless v1 DB cluster](#).

## Amazon CLI

To enable or disable Data API, run the [modify-db-cluster](#) Amazon CLI command, with the `--enable-http-endpoint` or `--no-enable-http-endpoint`, as applicable.

The following example enables Data API on `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --enable-http-endpoint
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --enable-http-endpoint
```

## RDS API

To enable Data API, use the [ModifyDBCluster](#) operation, and set the value of `EnableHttpEndpoint` to `true` or `false`, as applicable.

## Creating an Amazon VPC endpoint for the Amazon RDS Data API (Amazon PrivateLink)

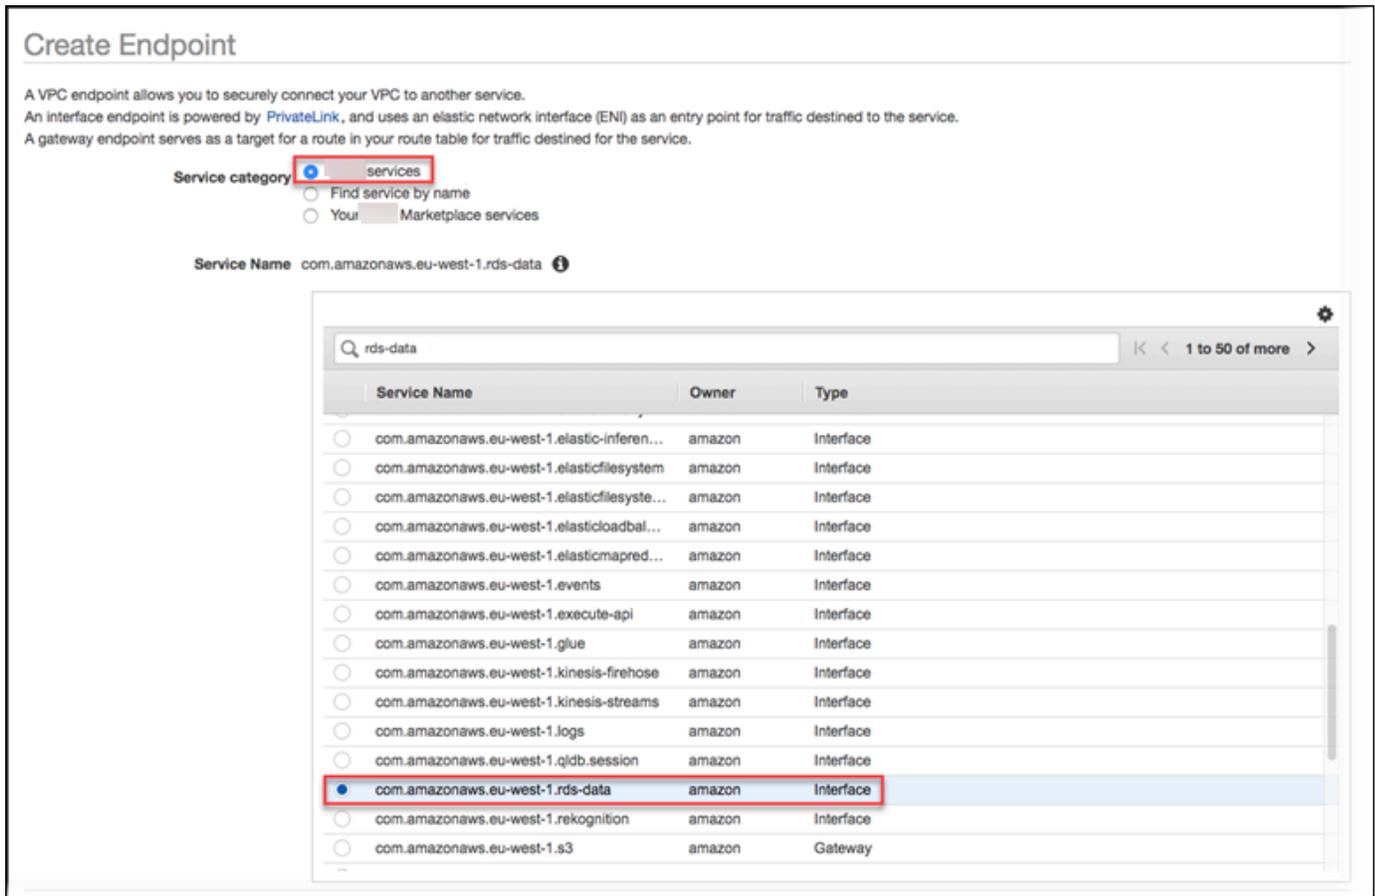

Amazon VPC enables you to launch Amazon resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). Amazon PrivateLink provides private connectivity between VPCs and Amazon services with high security on the Amazon network. Using Amazon PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about Amazon PrivateLink, see [VPC Endpoint Services \(Amazon PrivateLink\)](#) in the *Amazon Virtual Private Cloud User Guide*.

You can call RDS Data API (Data API) with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and Data API in the Amazon network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

### To create an Amazon VPC endpoint for Data API

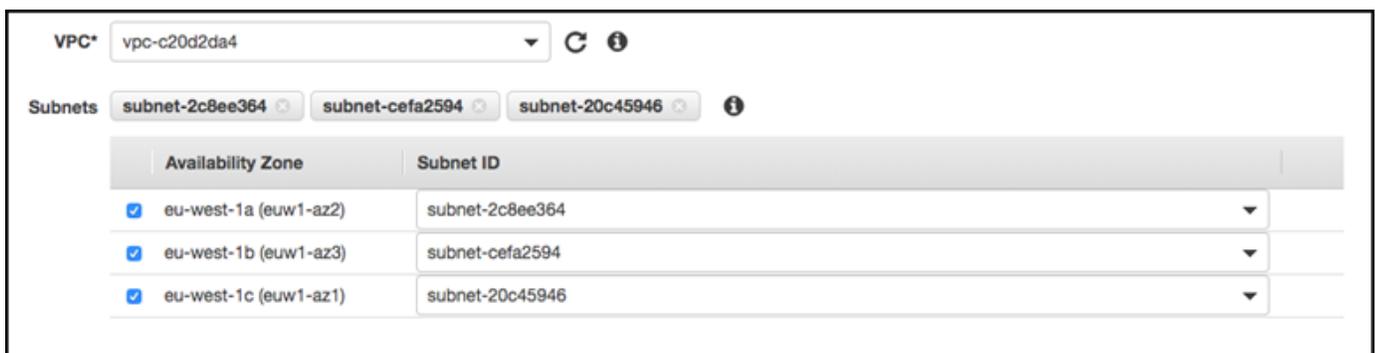

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **Endpoints**, and then choose **Create Endpoint**.
3. On the **Create Endpoint** page, for **Service category**, choose **Amazon services**. For **Service Name**, choose **rds-data**.

- For **VPC**, choose the VPC to create the endpoint in.

Choose the VPC that contains the application that makes Data API calls.

- For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the Amazon service that is running your application.

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

## 6. For **Enable DNS name**, select **Enable for this endpoint**.

Private DNS resolves the standard Data API DNS hostname (<https://rds-data.region.amazonaws.com>) to the private IP addresses associated with the DNS hostname specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the Amazon CLI or Amazon SDKs without making any code or configuration changes to update Data API's endpoint URL.

## 7. For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

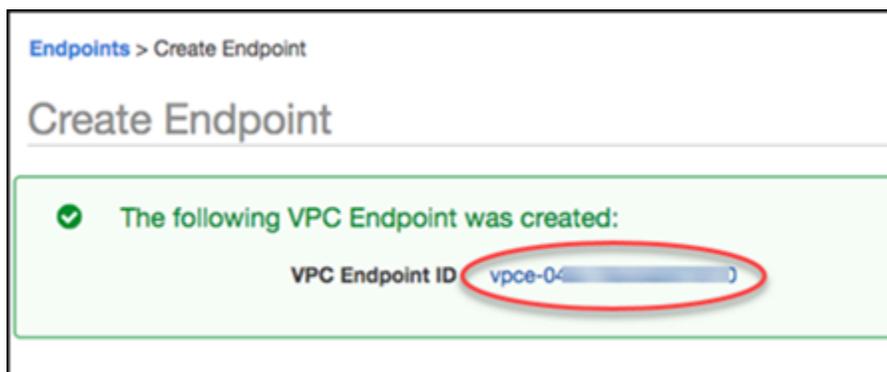

Choose the security group that allows access to the Amazon service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

## 8. For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

If you choose **Custom**, enter the policy in the policy creation tool.

## 9. Choose **Create endpoint**.

After the endpoint is created, choose the link in the Amazon Web Services Management Console to view the endpoint details.

The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.

**Endpoint:** vpce-04ec15ecbab57bf10

**Details** | Subnets | Security Groups | Policy | Notifications | Tags

<b>Endpoint ID</b>	vpce-04ec15ecbab57bf10	<b>VPC ID</b>	vpc-c20d2da4
<b>Status</b>	available	<b>Status message</b>	
<b>Creation time</b>	January 31, 2020 at 7:02:32 PM UTC-8	<b>Service name</b>	com.amazonaws.eu-west-1.rds-data
<b>Endpoint type</b>	Interface	<b>DNS names</b>	vpce-...-rds-data.eu-west-1.vpce.amazonaws.com (...) vpce-...-eu-west-1b.rds-data.eu-west-1.vpce.amazonaws.com (...) vpce-...-eu-west-1c.rds-data.eu-west-1.vpce.amazonaws.com (...) vpce-...-eu-west-1a.rds-data.eu-west-1.vpce.amazonaws.com (...) rds-data.eu-west-1.amazonaws.com (...)
<b>Private DNS names enabled</b>	true	<b>Private DNS name</b>	rds-data.eu-west-1.amazonaws.com

You can use the standard endpoint (`rds-data.region.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling Data API, see [Calling the Amazon RDS Data API](#).

## Calling the Amazon RDS Data API

With the Amazon RDS Data API (Data API) enabled on your Aurora DB cluster, you can run SQL statements on the Aurora DB cluster by using Data API or the Amazon CLI. Data API supports the programming languages supported by the Amazon SDKs. For more information, see [Tools to build on Amazon](#).

### Topics

- [Amazon RDS Data API operations reference](#)
- [Calling the Amazon RDS Data API with the Amazon CLI](#)
- [Calling the Amazon RDS Data API from a Python application](#)
- [Calling the Amazon RDS Data API from a Java application](#)
- [Controlling Data API timeout behavior](#)

## Amazon RDS Data API operations reference

The Amazon RDS Data API provides the following operations to perform SQL statements.

Data API operation	Amazon CLI command	Description
<a href="#">ExecuteStatement</a>	<a href="#">aws rds-data execute-statement</a>	Runs a SQL statement on a database.
<a href="#">BatchExecuteStatement</a>	<a href="#">aws rds-data batch-execute-statement</a>	Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.

You can use either operation to run individual SQL statements or to run transactions. For transactions, Data API provides the following operations.

Data API operation	Amazon CLI command	Description
<a href="#">BeginTransaction</a>	<a href="#">aws rds-data begin-transaction</a>	Starts a SQL transaction.
<a href="#">CommitTransaction</a>	<a href="#">aws rds-data commit-transaction</a>	Ends a SQL transaction and commits the changes.
<a href="#">RollbackTransaction</a>	<a href="#">aws rds-data rollback-transaction</a>	Performs a rollback of a transaction.

The operations for performing SQL statements and supporting transactions have the following common Data API parameters and Amazon CLI options. Some operations support other parameters or options.

Data API operation parameter	Amazon CLI command option	Required	Description
resourceArn	--resource-arn	Yes	The Amazon Resource Name (ARN) of the Aurora DB cluster. The cluster must be in the same Amazon Web Services account as the IAM role or user that invokes the Data API. To access a cluster in a different account, assume a role in that account.
secretArn	--secret-arn	Yes	The name or ARN of the secret that enables access to the DB cluster.

RDS Data API supports the following data types for Aurora MySQL:

- TINYINT(1), BOOLEAN, BOOL
- TINYINT
- SMALLINT [SIGNED | UNSIGNED]
- MEDIUMINT [SIGNED | UNSIGNED]
- INT [SIGNED | UNSIGNED]
- BIGINT [SIGNED | UNSIGNED]
- FLOAT
- DOUBLE
- VARCHAR, CHAR, TEXT, ENUM
- VARBINARY, BINARY, BLOB
- DATE, TIME, DATETIME, TIMESTAMP
- DECIMAL
- JSON

- BIT, BIT(N)

RDS Data API supports following Aurora PostgreSQL scalar types:

- BOOL
- BYTEA
- DATE
- CIDR
- DECIMAL, NUMERIC
- ENUM
- FLOAT8, DOUBLE PRECISION
- INET
- INT, INT4, SERIAL
- INT2, SMALLINT, SMALLSERIAL
- INT8, BIGINT, BIGSERIAL
- JSONB, JSON
- REAL, FLOAT
- TEXT, CHAR(N), VARCHAR, NAME
- TIME
- TIMESTAMP
- UUID
- VECTOR

RDS Data API supports the following Aurora PostgreSQL array types:

- BOOL[], BIT[]
- DATE[]
- DECIMAL[], NUMERIC[]
- FLOAT8[], DOUBLE PRECISION[]
- INT[], INT4[]
- INT2[]
- INT8[], BIGINT[]

- JSON[]
- REAL[], FLOAT[]
- TEXT[], CHAR(N)[], VARCHAR[], NAME[]
- TIME[]
- TIMESTAMP[]
- UUID[]

You can use parameters in Data API calls to `ExecuteStatement` and `BatchExecuteStatement`, and when you run the Amazon CLI commands `execute-statement` and `batch-execute-statement`. To use a parameter, you specify a name-value pair in the `SqlParameter` data type. You specify the value with the `Field` data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

JDBC data type	Data API data type
INTEGER, TINYINT, SMALLINT, BIGINT	LONG (or STRING)
FLOAT, REAL, DOUBLE	DOUBLE
DECIMAL	STRING
BOOLEAN, BIT	BOOLEAN
BLOB, BINARY, LONGVARBINARY, VARBINARY	BLOB
CLOB	STRING
Other types (including types related to date and time)	STRING

### Note

You can specify the LONG or STRING data type in your Data API call for LONG values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.

Certain types, such as `DECIMAL` and `TIME`, require a hint so that Data API passes `String` values to the database as the correct type. To use a hint, include values for `typeHint` in the `SqlParameter` data type. The possible values for `typeHint` are the following:

- `DATE` – The corresponding `String` parameter value is sent as an object of `DATE` type to the database. The accepted format is `YYYY-MM-DD`.
- `DECIMAL` – The corresponding `String` parameter value is sent as an object of `DECIMAL` type to the database.
- `JSON` – The corresponding `String` parameter value is sent as an object of `JSON` type to the database.
- `TIME` – The corresponding `String` parameter value is sent as an object of `TIME` type to the database. The accepted format is `HH:MM:SS[.FFF]`.
- `TIMESTAMP` – The corresponding `String` parameter value is sent as an object of `TIMESTAMP` type to the database. The accepted format is `YYYY-MM-DD HH:MM:SS[.FFF]`.
- `UUID` – The corresponding `String` parameter value is sent as an object of `UUID` type to the database.

 **Note**

Currently, Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

 **Note**

For Amazon Aurora PostgreSQL, Data API always returns the Aurora PostgreSQL data type `TIMESTAMPTZ` in UTC time zone.

## Calling the Amazon RDS Data API with the Amazon CLI

You can call RDS Data API (Data API) using the Amazon CLI.

The following examples use the Amazon CLI for Data API. For more information, see [Amazon CLI reference for the Data API](#).

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

### Note

The Amazon CLI can format responses in JSON.

## Topics

- [Starting a SQL transaction](#)
- [Running a SQL statement](#)
- [Running a batch SQL statement over an array of data](#)
- [Committing a SQL transaction](#)
- [Rolling back a SQL transaction](#)

## Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

### Important

Within Data API, a transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, Data API rolls it back automatically.

MySQL data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each MySQL DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.

In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data begin-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

For Windows:

```
aws rds-data begin-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```
{  
  "transactionId": "ABC1234567890xyz"  
}
```

## Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

### Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.
- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.

- `--parameters` (optional) – The parameters for the SQL statement.
- `--include-result-metadata` | `--no-include-result-metadata` (optional) – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database` (optional) – The name of the database.

The `--database` option might not work when you run a SQL statement after running `--sql "use database_name;"` in the previous request. We recommend that you use the `--database` option instead of running `--sql "use database_name;"` statements.

- `--continue-after-timeout` | `--no-continue-after-timeout` (optional) – A value that indicates whether to continue running the statement after the call exceeds the Data API timeout interval of 45 seconds. The default is `--no-continue-after-timeout`.

For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.

- `--format-records-as "JSON" | "NONE"` – An optional value that specifies whether to format the result set as a JSON string. The default is "NONE". For usage information about processing JSON result sets, see [Processing Amazon RDS Data API query results in JSON format](#).

The DB cluster returns a response for the call.

#### Note

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

For Aurora Serverless v1, the maximum number of requests per second is 1,000. For all other supported databases, there is no limit.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--sql "SELECT * FROM mytable"
```

```
--sql "select * from mytable"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^  
--sql "select * from mytable"
```

The following is an example of the response.

```
{  
  "numberOfRecordsUpdated": 0,  
  "records": [  
    [  
      {  
        "longValue": 1  
      },  
      {  
        "stringValue": "ValueOne"  
      }  
    ],  
    [  
      {  
        "longValue": 2  
      },  
      {  
        "stringValue": "ValueTwo"  
      }  
    ],  
    [  
      {  
        "longValue": 3  
      },  
      {  
        "stringValue": "ValueThree"  
      }  
    ]  
  ]  
}
```

The following CLI command runs a single SQL statement in a transaction by specifying the `--transaction-id` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^  
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
  "numberOfRecordsUpdated": 1  
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--sql "insert into mytable values (:id, :val)" --parameters "[{\\"name\\": \\"id\\",  
  \\"value\\": {\\"longValue\\": 1}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\":  
  \\"value1\\"}}]"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^
```

```
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" --parameters "[{\"name\": \"id\", \"value\": {\"longValue\": 1}}, {\"name\": \"val\", \"value\": {\"stringValue\": \"value1\"}}]"
```

The following is an example of the response.

```
{
  "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column `job` to column `role`.

### Important

For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
```

```
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

The following is an example of the response.

```
{
  "generatedFields": [],
  "numberOfRecordsUpdated": 0
}
```

### Note

The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see [Returning data from modified rows](#) in the PostgreSQL documentation.

## Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

### Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

**Tip**

For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.

- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameter-set` (optional) – The parameter sets for the batch operation.
- `--database` (optional) – The name of the database.

The DB cluster returns a response to the call.

**Note**

There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through Data API is 4 MiB. If the request exceeds this limit, Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

For Aurora Serverless v1, the maximum number of requests per second is 1,000. For all other supported databases, there is no limit.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--sql "insert into mytable values (:id, :val)" \  

```

```
--parameter-sets "[[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 1}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueOne\\"}}],
[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 2}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueTwo\\"}}],
[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 3}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueThree\\"}}]]]"
```

For Windows:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" ^
--parameter-sets "[[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 1}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueOne\\"}}],
[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 2}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueTwo\\"}}],
[{\\"name\\": \\"id\\", \\"value\\": {\\"longValue\\": 3}},{\\"name\\": \\"val\\", \\"value\\": {\\"stringValue\\": \\"ValueThree\\"}}]]]"
```

### Note

Don't include line breaks in the `--parameter-sets` option.

## Committing a SQL transaction

Using the `aws rds-data commit-transaction` CLI command, you can end a SQL transaction that you started with `aws rds-data begin-transaction` and commit the changes.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
aws rds-data commit-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data commit-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^  
--secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^  
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
  "transactionStatus": "Transaction Committed"  
}
```

## Rolling back a SQL transaction

Using the `aws rds-data rollback-transaction` CLI command, you can roll back a SQL transaction that you started with `aws rds-data begin-transaction`. Rolling back a transaction cancels its changes.

### Important

If the transaction ID has expired, the transaction was rolled back automatically. In this case, an `aws rds-data rollback-transaction` command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following Amazon CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data rollback-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" \  
--secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \  
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data rollback-transaction --resource-arn "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster" ^  
--secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^  
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
  "transactionStatus": "Rollback Complete"  
}
```

## Calling the Amazon RDS Data API from a Python application

You can call the Amazon RDS Data API (Data API) from a Python application.

The following examples use the Amazon SDK for Python (Boto). For more information about Boto, see the [Amazon SDK for Python \(Boto 3\) documentation](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

### Topics

- [Running a SQL query](#)
- [Running a DML SQL statement](#)
- [Running a SQL transaction](#)

## Running a SQL query

You can run a SELECT statement and fetch the results with a Python application.

The following example runs a SQL query.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

response1 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'select * from employees limit 3')

print (response1['records'])
[
  [
    {
      'longValue': 1
    },
    {
      'stringValue': 'ROSALEZ'
    },
    {
      'stringValue': 'ALEJANDRO'
    },
    {
      'stringValue': '2016-02-15 04:34:33.0'
    }
  ],
  [
    {
      'longValue': 1
    },
    {
      'stringValue': 'DOE'
    },
    {
      'stringValue': 'JANE'
    },
    {
      'stringValue': '2014-05-09 04:34:33.0'
    }
  ]
]
```

```
],
[
  {
    'longValue': 1
  },
  {
    'stringValue': 'STILES'
  },
  {
    'stringValue': 'JOHN'
  },
  {
    'stringValue': '2017-09-20 04:34:33.0'
  }
]
```

## Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

### Important

If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```
import boto3

cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

rdsData = boto3.client('rds-data')

param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}
param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}
paramSet = [param1, param2]
```

```
response2 = rdsData.execute_statement(resourceArn=cluster_arn,
                                     secretArn=secret_arn,
                                     database='mydb',
                                     sql='insert into employees(first_name, last_name)
                                     VALUES(:firstname, :lastname)',
                                     parameters = paramSet)

print (response2["numberOfRecordsUpdated"])
```

## Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

### Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically. If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

tr = rdsData.begin_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb')

response3 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG)'),
```

```
transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

### Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

## Calling the Amazon RDS Data API from a Java application

You can call the Amazon RDS Data API (Data API) from a Java application.

The following examples use the Amazon SDK for Java. For more information, see the [Amazon SDK for Java Developer Guide](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

### Topics

- [Running a SQL query](#)
- [Running a SQL transaction](#)
- [Running a batch SQL operation](#)

## Running a SQL query

You can run a SELECT statement and fetch the results with a Java application.

The following example runs a SQL query.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
import com.amazonaws.services.rdsdata.model.Field;

import java.util.List;

public class FetchResultsExample {
    public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        ExecuteStatementRequest request = new ExecuteStatementRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb")
            .withSql("select * from mytable");

        ExecuteStatementResult result = rdsData.executeStatement(request);

        for (List<Field> fields: result.getRecords()) {
            String stringValue = fields.get(0).getStringValue();
            long numberValue = fields.get(1).getLongValue();

            System.out.println(String.format("Fetched row: string = %s, number = %d",
                stringValue, numberValue));
        }
    }
}
```

## Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

### Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

public class TransactionExample {
    public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb");
        BeginTransactionResult beginTransactionResult =
            rdsData.beginTransaction(beginTransactionRequest);
        String transactionId = beginTransactionResult.getTransactionId();

        ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
```

```
        .withTransactionId(transactionId)
        .withResourceArn(RESOURCE_ARN)
        .withSecretArn(SECRET_ARN)
        .withSql("INSERT INTO test_table VALUES ('hello world!')");
rdsData.executeStatement(executeStatementRequest);

CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
    .withTransactionId(transactionId)
    .withResourceArn(RESOURCE_ARN)
    .withSecretArn(SECRET_ARN);
rdsData.commitTransaction(commitTransactionRequest);
}
}
```

### Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

## Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

### Important

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
```

```
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
    public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
            .withDatabase("test")
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
            .withParameterSets(Arrays.asList(
                Arrays.asList(
                    new SqlParameter().withName("string").withValue(new
Field().withStringValue("Hello")),
                    new SqlParameter().withName("number").withValue(new
Field().withLongValue(1L))
                ),
                Arrays.asList(
                    new SqlParameter().withName("string").withValue(new
Field().withStringValue("World")),
                    new SqlParameter().withName("number").withValue(new
Field().withLongValue(2L))
                )
            ));

        rdsData.batchExecuteStatement(request);
    }
}
```

## Controlling Data API timeout behavior

All calls to the Data API are synchronous. Suppose that you perform a Data API operation that runs a SQL statement such as `INSERT` or `CREATE TABLE`. If the Data API call returns successfully, the SQL processing is finished when the call returns.

By default, the Data API cancels an operation and returns a timeout error if the operation doesn't finish processing within 45 seconds. In that case, the data isn't inserted, the table isn't created, and so on.

You can use the Data API to perform long-running operations that can't complete within 45 seconds. If you expect that an operation such as a bulk INSERT or a DDL operation on a large table takes longer than 45 seconds, you can specify the `continueAfterTimeout` parameter for the `ExecuteStatement` operation. Your application still receives the timeout error. However, the operation continues running and isn't canceled. For an example, see [Running a SQL transaction](#).

If the Amazon SDK for your programming language has its own timeout period for API calls or HTTP socket connections, make sure that all such timeout periods are more than 45 seconds. For some SDKs, the timeout period is less than 45 seconds by default. We recommend setting any SDK-specific or client-specific timeout periods to at least one minute. Doing so avoids the possibility that your application receives a timeout error while the Data API operation still completes successfully. That way, you can be sure whether to retry the operation or not.

For example, suppose that the SDK returns a timeout error to your application, but the Data API operation still completes within the Data API timeout interval. In that case, retrying the operation might insert duplicate data or otherwise produce incorrect results. The SDK might retry the operation automatically, causing incorrect data without any action from your application.

The timeout interval is especially important for the Java 2 SDK. In that SDK, the API call timeout and the HTTP socket timeout are both 30 seconds by default. Here is an example of setting those timeouts to a higher value:

```
public RdsDataClient createRdsDataClient() {
    return RdsDataClient.builder()
        .region(Region.US_EAST_1) // Change this to your desired Region
        .overrideConfiguration(createOverrideConfiguration())
        .httpClientBuilder(createHttpClientBuilder())
        .credentialsProvider(defaultCredentialsProvider()) // Change this to your
desired credentials provider
        .build();
}

private static ClientOverrideConfiguration createOverrideConfiguration() {
    return ClientOverrideConfiguration.builder()
        .apiCallTimeout(Duration.ofSeconds(60))
        .build();
}
```

```
private HttpClientBuilder createHttpClientBuilder() {
    return ApacheHttpClient.builder() // Change this to your desired HttpClient
        .socketTimeout(Duration.ofSeconds(60));
}
```

Here is an equivalent example using the asynchronous data client:

```
public static RdsDataAsyncClient createRdsDataAsyncClient() {
    return RdsDataAsyncClient.builder()
        .region(Region.US_EAST_1) // Change this to your desired Region
        .overrideConfiguration(createOverrideConfiguration())
        .credentialsProvider(defaultCredentialsProvider()) // Change this to your
desired credentials provider
        .build();
}

private static ClientOverrideConfiguration createOverrideConfiguration() {
    return ClientOverrideConfiguration.builder()
        .apiCallAttemptTimeout(Duration.ofSeconds(60))
        .build();
}

private HttpClientBuilder createHttpClientBuilder() {
    return NettyNioAsyncHttpClient.builder() // Change this to your desired
AsyncHttpClient
        .readTimeout(Duration.ofSeconds(60));
}
```

## Using the Java client library for RDS Data API

You can download and use a Java client library for RDS Data API (Data API). This Java client library provides an alternative way to use Data API. Using this library, you can map your client-side classes to Data API requests and responses. This mapping support can ease integration with some specific Java types, such as Date, Time, and BigDecimal.

### Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

<https://github.com/awslabs/rds-data-api-client-library-java>

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with Amazon SDK 2.x, use the following:

```
<dependency>
  <groupId>software.amazon.rdsdata</groupId>
  <artifactId>rds-data-api-client-library-java</artifactId>
  <version>2.0.0</version>
</dependency>
```

For version 1.x, which is compatible with Amazon SDK 1.x, use the following:

```
<dependency>
  <groupId>software.amazon.rdsdata</groupId>
  <artifactId>rds-data-api-client-library-java</artifactId>
  <version>1.0.8</version>
</dependency>
```

## Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table `accounts` with two columns: `accountId` and `name`. You also have the following data transfer object (DTO).

```
public class Account {
    int accountId;
    String name;
    // getters and setters omitted
}
```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameters sets.

```
var account1 = new Account(1, "John");
var account2 = new Account(2, "Mary");
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParamSets(account1, account2)
    .execute();
```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParameter("accountId", 3)
    .withParameter("name", "Zhang")
    .execute();
```

The following is another example that works with simple values as input parameters.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
    .execute();
```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```
List<Account> result = client.forSql("SELECT * FROM accounts")
    .execute()
    .mapToList(Account.class);

Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
    .execute()
    .mapToSingle(Account.class);
```

In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```
int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
    .execute()
    .singleValue(Integer.class);
```

### Note

The `mapToList` function converts a SQL result set into a user-defined object list. We don't support using the `.withFormatRecordsAs(RecordsFormatType.JSON)` statement in an `ExecuteStatement` call for the Java client library, because it serves the same purpose. For more information, see [Processing Amazon RDS Data API query results in JSON format](#).

# Processing Amazon RDS Data API query results in JSON format

When you call the `ExecuteStatement` operation, you can choose to have the query results returned as a string in JSON format. That way, you can use your programming language's JSON parsing capabilities to interpret and reformat the result set. Doing so can help to avoid writing extra code to loop through the result set and interpret each column value.

To request the result set in JSON format, you pass the optional `formatRecordsAs` parameter with a value of `JSON`. The JSON-formatted result set is returned in the `formattedRecords` field of the `ExecuteStatementResponse` structure.

The `BatchExecuteStatement` action doesn't return a result set. Thus, the JSON option doesn't apply to that action.

To customize the keys in the JSON hash structure, define column aliases in the result set. You can do so by using the `AS` clause in the column list of your SQL query.

You might use the JSON capability to make the result set easier to read and map its contents to language-specific frameworks. Because the volume of the ASCII-encoded result set is larger than the default representation, you might choose the default representation for queries that return large numbers of rows or large column values that consume more memory than is available to your application.

## Topics

- [Retrieving query results in JSON format](#)
- [Data Type Mapping](#)
- [Troubleshooting](#)
- [Examples](#)

## Retrieving query results in JSON format

To receive the result set as a JSON string, include `.withFormatRecordsAs(RecordsFormatType.JSON)` in the `ExecuteStatement` call. The return value comes back as a JSON string in the `formattedRecords` field. In this case, the `columnMetadata` is `null`. The column labels are the keys of the object that represents each row. These column names are repeated for each row in the result set. The column values are quoted

strings, numeric values, or special values representing `true`, `false`, or `null`. Column metadata such as length constraints and the precise type for numbers and strings isn't preserved in the JSON response.

If you omit the `.withFormatRecordsAs()` call or specify a parameter of `NONE`, the result set is returned in binary format using the `Records` and `columnMetadata` fields.

## Data Type Mapping

The SQL values in the result set are mapped to a smaller set of JSON types. The values are represented in JSON as strings, numbers, and some special constants such as `true`, `false`, and `null`. You can convert these values into variables in your application, using strong or weak typing as appropriate for your programming language.

JDBC data type	JSON data type
INTEGER, TINYINT, SMALLINT, BIGINT	Number by default. String if the <code>LongReturnTypes</code> option is set to <code>STRING</code> .
FLOAT, REAL, DOUBLE	Number
DECIMAL	String by default. Number if the <code>DecimalReturnType</code> option is set to <code>DOUBLE_OR_LONG</code> .
STRING	String
BOOLEAN, BIT	Boolean
BLOB, BINARY, VARBINARY, LONGVARBINARY	String in base64 encoding.
CLOB	String
ARRAY	Array
NULL	<code>null</code>
Other types (including types related to date and time)	String

## Troubleshooting

The JSON response is limited to 10 megabytes. If the response is larger than this limit, your program receives a `BadRequestException` error. In this case, you can resolve the error using one of the following techniques:

- Reduce the number of rows in the result set. To do so, add a `LIMIT` clause. You might split a large result set into multiple smaller ones by submitting several queries with `LIMIT` and `OFFSET` clauses.

If the result set includes rows that are filtered out by application logic, you can remove those rows from the result set by adding more conditions in the `WHERE` clause.

- Reduce the number of columns in the result set. To do so, remove items from the select list of the query.
- Shorten the column labels by using column aliases in the query. Each column name is repeated in the JSON string for each row in the result set. Thus, a query result with long column names and many rows could exceed the size limit. In particular, use column aliases for complicated expressions to avoid having the entire expression repeated in the JSON string.
- Although with SQL you can use column aliases to produce a result set having more than one column with the same name, duplicate key names aren't allowed in JSON. The RDS Data API returns an error if you request the result set in JSON format and more than one column has the same name. Thus, make sure that all the column labels have unique names.

## Examples

The following Java examples show how to call `ExecuteStatement` with the response as a JSON-formatted string, then interpret the result set. Substitute the appropriate values for the *databaseName*, *secretStoreArn*, and *clusterArn* parameters.

The following Java example demonstrates a query that returns a decimal numeric value in the result set. The `assertThat` calls test that the fields of the response have the expected properties based on the rules for JSON result sets.

This example works with the following schema and sample data:

```
create table test_simplified_json (a float);
insert into test_simplified_json values(10.0);
```

```
public void JSON_result_set_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
        .withDatabase(databaseName)
        .withSecretArn(secretStoreArn)
        .withResourceArn(clusterArn)
        .withSql(sql)
        .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request);
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":10.0}]
```

The `Records` and `ColumnMetadata` fields in the response are both null, due to the presence of the JSON result set.

The following Java example demonstrates a query that returns an integer numeric value in the result set. The example calls `getFormattedRecords` to return only the JSON-formatted string and ignore the other response fields that are blank or null. The example deserializes the result into a structure representing a list of records. Each record has fields whose names correspond to the column aliases from the result set. This technique simplifies the code that parses the result set. Your application doesn't have to loop through the rows and columns of the result set and convert each value to the appropriate type.

This example works with the following schema and sample data:

```
create table test_simplified_json (a int);
insert into test_simplified_json values(17);
```

```
public void JSON_deserialization_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
        .withDatabase(databaseName)
        .withSecretArn(secretStoreArn)
        .withResourceArn(clusterArn)
        .withSql(sql)
        .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request)
        .getFormattedRecords();
}
```

```
/* Turn the result set into a Java object, a list of records.
   Each record has a field 'a' corresponding to the column
   labelled 'a' in the result set. */
private static class Record { public int a; }
var recordsList = new ObjectMapper().readValue(
    response, new TypeReference<List<Record>>() {
    });
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":17}]
```

To retrieve the `a` column of result row 0, the application would refer to `recordsList.get(0).a`.

In contrast, the following Java example shows the kind of code that's required to construct a data structure holding the result set when you don't use the JSON format. In this case, each row of the result set contains fields with information about a single user. Building a data structure to represent the result set requires looping through the rows. For each row, the code retrieves the value of each field, performs an appropriate type conversion, and assigns the result to the corresponding field in the object representing the row. Then the code adds the object representing each user to the data structure representing the entire result set. If the query was changed to reorder, add, or remove fields in the result set, the application code would have to change also.

```
/* Verbose result-parsing code that doesn't use the JSON result set format */
for (var row: response.getRecords()) {
    var user = User.builder()
        .userId(row.get(0).getLongValue())
        .firstName(row.get(1).getStringValue())
        .lastName(row.get(2).getStringValue())
        .dob(Instant.parse(row.get(3).getStringValue()))
        .build();
    result.add(user);
}
```

The following sample values show the values of the `formattedRecords` field for result sets with different numbers of columns, column aliases, and column data types.

If the result set includes multiple rows, each row is represented as an object that is an array element. Each column in the result set becomes a key in the object. The keys are repeated for each

row in the result set. Thus, for result sets consisting of many rows and columns, you might need to define short column aliases to avoid exceeding the length limit for the entire response.

This example works with the following schema and sample data:

```
create table sample_names (id int, name varchar(128));
insert into sample_names values (0, "Jane"), (1, "Mohan"), (2, "Maria"), (3, "Bruce"),
(4, "Jasmine");
```

```
[{"id":0,"name":"Jane"}, {"id":1,"name":"Mohan"},
{"id":2,"name":"Maria"}, {"id":3,"name":"Bruce"}, {"id":4,"name":"Jasmine"}]
```

If a column in the result set is defined as an expression, the text of the expression becomes the JSON key. Thus, it's typically convenient to define a descriptive column alias for each expression in the select list of the query. For example, the following query includes expressions such as function calls and arithmetic operations in its select list.

```
select count(*), max(id), 4+7 from sample_names;
```

Those expressions are passed through to the JSON result set as keys.

```
[{"count(*)":5,"max(id)":4,"4+7":11}]
```

Adding AS columns with descriptive labels makes the keys simpler to interpret in the JSON result set.

```
select count(*) as rows, max(id) as largest_id, 4+7 as addition_result from
sample_names;
```

With the revised SQL query, the column labels defined by the AS clauses are used as the key names.

```
[{"rows":5,"largest_id":4,"addition_result":11}]
```

The value for each key-value pair in the JSON string can be a quoted string. The string might contain unicode characters. If the string contains escape sequences or the " or \ characters, those characters are preceded by backslash escape characters. The following examples of JSON strings

demonstrate these possibilities. For example, the `string_with_escape_sequences` result contains the special characters backspace, newline, carriage return, tab, form feed, and `\`.

```
[{"quoted_string":"hello"}]
[{"unicode_string":"####"}]
[{"string_with_escape_sequences":"\b \n \r \t \f \\ \'"}]
```

The value for each key-value pair in the JSON string can also represent a number. The number might be an integer, a floating-point value, a negative value, or a value represented as exponential notation. The following examples of JSON strings demonstrate these possibilities.

```
[{"integer_value":17}]
[{"float_value":10.0}]
[{"negative_value":-9223372036854775808,"positive_value":9223372036854775807}]
[{"very_small_floating_point_value":4.9E-324,"very_large_floating_point_value":1.79769313486231}
```

Boolean and null values are represented with the unquoted special keywords `true`, `false`, and `null`. The following examples of JSON strings demonstrate these possibilities.

```
[{"boolean_value_1":true,"boolean_value_2":false}]
[{"unknown_value":null}]
```

If you select a value of a BLOB type, the result is represented in the JSON string as a base64-encoded value. To convert the value back to its original representation, you can use the appropriate decoding function in your application's language. For example, in Java you call the function `Base64.getDecoder().decode()`. The following sample output shows the result of selecting a BLOB value of `hello world` and returning the result set as a JSON string.

```
[{"blob_column":"aGVsbG8gd29ybGQ="}]
```

The following Python example shows how to access the values from the result of a call to the Python `execute_statement` function. The result set is a string value in the field `response['formattedRecords']`. The code turns the JSON string into a data structure by calling the `json.loads` function. Then each row of the result set is a list element within the data structure, and within each row you can refer to each field of the result set by name.

```
import json
```

```
result = json.loads(response['formattedRecords'])
print (result[0]["id"])
```

The following JavaScript example shows how to access the values from the result of a call to the JavaScript `executeStatement` function. The result set is a string value in the field `response.formattedRecords`. The code turns the JSON string into a data structure by calling the `JSON.parse` function. Then each row of the result set is an array element within the data structure, and within each row you can refer to each field of the result set by name.

```
<script>
  const result = JSON.parse(response.formattedRecords);
  document.getElementById("display").innerHTML = result[0].id;
</script>
```

## Troubleshooting Amazon RDS Data API

Use the following sections, titled with common error messages, to help troubleshoot problems that you have with the Amazon RDS Data API (Data API).

### Topics

- [Transaction <transaction\\_ID> isn't found](#)
- [Packet for query is too large](#)
- [Database response exceeded size limit](#)
- [HttpEndpoint isn't enabled for cluster <cluster\\_ID>](#)
- [DatabaseErrorException: Transaction is still running a query](#)
- [Unsupported result exception](#)
- [Multi-statements aren't supported](#)
- [Schema parameter isn't supported](#)
- [IPv6 connectivity issues](#)

### Transaction <transaction\_ID> isn't found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is appended to the error message, and is one of the following:

- Transaction may be expired.

Make sure that each transactional call runs within three minutes of the previous one.

It's also possible that the specified transaction ID wasn't created by a [BeginTransaction](#) call. Make sure that your call has a valid transaction ID.

- One previous call resulted in a termination of your transaction.

The transaction was already ended by your `CommitTransaction` or `RollbackTransaction` call.

- Transaction has been aborted due to an error from a previous call.

Check whether your previous calls have thrown any exceptions.

For information about running transactions, see [Calling the Amazon RDS Data API](#).

## Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the result set returned by the database.

To solve this issue, make sure that each row in a result set is 64 KB or less.

## Database response exceeded size limit

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple [ExecuteStatement](#) calls with the LIMIT clause in your query.

For more information about the LIMIT clause, see [SELECT syntax](#) in the MySQL documentation.

## HttpEndpoint isn't enabled for cluster <cluster\_ID>

Check the following potential causes for this issue:

- The Aurora DB cluster doesn't support Data API. For information about the types of DB clusters RDS Data API supports, see [the section called "Region and version availability for the Amazon RDS Data API"](#).

- Data API isn't enabled for the Aurora DB cluster. To use Data API with an Aurora DB cluster, Data API must be enabled for the DB cluster. For information about enabling Data API, see [Enabling the Amazon RDS Data API](#).
- The DB cluster was renamed after Data API was enabled for it. In that case, turn off Data API for that cluster and then enable it again.
- The ARN you specified doesn't precisely match the ARN of the cluster. Check that the ARN returned from another source or constructed by program logic matches the ARN of the cluster exactly. For example, make sure that the ARN you use has the correct letter case for all alphabetic characters.

## DatabaseErrorException: Transaction is still running a query

If your application sends a request with a transaction ID and that transaction is currently processing another request, Data API returns this error to your application immediately. This condition might arise if your application makes asynchronous requests, using a mechanism such as "promises" in Javascript.

To solve this issue, wait until the previous request finishes and then retry the request. You can keep retrying until the error no longer occurs, or the application receives some different kind of error.

This condition can happen with Data API for Aurora Serverless v2 and provisioned instances. In Data API for Aurora Serverless v1, subsequent requests for the same transaction ID automatically wait for the previous request to finish. However, that older behavior potentially could encounter timeouts due to the previous request taking too long. If you are porting an older Data API application that makes concurrent requests, modify your exception handling logic to account for this new kind of error.

## Unsupported result exception

The Data API doesn't support all data types. This error occurs when you execute a query that returns an unsupported data type.

To work around this issue, cast the unsupported data type to TEXT. For example:

```
SELECT custom_type::TEXT FROM my_table;  
-- OR  
SELECT CAST(custom_type AS TEXT) FROM my_table;
```

## Multi-statements aren't supported

Multi-statements are not supported in the Data API for Aurora Serverless v2 and provisioned clusters. Attempting to execute multiple statements in a single API call results in this error.

To execute multiple statements, use separate `ExecuteStatement` API calls or use the `BatchExecuteStatement` API for batch processing.

## Schema parameter isn't supported

Aurora Serverless v1 silently ignores the schema parameter. However, Aurora Serverless v2 and provisioned clusters explicitly reject API calls that include the schema parameter.

To solve this issue, remove the schema parameter from all calls to the Data API when you use Aurora Serverless v2 or provisioned clusters.

## IPv6 connectivity issues

If you experience issues when connecting to Data API using IPv6 endpoints, check the following potential causes:

- **Network doesn't support IPv6:** Verify that your network infrastructure supports IPv6 and that IPv6 routing is configured correctly.
- **DNS resolution issues:** Ensure that your DNS resolver can resolve AAAA records for the dual-stack endpoints (e.g., `rds-data.us-east-1.api.aws`).
- **Security group configuration:** Update security group rules to allow IPv6 traffic on port 443 (HTTPS). Add rules for IPv6 CIDR blocks (e.g., `:::/0` for all IPv6 addresses).
- **Network ACL configuration:** Ensure that network ACLs allow IPv6 traffic on the required ports.
- **Client library compatibility:** Verify that your HTTP client libraries and Amazon SDKs support IPv6 and dual-stack connectivity.
- **VPC endpoint configuration:** If using PrivateLink, ensure that your VPC endpoint is configured to support IPv6 and that the associated subnets have IPv6 CIDR blocks assigned.

To troubleshoot IPv6 connectivity issues:

1. Test connectivity using the IPv4-only endpoints (`.amazonaws.com`) to verify that the issue is specific to IPv6.

2. Use network diagnostic tools to verify IPv6 connectivity to the dual-stack endpoints.
3. Check CloudTrail logs for any authentication or authorization errors when using IPv6 endpoints.
4. Verify that your application is correctly configured to use the new dual-stack endpoint URLs.

## Logging Amazon RDS Data API calls with Amazon CloudTrail

RDS Data API (Data API) is integrated with Amazon CloudTrail, a service that provides a record of actions taken by a user, role, or an Amazon service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [Amazon CloudTrail User Guide](#).

## Working with Data API information in CloudTrail

CloudTrail is enabled on your Amazon account when you create the account. When supported activity (management events) occurs in Data API, that activity is recorded in a CloudTrail event along with other Amazon service events in **Event history**. You can view, search, and download recent management events in your Amazon account. For more information, see [Working with CloudTrail Event history](#) in the *Amazon CloudTrail User Guide*.

For an ongoing record of events in your Amazon account, including events for Data API, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Amazon Regions. The trail logs events from all Amazon Regions in the Amazon partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other Amazon services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the *Amazon CloudTrail User Guide*:

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)

- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

All Data API operations are logged by CloudTrail and documented in the [Amazon RDS data service API reference](#). For example, calls to the `BatchExecuteStatement`, `BeginTransaction`, `CommitTransaction`, and `ExecuteStatement` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another Amazon service.

For more information, see the [CloudTrail userIdentity element](#).

## Including and excluding Data API events from an Amazon CloudTrail trail

Most Data API users rely on the events in an Amazon CloudTrail trail to provide a record of Data API operations. Event data doesn't reveal the database name, schema name, or SQL statements in requests to the Data API. However, knowing which user made a type of call against a specific DB cluster at a given time can help to detect anomalous access patterns.

### Including Data API events in an Amazon CloudTrail trail

For Aurora PostgreSQL Serverless v2 and provisioned databases, the following Data API operations are logged to Amazon CloudTrail as *data events*. [Data events](#) are high-volume data-plane API operations that CloudTrail doesn't log by default. Additional charges apply for data events. For information about CloudTrail pricing, see [Amazon CloudTrail Pricing](#).

- [BatchExecuteStatement](#)
- [BeginTransaction](#)
- [CommitTransaction](#)
- [ExecuteStatement](#)

- [RollbackTransaction](#)

You can use the CloudTrail console, Amazon CLI, or CloudTrail API operations to log these Data API operations. In the CloudTrail console, choose **RDS Data API - DB Cluster** for the Data event type. For more information, see [Logging data events with the Amazon Web Services Management Console](#) in the *Amazon CloudTrail User Guide*.

Using the Amazon CLI, run the `aws cloudtrail put-event-selectors` command to log these Data API operations for your trail. To log all Data API events on DB clusters, specify `AWS::RDS::DBCluster` for the resource type. The following example logs all Data API events on DB clusters. For more information, see [Logging data events with the Amazon Command Line Interface](#) in the *Amazon CloudTrail User Guide*.

```
aws cloudtrail put-event-selectors --trail-name trail_name --advanced-event-selectors \  
'{  
  "Name": "RDS Data API Selector",  
  "FieldSelectors": [  
    {  
      "Field": "eventCategory",  
      "Equals": [  
        "Data"  
      ]  
    },  
    {  
      "Field": "resources.type",  
      "Equals": [  
        "AWS::RDS::DBCluster"  
      ]  
    }  
  ]  
'
```

You can configure advanced event selectors to additionally filter on the `readOnly`, `eventName`, and `resources.ARN` fields. For more information on these fields, see [AdvancedFieldSelector](#).

## Excluding Data API events from an Amazon CloudTrail trail (Aurora Serverless v1 only)

For Aurora Serverless v1, Data API events are management events. By default, all Data API events are included in an Amazon CloudTrail trail. However, because Data API can generate a large number

of events, you might want to exclude these events from your CloudTrail trail. The **Exclude Amazon RDS Data API events** setting excludes all Data API events from the trail. You can't exclude specific Data API events.

To exclude Data API events from a trail, do the following:

- In the CloudTrail console, choose the **Exclude Amazon RDS Data API events** setting when you [create a trail](#) or [update a trail](#).
- In the CloudTrail API, use the [PutEventSelectors](#) operation. If you're using advanced event selectors, you can exclude Data API events by setting the eventSource field not equal to `rdsdata.amazonaws.com`. If you're using basic event selectors, you can exclude Data API events by setting the value of the `ExcludeManagementEventSources` attribute to `rdsdata.amazonaws.com`. For more information, see [Logging events with the Amazon Command Line Interface](#) in the *Amazon CloudTrail User Guide*.

#### Warning

Excluding Data API events from a CloudTrail log can obscure Data API actions. Be cautious when giving principals the `cloudtrail:PutEventSelectors` permission that is required to perform this operation.

You can turn off this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording Data API events. However, it can't recover Data API events that occurred while the exclusion was effective.

When you exclude Data API events by using the console or API, the resulting CloudTrail `PutEventSelectors` API operation is also logged in your CloudTrail logs. If Data API events don't appear in your CloudTrail logs, look for a `PutEventSelectors` event with the `ExcludeManagementEventSources` attribute set to `rdsdata.amazonaws.com`.

For more information, see [Logging management events for trails](#) in the *Amazon CloudTrail User Guide*.

## Understanding Data API log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single

request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

## Aurora PostgreSQL Serverless v2 and provisioned

The following example shows a CloudTrail log entry that demonstrates the `ExecuteStatement` operation for Aurora PostgreSQL Serverless v2 and provisioned databases. For these databases, all Data API events are data events where the event source is **`rdsdataapi.amazonaws.com`** and the event type is **Rds Data Service**.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws-cn:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2019-12-18T00:49:34Z",
  "eventSource": "rdsdataapi.amazonaws.com",
  "eventName": "ExecuteStatement",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",
  "requestParameters": {
    "continueAfterTimeout": false,
    "database": "*****",
    "includeResultMetadata": false,
    "parameters": [],
    "resourceArn": "arn:aws-cn:rds:us-east-1:123456789012:cluster:my-database-1",
    "schema": "*****",
    "secretArn": "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:dataapisecret-ABC123",
    "sql": "*****"
  },
  "responseElements": null,
  "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",
  "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",
  "eventType": "Rds Data Service",
}
```

```
"recipientAccountId": "123456789012"
}
```

## Aurora Serverless v1

The following example shows how the preceding example CloudTrail log entry appears for Aurora Serverless v1. For Aurora Serverless v1, all events are management events where the event source is **rdsdata.amazonaws.com** and the event type is **AwsApiCall**.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws-cn:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2019-12-18T00:49:34Z",
  "eventSource": "rdsdata.amazonaws.com",
  "eventName": "ExecuteStatement",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",
  "requestParameters": {
    "continueAfterTimeout": false,
    "database": "*****",
    "includeResultMetadata": false,
    "parameters": [],
    "resourceArn": "arn:aws-cn:rds:us-east-1:123456789012:cluster:my-database-1",
    "schema": "*****",
    "secretArn": "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:dataapisecret-ABC123",
    "sql": "*****"
  },
  "responseElements": null,
  "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",
  "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",
  "eventType": "AwsApiCall",
  "recipientAccountId": "123456789012"
}
```

## Monitoring RDS Data API queries with Performance Insights

If your Aurora cluster is running Aurora Serverless v2 or provisioned instances, you can use Performance Insights with RDS Data API.

For more information about how to use Performance Insights with Aurora, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

### How RDS Data API queries are represented in Performance Insights

With Data API, your Aurora cluster processes queries based on Data API calls that you submit from your application. Data API also performs some SQL statements as part of its own internal workings, such as canceling queries that exceed the timeout threshold. Both kinds of SQL operations are shown in Performance Insights statistics and charts.

- For Data API queries that you submit to an Aurora cluster, the **Host** field in the PI dashboard is marked as **RDS Data API**. For Aurora PostgreSQL, the **application\_name** field has the value `rds-data-api`. Look for these labels when you analyze database load using **Top hosts** or **Top Applications** as a dimension.
- All internal queries that Data API runs to manage database aspects such as the connection pool and query timeouts are annotated with a prefix **RDS Data API**. Example: `/* RDS Data API */ select * from my_table;` Looks for these prefixes when you analyze database load by **Top SQL** as a dimension. statements are annotated with a SQL comment of `/* RDS Data API */`.

# Using the Aurora query editor

The Aurora query editor lets you run SQL statements on your Aurora DB cluster through the Amazon Web Services Management Console. You can run SQL queries, data manipulation (DML) statements, and data definition (DDL) statements. Using the console interface lets you perform database maintenance, produce reports, and conduct SQL experiments. You can avoid setting up the network configuration to connect to your DB cluster from a separate client system such as an EC2 instance or a laptop computer.

The query editor requires an Aurora DB cluster with RDS Data API (Data API) enabled. For information about DB clusters that support Data API and how to enable it, see [Using the Amazon RDS Data API](#). The SQL that you can run is subject to the Data API limitations. For more information, see [the section called "Limitations"](#).

## Availability of the query editor

The query editor is available for Aurora DB clusters using Aurora MySQL and Aurora PostgreSQL engine versions that support Data API, and in the Amazon Web Services Regions where Data API is available. For more information, see [Supported Regions and Aurora DB engines for RDS Data API](#).

## Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the AmazonRDSDataFullAccess policy, a predefined Amazon Identity and Access Management (IAM) policy, to that user.

### Note

Make sure to use the same user name and password when you create the IAM user as you did for the database user, such as the administrative user name and password. For more information, see [Creating an IAM user in your Amazon Web Services account](#) in the *Amazon Identity and Access Management User Guide*.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

The following policy provides the minimum required permissions for a user to access the query editor.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "QueryEditor0",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutResourcePolicy",
        "secretsmanager:PutSecretValue",
        "secretsmanager>DeleteSecret",
        "secretsmanager:DescribeSecret",
        "secretsmanager:TagResource"
      ],
      "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/*"
    },
    {
      "Sid": "QueryEditor1",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetRandomPassword",
        "tag:GetResources",
        "secretsmanager>CreateSecret",
        "secretsmanager:ListSecrets",
        "dbqms>CreateFavoriteQuery",
        "dbqms:DescribeFavoriteQueries",
        "dbqms:UpdateFavoriteQuery",
        "dbqms>DeleteFavoriteQueries",
        "dbqms:GetQueryString",
        "dbqms>CreateQueryHistory",
        "dbqms:UpdateQueryHistory",
        "dbqms>DeleteQueryHistory",
        "dbqms:DescribeQueryHistory",
        "rds-data:BatchExecuteStatement",
        "rds-data:BeginTransaction",
        "rds-data:CommitTransaction",

```

```
        "rds-data:ExecuteStatement",
        "rds-data:RollbackTransaction"
    ],
    "Resource": "*"
}
]
```

For information about creating an IAM policy, see [Creating IAM policies](#) in the *Amazon Identity and Access Management User Guide*.

For information about adding an IAM policy to a user, see [Adding and removing IAM identity permissions](#) in the *Amazon Identity and Access Management User Guide*.

## Running queries in the query editor

You can run SQL statements on an Aurora DB cluster in the query editor. The SQL that you can run is subject to the Data API limitations. For more information, see [the section called "Limitations"](#).

### To run a query in the query editor

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the upper-right corner of the Amazon Web Services Management Console, choose the Amazon Web Services Region in which you created the Aurora DB clusters that you want to query.
3. In the navigation pane, choose **Databases**.
4. Choose the Aurora DB cluster that you want to run SQL queries on.
5. For **Actions**, choose **Query**. If you haven't connected to the database before, the **Connect to database** page opens.

### Connect to database ✕

You need to choose a database and enter the database credentials to use the query editor. We will be storing your credentials and the connection in the Secrets Manager service. [Learn more](#)

Database instance or cluster

database-1 ▼

Database username

Add new database credentials ▼

Enter database username

Enter database password

Enter the name of the database or schema (optional)  
Enter the name for schemas collection

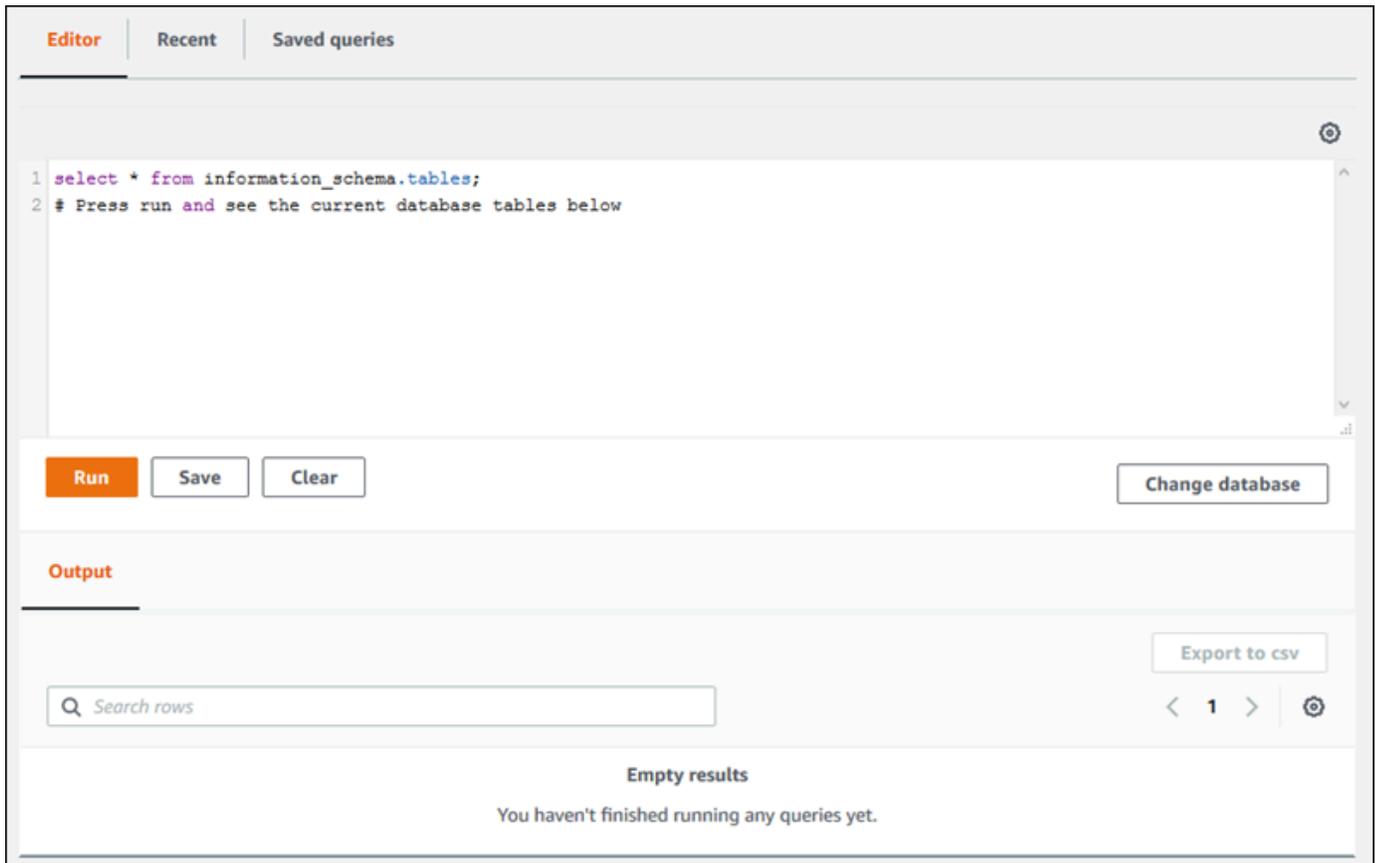

Cancel Connect to database

6. Enter the following information:
  - a. For **Database instance or cluster**, choose the Aurora DB cluster that you want to run SQL queries on.
  - b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.
  - c. For **Enter database password**, enter the password for the database user that you chose.
  - d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.
  - e. Choose **Connect to database**.

**Note**

If your connection is successful, your connection and authentication information are stored in Amazon Secrets Manager. You don't need to enter the connection information again.

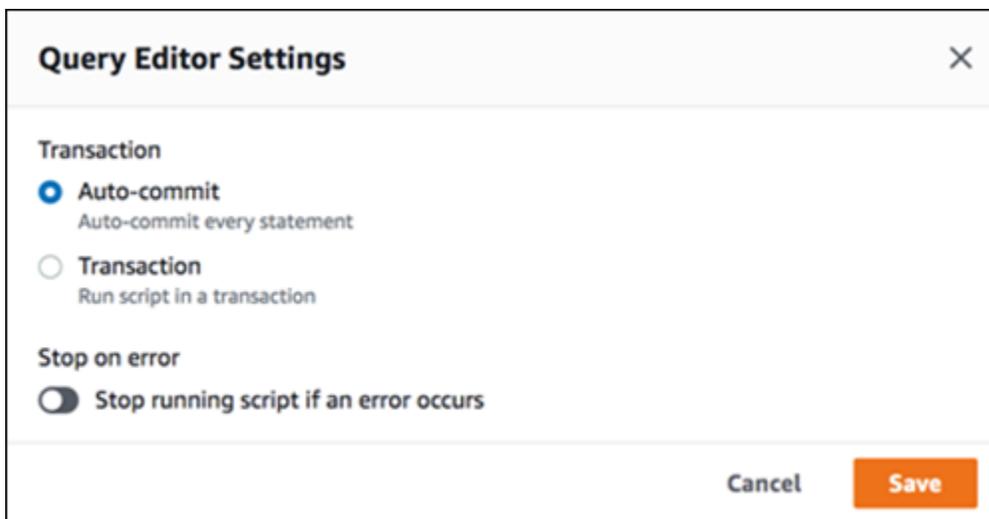

7. In the query editor, enter the SQL query that you want to run on the database.

Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.

The **Query Editor Settings** window appears.

If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

**Note**

In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include COMMIT and ROLLBACK statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

After running the query, save it to **Saved queries** by choosing **Save**.

Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

## Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the Amazon Web Services Management Console for multiple Amazon services, including Amazon RDS.

### Supported DBQMS actions

- [CreateFavoriteQuery](#)
- [CreateQueryHistory](#)
- [CreateTab](#)
- [DeleteFavoriteQueries](#)
- [DeleteQueryHistory](#)
- [DeleteTab](#)
- [DescribeFavoriteQueries](#)
- [DescribeQueryHistory](#)
- [DescribeTabs](#)

- [GetQueryString](#)
- [UpdateFavoriteQuery](#)
- [UpdateQueryHistory](#)
- [UpdateTab](#)

## CreateFavoriteQuery

Save a new favorite query. Each user can create up to 1000 saved queries. This limit is subject to change in the future.

## CreateQueryHistory

Save a new query history entry.

## CreateTab

Save a new query tab. Each user can create up to 10 query tabs.

## DeleteFavoriteQueries

Delete one or more saved queries.

## DeleteQueryHistory

Delete query history entries.

## DeleteTab

Delete query tab entries.

## DescribeFavoriteQueries

List saved queries created by a user in a given account.

## DescribeQueryHistory

List query history entries.

## **DescribeTabs**

List query tabs created by a user in a given account.

## **GetQueryString**

Retrieve full query text from a query ID.

## **UpdateFavoriteQuery**

Update the query string, description, name, or expiration date.

## **UpdateQueryHistory**

Update the status of query history.

## **UpdateTab**

Update the query tab name and query string.

# Using Amazon Aurora machine learning

By using Amazon Aurora machine learning, you can integrate your Aurora DB cluster with the following Amazon machine learning service.

## SageMaker AI

Amazon SageMaker AI is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker AI to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready for use in production, it can be deployed to the Amazon SageMaker AI hosted environment. For more information, see [What Is Amazon SageMaker AI?](#) in the *Amazon SageMaker AI Developer Guide*.

## Requirements for using Aurora machine learning with Aurora MySQL

Amazon machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Bedrock, Amazon Comprehend, and SageMaker AI. Before trying to set up your Aurora MySQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The machine learning services must be running in the same Amazon Web Services Region as your Aurora MySQL DB cluster. You can't use machine learning services from an Aurora MySQL DB cluster in a different Region.
- If your Aurora MySQL DB cluster is in a different virtual public cloud (VPC) from your Amazon Bedrock, Amazon Comprehend, or SageMaker AI service, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see [Control traffic to your Amazon resources using security groups](#) in the *Amazon VPC User Guide*.
- You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see [Database engine updates for Amazon Aurora MySQL](#).
- Your Aurora MySQL DB cluster must use a custom DB cluster parameter group. At the end of the setup process for each Aurora machine learning service that you want to use, you add the

Amazon Resource Name (ARN) of the associated IAM role that was created for the service.

We recommend that you create a custom DB cluster parameter group for your Aurora MySQL in advance and configure your Aurora MySQL DB cluster to use it so that it's ready for you to modify at the end of the setup process.

- For SageMaker AI:
  - The machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora MySQL DB cluster, make sure to have the ARN of the SageMaker AI endpoint available. The data scientists on your team are likely best able to handle working with SageMaker AI to prepare the models and handle the other such tasks. To get started with Amazon SageMaker AI, see [Get Started with Amazon SageMaker AI](#). For more information about inferences and endpoints, see [Real-time inference](#).
  - To use SageMaker AI with your own training data, you must set up an Amazon S3 bucket as part of your Aurora MySQL configuration for Aurora machine learning. To do so, you follow the same general process as for setting up the SageMaker AI integration. For a summary of this optional setup process, see [Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI \(Optional\)](#).
- For Aurora global databases, you set up the Aurora machine learning services that you want to use in all Amazon Web Services Regions that make up your Aurora global database. For example, if you want to use Aurora machine learning with SageMaker AI for your Aurora global database, you do the following for every Aurora MySQL DB cluster in every Amazon Web Services Region:
  - Set up the Amazon SageMaker AI services with the same SageMaker AI training models and endpoints. These must also use the same names.
  - Create the IAM roles as detailed in [Setting up your Aurora MySQL DB cluster to use Aurora machine learning](#).
  - Add the ARN of the IAM role to the custom DB cluster parameter group for each Aurora MySQL DB cluster in every Amazon Web Services Region.

These tasks require that Aurora machine learning is available for your version of Aurora MySQL in all Amazon Web Services Regions that make up your Aurora global database.

## Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions.

- For information on version and Region availability for Amazon Comprehend and Amazon SageMaker AI with Aurora MySQL, see [Aurora machine learning with Aurora MySQL](#).
- Amazon Bedrock is supported only on Aurora MySQL version 3.06 and higher.

For information on Region availability for Amazon Bedrock, see [Model support by Amazon Web Services Region](#) in the *Amazon Bedrock User Guide*.

## Supported features and limitations of Aurora machine learning with Aurora MySQL

When using Aurora MySQL with Aurora machine learning, the following limitations apply:

- The Aurora machine learning extension doesn't support vector interfaces.
- Aurora machine learning integrations aren't supported when used in a trigger.
- Aurora machine learning functions aren't compatible with binary logging (binlog) replication.
  - The setting `--binlog-format=STATEMENT` throws an exception for calls to Aurora machine learning functions.
  - Aurora machine learning functions are nondeterministic, and nondeterministic stored functions aren't compatible with the binlog format.

For more information, see [Binary Logging Formats](#) in the MySQL documentation.

- Stored functions that call tables with generated-always columns aren't supported. This applies to any Aurora MySQL stored function. To learn more about this column type, see [CREATE TABLE and Generated Columns](#) in the MySQL documentation.
- Amazon Bedrock functions don't support RETURNS JSON. You can use CONVERT or CAST to convert from TEXT to JSON if needed.
- Amazon Bedrock doesn't support batch requests.
- Aurora MySQL supports any SageMaker AI endpoint that reads and writes the comma-separated value (CSV) format, through a ContentType of text/csv. This format is accepted by the following built-in SageMaker AI algorithms:
  - Linear Learner
  - Random Cut Forest
  - XGBoost

To learn more about these algorithms, see [Choose an Algorithm](#) in the *Amazon SageMaker AI Developer Guide*.

## Setting up your Aurora MySQL DB cluster to use Aurora machine learning

In the following topics, you can find separate setup procedures for each of these Aurora machine learning services.

### Topics

- [Setting up your Aurora MySQL DB cluster to use Amazon Bedrock](#)
- [Setting up your Aurora MySQL DB cluster to use Amazon Comprehend](#)
- [Setting up your Aurora MySQL DB cluster to use SageMaker AI](#)
  - [Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI \(Optional\)](#)
- [Granting database users access to Aurora machine learning](#)
  - [Granting access to Amazon Bedrock functions](#)
  - [Granting access to Amazon Comprehend functions](#)
  - [Granting access to SageMaker AI functions](#)

## Setting up your Aurora MySQL DB cluster to use Amazon Bedrock

Aurora machine learning relies on Amazon Identity and Access Management (IAM) roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Bedrock services. The following procedures create an IAM permission policy and role so that your DB cluster can integrate with Amazon Bedrock.

### To create the IAM policy

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Choose **Policies** in the navigation pane.
3. Choose **Create a policy**.
4. On the **Specify permissions** page, for **Select a service**, choose **Bedrock**.

The Amazon Bedrock permissions display.

5. Expand **Read**, then select **InvokeModel**.
6. For **Resources**, select **All**.

The **Specify permissions** page should resemble the following figure.

## Specify permissions [Info](#)

Add permissions by selecting services, actions, resources, and conditions. Build permission statements using the JSON editor.

**Policy editor**

Next

7. Choose **Next**.

8. On the **Review and create** page, enter a name for your policy, for example **BedrockInvokeModel1**.

9. Review your policy, then choose **Create policy**.

Next you create the IAM role that uses the Amazon Bedrock permission policy.

### To create the IAM role

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Choose **Roles** in the navigation pane.
3. Choose **Create role**.
4. On the **Select trusted entity** page, for **Use case**, choose **RDS**.
5. Select **RDS - Add Role to Database**, then choose **Next**.
6. On the **Add permissions** page, for **Permissions policies**, select the IAM policy that you created, then choose **Next**.
7. On the **Name, review, and create** page, enter a name for your role, for example **ams-bedrock-invoke-model-role**.

The role should resemble the following figure.

## Name, review, and create

Role details

Role name

Enter a meaningful name to identify this role.

Maximum 64 characters. Use alphanumeric and '+\*,@,-\_' characters.

Description

Add a short explanation for this role.

Allows you to grant RDS access to additional resources on your behalf.

Maximum 1000 characters. Use alphanumeric and '+\*,@,-\_' characters.

---

Step 1: Select trusted entities Edit

Trust policy

```

1 {
2   "Version": "2012-10-17",
3   "Statement": [
4     {
5       "Sid": "",
6       "Effect": "Allow",
7       "Principal": {
8         "Service": [
9           "rds.amazonaws.com"
10        ]
11      },
12      "Action": [
13        "sts:AssumeRole"
14      ]
15    }
16  ]
17 }

```

---

Step 2: Add permissions Edit

Permissions policy summary

Policy name <a href="#">?</a>	Type	Attached as
<a href="#">BedrockInvokeModel</a>	Customer managed	Permissions policy

---

Step 3: Add tags

Add tags - *optional* [Info](#)

Tags are key-value pairs that you can add to AWS resources to help identify, organize, or search for resources.

No tags associated with the resource.

Add new tag

You can add up to 50 more tags.

Cancel Previous Create role

8. Review your role, then choose **Create role**.

Next you associate the Amazon Bedrock IAM role with your DB cluster.

## To associate the IAM role with your DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Bedrock services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select IAM to add to this cluster**.
6. Choose the IAM that you created, and then choose **Add role**.

The IAM role is associated with your DB cluster, first with the status **Pending**, then **Active**. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.

The screenshot shows the 'Manage IAM roles' interface. It has a title bar with a refresh icon. Below the title, there are two radio button options: 'Select IAM roles to add to this cluster' (which is selected) and 'Select a service to connect to this cluster'. Under the first option, there is a dropdown menu with the text 'Choose an IAM role to add' and an 'Add role' button. Below this, there is a section titled 'Current IAM roles for this cluster (1)' with a 'Delete' button. This section contains a table with two columns: 'Role' and 'Status'. The table has one row with the role name 'ams-bedrock-invoke-model-role' and a status of 'Active' (indicated by a green checkmark).

You must add the ARN of this IAM role to the `aws_default_bedrock_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

## To configure the DB cluster parameter

1. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.
2. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.

3. Find the `aws_default_bedrock_role` parameter in your custom DB cluster parameter group.
4. In the **Value** field, enter the ARN of the IAM role.
5. Choose **Save changes** to save the setting.
6. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM integration for Amazon Bedrock is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Bedrock by [Granting database users access to Aurora machine learning](#).

## Setting up your Aurora MySQL DB cluster to use Amazon Comprehend

Aurora machine learning relies on Amazon Identity and Access Management roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Comprehend services. The following procedure automatically creates an IAM role and policy for your cluster so that it can use Amazon Comprehend.

### To set up your Aurora MySQL DB cluster to use Amazon Comprehend

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Comprehend services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select a service to connect to this cluster**.
6. Choose **Amazon Comprehend** from the menu, and then choose **Connect service**.

**Manage IAM roles**

Select IAM roles to add to this cluster  
Add an existing IAM role to this cluster.

Select a service to connect to this cluster  
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

Amazon Comprehend ▼ Connect service

Current IAM roles for this cluster (0)

- The **Connect cluster to Amazon Comprehend** dialog doesn't require any additional information. However, you might see a message notifying you that the integration between Aurora and Amazon Comprehend is currently in preview. Be sure to read the message before you continue. You can choose **Cancel** if you prefer not to proceed.
- Choose **Connect service** to complete the integration process.

Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use Amazon Comprehend services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list as shown in the following image.

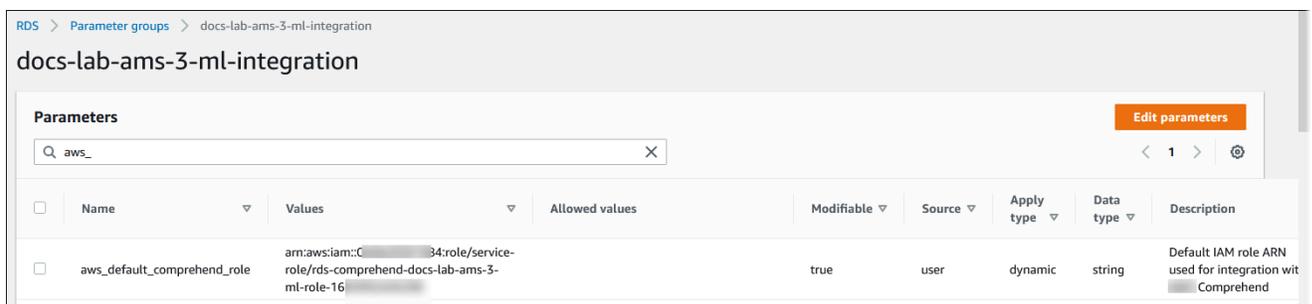

Current IAM roles for this cluster (1)		Delete
Role	Status	
<input checked="" type="radio"/> rds-comprehend-docs-lab-ams-ml-role-...	<span>✔ Active</span>	

You need to add the ARN of this IAM role to the `aws_default_comprehend_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see [DB cluster parameter groups for Amazon Aurora DB clusters](#).

After creating your custom DB cluster parameter group and associating it with your Aurora MySQL DB cluster, you can continue following these steps.

If your cluster uses a custom DB cluster parameter group, do as follows.

- a. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.
- b. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.
- c. Find the `aws_default_comprehend_role` parameter in your custom DB cluster parameter group.
- d. In the **Value** field, enter the ARN of the IAM role.
- e. Choose **Save changes** to save the setting. In the following image, you can find an example.

Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM integration for Amazon Comprehend is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Comprehend by granting access to the appropriate database users.

## Setting up your Aurora MySQL DB cluster to use SageMaker AI

The following procedure automatically creates the IAM role and policy for your Aurora MySQL DB cluster so that it can use SageMaker AI. Before trying to follow this procedure, be sure that you have the SageMaker AI endpoint available so that you can enter it when needed. Typically, data scientists on your team would do the work to produce an endpoint that you can use from your Aurora MySQL DB cluster. You can find such endpoints in the [SageMaker AI console](#). In the navigation pane, open the **Inference** menu and choose **Endpoints**. In the following image, you can find an example.

Amazon SageMaker > Endpoints

**Endpoints** Update endpoint Actions Create endpoint

Search endpoints

Name	ARN	Creation time	Status	Last updated
docs-lab-aurora-ml-testing-sagemaker-endpoint	arn:aws:sagemaker:us-east-2:( <span style="background-color: #ccc; color: #000;">XXXXXXXXXX</span> ):endpoint/docs-lab-aurora-ml-testing-sagemaker-endpoint	Sep 20, 2022 21:18 UTC	InService	Sep 20, 2022 21:20 UTC

### To set up your Aurora MySQL DB cluster to use SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker AI services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **SageMaker AI** from the selector.

**Manage IAM roles** Refresh

Select IAM roles to add to this cluster  
Add an existing IAM role to this cluster.

**Select a service to connect to this cluster**  
Connect a service to this cluster by creating a new IAM role with permissions to access the service.

Amazon SageMaker ▼ Connect service

Current IAM roles for this cluster (1) Delete

Role	Status
<input type="radio"/> rds-comprehend-docs-lab-ams-ml-role-166 <span style="background-color: #ccc; color: #000;">XXXXXXXXXX</span>	<span>Active</span>

5. Choose **Connect service**.
6. In the **Connect cluster to SageMaker AI** dialog, enter the ARN of the SageMaker AI endpoint.

**Connect cluster to Amazon SageMaker** ✕

An Amazon Resource Name (ARN) of an Amazon SageMaker endpoint is required to connect to the service.

arn:aws:sagemaker:us-east-2:(redacted):4:automl-job/docs

Format: arn:aws:sagemaker:::endpoint/endpointName

Cancel **Connect service**

- Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use SageMaker AI services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.
- Open the IAM console at <https://console.amazonaws.cn/iam/>.
- Choose **Roles** from the Access management section of the Amazon Identity and Access Management navigation menu.
- Find the role from among those listed. Its name uses the following pattern.

```
rds-sagemaker-your-cluster-name-role-auto-generated-digits
```

- Open the role's Summary page and locate the ARN. Note the ARN or copy it using the copy widget.
- Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
- Choose your Aurora MySQL DB cluster, and then choose its **Configuration** tab.
- Locate the DB cluster parameter group, and choose the link to open your custom DB cluster parameter group. Find the `aws_default_sagemaker_role` parameter and enter the ARN of the IAM role in the Value field and Save the setting.
- Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM setup is now complete. Continue setting up your Aurora MySQL DB cluster to work with SageMaker AI by granting access to the appropriate database users.

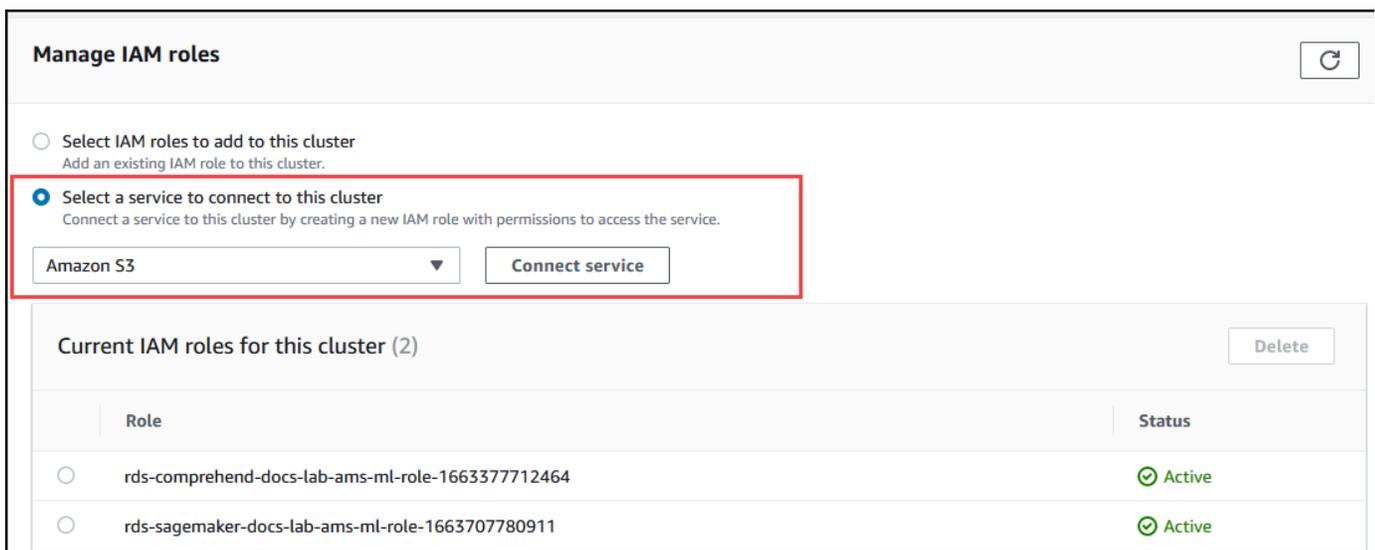

If you want to use your SageMaker AI models for training rather than using pre-built SageMaker AI components, you also need to add the Amazon S3 bucket to your Aurora MySQL DB cluster, as outlined in the [Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI \(Optional\)](#) that follows.

## Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI (Optional)

To use SageMaker AI with your own models rather than using the pre-built components provided by SageMaker AI, you need to set up an Amazon S3 bucket for the Aurora MySQL DB cluster to use. For more information about creating an Amazon S3 bucket, see [Creating a bucket](#) in the *Amazon Simple Storage Service User Guide*.

### To set up your Aurora MySQL DB cluster to use an Amazon S3 bucket for SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker AI services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **Amazon S3** from the selector.

5. Choose **Connect service**.
6. In the **Connect cluster to Amazon S3** dialog, enter the ARN of the Amazon S3 bucket, as shown in the following image.

### Connect cluster to Amazon S3

✕

An Amazon Resource Name (ARN) of an Amazon S3 bucket is required to access the S3 bucket.

arn:aws:s3::docs-lab-bucket-for-sagemaker-models

Format: *arn:aws:s3::example-bucket*

Cancel
Connect service

7. Choose **Connect service** to complete this process.

For more information about using Amazon S3 buckets with SageMaker AI, see [Specify an Amazon S3 Bucket to Upload Training Datasets and Store Output Data](#) in the *Amazon SageMaker AI Developer Guide*. To learn more about working with SageMaker AI, see [Get Started with Amazon SageMaker AI Notebook Instances](#) in the *Amazon SageMaker AI Developer Guide*.

## Granting database users access to Aurora machine learning

Database users must be granted permission to invoke Aurora machine learning functions. How you grant permission depends on the version of MySQL that you use for your Aurora MySQL DB cluster, as outlined in the following. How you do so depends on the version of MySQL that your Aurora MySQL DB cluster uses.

- For Aurora MySQL version 3 (MySQL 8.0 compatible), database users must be granted the appropriate *database role*. For more information, see [Using Roles](#) in the *MySQL 8.0 Reference Manual*.
- For Aurora MySQL version 2 (MySQL 5.7 compatible), database users are granted *privileges*. For more information, see [Access Control and Account Management](#) in the *MySQL 5.7 Reference Manual*.

The following table shows the roles and privileges that database users need to work with machine learning functions.

Aurora MySQL version 3 (role)	Aurora MySQL version 2 (privilege)
Amazon_BEDROCK_ACCESS	–
Amazon_COMPREHEND_ACCESS	INVOKE COMPREHEND
Amazon_SAGEMAKER_ACCESS	INVOKE SAGEMAKER

## Granting access to Amazon Bedrock functions

To give database users access to Amazon Bedrock functions, use the following SQL statement:

```
GRANT Amazon_BEDROCK_ACCESS TO user@domain-or-ip-address;
```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with Amazon Bedrock:

```
GRANT EXECUTE ON FUNCTION database_name.function_name TO user@domain-or-ip-address;
```

Finally, database users must have their roles set to Amazon\_BEDROCK\_ACCESS:

```
SET ROLE Amazon_BEDROCK_ACCESS;
```

The Amazon Bedrock functions are now available for use.

## Granting access to Amazon Comprehend functions

To give database users access to Amazon Comprehend functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

```
GRANT Amazon_COMPREHEND_ACCESS TO user@domain-or-ip-address;
```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

```
GRANT INVOKE COMPREHEND ON *.* TO user@domain-or-ip-address;
```

The Amazon Comprehend functions are now available for use. For usage examples, see [Using Amazon Comprehend with your Aurora MySQL DB cluster](#).

## Granting access to SageMaker AI functions

To give database users access to SageMaker AI functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

```
GRANT Amazon_SAGEMAKER_ACCESS TO user@domain-or-ip-address;
```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

```
GRANT INVOKE SAGEMAKER ON *.* TO user@domain-or-ip-address;
```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with SageMaker AI. Suppose that you created two functions, `db1.anomaly_score` and `db2.company_forecasts`, to invoke the services of your SageMaker AI endpoint. You grant execute privileges as shown in the following example.

```
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1;  
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2;
```

The SageMaker AI functions are now available for use. For usage examples, see [Using SageMaker AI with your Aurora MySQL DB cluster](#).

## Using Amazon Bedrock with your Aurora MySQL DB cluster

To use Amazon Bedrock, you create a user-defined function (UDF) in your Aurora MySQL database that invokes a model. For more information, see [Supported models in Amazon Bedrock](#) in the *Amazon Bedrock User Guide*.

A UDF uses the following syntax:

```
CREATE FUNCTION function_name (argument type)  
    [DEFINER = user]  
    RETURNS mysql_data_type  
    [SQL SECURITY {DEFINER | INVOKER}]  
    ALIAS AWS_BEDROCK_INVOKE_MODEL
```

```
MODEL ID 'model_id'
[CONTENT_TYPE 'content_type']
[ACCEPT 'content_type']
[TIMEOUT_MS timeout_in_milliseconds];
```

- Amazon Bedrock functions don't support RETURNS JSON. You can use CONVERT or CAST to convert from TEXT to JSON if needed.
- If you don't specify CONTENT\_TYPE or ACCEPT, the default is application/json.
- If you don't specify TIMEOUT\_MS, the value for aurora\_ml\_inference\_timeout is used.

For example, the following UDF invokes the Amazon Titan Text Express model:

```
CREATE FUNCTION invoke_titan (request_body TEXT)
  RETURNS TEXT
  ALIAS AWS_BEDROCK_INVOKE_MODEL
  MODEL ID 'amazon.titan-text-express-v1'
  CONTENT_TYPE 'application/json'
  ACCEPT 'application/json';
```

To allow a DB user to use this function, use the following SQL command:

```
GRANT EXECUTE ON FUNCTION database_name.invoke_titan TO user@domain-or-ip-address;
```

Then the user can call `invoke_titan` like any other function, as shown in the following example. Make sure to format the request body according to the [Amazon Titan text models](#).

```
CREATE TABLE prompts (request varchar(1024));
INSERT INTO prompts VALUES (
'{
  "inputText": "Generate synthetic data for daily product sales in various categories
- include row number, product name, category, date of sale and price. Produce output
in JSON format. Count records and ensure there are no more than 5.",
  "textGenerationConfig": {
    "maxTokenCount": 1024,
    "stopSequences": [],
    "temperature":0,
    "topP":1
  }
}');
```

```
SELECT invoke_titan(request) FROM prompts;

{"inputTextTokenCount":44,"results":[{"tokenCount":296,"outputText":"
```tabular-data-json
{
  "rows": [
    {
      "Row Number": "1",
      "Product Name": "T-Shirt",
      "Category": "Clothing",
      "Date of Sale": "2024-01-01",
      "Price": "$20"
    },
    {
      "Row Number": "2",
      "Product Name": "Jeans",
      "Category": "Clothing",
      "Date of Sale": "2024-01-02",
      "Price": "$30"
    },
    {
      "Row Number": "3",
      "Product Name": "Hat",
      "Category": "Accessories",
      "Date of Sale": "2024-01-03",
      "Price": "$15"
    },
    {
      "Row Number": "4",
      "Product Name": "Watch",
      "Category": "Accessories",
      "Date of Sale": "2024-01-04",
      "Price": "$40"
    },
    {
      "Row Number": "5",
      "Product Name": "Phone Case",
      "Category": "Accessories",
      "Date of Sale": "2024-01-05",
      "Price": "$25"
    }
  ]
}
```

```
```, "completionReason": "FINISH"]}]}
```

For other models that you use, make sure to format the request body appropriately for them. For more information, see [Inference parameters for foundation models](#) in the *Amazon Bedrock User Guide*.

## Using Amazon Comprehend with your Aurora MySQL DB cluster

For Aurora MySQL, Aurora machine learning provides the following two built-in functions for working with Amazon Comprehend and your text data. You provide the text to analyze (`input_data`) and specify the language (`language_code`).

### `aws_comprehend_detect_sentiment`

This function identifies the text as having a positive, negative, neutral, or mixed emotional posture. This function's reference documentation is as follows.

```
aws_comprehend_detect_sentiment(  
  input_text,  
  language_code  
  [,max_batch_size]  
)
```

To learn more, see [Sentiment](#) in the *Amazon Comprehend Developer Guide*.

### `aws_comprehend_detect_sentiment_confidence`

This function measures the confidence level of the sentiment detected for a given text. It returns a value (type, `double`) that indicates the confidence of the sentiment assigned by the `aws_comprehend_detect_sentiment` function to the text. Confidence is a statistical metric between 0 and 1. The higher the confidence level, the more weight you can give the result. A summary of the function's documentation is as follows.

```
aws_comprehend_detect_sentiment_confidence(  
  input_text,  
  language_code  
  [,max_batch_size]  
)
```

In both functions (`aws_comprehend_detect_sentiment_confidence`, `aws_comprehend_detect_sentiment`) the `max_batch_size` uses a default value of 25 if none is specified. Batch size should always be greater than 0. You can use `max_batch_size` to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora MySQL DB cluster. For more information, see [Performance considerations for using Aurora machine learning with Aurora MySQL](#).

For more information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see [DetectSentiment](#)

### Example Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes these two functions to see how happy your customers are with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies both built-in functions to the text in the `feedback` column of the table and outputs the results. The confidence values returned by the function are doubles between 0.0 and 1.0. For more readable output, this query rounds the results to 6 decimal points. For easier comparisons, this query also sorts the results in descending order, from the result having the highest degree of confidence, first.

```
SELECT feedback AS 'Customer feedback',
       aws_comprehend_detect_sentiment(feedback, 'en') AS Sentiment,

## Example Example: Determining the average sentiment for text above a specific confidence level

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')
  WHEN 'POSITIVE' THEN 1.0
  WHEN 'NEGATIVE' THEN -1.0
  ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total
FROM productTable
WHERE productTable.productCode = 1302 AND
  aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

## Using SageMaker AI with your Aurora MySQL DB cluster

To use SageMaker AI functionality from your Aurora MySQL DB cluster, you need to create stored functions that embed your calls to the SageMaker AI endpoint and its inference features. You do so by using MySQL's `CREATE FUNCTION` in generally the same way that you do for other processing tasks on your Aurora MySQL DB cluster.

To use models deployed in SageMaker AI for inference, you create user-defined functions using MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker AI endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker AI endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker AI endpoint after applying the model to the input parameters.

All Aurora machine learning stored functions return numeric types or `VARCHAR`. You can use any numeric type except `BIT`. Other types, such as `JSON`, `BLOB`, `TEXT`, and `DATE` aren't allowed.

The following example shows the `CREATE FUNCTION` syntax for working with SageMaker AI.

```
CREATE FUNCTION function_name (
  arg1 type1,
  arg2 type2, ...)
  [DEFINER = user]
  RETURNS mysql_type
  [SQL SECURITY { DEFINER | INVOKER } ]
  ALIAS Amazon_SAGEMAKER_INVOKE_ENDPOINT
```

```
ENDPOINT NAME 'endpoint_name'  
[MAX_BATCH_SIZE max_batch_size];
```

This is an extension of the regular `CREATE FUNCTION` DDL statement. In the `CREATE FUNCTION` statement that defines the SageMaker AI function, you don't specify a function body. Instead, you specify the keyword `ALIAS` where the function body usually goes. Currently, Aurora machine learning only supports `aws_sagemaker_invoke_endpoint` for this extended syntax. You must specify the `endpoint_name` parameter. An SageMaker AI endpoint can have different characteristics for each model.

### Note

For more information about `CREATE FUNCTION`, see [CREATE PROCEDURE and CREATE FUNCTION Statements](#) in the MySQL 8.0 Reference Manual.

The `max_batch_size` parameter is optional. By default, maximum batch size is 10,000. You can use this parameter in your function to restrict the maximum number of inputs processed in a batched request to SageMaker AI. The `max_batch_size` parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker AI return a response more quickly. This parameter affects the size of an internal buffer used for SageMaker AI request processing. Specifying too large a value for `max_batch_size` might cause substantial memory overhead on your DB instance.

We recommend that you leave the `MANIFEST` setting at its default value of `OFF`. Although you can use the `MANIFEST ON` option, some SageMaker AI features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker AI.

You create a separate stored function for each of your SageMaker AI models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the Amazon services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the `NOT DETERMINISTIC` property. If you don't specify that property explicitly, Aurora sets `NOT DETERMINISTIC` automatically. This

requirement is because the SageMaker AI model can be changed without any notification to the database. If that happens, calls to an Aurora machine learning function might return different results for the same input within a single transaction.

You can't use the characteristics `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA` in your `CREATE FUNCTION` statement.

Following is an example usage of invoking a SageMaker AI endpoint to detect anomalies. There is a SageMaker AI endpoint `random-cut-forest-model`. The corresponding model is already trained by the `random-cut-forest` algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```
CREATE FUNCTION anomaly_score(value real) returns real
  alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value))
  from nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
  where anomaly_detection(value) > @score_cutoff;
```

## Character set requirement for SageMaker AI functions that return strings

We recommend specifying a character set of `utf8mb4` as the return type for your SageMaker AI functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the `utf8mb4` character set. The following example shows how to declare the `utf8mb4` character set for your function.

```
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...
```

Currently, each SageMaker AI function that returns a string uses the character set `utf8mb4` for the return value. The return value uses this character set even if your SageMaker AI function declares a different character set for its return type implicitly or explicitly. If your SageMaker AI function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a `DISTINCT` clause creates a temporary table. Thus, the SageMaker AI function result might be truncated due to the way strings are handled internally during a query.

## Exporting data to Amazon S3 for SageMaker AI model training (Advanced)

We recommend that you get started with Aurora machine learning and SageMaker AI by using some of the provided algorithms, and that the data scientists on your team provide you with the SageMaker AI endpoints that you can use with your SQL code. In the following, you can find minimal information about using your own Amazon S3 bucket with your own SageMaker AI models and your Aurora MySQL DB cluster.

Machine learning consists of two major steps: training, and inference. To train SageMaker AI models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker AI notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE S3` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format TEXT is the same as the existing MySQL export format. This is the default format.
- Format CSV is a newly introduced format that follows the specification in [RFC-4180](#).
- If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement.
- You can still use the keywords CSV and HEADER as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```
INTO OUTFILE S3 's3_uri'  
[CHARACTER SET charset_name]  
[FORMAT {CSV|TEXT} [HEADER]]  
[{FIELDS | COLUMNS}]  
  [TERMINATED BY 'string']  
  [[OPTIONALLY] ENCLOSED BY 'char']  
  [ESCAPED BY 'char']
```

```
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
```

## Performance considerations for using Aurora machine learning with Aurora MySQL

The Amazon Bedrock, Amazon Comprehend, and SageMaker AI services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora MySQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning.

### Model and prompt

Performance when using Amazon Bedrock is highly dependent on the model and prompt that you use. Choose a model and prompt that are optimal for your use case.

### Query cache

The Aurora MySQL query cache doesn't work for Aurora machine learning functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call Aurora machine learning functions.

### Batch optimization for Aurora machine learning function calls

The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker AI endpoint, you define the batch size parameter. This parameter influences how many rows are transferred

for every underlying call to SageMaker AI. For queries that process large numbers of rows, the overhead to make a separate SageMaker AI call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker AI function, you can tell by checking the query plan produced by the `EXPLAIN PLAN` statement. In this case, the extra column in the execution plan includes `Batched machine learning`. The following example shows a call to an SageMaker AI function that uses batch mode.

```
mysql> CREATE FUNCTION anomaly_score(val real) returns real alias
  aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)

mysql> explain select timestamp, value, anomaly_score(value) from nyc_taxi;
+----+-----+-----+-----+-----+-----+-----+-----+
+----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table   | partitions | type | possible_keys | key  | key_len |
ref | rows | filtered | Extra          |
+----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE      | nyc_taxi | NULL        | ALL | NULL          | NULL | NULL    |
NULL | 48 | 100.00 | Batched machine learning |
+----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.01 sec)
```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional `max_batch_size` parameter. This parameter restricts the maximum number of `input_text` values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a `LIMIT` clause. By using a small value for `max_batch_size`, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

- Function calls within the select list or the `WHERE` clause of `SELECT` statements
- Function calls in the `VALUES` list of `INSERT` and `REPLACE` statements
- SageMaker AI functions in `SET` values in `UPDATE` statements:

```
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
  (ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
  (ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

## Monitoring Aurora machine learning

You can monitor Aurora machine learning batch operations by querying several global variables, as shown in the following example.

```
show status like 'Aurora_ml%';
```

You can reset the status variables by using a `FLUSH STATUS` statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

### `Aurora_ml_logical_request_cnt`

The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than `Aurora_ml_actual_request_cnt`.

### `Aurora_ml_logical_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

### `Aurora_ml_actual_request_cnt`

The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance.

### `Aurora_ml_actual_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

### `Aurora_ml_cache_hit_cnt`

The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

## Aurora\_ml\_retry\_request\_cnt

The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset.

## Aurora\_ml\_single\_request\_cnt

The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker AI operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker AI](#).

# Using Amazon Aurora machine learning with Aurora PostgreSQL

By using Amazon Aurora machine learning with your Aurora PostgreSQL DB cluster, you can use Amazon Comprehend or Amazon SageMaker AI or Amazon Bedrock, depending on your needs. These services each support specific machine learning use cases.

Aurora machine learning is supported in certain Amazon Web Services Regions and for specific versions of Aurora PostgreSQL only. Before trying to set up Aurora machine learning, check availability for your Aurora PostgreSQL version and your Region. For details, see [Aurora machine learning with Aurora PostgreSQL](#).

# Requirements for using Aurora machine learning with Aurora PostgreSQL

Amazon machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Comprehend, SageMaker AI, and Amazon Bedrock. Before trying to set up your Aurora PostgreSQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The Amazon Comprehend, SageMaker AI, and Amazon Bedrock services must be running in the same Amazon Web Services Region as your Aurora PostgreSQL DB cluster. You can't use Amazon Comprehend or SageMaker AI or Amazon Bedrock services from an Aurora PostgreSQL DB cluster in a different Region.
- If your Aurora PostgreSQL DB cluster is in a different virtual public cloud (VPC) based on the Amazon VPC service than your Amazon Comprehend and SageMaker AI services, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see [Enabling network communication from Amazon Aurora to other Amazon services](#).
- For SageMaker AI, the machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora PostgreSQL DB cluster, you need to have the Amazon Resource Name (ARN) of the SageMaker AI endpoint available. The data scientists on your team are likely best able to handle working with SageMaker AI to prepare the models and handle the other such tasks. To get started with Amazon SageMaker AI, see [Get Started with Amazon SageMaker AI](#). For more information about inferences and endpoints, see [Real-time inference](#).
- For Amazon Bedrock, you need to have the model ID of the Bedrock models that you want to use for inferences available during the configuration process of your Aurora PostgreSQL DB cluster. The data scientists on your team are likely best able to work with Bedrock to decide which models to use, fine tune them if needed and handle other such tasks. To get started with Amazon Bedrock, see [How to setup Bedrock](#).
- Amazon Bedrock users need to request access to models before they are available for use. If you want to add additional models for text, chat, and image generation, you need to request access to models in Amazon Bedrock. For more information, see [Model access](#).

## Supported features and limitations of Aurora machine learning with Aurora PostgreSQL

Aurora machine learning supports any SageMaker AI endpoint that can read and write the comma-separated value (CSV) format through a `ContentType` value of `text/csv`. The built-in SageMaker AI algorithms that currently accept this format are the following.

- Linear Learner
- Random Cut Forest
- XGBoost

To learn more about these algorithms, see [Choose an Algorithm](#) in the *Amazon SageMaker AI Developer Guide*.

When using Amazon Bedrock with Aurora machine learning, the following limitations apply:

- The user-defined functions (UDFs) provide a native way to interact with Amazon Bedrock. The UDFs don't have specific request or response requirements, so they can use any model.
- You can use UDFs to build any work flow desired. For example, you can combine base primitives such as `pg_cron` to run a query, fetch data, generate inferences, and write to tables to serve queries directly.
- UDFs don't support batched or parallel calls.
- The Aurora Machine Learning extension doesn't support vector interfaces. As part of the extension, a function is available to output the embeddings of model's response in the `float8[]` format to store those embeddings in Aurora. For more information on the usage of `float8[]`, see [Using Amazon Bedrock with your Aurora PostgreSQL DB cluster](#).

## Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning

For Aurora machine learning to work with your Aurora PostgreSQL DB cluster, you need to create an Amazon Identity and Access Management (IAM) role for each of the services that you want to use. The IAM role allows your Aurora PostgreSQL DB cluster to use the Aurora machine learning service on the cluster's behalf. You also need to install the Aurora machine learning extension.

In the following topics, you can find setup procedures for each of these Aurora machine learning services.

## Topics

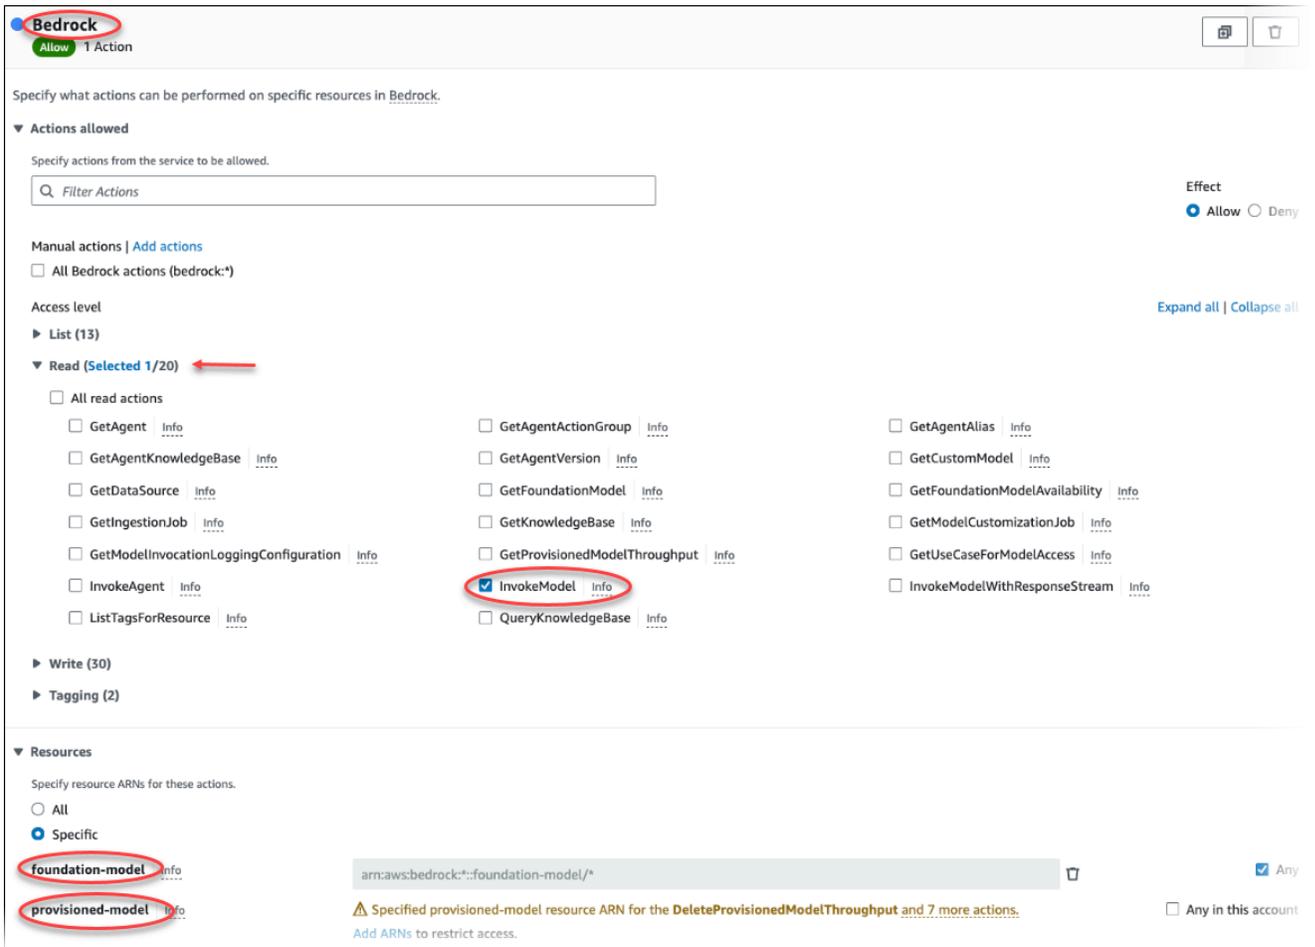

- [Setting up Aurora PostgreSQL to use Amazon Bedrock](#)
- [Setting up Aurora PostgreSQL to use Amazon Comprehend](#)
- [Setting up Aurora PostgreSQL to use Amazon SageMaker AI](#)
  - [Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker AI \(Advanced\)](#)
- [Installing the Aurora machine learning extension](#)

## Setting up Aurora PostgreSQL to use Amazon Bedrock

In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Bedrock on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Bedrock. For simplicity's sake, this procedure uses the Amazon Web Services Management Console to complete all tasks.

### To set up your Aurora PostgreSQL DB cluster to use Amazon Bedrock

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Open the IAM console at <https://console.amazonaws.cn/iam/>.
3. Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu.
  - a. Choose **Create policy**. In the Visual editor page, choose **Service** and then enter **Bedrock** in the Select a service field. Expand the Read access level. Choose **InvokeModel** from the Amazon Bedrock read settings.
  - b. Choose the Foundation/Provisioned model you want to grant read access via the policy.

4. Choose **Next: Tags** and define any tags (this is optional). Choose **Next: Review**. Enter a Name for the policy and description, as shown in the image.

## Review and create [Info](#)

Review the permissions, specify details, and tags.

### Policy details

**Policy name**  
Enter a meaningful name to identify this policy.

**docs-lab-apg-bedrock-policy**

Maximum 128 characters. Use alphanumeric and '+', '@', '-' characters.

**Description - optional**  
Add a short explanation for this policy.

Maximum 1,000 characters. Use alphanumeric and '+', '@', '-' characters.

### Permissions defined in this policy [Info](#) Edit

Permissions defined in this policy document specify which actions are allowed or denied. To define permissions for an IAM identity (user, user group, or role), attach a policy to it

**Allow (1 of 399 services)** Show remaining 398 services

Service	Access level	Resource	Request condition
<a href="#">Bedrock</a>	Limited: Read	region  string like  All	None

### Add tags - optional [Info](#)

Tags are key-value pairs that you can add to AWS resources to help identify, organize, or search for resources.

No tags associated with the resource.

You can add up to 50 more tags.

Cancel Previous Create policy

5. Choose **Create policy**. The Console displays an alert when the policy has been saved. You can find it in the list of Policies.
6. Choose **Roles** (under Access management) on the IAM Console.
7. Choose **Create role**.
8. On the Select trusted entity page, choose the **Amazon service** tile, and then choose **RDS** to open the selector.
9. Choose **RDS – Add Role to Database**.

**Select trusted entity** [Info](#)

**Trusted entity type**

**AWS service**  
Allow AWS services like EC2, Lambda, or others to perform actions in this account.

**AWS account**  
Allow entities in other AWS accounts belonging to you or a 3rd party to perform actions in this account.

**Web identity**  
Allows users federated by the specified external web identity provider to assume this role to perform actions in this account.

**SAML 2.0 federation**  
Allow users federated with SAML 2.0 from a corporate directory to perform actions in this account.

**Custom trust policy**  
Create a custom trust policy to enable others to perform actions in this account.

**Use case**  
Allow an AWS service like EC2, Lambda, or others to perform actions in this account.

Service or use case  
RDS

Choose a use case for the specified service.  
Use case

**RDS - CloudHSM**  
Allows RDS to manage CloudHSM resources on your behalf.

**RDS - Directory Service**  
Allows RDS to manage Directory Service resources on your behalf.

**RDS - Enhanced Monitoring**  
Allows RDS to manage CloudWatch Logs resources for Enhanced Monitoring on your behalf.

**RDS - Add Role to Database**  
Allows you to grant RDS access to additional resources on your behalf.

**RDS**  
Allows RDS to perform operations using AWS resources on your behalf.

**RDS - Beta**  
Allows RDS to perform operations using AWS resources on your behalf in the Beta region.

**RDS - Preview**  
Allows RDS Preview to manage AWS resources on your behalf.

Cancel **Next**

10. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**.
11. **Next: Review**. Enter a name for the IAM role and a description.
12. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
13. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.
14. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Bedrock.
15. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Bedrock, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.

**Manage IAM roles** ↻

Add IAM roles to this cluster: docs-lab-apg-bedrock-role Feature: Bedrock Add role

Current IAM roles for this cluster (0) Delete

Role	Feature	Status
------	---------	--------

The IAM setup for Amazon Bedrock is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in [Installing the Aurora machine learning extension](#)

## Setting up Aurora PostgreSQL to use Amazon Comprehend

In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Comprehend on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Comprehend. For simplicity's sake, this procedure uses the Amazon Web Services Management Console to complete all tasks.

### To set up your Aurora PostgreSQL DB cluster to use Amazon Comprehend

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. Open the IAM console at <https://console.amazonaws.cn/iam/>.
3. Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu.

## Create policy

1 2 3

A policy defines the permissions that you can assign to a user, group, or role. You can create and edit a policy in the visual editor and using JSON. [Learn more](#)

Step 2  
Add permissions

Step 3  
Name, review, and create

## Select trusted entity

### Trusted entity type

**service**  
 Allow   services like EC2, Lambda, or others to perform actions in this account.

**account**  
 Allow entities in other   accounts belonging to you or a 3rd party to perform actions in this account.

**Web identity**  
 Allows users federated by the specified external web identity provider to assume this role to perform actions in this account.

**SAML 2.0 federation**  
 Allow users federated with SAML 2.0 from a corporate directory to perform actions in this account.

**Custom trust policy**  
 Create a custom trust policy to enable others to perform actions in this account.

### Use case

Allow an   service like EC2, Lambda, or others to perform actions in this account.

---

Common use cases

- EC2**  
Allows EC2 instances to call   services on your behalf.
- Lambda**  
Allows Lambda functions to call   services on your behalf.

Use cases for other   services:

RDS ▼

- RDS - CloudHSM**  
Allows RDS to manage CloudHSM resources on your behalf.
- RDS - Directory Service**  
Allows RDS to manage Directory Service resources on your behalf.
- RDS - Enhanced Monitoring**  
Allows RDS to manage CloudWatch Logs resources for Enhanced Monitoring on your behalf.
- RDS - Add Role to Database**  
Allows you to grant RDS access to additional resources on your behalf.

11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**
12. **Next: Review**. Enter a name for the IAM role and a description.
13. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
14. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.

15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Amazon Comprehend.
16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Comprehend, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.

The screenshot shows the 'Manage IAM roles' interface. At the top, there are two dropdown menus: 'Add IAM roles to this cluster' (set to 'Choose an IAM role to add') and 'Feature' (set to 'Choose a feature to add'). An 'Add role' button is to the right. Below these is a table titled 'Current IAM roles for this cluster (2)' with a 'Delete' button. The table has three columns: Role, Feature, and Status. Two roles are listed:

Role	Feature	Status
docs-lab-aur-ml-role-for-sagemaker	SageMaker	Active
docs-lab-role-for-comprehend-and-apg	Comprehend	Active

The IAM setup for Amazon Comprehend is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in [Installing the Aurora machine learning extension](#)

## Setting up Aurora PostgreSQL to use Amazon SageMaker AI

Before you can create the IAM policy and role for your Aurora PostgreSQL DB cluster, you need to have your SageMaker AI model setup and your endpoint available.

### To set up your Aurora PostgreSQL DB cluster to use SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.

- Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu, and then choose **Create policy**. In the Visual editor, choose **SageMaker** for the Service. For Actions, open the Read selector (under Access level) and choose **InvokeEndpoint**. When you do this, a warning icon displays.
- Open the Resources selector and choose the **Add ARN to restrict access** link under the Specify endpoint resource ARN for the InvokeEndpoint action.
- Enter the Amazon Web Services Region of your SageMaker AI resources and the name of your endpoint. Your Amazon account is prefilled.

### Add ARN(s) ✕

Amazon Resource Names (ARNs) uniquely identify   resources. Resources are unique to each service. [Learn more](#) ↗

**Specify ARN for endpoint** List ARNs manually

arn:aws:sagemaker:us-east-2:04 :endpoint/docs-lab-aurora-ml-testing-sa

<b>Region *</b>	<input type="text" value="us-east-2"/>	<input type="checkbox"/> Any
<b>Account *</b>	<input #ccc;="" 0="" 5px;"="" background-color:="" padding:="" type="text" value="04&lt;span style="/> "/>	<input type="checkbox"/> Any
<b>Endpoint name *</b>	<input type="text" value="docs-lab-aurora-ml-testing-sa"/>	<input type="checkbox"/> Any

Cancel Add

- Choose **Add** to save. Choose **Next: Tags** and **Next: Review** to get to the last page of the policy creation process.
- Enter a Name and Description for this policy, and then choose **Create policy**. The policy is created and is added to the Policies list. You see an alert in the Console as this occurs.
- On the IAM Console, choose **Roles**.
- Choose **Create role**.
- On the Select trusted entity page, choose the **Amazon service** tile, and then choose **RDS** to open the selector.

10. Choose **RDS – Add Role to Database**.
11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**
12. **Next: Review**. Enter a name for the IAM role and a description.
13. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
14. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.
15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with SageMaker AI.
16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose SageMaker AI, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing.

The IAM setup for SageMaker AI is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in [Installing the Aurora machine learning extension](#).

### Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker AI (Advanced)

To use SageMaker AI with your own models rather than using the pre-built components provided by SageMaker AI, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket for Aurora PostgreSQL DB cluster to use. This is an advanced topic, and isn't fully documented in this *Amazon Aurora User Guide*. The general process is the same as for integrating support for SageMaker AI, as follows.

1. Create the IAM policy and role for Amazon S3.
2. Add the IAM role and the Amazon S3 import or export as a feature on the Connectivity & security tab of your Aurora PostgreSQL DB cluster.
3. Add the ARN of the role to your custom DB cluster parameter group for your Aurora DB cluster.

For basic usage information, see [Exporting data to Amazon S3 for SageMaker AI model training \(Advanced\)](#).

## Installing the Aurora machine learning extension

The Aurora machine learning extensions `aws_ml 1.0` provides two functions that you can use to invoke Amazon Comprehend, SageMaker AI services and `aws_ml 2.0` provides two additional functions that you can use to invoke Amazon Bedrock services. Installing these extensions on your Aurora PostgreSQL DB cluster also creates an administrative role for the feature.

### Note

Using these functions depends on having the IAM setup for the Aurora machine learning service (Amazon Comprehend, SageMaker AI, Amazon Bedrock) complete, as detailed in [Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning](#).

- **`aws_comprehend.detect_sentiment`** – You use this function to apply sentiment analysis to text stored in the database on your Aurora PostgreSQL DB cluster.
- **`aws_sagemaker.invoke_endpoint`** – You use this function in your SQL code to communicate with the SageMaker AI endpoint from your cluster.
- **`aws_bedrock.invoke_model`** – You use this function in your SQL code to communicate with the Bedrock Models from your cluster. The response of this function will be in the format of a TEXT, so if a model responds in the format of a JSON body then the output of this function will be relayed in the format of a string to the end user.
- **`aws_bedrock.invoke_model_get_embeddings`** – You use this function in your SQL code to invoke Bedrock Models that return output embeddings within a JSON response. This can be leveraged when you want to extract the embeddings directly associated with the json-key to streamline the response with any self-managed workflows.

### To install the Aurora machine learning extension in your Aurora PostgreSQL DB cluster

- Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster. Connect to the specific database in which to install the `aws_ml` extension.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password --dbname=labdb
```

```
labdb=> CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
```

```
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION  
labdb=>
```

Installing the `aws_ml` extensions also creates the `aws_ml` administrative role and three new schemas, as follows.

- `aws_comprehend` – Schema for the Amazon Comprehend service and source of the `detect_sentiment` function (`aws_comprehend.detect_sentiment`).
- `aws_sagemaker` – Schema for the SageMaker AI service and source of the `invoke_endpoint` function (`aws_sagemaker.invoke_endpoint`).
- `aws_bedrock` – Schema for the Amazon Bedrock service and source of the `invoke_model` (`aws_bedrock.invoke_model`) and `invoke_model_get_embeddings` (`aws_bedrock.invoke_model_get_embeddings`) functions.

The `rds_superuser` role is granted the `aws_ml` administrative role and is made the OWNER of these three Aurora machine learning schemas. To allow other database users to access the Aurora machine learning functions, the `rds_superuser` needs to grant EXECUTE privileges on the Aurora machine learning functions. By default, EXECUTE privileges are revoked from PUBLIC on the functions in the two Aurora machine learning schemas.

In a multi-tenant database configuration, you can prevent tenants from accessing Aurora machine learning functions by using REVOKE USAGE on the specific Aurora machine learning schema that you want to protect.

## Using Amazon Bedrock with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Bedrock function for working with your text data. This function is available only after you install the `aws_ml` 2.0 extension and complete all setup procedures. For more information, see [Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning](#).

### `aws_bedrock.invoke_model`

This function takes text formatted in JSON as input and processes it for variety of models hosted on Amazon Bedrock and gets back the JSON text response from the model.

This response could contain text, image, or embeddings. A summary of the function's documentation is as follows.

```
aws_bedrock.invoke_model(  
  IN model_id      varchar,  
  IN content_type  text,  
  IN accept_type   text,  
  IN model_input   text,  
  OUT model_output varchar)
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model.
- `accept_type` – The type of the response to expect from Bedrock's model. Usually application/JSON for most of the models.
- `model_input` – Prompts; a specific set of inputs to the model in the format as specified by `content_type`. For more information on the request format/structure the model accepts, see [Inference parameters for foundation models](#).
- `model_output` – The Bedrock model's output as text.

The following example shows how to invoke a Anthropic Claude 2 model for Bedrock using `invoke_model`.

### Example Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model (  
  model_id      := 'anthropic.claude-v2',  
  content_type:= 'application/json',  
  accept_type  := 'application/json',  
  model_input  := '{"prompt": "\n\nHuman: You are a helpful assistant that answers  
questions directly and only using the information provided in the context below.  
\nDescribe the answer  
in detail.\n\nContext: %s \n\nQuestion: %s \n\nAssistant:", "max_tokens_to_sample":4096, "temperature":0.5, "top_k":250, "top_p":0.5, "stop_sequences":  
[""]}'  
);
```

## aws\_bedrock.invoke\_model\_get\_embeddings

The model output can point to vector embeddings for some cases. Given the response varies per model, another function `invoke_model_get_embeddings` can be leveraged which works exactly like `invoke_model` but outputs the embeddings by specifying the appropriate json-key.

```
aws_bedrock.invoke_model_get_embeddings(  
  IN model_id      varchar,  
  IN content_type  text,  
  IN json_key      text,  
  IN model_input   text,  
  OUT model_output float8[])
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model. Here, the `accept_type` is set to default value `application/json`.
- `model_input` – Prompts; a specific set of inputs to the Model in the format as specified by `content_type`. For more information on the request format/structure the Model accepts, see [Inference parameters for foundation models](#).
- `json_key` – Reference to the field to extract the embedding from. This may vary if the embedding model changes.
- `model_output` – The Bedrock model's output as an array of embeddings having 16 bit decimals.

The following example shows how to generate an embedding using the Titan Embeddings G1 – Text embedding model for the phrase PostgreSQL I/O monitoring views.

### Example Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model_get_embeddings(  
  model_id      := 'amazon.titan-embed-text-v1',  
  content_type  := 'application/json',  
  json_key      := 'embedding',  
  model_input   := '{ "inputText": "PostgreSQL I/O monitoring views"}') AS embedding;
```

## Using Amazon Comprehend with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Comprehend function for working with your text data. This function is available only after you install the `aws_ml` extension and complete all setup procedures. For more information, see [Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning](#).

### `aws_comprehend.detect_sentiment`

This function takes text as input and evaluates whether the text has a positive, negative, neutral, or mixed emotional posture. It outputs this sentiment along with a confidence level for its evaluation. A summary of the function's documentation is as follows.

```
aws_comprehend.detect_sentiment(  
  IN input_text varchar,  
  IN language_code varchar,  
  IN max_rows_per_batch int,  
  OUT sentiment varchar,  
  OUT confidence real)
```

The inputs and outputs of this function are as follows.

- `input_text` – The text to evaluate and to assign sentiment (negative, positive, neutral, mixed).
- `language_code` – The language of the `input_text` identified using the 2-letter ISO 639-1 identifier with regional subtag (as needed) or the ISO 639-2 three-letter code, as appropriate. For example, `en` is the code for English, `zh` is the code for simplified Chinese. For more information, see [Supported languages](#) in the *Amazon Comprehend Developer Guide*.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see [Understanding batch mode and Aurora machine learning functions](#).
- `sentiment` – The sentiment of the input text, identified as `POSITIVE`, `NEGATIVE`, `NEUTRAL`, or `MIXED`.
- `confidence` – The degree of confidence in the accuracy of the specified sentiment. Values range from 0.0 to 1.0.

In the following, you can find examples of how to use this function.

## Example Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes this function to assess customer satisfaction with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies the `aws_comprehend.detect_sentiment` function to the text in the `feedback` column of the table and outputs the sentiment and the confidence level for that sentiment. This query also outputs results in descending order.

```
SELECT feedback, s.sentiment,s.confidence
   FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
   ORDER BY s.confidence DESC;
```

feedback	sentiment	confidence
Thank you for the excellent customer support!	POSITIVE	0.999771
The latest version of this product stinks!	NEGATIVE	0.999184
Your support team is just awesome! I am blown away.	POSITIVE	0.997774
Your product is too complex, but your support is great.	MIXED	0.957958
Your support tech helped me in fifteen minutes.	POSITIVE	0.949491
My problem was never resolved!	NEGATIVE	0.920644
When will the new version of this product be released?	NEUTRAL	0.902706
I cannot stand that chatbot.	NEGATIVE	0.895219
Your support tech talked down to me.	NEGATIVE	0.868598
It took me way too long to get a real person.	NEGATIVE	0.481805

(10 rows)

To avoid being charged for sentiment detection more than once per table row, you can materialize the results. Do this on the rows of interest. For example, the clinician's notes are being updated so that only those in French (`fr`) use the sentiment detection function.

```
UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
    confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE
    clinician_notes.french_notes IS NOT NULL AND
    LENGTH(TRIM(clinician_notes.french_notes)) > 0 AND
    clinician_notes.sentiment IS NULL;
```

For more information on optimizing your function calls, see [Performance considerations for using Aurora machine learning with Aurora PostgreSQL](#).

## Using SageMaker AI with your Aurora PostgreSQL DB cluster

After setting up your SageMaker AI environment and integrating with Aurora PostgreSQL as outlined in [Setting up Aurora PostgreSQL to use Amazon SageMaker AI](#), you can invoke operations by using the `aws_sagemaker.invoke_endpoint` function. The `aws_sagemaker.invoke_endpoint` function connects only to a model endpoint in the same Amazon Web Services Region. If your database instance has replicas in multiple Amazon Web Services Regions be sure that you setup and deploy each SageMaker AI model to every Amazon Web Services Region.

Calls to `aws_sagemaker.invoke_endpoint` are authenticated using the IAM role that you set up to associated your Aurora PostgreSQL DB cluster with the SageMaker AI service and the endpoint that you provided during the setup process. SageMaker AI model endpoints are scoped to an individual account and are not public. The `endpoint_name` URL doesn't contain the account ID. SageMaker AI determines the account ID from the authentication token that is supplied by the SageMaker AI IAM role of the database instance.

### `aws_sagemaker.invoke_endpoint`

This function takes the SageMaker AI endpoint as input and the number of rows that should be processed as a batch. It also takes as input the various parameters expected by the SageMaker AI model endpoint. This function's reference documentation is as follows.

```
aws_sagemaker.invoke_endpoint(  
  IN endpoint_name varchar,  
  IN max_rows_per_batch int,  
  VARIADIC model_input "any",  
  OUT model_output varchar  
)
```

The inputs and outputs of this function are as follows.

- `endpoint_name` – An endpoint URL that is Amazon Web Services Region-independent.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see [Understanding batch mode and Aurora machine learning functions](#).

- `model_input` – One or more input parameters for the model. These can be any data type needed by the SageMaker AI model. PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker AI model. The number of inputs to a SageMaker AI model is limited only by the SageMaker AI 6 MB message size limit.
- `model_output` – The SageMaker AI model's output as text.

## Creating a user-defined function to invoke a SageMaker AI model

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker AI models. Your user-defined function represents the SageMaker AI endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

- You can give your SageMaker AI model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your SageMaker AI models.
- You can specify the model endpoint URL in just one place in your SQL application code.
- You can control EXECUTE privileges to each Aurora machine learning function independently.
- You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your SageMaker AI model and performs type conversion if necessary. Using SQL types will also translate SQL NULL to the appropriate default value expected by your SageMaker AI model.
- You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement CREATE FUNCTION. When you define the function, you specify the following:

- The input parameters to the model.
- The specific SageMaker AI endpoint to invoke.
- The return type.

The user-defined function returns the inference computed by the SageMaker AI endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker AI model with two input parameters.

```
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', NULL,
        arg1, arg2                                -- model inputs are separate arguments
    )::INT                                        -- cast the output to INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- The `aws_sagemaker.invoke_endpoint` function input can be one or more parameters of any data type.
- This example uses an `INT` output type. If you cast the output from a `varchar` type to a different type, then it must be cast to a PostgreSQL builtin scalar type such as `INTEGER`, `REAL`, `FLOAT`, or `NUMERIC`. For more information about these types, see [Data types](#) in the PostgreSQL documentation.
- Specify `PARALLEL SAFE` to enable parallel query processing. For more information, see [Improving response times with parallel query processing](#).
- Specify `COST 5000` to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of `cpu_operator_cost`.

## Passing an array as input to a SageMaker AI model

The `aws_sagemaker.invoke_endpoint` function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker AI model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example defines a function that passes an array as input to the SageMaker AI regression model. The output is cast to a `REAL` value.

```
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name',
        NULL,
        params
    )::REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

## Specifying batch size when invoking a SageMaker AI model

The following example creates a user-defined function for a SageMaker AI model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```
CREATE FUNCTION classify_event (  
    IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs  
    max_rows_per_batch INT DEFAULT NULL, -- optional batch size limit  
    OUT category INT) -- model output  
AS $$  
    SELECT aws_sagemaker.invoke_endpoint (  
        'sagemaker_model_endpoint_name', max_rows_per_batch,  
        event_type, event_day, COALESCE(amount, 0.0)  
    )::INT -- casts output to type INT  
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- Use the optional `max_rows_per_batch` parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see [Understanding batch mode and Aurora machine learning functions](#).
- By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker AI. For this example the inputs have different types.
- If you have a non-text input, or text input that needs to default to some value other than an empty string, use the COALESCE statement. Use COALESCE to translate NULL to the desired null replacement value in the call to `aws_sagemaker.invoke_endpoint`. For the amount parameter in this example, a NULL value is converted to 0.0.

## Invoking a SageMaker AI model that has multiple outputs

The following example creates a user-defined function for a SageMaker AI model that returns multiple outputs. Your function needs to cast the output of the `aws_sagemaker.invoke_endpoint` function to a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```
CREATE TYPE company_forecasts AS (  
    six_month_estimated_return real,  
    one_year_bankruptcy_probability float);  
CREATE FUNCTION analyze_company (  
    IN free_cash_flow NUMERIC(18, 6),  
    IN debt NUMERIC(18,6),  
    IN max_rows_per_batch INT DEFAULT NULL,  
    OUT prediction company_forecasts)  
AS $$  
    SELECT (aws_sagemaker.invoke_endpoint('endpt_name',  
        max_rows_per_batch,free_cash_flow, debt))::company_forecasts;  
  
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL `"."` notation.

## Exporting data to Amazon S3 for SageMaker AI model training (Advanced)

We recommend that you become familiar with Aurora machine learning and SageMaker AI by using the provided algorithms and examples rather than trying to train your own models. For more information, see [Get Started with Amazon SageMaker AI](#)

To train SageMaker AI models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker AI to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker AI consumes the data from the Amazon S3 bucket for training. For more about SageMaker AI model training, see [Train a model with Amazon SageMaker AI](#).

### Note

When you create an Amazon S3 bucket for SageMaker AI model training or batch scoring, use `sagemaker` in the Amazon S3 bucket name. For more information, see [Specify a Amazon S3 Bucket to Upload Training Datasets and Store Output Data](#) in the *Amazon SageMaker AI Developer Guide*.

For more information about exporting your data, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).

## Performance considerations for using Aurora machine learning with Aurora PostgreSQL

The Amazon Comprehend and SageMaker AI services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora PostgreSQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning from Aurora PostgreSQL.

### Topics

- [Understanding batch mode and Aurora machine learning functions](#)
- [Improving response times with parallel query processing](#)
- [Using materialized views and materialized columns](#)

### Understanding batch mode and Aurora machine learning functions

Typically, PostgreSQL runs functions one row at a time. Aurora machine learning can reduce this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called *batch-mode execution*. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the SELECT list, a WHERE clause, or a HAVING clause. Note that top-level simple CASE expressions are eligible for batch-mode execution. Top-level searched CASE expressions are also eligible for batch-mode execution provided that the first WHEN clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a LANGUAGE SQL function and should specify PARALLEL SAFE and COST 5000.

### Function migration from the SELECT statement to the FROM clause

Usually, an `aws_ml` function that is eligible for batch-mode execution is automatically migrated by Aurora to the FROM clause.

The migration of eligible batch-mode functions to the FROM clause can be examined manually on a per-query level. To do this, you use EXPLAIN statements (and ANALYZE and VERBOSE) and find the "Batch Processing" information below each batch-mode Function Scan. You can also use EXPLAIN (with VERBOSE) without running the query. You then observe whether the calls to the function appear as a Function Scan under a nested loop join that was not specified in the original statement.

In the following example, the nested loop join operator in the plan shows that Aurora migrated the `anomaly_score` function. It migrated this function from the SELECT list to the FROM clause, where it's eligible for batch-mode execution.

```
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
          QUERY PLAN
-----
Nested Loop
  Output: anomaly_score((r.description)::text)
  -> Seq Scan on ts.r
      Output: r.id, r.description, r.score
  -> Function Scan on public.anomaly_score
      Output: anomaly_score.anomaly_score
      Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the `apg_enable_function_migration` parameter to `false`. This prevents the migration of `aws_ml` functions from the SELECT to the FROM clause. The following shows how.

```
SET apg_enable_function_migration = false;
```

The `apg_enable_function_migration` parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL `apg_plan_mgmt` extension for query plan management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its `apg_enable_function_migration` setting. This enforcement occurs regardless of the `apg_enable_function_migration` GUC parameter setting. For more information, see [Managing query execution plans for Aurora PostgreSQL](#).

## Using the `max_rows_per_batch` parameter

Both the `aws_comprehend.detect_sentiment` and the `aws_sagemaker.invoke_endpoint` functions have a `max_rows_per_batch` parameter. This parameter specifies the number of rows that can be sent to the Aurora machine learning service. The larger the dataset processed by your function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a `SELECT` statement finishes early due to a `LIMIT` clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your Amazon account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the `max_rows_per_batch` parameter in your function calls.

If you do an `EXPLAIN (VERBOSE, ANALYZE)` of a query that uses batch-mode execution, you see a `FunctionScan` operator that is below a nested loop join. The number of loops reported by `EXPLAIN` equals the number of times a row was fetched from the `FunctionScan` operator. If a statement uses a `LIMIT` clause, the number of fetches is consistent. To optimize the size of the batch, set the `max_rows_per_batch` parameter to this value. However, if the batch-mode function is referenced in a predicate in the `WHERE` clause or `HAVING` clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with `max_rows_per_batch` to find a setting that optimizes performance.

## Verifying batch-mode execution

To see if a function ran in batch mode, use `EXPLAIN ANALYZE`. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
                  avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the `max_rows_per_batch` parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a `LIMIT` in your user-defined function, set the `max_rows_per_batch` parameter to a smaller value.

## Improving response times with parallel query processing

To get results as fast as possible from a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for `SELECT`, `CREATE TABLE AS SELECT`, and `CREATE MATERIALIZED VIEW` statements.

### Note

PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the task among a set of parallel workers. Then each of these workers can build batched requests containing tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the SageMaker AI endpoint. The degree of parallelism that the endpoint can support is constrained by the number and type of instances that support it. For  $K$  degrees of parallelism, you need a database instance class that has at least  $K$  cores. You also need to configure the SageMaker AI endpoint for your model to have  $K$  initial instances of a sufficiently high-performing instance class.

To use parallel query processing, you can set the `parallel_workers` storage parameter of the table that contains the data that you plan to pass. You set `parallel_workers` to a batch-mode function such as `aws_comprehend.detect_sentiment`. If the optimizer chooses a parallel query plan, the Amazon ML services can be called both in batch and in parallel.

You can use the following parameters with the `aws_comprehend.detect_sentiment` function to get a plan with four-way parallelism. If you change either of the following two parameters, you must restart the database instance for the changes to take effect

```
-- SET max_worker_processes to 8; -- default value is 8
-- SET max_parallel_workers to 8; -- not greater than max_worker_processes
SET max_parallel_workers_per_gather to 4; -- not greater than max_parallel_workers

-- You can set the parallel_workers storage parameter on the table that the data
-- for the Aurora machine learning function is coming from in order to manually
  override the degree of
  parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);

-- Example query to exploit both batch-mode execution and parallel query
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en').*
FROM yourTable
WHERE id < 100;
```

For more information about controlling parallel query, see [Parallel plans](#) in the PostgreSQL documentation.

## Using materialized views and materialized columns

When you invoke an Amazon service such as SageMaker AI or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the Amazon service into a materialized column so that the Amazon service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an Amazon service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.

UPDATE takes a row-level lock that can impact a running application. So you might need to use `SELECT . . . FOR UPDATE SKIP LOCKED`, or use `MATERIALIZED VIEW`.

Analytic queries that operate on a large number of rows in real time can combine batch-mode materialization with real-time processing. To do this, these queries assemble a `UNION ALL` of the pre-materialized results with a query over the rows that don't yet have materialized results. In some cases, such a `UNION ALL` is needed in multiple places, or the query is generated by a third-party application. If so, you can create a `VIEW` to encapsulate the `UNION ALL` operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary `SELECT` statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the `CONCURRENTLY` option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

## Monitoring Aurora machine learning

You can monitor the `aws_ml` functions by setting the `track_functions` parameter in your custom DB cluster parameter group to `all`. By default, this parameter is set to `pl` which means that only procedure-language functions are tracked. By changing this to `all`, the `aws_ml` functions are also tracked. For more information, see [Run-time Statistics](#) in the PostgreSQL documentation.

For information about monitoring the performance of the SageMaker AI operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker AI](#) in the *Amazon SageMaker AI Developer Guide*.

With `track_functions` set to `all`, you can query the `pg_stat_user_functions` view to get statistics about the functions that you define and use to invoke Aurora machine learning services. For each function, the view provides the number of calls, `total_time`, and `self_time`.

To view the statistics for the `aws_sagemaker.invoke_endpoint` and the `aws_comprehend.detect_sentiment` functions, you can filter results by schema name using the following query.

```
SELECT * FROM pg_stat_user_functions
```

```
WHERE schemaname  
LIKE 'aws_%';
```

To clear the statistics, do as follows.

```
SELECT pg_stat_reset();
```

You can get the names of your SQL functions that call the `aws_sagemaker.invoke_endpoint` function by querying the PostgreSQL `pg_proc` system catalog. This catalog stores information about functions, procedures, and more. For more information, see [pg\\_proc](#) in the PostgreSQL documentation. Following is an example of querying the table to get the names of functions (`proname`) whose source (`prosrc`) includes the text `invoke_endpoint`.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

# Code examples for Aurora using Amazon SDKs

The following code examples show how to use Aurora with an Amazon software development kit (SDK).

*Basics* are code examples that show you how to perform the essential operations within a service.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

*Scenarios* are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

# Hello Aurora

The following code examples show how to get started using Aurora.

.NET

## Amazon SDK for .NET (v4)

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
using Amazon.RDS;
using Amazon.RDS.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace AuroraActions;

public static class HelloAurora
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
        // the
        // Amazon Relational Database Service (Amazon RDS).
        // Use your AWS profile name, or leave it blank to use the default
        // profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonRDS>()
            ).Build();

        // Now the client is available for injection. Fetching it directly here
        // for example purposes only.
        var rdsClient = host.Services.GetRequiredService<IAmazonRDS>();

        // You can use await and any of the async methods to get a response.
```

```
var response = await rdsClient.DescribeDBClustersAsync(new
DescribeDBClustersRequest { IncludeShared = true });
Console.WriteLine($"Hello Amazon RDS Aurora! Let's list some clusters in
this account:");
if (response.DBClusters == null)
{
    Console.WriteLine($"\\tNo clusters found.");
}
else
{
    foreach (var cluster in response.DBClusters)
    {
        Console.WriteLine(
            $"\\tCluster: database: {cluster.DatabaseName} identifier:
{cluster.DBClusterIdentifier}.");
    }
}
}
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
```

```
project("hello_aurora")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.
  string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
    "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
  list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD AND AWSSDK_INSTALL_AS_SHARED_LIBS)
  # Copy relevant AWS SDK for C++ libraries into the current binary directory
  for running and debugging.

  # set(BIN_SUB_DIR "/Debug") # If you are building from the command line, you
  may need to uncomment this
  # and set the proper subdirectory to the
  executables' location.

  AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
    ${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})
endif ()

add_executable(${PROJECT_NAME}
  hello_aurora.cpp)

target_link_libraries(${PROJECT_NAME}
  ${AWSSDK_LINK_LIBRARIES})
```

Code for the `hello_aurora.cpp` source file.

```
#include <aws/core/Aws.h>
#include <aws/rds/RDSClient.h>
```

```
#include <aws/rds/model/DescribeDBClustersRequest.h>
#include <iostream>

/*
 * A "Hello Aurora" starter application which initializes an Amazon Relational
 * Database Service (Amazon RDS) client
 * and describes the Amazon Aurora (Aurora) clusters.
 *
 * main function
 *
 * Usage: 'hello_aurora'
 */
int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
    // options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

        Aws::RDS::RDSClient rdsClient(clientConfig);

        Aws::String marker; // Used for pagination.
        std::vector<Aws::String> clusterIds;

                rdsClient.DescribeDBClusters(request);

            if (outcome.IsSuccess()) {
                for (auto &cluster: outcome.GetResult().GetDBClusters()) {
                    clusterIds.push_back(cluster.GetDBClusterIdentifier());
                }
                marker = outcome.GetResult().GetMarker();
            } else {
                result = 1;
                std::cerr << "Error with Aurora::GDescribeDBClusters. "
                    << outcome.GetError().GetMessage()
                    << std::endl;
            }
        }
    }
}
```

```
        break;
    }
} while (!marker.empty());

std::cout << clusterIds.size() << " Aurora clusters found." << std::endl;
for (auto &clusterId: clusterIds) {
    std::cout << "  clusterId " << clusterId << std::endl;
}
}

Aws::ShutdownAPI(options); // Should only be called once.
return 0;
}
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for C++ API Reference*.

Go

## SDK for Go V2

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
package main

import (
    "context"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/rds"
)

// main uses the AWS SDK for Go V2 to create an Amazon Aurora client and list up
// to 20
// DB clusters in your account.
```

```
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
    ctx := context.Background()
    sdkConfig, err := config.LoadDefaultConfig(ctx)
    if err != nil {
        fmt.Println("Couldn't load default configuration. Have you set up your AWS
account?")
        fmt.Println(err)
        return
    }
    auroraClient := rds.NewFromConfig(sdkConfig)
    const maxClusters = 20
    fmt.Printf("Let's list up to %v DB clusters.\n", maxClusters)
    output, err := auroraClient.DescribeDBClusters(
        ctx, &rds.DescribeDBClustersInput{MaxRecords: aws.Int32(maxClusters)})
    if err != nil {
        fmt.Printf("Couldn't list DB clusters: %v\n", err)
        return
    }
    if len(output.DBClusters) == 0 {
        fmt.Println("No DB clusters found.")
    } else {
        for _, cluster := range output.DBClusters {
            fmt.Printf("DB cluster %v has database %v.\n", *cluster.DBClusterIdentifier,
                *cluster.DatabaseName)
        }
    }
}
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for Go API Reference*.

## Java

### SDK for Java 2.x

#### Note

## Python

### SDK for Python (Boto3)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
import boto3
```

```
# Create an RDS client
rds = boto3.client("rds")

# Create a paginator for the describe_db_clusters operation
paginator = rds.get_paginator("describe_db_clusters")

# Use the paginator to get a list of DB clusters
response_iterator = paginator.paginate(
    PaginationConfig={
        "PageSize": 50, # Adjust PageSize as needed
        "StartingToken": None,
    }
)

# Iterate through the pages of the response
clusters_found = False
for page in response_iterator:
    if "DBClusters" in page and page["DBClusters"]:
        clusters_found = True
        print("Here are your RDS Aurora clusters:")
        for cluster in page["DBClusters"]:
            print(
                f"Cluster ID: {cluster['DBClusterIdentifier']}, Engine:
{cluster['Engine']}"
            )

if not clusters_found:
    print("No clusters found!")
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for Python (Boto3) API Reference*.

## Ruby

### SDK for Ruby

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
require 'aws-sdk-rds'

# Creates an Amazon RDS client for the AWS Region
rds = Aws::RDS::Client.new

puts 'Listing clusters in this AWS account...'

# Calls the describe_db_clusters method to get information about clusters
resp = rds.describe_db_clusters(max_records: 20)

# Checks if any clusters are found and prints the appropriate message
if resp.db_clusters.empty?
  puts 'No clusters found!'
else
  # Loops through the array of cluster objects and prints the cluster identifier
  resp.db_clusters.each do |cluster|
    puts "Cluster identifier: #{cluster.db_cluster_identifier}"
  end
end
end
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for Ruby API Reference*.

## Rust

### SDK for Rust

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
use aws_sdk_rds::Client;

#[derive(Debug)]

  fn fmt(&self, f: &mut std::fmt::Formatter<'_>) -> std::fmt::Result {
    write!(f, "{}", self.0)
  }
}
```

```
    }  
  }  
  impl std::error::Error for Error {}  
  
  #[tokio::main]  
  async fn main() -> Result<(), Error> {  
    tracing_subscriber::fmt::init();  
    let sdk_config = aws_config::from_env().load().await;  
    let client = Client::new(&sdk_config);  
  
    let describe_db_clusters_output = client  
      .describe_db_clusters()  
      .send()  
      .await  
      .map_err(|e| Error(e.to_string()))?;  
    println!(  
      "Found {} clusters:",  
      describe_db_clusters_output.db_clusters().len()  
    );  
    for cluster in describe_db_clusters_output.db_clusters() {  
      let name = cluster.database_name().unwrap_or("Unknown");  
      let engine = cluster.engine().unwrap_or("Unknown");  
      let id = cluster.db_cluster_identifier().unwrap_or("Unknown");  
      let class = cluster.db_cluster_instance_class().unwrap_or("Unknown");  
      println!("\tDatabase: {name}",);  
      println!("\t Engine: {engine}",);  
      println!("\t      ID: {id}",);  
      println!("\tInstance: {class}",);  
    }  
  
    Ok(())  
  }  
}
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for Rust API reference*.

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Learn the basics of Aurora with an Amazon SDK

The following code examples show how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using AuroraActions;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
using Microsoft.Extensions.Logging;
using Microsoft.Extensions.Logging.Console;
using Microsoft.Extensions.Logging.Debug;

namespace AuroraScenario;

/// <summary>
/// Scenario for Amazon Aurora examples.
/// </summary>
public class AuroraScenario
{
    /*
```

Before running this .NET code example, set up your development environment, including your credentials.

This .NET example performs the following tasks:

1. Return a list of the available DB engine families for Aurora MySQL using the `DescribeDBEngineVersionsAsync` method.
2. Select an engine family and create a custom DB cluster parameter group using the `CreateDBClusterParameterGroupAsync` method.
3. Get the parameter group using the `DescribeDBClusterParameterGroupsAsync` method.
4. Get some parameters in the group using the `DescribeDBClusterParametersAsync` method.
5. Parse and display some parameters in the group.
6. Modify the `auto_increment_offset` and `auto_increment_increment` parameters using the `ModifyDBClusterParameterGroupAsync` method.
7. Get and display the updated parameters using the `DescribeDBClusterParametersAsync` method with a source of "user".
8. Get a list of allowed engine versions using the `DescribeDBEngineVersionsAsync` method.
9. Create an Aurora DB cluster that contains a MySQL database and uses the parameter group.  
using the `CreateDBClusterAsync` method.
10. Wait for the DB cluster to be ready using the `DescribeDBClustersAsync` method.
11. Display and select from a list of instance classes available for the selected engine and version  
using the paginated `DescribeOrderableDBInstanceOptions` method.
12. Create a database instance in the cluster using the `CreateDBInstanceAsync` method.
13. Wait for the DB instance to be ready using the `DescribeDBInstances` method.
14. Display the connection endpoint string for the new DB cluster.
15. Create a snapshot of the DB cluster using the `CreateDBClusterSnapshotAsync` method.
16. Wait for DB snapshot to be ready using the `DescribeDBClusterSnapshotsAsync` method.
17. Delete the DB instance using the `DeleteDBInstanceAsync` method.
18. Delete the DB cluster using the `DeleteDBClusterAsync` method.
19. Wait for DB cluster to be deleted using the `DescribeDBClustersAsync` methods.
20. Delete the cluster parameter group using the `DeleteDBClusterParameterGroupAsync`.

## Java

## SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
 * by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
 * 2. Selects an engine family and creates a custom DB cluster parameter group
 * by invoking the describeDBClusterParameters method.
 * 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
 * method.
 * 4. Gets parameters in the group by invoking the describeDBClusterParameters
 * method.
 * 5. Modifies the auto_increment_offset parameter by invoking the
 * modifyDbClusterParameterGroupRequest method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the
 * describeDbEngineVersions method.
 * 8. Creates an Aurora DB cluster database cluster that contains a MySQL
```

```

* database.
* 9. Waits for DB instance to be ready.
* 10. Gets a list of instance classes available for the selected engine.
* 11. Creates a database instance in the cluster.
* 12. Waits for DB instance to be ready.
* 13. Creates a snapshot.
* 14. Waits for DB snapshot to be ready.
* 15. Deletes the DB cluster.
* 16. Deletes the DB cluster group.

## Kotlin

### SDK for Kotlin

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/**
```

```
Before running this Kotlin code example, set up your development environment, including your credentials.
```

```
For more information, see the following documentation topic:
```

```
https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html
```

```
This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:
```

```
https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating\_how-services-use-secrets\_RS.html
```

```
This Kotlin example performs the following tasks:
```

1. Returns a list of the available DB engines.
2. Creates a custom DB parameter group.
3. Gets the parameter groups.
4. Gets the parameters in the group.
5. Modifies the `auto_increment_increment` parameter.
6. Displays the updated parameter value.
7. Gets a list of allowed engine versions.
8. Creates an Aurora DB cluster database.
9. Waits for DB instance to be ready.
10. Gets a list of instance classes available for the selected engine.
11. Creates a database instance in the cluster.
12. Waits for the database instance in the cluster to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB instance.
16. Deletes the DB cluster.
17. Deletes the DB cluster group.

## Actions for Aurora using Amazon SDKs

The following code examples demonstrate how to perform individual Aurora actions with Amazon SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Aurora API and are code excerpts from larger programs that must be run in context. You can see actions in context in [Scenarios for Aurora using Amazon SDKs](#).

The following examples include only the most commonly used actions. For a complete list, see the [Amazon Aurora API Reference](#).

### Examples

- [Use CreateDBCluster with an Amazon SDK](#)
- [Use CreateDBClusterParameterGroup with an Amazon SDK](#)
- [Use CreateDBClusterSnapshot with an Amazon SDK](#)
- [Use CreateDBInstance with an Amazon SDK](#)
- [Use DeleteDBCluster with an Amazon SDK](#)

- [Use DeleteDBClusterParameterGroup with an Amazon SDK](#)
- [Use DeleteDBInstance with an Amazon SDK](#)
- [Use DescribeDBClusterParameterGroups with an Amazon SDK](#)
- [Use DescribeDBClusterParameters with an Amazon SDK](#)
- [Use DescribeDBClusterSnapshots with an Amazon SDK](#)

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use CreateDBClusterParameterGroup with an Amazon SDK

The following code examples show how to use `CreateDBClusterParameterGroup`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Create a custom cluster parameter group.
/// </summary>
/// <param name="parameterGroupFamily">The family of the parameter group.</
param>
/// <param name="groupName">The name for the new parameter group.</param>
/// <param name="description">A description for the new parameter group.</
param>
/// <returns>The new parameter group object.</returns>
public async Task<DBClusterParameterGroup>
CreateCustomClusterParameterGroupAsync(
```

```

    string parameterGroupFamily,
    string groupName,
    string description)
{
    var request = new CreateDBClusterParameterGroupRequest
    {
        DBParameterGroupFamily = parameterGroupFamily,
        DBClusterParameterGroupName = groupName,
        Description = description,
    };

    var response = await
    _amazonRDS.CreateDBClusterParameterGroupAsync(request);
    return response.DBClusterParameterGroup;
}

```

- For API details, see [CreateDBClusterParameterGroup](#) in *Amazon SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

## Use CreateDBClusterSnapshot with an Amazon SDK

The following code examples show how to use CreateDBClusterSnapshot.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use CreateDBInstance with an Amazon SDK

The following code examples show how to use CreateDBInstance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use DeleteDBCluster with an Amazon SDK

The following code examples show how to use DeleteDBCluster.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Delete a particular DB cluster.
/// </summary>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <returns>DB cluster object.</returns>
public async Task<DBCluster> DeleteDBClusterByIdentifierAsync(string
dbClusterIdentifier)
{
    var response = await _amazonRDS.DeleteDBClusterAsync(
        new DeleteDBClusterRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            SkipFinalSnapshot = true
        });

    return response.DBCluster;
}
```

- For API details, see [DeleteDBCluster](#) in *Amazon SDK for .NET API Reference*.

## C++

## SDK for C++

 **Note**

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use DeleteDBClusterParameterGroup with an Amazon SDK

The following code examples show how to use `DeleteDBClusterParameterGroup`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Delete a particular parameter group by name.
/// </summary>
/// <param name="groupName">The name of the parameter group.</param>
/// <returns>True if successful.</returns>
public async Task<bool> DeleteClusterParameterGroupNameAsync(string
groupName)
{
    var request = new DeleteDBClusterParameterGroupRequest
    {
        DBClusterParameterGroupName = groupName,
    };

    var response = await
_amazonRDS.DeleteDBClusterParameterGroupAsync(request);
    return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

- For API details, see [DeleteDBClusterParameterGroup](#) in *Amazon SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::DeleteDBClusterParameterGroupRequest request;
request.SetDBClusterParameterGroupName(parameterGroupName);

Aws::RDS::Model::DeleteDBClusterParameterGroupOutcome outcome =
    client.DeleteDBClusterParameterGroup(request);

if (outcome.IsSuccess()) {
    std::cout << "The DB parameter group was successfully deleted."
              << std::endl;
}
else {
    std::cerr << "Error with Aurora::DeleteDBClusterParameterGroup. "
              << outcome.GetError().GetMessage()
              << std::endl;
    result = false;
}
```

## Use DeleteDBInstance with an Amazon SDK

The following code examples show how to use DeleteDBInstance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```

/// <summary>
/// Delete a particular DB instance.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <returns>DB instance object.</returns>

```

```
public async Task<DBInstance> DeleteDBInstanceByIdentifierAsync(string
dbInstanceIdIdentifier)
{
    var response = await _amazonRDS.DeleteDBInstanceAsync(
        new DeleteDBInstanceRequest()
        {
            DBInstanceIdentifier = dbInstanceIdIdentifier,
            SkipFinalSnapshot = true,
            DeleteAutomatedBackups = true
        });

    return response.DBInstance;
}
```

- For API details, see [DeleteDBInstance](#) in *Amazon SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

## Use DescribeDBClusterSnapshots with an Amazon SDK

The following code examples show how to use DescribeDBClusterSnapshots.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

## Use DescribeDBClusters with an Amazon SDK

The following code examples show how to use DescribeDBClusters.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

### Amazon SDK for .NET (v4)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Returns a list of DB clusters.
/// </summary>
/// <param name="dbInstanceIdentifier">Optional name of a specific DB
cluster.</param>
/// <returns>List of DB clusters.</returns>
public async Task<List<DBCluster>> DescribeDBClustersPagedAsync(string?
dbClusterIdentifier = null)
{
    var results = new List<DBCluster>();

    DescribeDBClustersResponse response;
    DescribeDBClustersRequest request = new DescribeDBClustersRequest
    {
```

```

        DBClusterIdentifier = dbClusterIdentifier
    };
    // Get the full list if there are multiple pages.
    do
    {
        response = await _amazonRDS.DescribeDBClustersAsync(request);
        if (response.DBClusters != null)
        {
            results.AddRange(response.DBClusters);
        }
        request.Marker = response.Marker;
    }
    while (response.Marker is not null);
    return results;
}

```

## Scenarios for Aurora using Amazon SDKs

The following code examples show you how to implement common scenarios in Aurora with Amazon SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Aurora or combined with other Amazon Web Services services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

### Examples

- [Create a lending library REST API](#)
- [Create an Aurora Serverless work item tracker](#)

## Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

### SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and Amazon Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.
- Use Amazon Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.

- Use Amazon Chalice to deploy a serverless REST API to Amazon API Gateway and Amazon Lambda.
- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

### Amazon SDK for .NET

Shows how to use the Amazon SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with Amazon services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## C++

### SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## Java

### SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## JavaScript

### SDK for JavaScript (v3)

Shows how to use the Amazon SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with Amazon Web Services services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## Kotlin

### SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## PHP

### SDK for PHP

Shows how to use the Amazon SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with Amazon services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service

- Amazon SES

## Python

### SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with Amazon Web Services services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an Amazon Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

# Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

Database engine	Best practices
Amazon Aurora MySQL	See <a href="#">Best practices with Amazon Aurora MySQL</a>
Amazon Aurora PostgreSQL	See <a href="#">Best practices with Amazon Aurora PostgreSQL</a>

## Note

For common recommendations for Aurora, see [Recommendations from Amazon Aurora](#).

## Topics

- [Basic operational guidelines for Amazon Aurora](#)
- [DB instance RAM recommendations](#)
- [Amazon database drivers](#)
- [Monitoring Amazon Aurora](#)
- [Working with DB parameter groups and DB cluster parameter groups](#)
- [Amazon Aurora best practices video](#)

## Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

## DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:

- `VolumeReadIOPS` – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of `VolumeReadIOPS` should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

### Tip

If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

- `BufferCacheHitRatio` – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory.

A high hit ratio indicates that your DB instance has enough memory available. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. Investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

For more information, see [Amazon CloudWatch metrics for Amazon Aurora](#).

## Amazon database drivers

We recommend the Amazon suite of drivers for application connectivity. The drivers have been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the Amazon suite of drivers is to have built-in support for these service features.

For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

## Monitoring Amazon Aurora

Amazon Aurora provides various metrics and insights that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the Amazon Web Services Management Console, Amazon CLI, and CloudWatch API, to view Aurora metrics. You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see [Viewing combined metrics with the Performance Insights dashboard](#).

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, [Creating a performance analysis report in Performance Insights](#).

## Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see [Backing up and restoring an Amazon Aurora DB cluster](#).

### Amazon Aurora best practices video

The Amazon Online Tech Talks channel on YouTube includes a video presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. See [Amazon Aurora best practices for high availability](#).

# Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

## Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as [Managing performance and scaling for Aurora DB clusters](#), [Amazon Aurora MySQL performance enhancements](#), [Performance and scaling for Amazon Aurora PostgreSQL](#), and [Monitoring DB load with Performance Insights on Amazon Aurora](#).

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your

Amazon representative to see if there are Aurora best practices or case studies for your type of application.

## 1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as *provisioned*. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the Amazon Database Blog post [How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads](#). Another might be demand-based scaling, described in [Amazon Aurora Auto Scaling with Aurora Replicas](#) in the *Amazon Aurora User Guide*. Others might be performance gains or simplified database operations.

## 2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. *High velocity* involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 SELECT statements per second. Again depending on workload, such a cluster can process 200,000 INSERT, UPDATE, and DELETE statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 [replicas](#), each of which is on average within 10–20 milliseconds of the primary instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other Amazon services, the Amazon Web Services Management Console, and the Amazon CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

## 3. Practice with the Amazon Web Services Management Console or Amazon CLI

As a next step, practice with the Amazon Web Services Management Console or the Amazon CLI, to become familiar with these tools and with Aurora.

### Practice with the Amazon Web Services Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the Amazon Web Services Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see [Replication with Amazon Aurora](#). Scale the DB instances up or down by changing the Amazon instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the Amazon Web Services Management Console in the beginning. After you understand what you can do with Aurora, you

can progress to automating those operations using the Amazon CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

## Practice with the Amazon CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the Amazon CLI if you're not already. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as Amazon CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the Amazon CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see [Update behaviors of stack resources](#) in the *Amazon CloudFormation User Guide*.

## 4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see [Creating an Amazon Aurora DB cluster](#).

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Turn off **Easy create**. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Use a recent DB engine version. These combinations of database engine and version have wide compatibility with other Aurora features and substantial customer usage for production applications.
  - Aurora MySQL version 3.x (MySQL 8.0 compatibility)
  - Aurora PostgreSQL version 15.x or 16.x
- Choose the **Dev/Test** template. This choice isn't significant for your proof-of-concept activities.
- For **DB instance class**, choose **Memory optimized classes** and one of the **xlarge** instance classes. You can adjust the instance class up or down later.
- Under **Multi-AZ Deployment**, choose **Create an Aurora Replica or Reader node in a different AZ**. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "writer," because different DB instances assume those roles as needed. We recommend using something like `clustername-az-serialnumber`, for example `myprodapddb-a-01`. These pieces uniquely identify the DB instance and its placement.
- Set the backup retention high for the Aurora cluster. With a long retention period, you can do point-in-time recovery (PITR) for a period up to 35 days. You can reset your database to a known state after running tests involving DDL and data manipulation language (DML) statements. You can also recover if you delete or change data by mistake.
- Turn on additional recovery, logging, and monitoring features at cluster creation. Turn on all the choices that are available under **Backtrack**, **Performance Insights**, **Monitoring**, and **Log exports**. With these features enabled, you can test the suitability of features such as backtracking, Enhanced Monitoring, or Performance Insights for your workload. You can also easily investigate performance and perform troubleshooting during the proof of concept.

## 5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the **Connectivity** tab of the detail page of your cluster. The cluster endpoint is the one labeled **Writer**. The other endpoint, labeled **Reader**, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see [Connecting to an Amazon Aurora DB cluster](#).

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the Amazon Schema Conversion Tool (Amazon SCT) to simplify the process. For details, see the [Amazon Schema Conversion Tool User Guide](#). For general details about migration and porting activities, see the [Migrating Your Databases to Amazon Aurora](#) Amazon whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

## 6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see [Migrating data to an Amazon Aurora MySQL DB cluster](#) or [Migrating data to Amazon Aurora with PostgreSQL compatibility](#) depending on the database engine you're using in the proof of concept.

Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the Amazon Database Migration Service (Amazon DMS). For details about Amazon DMS, see the [Amazon Database Migration Service User Guide](#).

For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

## 7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the Amazon SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see [9. Connect to Aurora](#).

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

## 8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in [Introducing the Aurora storage engine](#) on the Amazon Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see [Amazon Aurora DB cluster and DB instance parameters](#). For the configuration settings that are or aren't applicable to Aurora clusters, see [Aurora MySQL configuration parameters](#) or [Amazon Aurora PostgreSQL parameters](#) depending on your database engine.

## 9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as SELECT statement, or a write such as a CREATE or INSERT statement.

As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the *primary instance*. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing SELECT statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

 **Note**

Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle SELECT statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.
- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.

- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.

For general information about connection management and endpoints for Aurora, see [Connecting to an Amazon Aurora DB cluster](#). For a deep dive on this subject, see [Aurora MySQL database administrator's handbook – Connection management](#).

## 10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same Amazon Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on Amazon Regions, see [Regions and Availability Zones](#) in the *Amazon RDS User Guide*. To learn more about the Amazon VPC service, see [What is Amazon VPC?](#) in the *Amazon VPC User Guide*.

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in [8. Specify configuration settings](#).

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different Amazon instance classes, numbers of Amazon Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see [Creating a DB cluster snapshot](#) and [Restoring from a DB cluster snapshot](#).

## 11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the **Monitoring** tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

To have more choices on the **Monitoring** tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

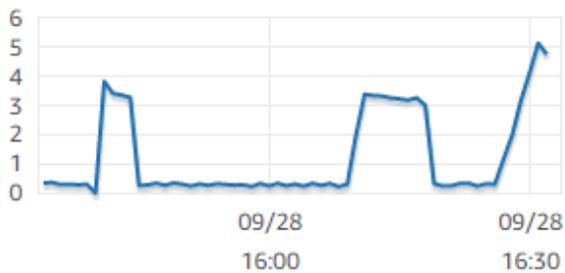

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the **Monitoring** tab for that specific instance.

After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

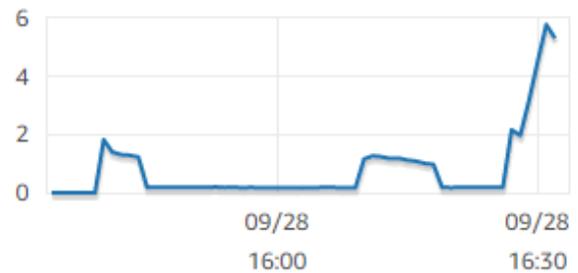

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To view the throughput and latency metrics, check the **Monitoring** tab for a given Aurora cluster in the [Amazon RDS console](#). The following screenshot shows an example of the **Select Latency**, **DML Latency**, **Select Throughput**, and **DML Throughput** metrics on the **Monitoring** tab.

Select Latency (Milliseconds)

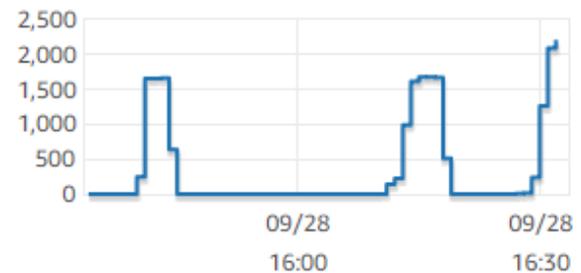

DML Latency (Milliseconds)

Select Throughput (Count/Second)

DML Throughput (Count/Second)

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

**Tip**

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

**Tip**

Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the SELECT queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

## 12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add

DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

** Tip**

For a proof of concept, set up all the DB instances in an Aurora cluster with the same Amazon instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your Amazon Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

** Tip**

The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.

When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see [Testing Amazon Aurora MySQL using fault injection queries](#).

As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for SELECT queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only SELECT statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other Amazon Regions and restore into other Amazon Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

## 13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore Amazon services and features such as Amazon Secrets Manager and Amazon Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see [Managing performance and scaling for Aurora DB clusters](#), [Amazon Aurora MySQL performance enhancements](#), [Performance and scaling for Amazon Aurora PostgreSQL](#), and [Monitoring DB load with Performance Insights on Amazon Aurora](#). If you do additional tuning, make sure that you're familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the Amazon whitepaper [Aurora MySQL database administrator's handbook – Connection management](#).

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other Amazon services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. Amazon services that address such use cases include the following:
  - [Amazon Redshift](#)
  - [Amazon EMR](#)
  - [Amazon Athena](#)
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - [Amazon Glue](#)
  - [Amazon DMS](#)
  - [Importing from Amazon S3](#), as described in the *Amazon Aurora User Guide*
  - [Exporting to Amazon S3](#), as described in the *Amazon Aurora User Guide*
  - Many other popular ETL tools

# Security in Amazon Aurora

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [Amazon compliance programs](#). To learn about the compliance programs that apply to Amazon Aurora (Aurora), see [Amazon services in scope by compliance program](#).
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other Amazon services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see [Amazon VPC and Amazon Aurora](#) .
- Use Amazon Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

To review IAM policy examples, see [Identity-based policy examples for Amazon Aurora](#) .

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).
- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see [Encrypting Amazon Aurora resources](#).
- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

For information about security with Aurora MySQL, see [Security with Amazon Aurora MySQL](#). For information about security with Aurora PostgreSQL, see [Security with Amazon Aurora PostgreSQL](#).

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the [Amazon RDS user guide](#).

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the Amazon CLI to access the RDS API interactively. Some RDS API operations and Amazon CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see [Amazon RDS API reference](#). For more information about the Amazon CLI, see [Amazon Command Line Interface reference for Amazon RDS](#).

**Note**

You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, automatic failover, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

## Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL and Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

## Topics

- [Password authentication](#)
- [IAM database authentication](#)
- [Kerberos authentication](#)

## Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database

authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with Amazon Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *Amazon Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *Amazon Secrets Manager User Guide*.

## IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication](#).

## Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

To use credentials from your self-managed Active Directory, you need to setup a trust relationship to the Amazon Directory Service for Microsoft Active Directory that the DB cluster is joined to.

Aurora PostgreSQL and Aurora MySQL support one-way and two-way forest trust relationships with forest-wide authentication or selective authentication.

In some scenarios, you can configure Kerberos authentication over an external trust relationship. This requires your self-managed Active Directory to have additional settings. This includes but is not limited to [Kerberos Forest Search Order](#).

Aurora supports Kerberos authentication for Aurora MySQL and Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication for Aurora MySQL](#) and [Using Kerberos authentication with Aurora PostgreSQL](#).

# Password management with Amazon Aurora and Amazon Secrets Manager

Amazon Aurora integrates with Secrets Manager to manage master user passwords for your DB clusters.

## Topics

- [Managing the master user password for a DB cluster with Secrets Manager](#)
- [Rotating the master user password secret for a DB cluster](#)
- [Viewing the details about a secret for a DB cluster](#)

## Region and version availability

Feature availability and support varies across specific versions of each database engine and across Amazon Web Services Regions. For more information about version and Region availability with Secrets Manager integration with Amazon Aurora, see [Supported Regions and Aurora DB engines for Secrets Manager integration](#).

## Limitations for Secrets Manager integration with Amazon Aurora

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Amazon RDS Blue/Green Deployments
- DB clusters that are part of an Aurora global database
- Aurora Serverless v1 DB clusters
- Cross-Region read replicas
- Binary log external replication

# Overview of managing master user passwords with Amazon Secrets Manager

With Amazon Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the [Amazon Secrets Manager User Guide](#).

When you store database secrets in Secrets Manager, your Amazon Web Services account incurs charges. For information about pricing, see [Amazon Secrets Manager Pricing](#).

You can specify that Aurora manages the master user password in Secrets Manager for an Amazon Aurora DB cluster when you perform one of the following operations:

- Create a DB cluster
- Modify a DB cluster
- Restore a DB cluster from Amazon S3 (Aurora MySQL only)

When you specify that Aurora manages the master user password in Secrets Manager, Aurora generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

Aurora manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB cluster that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see [Retrieve secrets from Amazon Secrets Manager](#) and [Connect to a SQL database with credentials in an Amazon Secrets Manager secret](#) in the *Amazon Secrets Manager User Guide*.

## Benefits of managing master user passwords with Secrets Manager

Managing Aurora master user passwords with Secrets Manager provides the following benefits:

- Aurora automatically generates database credentials.
- Aurora automatically stores and manages database credentials in Amazon Secrets Manager.

- Aurora rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with Amazon CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the [Amazon Secrets Manager User Guide](#).

## Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see [Identity and access management for Amazon Aurora](#).

For create, modify, or restore operations, the user who specifies that Aurora manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

The `kms:DescribeKey` permission is required to access your customer-managed key for the `MasterUserSecretKmsKeyId` and to describe `aws/secretsmanager`.

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`

- kms:CreateGrant

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- secretsmanager:RotateSecret

## Enforcing Aurora management of the master user password in Amazon Secrets Manager

You can use IAM condition keys to enforce Aurora management of the master user password in Amazon Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by Aurora in Secrets Manager.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
        "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
      "Resource": "*",
      "Condition": {
        "Bool": {
          "rds:ManageMasterUserPassword": false
        }
      }
    }
  ]
}
```

### Note

This policy enforces password management in Amazon Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the cluster.

To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing clusters that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see [Policy condition keys for Aurora](#) and [Example policies: Using condition keys](#).

## Managing the master user password for a DB cluster with Secrets Manager

You can configure Aurora management of the master user password in Secrets Manager when you perform the following actions:

- [Creating an Amazon Aurora DB cluster](#)
- [Modifying an Amazon Aurora DB cluster](#)
- [Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster](#)

You can use the RDS console, the Amazon CLI, or the RDS API to perform these actions.

### Console

Follow the instructions for creating or modifying a DB cluster with the RDS console:

- [Creating a DB cluster](#)
- [Modifying a DB instance in a DB cluster](#)

In the RDS console, you can modify any DB instance to specify the master user password management settings for the entire DB cluster.

- [Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket](#)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by Aurora in Secrets Manager. To do so when you are creating or restoring a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in Amazon Secrets Manager** setting when you are creating or restoring a DB cluster.

**▼ Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in  Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

**Confirm master password** [Info](#)

When you select this option, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

**▼ Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in  Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Select the encryption key** [Info](#)  
You can encrypt using the KMS key that Secrets Manager creates or a customer managed KMS key that you create.

 /secretsmanager (default) ▼

[Add new key](#) 

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see [Settings for Aurora DB clusters](#). For more information about the available settings when you are modifying a DB cluster, see [Settings for Amazon Aurora](#).

## Amazon CLI

To specify that Aurora manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- [create-db-cluster](#)
- [modify-db-cluster](#)
- [restore-db-cluster-from-s3](#)

When you specify the `--manage-master-user-password` option in these commands, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see [Settings for Aurora DB clusters](#). For more information about the available settings when you are modifying a DB cluster, see [Settings for Amazon Aurora](#).

This example creates a DB cluster and specifies that Aurora manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

## Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --engine aurora-mysql \  
  --engine-version 8.0 \  
  --master-username admin \  
  --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --engine aurora-mysql ^  
  --engine-version 8.0 ^  
  --master-username admin ^  
  --manage-master-user-password
```

## RDS API

To specify that Aurora manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)
- [RestoreDBClusterFromS3](#)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

## Rotating the master user password secret for a DB cluster

When Aurora rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Aurora changes the master user password for the DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB cluster. For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

You can rotate a master user password secret immediately with the RDS console, the Amazon CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

### Console

To rotate a master user password secret using the RDS console, modify the DB cluster and select **Rotate secret immediately** in **Settings**.

## Settings

**DB engine version**  
Version number of the database engine to be used for this database

5.7.mysql\_aurora.2.10.2 ▼

**DB instance identifier** [Info](#)  
Type a name for your DB instance. The name must be unique across all DB instances owned by your  account in the current  Region.

database-1-instance-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

**DB cluster identifier**  
Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your  account in the current  Region.

database-1

**Manage master credentials in**  **Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Rotate secret immediately**  
When you rotate a secret, you update the credentials in both the secret and the database.

Follow the instructions for modifying a DB cluster with the RDS console in [Modifying the DB cluster by using the console, CLI, and API](#). You must choose **Apply immediately** on the confirmation page.

## Amazon CLI

To rotate a master user password secret using the Amazon CLI, use the [modify-db-cluster](#) command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```

```
--db-cluster-identifier mydbcluster \  
--rotate-master-user-password \  
--apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
--db-cluster-identifier mydbcluster ^  
--rotate-master-user-password ^  
--apply-immediately
```

## RDS API

You can rotate a master user password secret using the [ModifyDBCluster](#) operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

## Viewing the details about a secret for a DB cluster

You can retrieve your secrets using the console (<https://console.amazonaws.cn/secretsmanager/>) or the Amazon CLI ([get-secret-value](#) Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by Aurora in Secrets Manager with the RDS console, the Amazon CLI, or the RDS API.

### Console

#### To view the details about a secret managed by Aurora in Secrets Manager

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster to show its details.
4. Choose the **Configuration** tab.

In **Master Credentials ARN**, you can view the secret ARN.

The screenshot shows the Amazon Aurora console interface. At the top, there are navigation tabs: Connectivity & security, Monitoring, Logs & events, Configuration (selected), Maintenance & backups, and Tags. Below the tabs is the 'Database' section. The 'Configuration' tab is active, displaying various settings for a database cluster. The settings are organized into columns:

- Configuration:** DB cluster role (Regional cluster), Engine version (5.7.mysql\_aurora.2.10.2), Resource ID (cluster-...), Amazon Resource Name (ARN) (arn:aws:rds:ap-south-1:...:cluster:database-1), Network type (IPv4).
- Capacity type:** Provisioned: single-master, DB cluster ID (database-1), DB cluster parameter group (default.aurora-mysql5.7), Deletion protection (Enabled).
- Availability:** IAM DB authentication (Not enabled), Master username (admin), Multi-AZ (2 Zones).
- Master Credentials ARN:** This field is highlighted with a red box. It contains the text: `arn:aws:secretsmanager:ap-south-1:...:secret:rds!cluster-a786cc29-a459-4922-9c03-9442b290c1d1-4TWyUb` and a link labeled 'Manage in Secrets Manager' with an external link icon.

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

## Amazon CLI

You can use the RDS Amazon CLI [describe-db-clusters](#) command to find the following information about a secret managed by Aurora in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

The possible status values include the following:

- `creating` – The secret is being created.
- `active` – The secret is available for normal use and rotation.
- `rotating` – The secret is being rotated.
- `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database

credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the [modify-db-cluster](#) command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

### Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
    "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
    "SecretStatus": "active",
    "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the [get-secret-value](#) Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

### Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

## RDS API

You can view the ARN, status, and KMS key for a secret managed by Aurora in Secrets Manager using the [DescribeDBClusters](#) RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the [GetSecretValue](#) Secrets Manager operation.

## Data protection in Amazon RDS

The Amazon [shared responsibility model](#) applies to data protection in Amazon Relational Database Service. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see the [Data Privacy FAQ](#).

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see [Working with CloudTrail trails](#) in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

## Topics

- [Protecting data using encryption](#)
- [Internet traffic privacy](#)

## Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

## Topics

- [Encrypting Amazon Aurora resources](#)
- [Amazon KMS key management](#)
- [Using SSL/TLS to encrypt a connection to a DB cluster](#)
- [Rotating your SSL/TLS certificate](#)

## Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.

Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

**Note**

For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across Amazon Regions.

**Topics**

- [Overview of encrypting Amazon Aurora resources](#)
- [Encrypting an Amazon Aurora DB cluster](#)
- [Determining whether encryption is turned on for a DB cluster](#)
- [Availability of Amazon Aurora encryption](#)
- [Encryption in transit](#)
- [Limitations of Amazon Aurora encrypted DB clusters](#)

**Overview of encrypting Amazon Aurora resources**

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest. For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. For more information about the availability and limitations of encryption, see [Availability of Amazon Aurora encryption](#) and [Limitations of Amazon Aurora encrypted DB clusters](#).

Amazon Aurora uses an Amazon Key Management Service key to encrypt these resources. Amazon KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. You can use an Amazon managed key, or you can create customer managed keys.

When you create an encrypted DB cluster, you can choose a customer managed key or the Amazon managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the Amazon managed key for your new DB cluster. Amazon Aurora creates an Amazon managed key for Amazon Aurora for your Amazon account. Your Amazon account has a different Amazon managed key for Amazon Aurora for each Amazon Region.

To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the [Amazon Key Management Service \(Amazon KMS\)](#).

Using Amazon KMS, you can create customer managed keys and define the policies to control the use of these customer managed keys. Amazon KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported Amazon services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with Amazon KMS, see [Amazon Service Integration](#). Some considerations about using KMS keys:

- Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you must change the encryption key for your DB cluster, create a manual snapshot of your cluster and enable encryption while copying the snapshot. For more information, see [re:Post Knowledge article](#).

- If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.
- You can't share a snapshot that has been encrypted using the Amazon managed key of the Amazon account that shared the snapshot.
- Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster.
- You can also encrypt a read replica of an Amazon Aurora encrypted cluster.

### Important

Amazon Aurora can lose access to the KMS key for a DB cluster when you disable the KMS key. In these cases, the encrypted DB cluster goes into `inaccessible-encryption-credentials-recoverable` state. The DB cluster remains in this state for seven days, during which the instance is stopped. API calls made to the DB cluster during this time might not succeed. To recover the DB cluster, enable the KMS key and restart this DB cluster. Enable the KMS key from the Amazon Web Services Management Console, Amazon CLI, or RDS API. Restart the DB cluster using the Amazon CLI command [start-db-cluster](#) or Amazon Web Services Management Console.

The `inaccessible-encryption-credentials-recoverable` state only applies to DB clusters that can stop. This recoverable state is not applicable to instances that can't

stop, such as clusters with cross-Region read replicas. For more information, see [the section called "Limitations"](#).

If the DB cluster isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB cluster is not usable anymore and you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups for encrypted DB clusters to guard against the loss of encrypted data in your databases.

During the creation of a DB cluster, Aurora checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB cluster. Revoking the calling principals access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB cluster from the snapshot without specifying a different KMS key, the new cluster uses the KMS key from the source account. Revoking access to the key after you create the DB cluster does not affect the cluster. However, disabling the key impacts all DB clusters encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

For more information about KMS keys, see [Amazon KMS keys](#) in the *Amazon Key Management Service Developer Guide* and [Amazon KMS key management](#).

## Encrypting an Amazon Aurora DB cluster

To encrypt a new DB cluster, choose **Enable encryption** on the console. For information on creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#).

If you use the [create-db-cluster](#) Amazon CLI command to create an encrypted DB cluster, set the `--storage-encrypted` parameter. If you use the [CreateDBCluster](#) API operation, set the `StorageEncrypted` parameter to `true`.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

If you use the Amazon CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to

any key identifier for the KMS key. To use a customer managed key in a different Amazon account, specify the key ARN or alias ARN.

## Determining whether encryption is turned on for a DB cluster

You can use the Amazon Web Services Management Console, Amazon CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

### Console

#### To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the **Configuration** tab and check the **Encryption** value.

It shows either **Enabled** or **Not enabled**.

The screenshot shows the Amazon RDS console interface for an Aurora MySQL DB cluster named 'aurora-cl-mysql'. The 'Configuration' tab is selected, and the 'Encryption' section is highlighted with a red box, showing 'Encryption Enabled'.

DB identifier	Role	Engine	Region & AZ	Size	Status
aurora-cl-mysql	Regional cluster	Aurora MySQL	us-east-1	2 instances	Available
dbinstance4	Writer instance	Aurora MySQL	us-east-1a	db.t3.medium	Available
dbinstance1	Reader instance	Aurora MySQL	us-east-1b	db.t3.medium	Available

Configuration details:

Configuration	Capacity type	Availability	Encryption
DB cluster role Regional cluster	Provisioned: single-master DB cluster ID aurora-cl-mysql	IAM DB authentication Enabled	Encryption Enabled

## Amazon CLI

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon CLI, call the [describe-db-clusters](#) command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB cluster.

### Example

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "*[].[StorageEncrypted:StorageEncrypted]" --output text
```

## RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the [DescribeDBClusters](#) operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

## Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

### Note

Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

## Encryption in transit

### Encryption at the physical layer

All data flowing across Amazon Web Services Regions over the Amazon global network is automatically encrypted at the physical layer before it leaves Amazon secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section may provide additional protections.

## Encryption provided by Amazon VPC peering and Transit Gateway cross-Region peering

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves Amazon secured facilities.

## Encryption between instances

Amazon provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose:** M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized:** R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same Amazon Web Services Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

## Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't turn off encryption on an encrypted DB cluster.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
- To copy an encrypted snapshot from one Amazon Region to another, you must specify the KMS key in the destination Amazon Region. This is because KMS keys are specific to the Amazon Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see [Envelope encryption](#) in the *Amazon Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

## Amazon KMS key management

Amazon Aurora automatically integrates with [Amazon Key Management Service \(Amazon KMS\)](#) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see [Envelope encryption](#) in the *Amazon Key Management Service Developer Guide*.

You can use two types of Amazon KMS keys to encrypt your DB clusters.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see [Customer managed keys](#) in the *Amazon Key Management Service Developer Guide*.
- *Amazon managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an Amazon service that is integrated with Amazon KMS. By default, the RDS Amazon managed key ( `aws/rds` ) is used for encryption. You can't manage, rotate, or delete the RDS Amazon managed key. For more information about Amazon managed keys, see [Amazon managed keys](#) in the *Amazon Key Management Service Developer Guide*.

To manage KMS keys used for Amazon Aurora encrypted DB clusters, use the [Amazon Key Management Service \(Amazon KMS\)](#) in the [Amazon KMS console](#), the Amazon CLI, or the Amazon KMS API. To view audit logs of every action taken with an Amazon managed or customer managed key, use [Amazon CloudTrail](#). For more information about key rotation, see [Rotating Amazon KMS keys](#).

### Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- kms:CreateGrant
- kms:DescribeKey

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

### Important

When you use explicit deny statements for all resources (\*) in Amazon KMS key policies with managed services like Amazon RDS, you must specify a condition to allow the resource owning account. Operations might fail without this condition, even if the deny rule includes exceptions for your IAM user.

### Tip

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the [kms:ViaService condition key](#) to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an Amazon service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in Aurora, use the [kms:ViaService condition key](#) with the rds.<region>.amazonaws.com value. Also, you can use the keys or values in the [Amazon RDS encryption context](#) as a condition for using the customer managed key for encryption.

For more information, see [Allowing users in other accounts to use a KMS key](#) in the *Amazon Key Management Service Developer Guide* and [Key policies in Amazon KMS](#).

## Amazon RDS encryption context

When Aurora uses your KMS key, or when Amazon EBS uses the KMS key on behalf of Aurora, the service specifies an [encryption context](#). The encryption context is [additional authenticated data](#) (AAD) that Amazon KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your [Amazon](#)

[CloudTrail](#) logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Aurora always uses the DB cluster ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:dbc-id": "cluster-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB cluster for which your KMS key was used.

When your KMS key is used for a specific DB cluster and a specific Amazon EBS volume, both the DB cluster ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:dbc-id": "cluster-BRG7VYS3SVIFQW7234EJQ0M5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

## Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate**, for your database. For more information about certificate authorities, see [Certificate authorities](#) .
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see [Certificate bundles for specific Amazon Web Services Regions](#) .

### Note

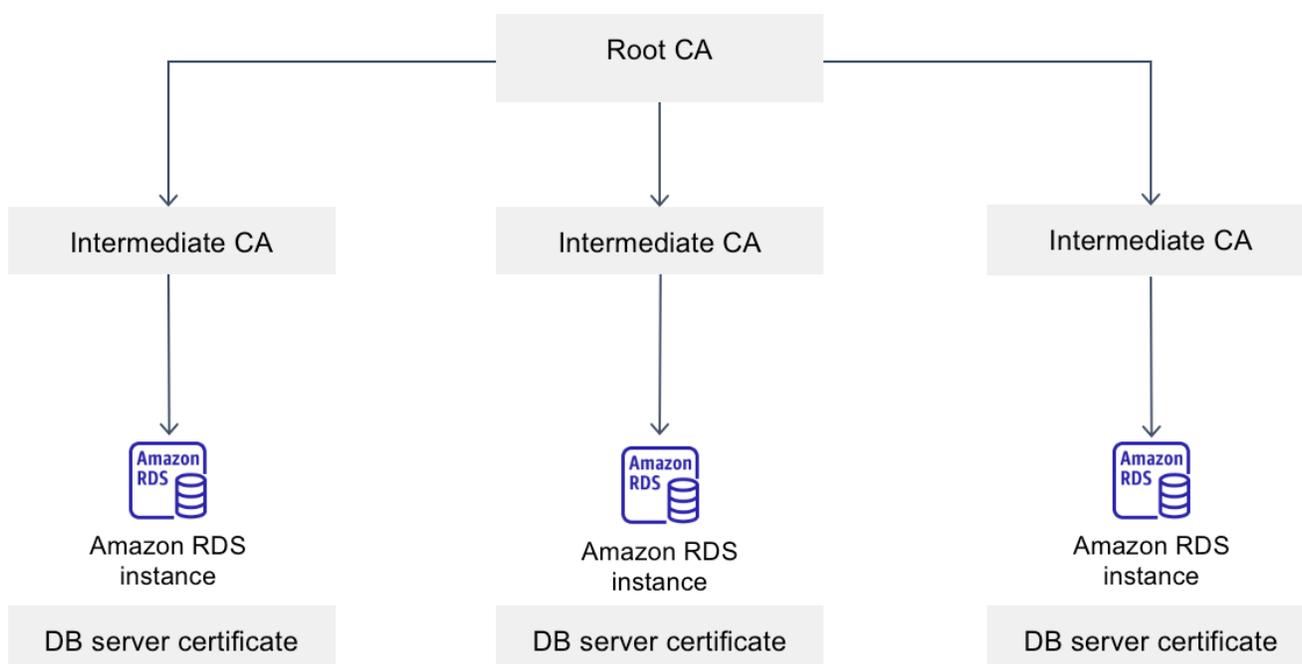

All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:

- [Security with Amazon Aurora MySQL](#)
- [Security with Amazon Aurora PostgreSQL](#)

## Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most Amazon Web Services Regions.	Amazon RDS <i>region-id</i>

Certificate authority (CA)	Description	Common name (CN)
	<p>In the Amazon GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.</p> <p>This CA supports automatic server certificate rotation.</p>	<i>entifier</i> Root CA RSA2048 G1
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS <i>region-id entifier</i> Root CA RSA4096 G1
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS <i>region-id entifier</i> Root CA ECC384 G1

### Note

If you are using the Amazon CLI, you can see the validities of the certificate authorities listed above by using [describe-certificates](#).

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

## Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create an Aurora DB cluster – You can set the CA for a DB instance in an Aurora cluster when you create the first DB instance in the DB cluster using the Amazon CLI or RDS API. Currently, you

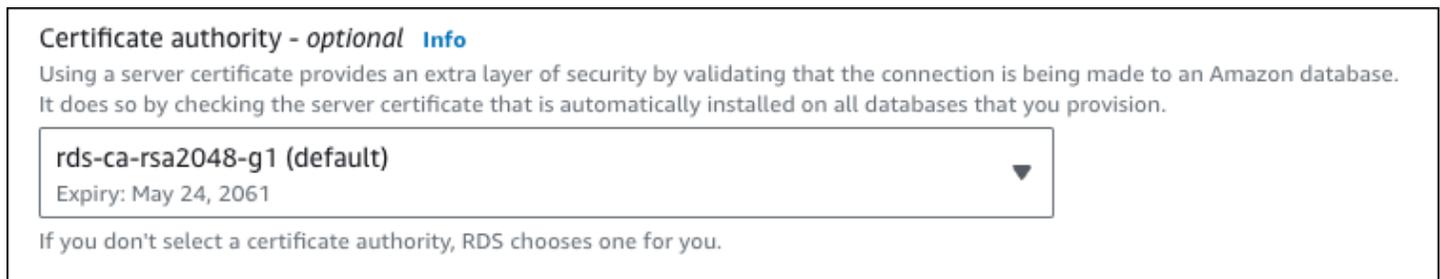

can't set the CA for the DB instances in a DB cluster when you create the DB cluster using the RDS console. For instructions, see [Creating an Amazon Aurora DB cluster](#) .

- Modify a DB instance – You can set the CA for a DB instance in a DB cluster by modifying it. For instructions, see [Modifying a DB instance in a DB cluster](#) .

### Note

The default CA is set to `rds-ca-rsa2048-g1`. You can override the default CA for your Amazon Web Services account by using the [modify-certificates](#) command.

The available CAs depend on the DB engine and DB engine version. When you use the Amazon Web Services Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the Amazon CLI, you can set the CA for a DB instance using the [create-db-instance](#) or [modify-db-instance](#) command.

If you're using the Amazon CLI, you can see the available CAs for your account by using the [describe-certificates](#) command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the [describe-db-engine-versions](#) command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether

the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
  "DBEngineVersions": [
    {
      "Engine": "postgres",
      "MajorEngineVersion": "13",
      "EngineVersion": "13.4",
      "DBParameterGroupFamily": "postgres13",
      "DBEngineDescription": "PostgreSQL",
      "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
      "ValidUpgradeTarget": [],
      "SupportsLogExportsToCloudwatchLogs": false,
      "SupportsReadReplica": true,
      "SupportedFeatureNames": [
        "Lambda"
      ],
      "Status": "available",
      "SupportsParallelQuery": false,
      "SupportsGlobalDatabases": false,
      "SupportsBabelfish": false,
      "SupportsCertificateRotationWithoutRestart": true,
      "SupportedCACertificateIdentifiers": [
        "rds-ca-rsa2048-g1",
        "rds-ca-ecc384-g1",
        "rds-ca-rsa4096-g1"
      ]
    }
  ]
}
```

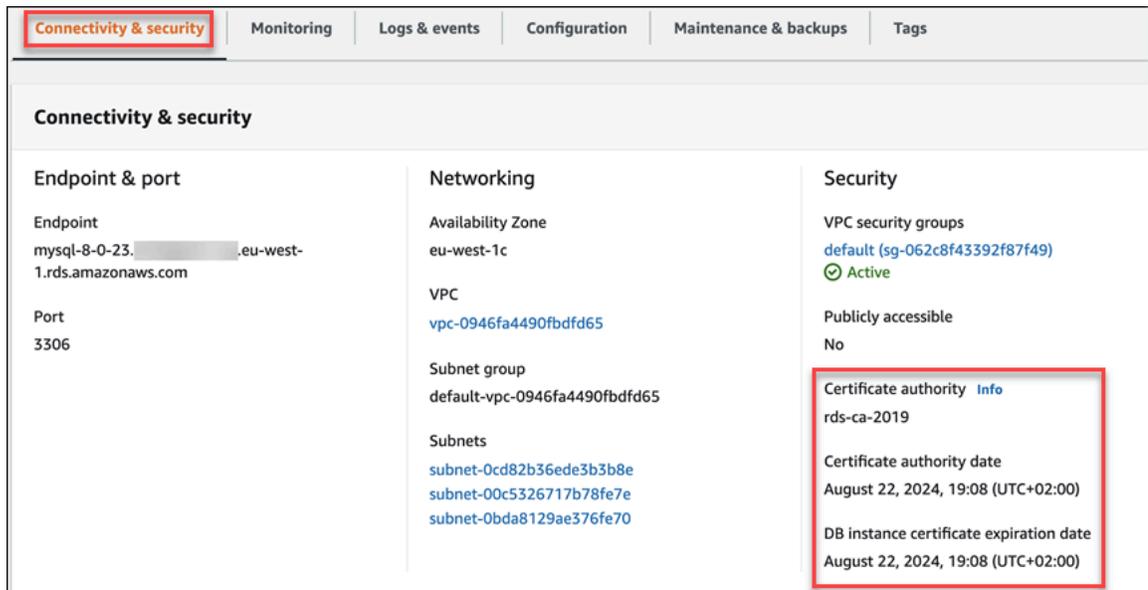

## DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](#).

## Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.

If you're using the Amazon CLI, you can view the details about the CA for a DB instance by using the [describe-db-instances](#) command.

## Download certificate bundles for Aurora

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the Amazon Web Services Region where you host your database.

### Certificate bundles for specific Amazon Web Services Regions

To get a certificate bundle for the China (Beijing) Amazon Region or China (Ningxia) Amazon Region, download it from <https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.pem>. If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle from <https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.p7b>.

The bundle contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

To get a certificate bundle, download from the link for the Amazon Region in the following table.

Amazon Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
China (Beijing)	<a href="#">cn-north-1-bundle.pem</a>	<a href="#">cn-north-1-bundle.p7b</a>
China (Ningxia)	<a href="#">cn-northwest-1-bundle.pem</a>	<a href="#">cn-northwest-1-bundle.p7b</a>

## Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

## Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates `rds-ca-2019` expired in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, consider using the new CA certificate `rds-ca-rsa2048-g1`. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an Amazon security best practice. For information about the new certificates and the supported Amazon Regions, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

To update the CA certificate for your database, use the following methods:

- [Updating your CA certificate by modifying your DB instance](#)
- [Updating your CA certificate by applying maintenance](#)

Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

## Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy and Aurora Serverless v1 use certificates from the Amazon Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't

need to update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](#).

- If you're using Aurora Serverless v1, downloading Amazon RDS certificates isn't required. For more information, see [Using TLS/SSL with Aurora Serverless v1](#).
- If you're using a Go version 1.15 application with a DB instance that was created or updated to the `rds-ca-2019` certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to `rds-ca-rsa2048-g1`.

Use the `modify-db-instance` command, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see [Go GitHub issue #39568](#).

## Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from `rds-ca-2019` to `rds-ca-rsa2048-g1`.

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see [Automatic server certificate rotation](#).

## To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in [Using SSL/TLS to encrypt a connection to a DB cluster](#).
2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- [Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates](#)
- [Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates](#)

For a sample script that updates a trust store for a Linux operating system, see [Sample script for importing certificates into your trust store](#) .

 **Note**

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the Amazon Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the [describe-db-engine-versions](#) command and check the SupportsCertificateRotationWithoutRestart flag.

 **Note**

Reboot your Babelfish cluster after modifying to update the CA certificate.

 **Important**

If you are experiencing connectivity issues after certificate expiry, use the `apply immediately` option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the Amazon CLI. By default, this operation is scheduled to run during your next maintenance window.

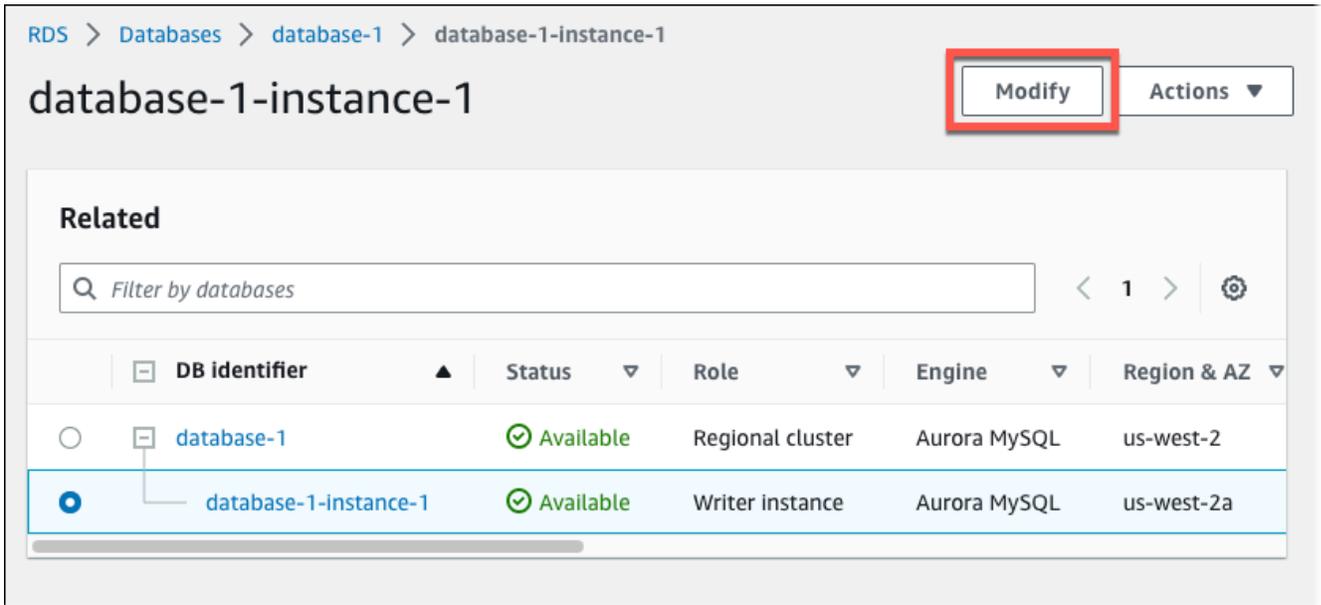

To set an override for your cluster CA that's different from the default RDS CA, use the [modify-certificates](#) CLI command.

You can use the Amazon Web Services Management Console or the Amazon CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance .

### Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

- In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
- Choose **Modify**.

- In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.

- Choose **Continue** and check the summary of modifications.
- To apply the changes immediately, choose **Apply immediately**.
- On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

**⚠ Important**

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## Amazon CLI

To use the Amazon CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance, call the [modify-db-instance](#) or [modify-db-cluster](#) command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

### Important

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

## Example

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

### Note

If your instance requires reboot, you can use the [modify-db-instance](#) CLI command and specify the `--no-certificate-rotation-restart` option.

## The Databases requiring certificate update page appears.

	DB identifier ▲	Status ▼	Certificate authority ▼	CA expiration date ▼	Role ▼	Restart Required ▼	Scheduled Changes ▼	Mainten
<input type="radio"/>	<a href="#">database-1</a>	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Instance	No	No	March 03
<input type="radio"/>	<a href="#">database-2</a>	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Multi-AZ DB cluster	No	No	March 07

### Note

This page only shows the DB instances for the current Amazon Web Services Region. If you have databases in more than one Amazon Web Services Region, check this page in each Amazon Web Services Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance that you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

### Important

If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

### Schedule updating your certificates ✕

**Select Certificate Authority (CA)**  
Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1  
Expiry: May 24, 2061

 **RDS Certificate Authority**  
For more information about the certificate, see [RDS Certificate Authority](#).  
Certificate update **does not require restarting your database.**

Click **Schedule** to update your certificate during the next scheduled maintenance window at September 11, 2023 02:17 - 02:47 UTC-7

Cancel **Schedule**

- b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.

### Confirm updating your certificates now ✕

**Select Certificate Authority (CA)**  
Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1  
Expiry: May 24, 2061

 **RDS Certificate Authority**  
For more information about the certificate, see [RDS Certificate Authority](#) .

Certificate update **does not require restarting your database.**

Click **Confirm** to apply certificate immediately.

Cancel Confirm

 **Important**

Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

- Repeat steps 3 and 4 for each DB instance that you want to update.

## Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See [Certificate authorities](#) .

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, Amazon RDS makes a `server-certificate-rotation Pending Maintenance Action` visible via `Describe-pending-maintenance-actions` API, at the half life of the certificate, or at least 3 months before expiry. You can apply the rotation using the `apply-pending-maintenance-action` API. The new DB server certificate is valid for 36 months.

Use the [describe-db-engine-versions](#) command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see [Setting the CA for your database](#) .

## Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses `keytool`, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

### Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
```

```

mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
{split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
'next unless /Subject:/; s/.*(CN=|CN = )//; print')
echo "Importing $alias"
keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }`
echo " Certificate ${alias} expires in '$expiry'"
done

```

## macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```

mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

```

```
for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
  cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }'`
  echo " Certificate ${alias} expires in '$expiry'"
done
```

To learn more best practices about using SSL with Amazon RDS, see [Best practices for successful SSL connections to Amazon RDS for Oracle](#).

## Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other Amazon resources within the same Amazon Region.

### Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and Amazon:

- An Amazon Site-to-Site VPN connection. For more information, see [What is Amazon Site-to-Site VPN?](#)
- An Amazon Direct Connect connection. For more information, see [What is Amazon Direct Connect?](#)

You get access to Amazon Aurora through the network by using Amazon-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.

- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [Amazon Security Token Service](#) (Amazon STS) to generate temporary security credentials to sign requests.

# Identity and access management for Amazon Aurora

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an Amazon Web Services service that you can use with no additional charge.

## Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon Aurora works with IAM](#)
- [Identity-based policy examples for Amazon Aurora](#)
- [Amazon managed policies for Amazon RDS](#)
- [Amazon RDS updates to Amazon managed policies](#)
- [Preventing cross-service confused deputy problems](#)
- [IAM database authentication](#)
- [Troubleshooting Amazon Aurora identity and access](#)

## Audience

How you use Amazon Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

**Service user** – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see [Troubleshooting Amazon Aurora identity and access](#).

**Service administrator** – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your

employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see [How Amazon Aurora works with IAM](#).

**Administrator** – If you're an administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see [Identity-based policy examples for Amazon Aurora](#).

## Authenticating with identities

Authentication is how you sign in to Amazon using your identity credentials. You must be authenticated as the Amazon Web Services account root user, an IAM user, or by assuming an IAM role.

For programmatic access, Amazon provides an SDK and CLI to cryptographically sign requests. For more information, see [Amazon Signature Version 4 for API requests](#) in the *IAM User Guide*.

### Amazon account root user

When you create an Amazon Web Services account, you begin with one sign-in identity called the Amazon Web Services account *root user* that has complete access to all Amazon Web Services services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

### Federated identity

As a best practice, require human users to use federation with an identity provider to access Amazon Web Services services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Amazon Directory Service that accesses Amazon Web Services services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

### IAM users and groups

An [IAM user](#) is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more

information, see [Require human users to use federation with an identity provider to access Amazon using temporary credentials](#) in the *IAM User Guide*.

An [IAM group](#) specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see [Use cases for IAM users](#) in the *IAM User Guide*.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see [IAM database authentication](#).

## IAM roles

An [IAM role](#) is an identity within your Amazon Web Services account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the Amazon Web Services Management Console by [switching roles](#). You can assume a role by calling an Amazon CLI or Amazon API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some Amazon Web Services services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.
- **Cross-service access** – Some Amazon Web Services services use features in other Amazon Web Services services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions** – Forward access sessions (FAS) use the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. For policy details when making FAS requests, see [Forward access sessions](#).
- **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an Amazon Web Services service](#) in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making Amazon CLI or Amazon API requests. This is preferable to storing access keys within the EC2 instance. To assign an Amazon role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Use an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

## Managing access using policies

You control access in Amazon by creating policies and attaching them to IAM identities or Amazon resources. A policy is an object in Amazon that, when associated with an identity or resource, defines their permissions. Amazon evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in Amazon as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

An administrator can use policies to specify who has access to Amazon resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no

permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the Amazon Web Services Management Console, the Amazon CLI, or the Amazon API.

## Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your Amazon account. Managed policies include Amazon managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

For information about Amazon managed policies that are specific to Amazon Aurora, see [Amazon managed policies for Amazon RDS](#).

## Other policy types

Amazon supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in Amazon Organizations. Amazon Organizations is a service for grouping and centrally managing multiple Amazon accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each Amazon Web Services account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *Amazon Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

## Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how Amazon determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

## How Amazon Aurora works with IAM

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

The following table lists IAM features you can use with Amazon Aurora:

IAM feature	Amazon Aurora support
<a href="#">Identity-based policies</a>	Yes
<a href="#">Resource-based policies</a>	No
<a href="#">Policy actions</a>	Yes
<a href="#">Policy resources</a>	Yes
<a href="#">Policy condition keys (service-specific)</a>	Yes

IAM feature	Amazon Aurora support
<a href="#">ACLs</a>	No
<a href="#">Attribute-based access control (ABAC) (tags in policies)</a>	Yes
<a href="#">Temporary credentials</a>	Yes
<a href="#">Forward access sessions</a>	Yes
<a href="#">Service roles</a>	Yes
<a href="#">Service-linked roles</a>	Yes

To get a high-level view of how Amazon Aurora and other Amazon services work with IAM, see [Amazon services that work with IAM](#) in the *IAM User Guide*.

## Topics

- [Aurora identity-based policies](#)
- [Resource-based policies within Aurora](#)
- [Policy actions for Aurora](#)
- [Policy resources for Aurora](#)
- [Policy condition keys for Aurora](#)
- [Access control lists \(ACLs\) in Aurora](#)
- [Attribute-based access control \(ABAC\) in policies with Aurora tags](#)
- [Using temporary credentials with Aurora](#)
- [Forward access sessions for Aurora](#)
- [Service roles for Aurora](#)
- [Service-linked roles for Aurora](#)

## Aurora identity-based policies

**Supports identity-based policies:** Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

## Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see [Identity-based policy examples for Amazon Aurora](#).

## Resource-based policies within Aurora

**Supports resource-based policies:** No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

## Policy actions for Aurora

**Supports policy actions:** Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: `rds:.` For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [  
    "rds:action1",  
    "rds:action2"
```

You can specify multiple actions using wildcards (\*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

## Policy resources for Aurora

**Supports policy resources:** Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). For actions that don't support resource-level permissions, use a wildcard (\*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\) and Amazon service namespaces](#).

For example, to specify the dbtest DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (\*).

```
"Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (\*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [  
    "resource1",  
    "resource2"
```

To see a list of Aurora resource types and their ARNs, see [Resources Defined by Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions Defined by Amazon RDS](#).

## Policy condition keys for Aurora

**Supports service-specific policy condition keys:** Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match

the condition in the policy with values in the request. To see all Amazon global condition keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all Amazon global condition keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see [Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS](#).

## Access control lists (ACLs) in Aurora

**Supports access control lists (ACLs):** No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

## Attribute-based access control (ABAC) in policies with Aurora tags

**Supports attribute-based access control (ABAC) tags in policies:** Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and Amazon resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [Define permissions with ABAC authorization](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Aurora resources, see [Specifying conditions: Using custom tags](#). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant permission for actions on a resource with a specific tag with two different values](#).

## Using temporary credentials with Aurora

**Supports temporary credentials:** Yes.

Temporary credentials provide short-term access to Amazon resources and are automatically created when you use federation or switch roles. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#) and [Amazon Web Services services that work with IAM](#) in the *IAM User Guide*.

## Forward access sessions for Aurora

**Supports forward access sessions:** Yes.

Forward access sessions (FAS) use the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. For policy details when making FAS requests, see [Forward access sessions](#).

## Service roles for Aurora

**Supports service roles:** Yes.

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an Amazon Web Services service](#) in the *IAM User Guide*.

### Warning

Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

## Service-linked roles for Aurora

**Supports service-linked roles:** Yes.

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see [Using service-linked roles for Amazon Aurora](#).

## Identity-based policy examples for Amazon Aurora

By default, permission sets and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the Amazon Web Services Management Console, Amazon CLI, or Amazon API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see [Creating policies on the JSON tab](#) in the *IAM User Guide*.

### Topics

- [Policy best practices](#)
- [Using the Aurora console](#)
- [Permissions required to use the console](#)
- [Allow users to view their own permissions](#)
- [Permission policies to create, modify and, delete resources in Aurora](#)
- [Example policies: Using condition keys](#)
- [Specifying conditions: Using custom tags](#)
- [Grant permission to tag Aurora resources during creation](#)

### Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see [Amazon managed policies](#) or [Amazon managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [Validate policies with IAM Access Analyzer](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Secure API access with MFA](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

## Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your Amazon Web Services account. If you create an identity-based policy that is more restrictive than

the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following Amazon managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

## Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their Amazon account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in [Managing access using policies](#).

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root Amazon account:

```
AmazonRDSFullAccess
```

## Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the Amazon CLI or Amazon API.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsForUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:GetUser"
      ],
      "Resource": ["arn:aws-cn:iam::*:user/${aws:username}"]
    },
    {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
      "Action": [
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListGroupPolicies",
        "iam:ListPolicyVersions",
        "iam:ListPolicies",
        "iam:ListUsers"
      ],
      "Resource": "*"
    }
  ]
}

```

## Permission policies to create, modify and, delete resources in Aurora

The following sections present examples of permission policies that grant and restrict access to resources:

### Allow a user to create DB instances in an Amazon account

The following is an example policy that allows the account with the ID 123456789012 to create DB instances for your Amazon account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the

db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateDBInstanceOnly",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance"
      ],
      "Resource": [
        "arn:aws-cn:rds*:123456789012:db:test*",
        "arn:aws-cn:rds*:123456789012:og:default*",
        "arn:aws-cn:rds*:123456789012:pg:default*",
        "arn:aws-cn:rds*:123456789012:subgrp:default"
      ],
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql",
          "rds:DatabaseClass": "db.t2.micro"
        }
      }
    }
  ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the [CreateDBInstance](#) API operation (this also applies to the [create-db-instance](#) Amazon CLI command and the Amazon Web Services Management Console).
- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resource Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the Amazon Region (\* indicates any region in this example), the Amazon account number (123456789012 is the account number in this example),

and the type of resource. For more information about creating ARNs, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The Resource element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with test (for example, testCustomerData1, test-region2-data).
- The option group for the new DB instance must begin with default.
- The DB parameter group for the new DB instance must begin with default.
- The subnet group for the new DB instance must be the default subnet group.
- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be db.t2.micro. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see [Policy condition keys for Aurora](#). This example specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in [CreateDBInstance](#). For information about the valid condition values for rds:DatabaseClass, see [Supported DB engines for DB instance classes](#).

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

### **Allow a user to perform any describe action on any RDS resource**

The following permissions policy grants permissions to a user to run all of the actions that begin with Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard character (\*) in the Resource element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

JSON

```
{
```

```

"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "AllowRDSDescribe",
    "Effect": "Allow",
    "Action": "rds:Describe*",
    "Resource": "*"
  }
]
}

```

## Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the mydbpg DB parameter group and the mydbsubnetgroup DB subnet group.

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": [
        "arn:aws-cn:rds:*:*:pg:mydbpg",
        "arn:aws-cn:rds:*:*:subgrp:mydbsubnetgroup"
      ]
    }
  ]
}

```

## Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

## JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAnySnapshotName",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
    },
    {
      "Sid": "AllowDevTestToCreateSnapshot",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to `development` or `test`.

## JSON

```

{
  "Version": "2012-10-17",
  "Statement": [

```

```
{
  "Sid":"AllowChangingParameterOptionSecurityGroups",
  "Effect":"Allow",
  "Action":[
    "rds:ModifyDBInstance"
  ],
  "Resource": [
    "arn:aws:rds*:123456789012:pg:*",
    "arn:aws:rds*:123456789012:secgrp:*",
    "arn:aws:rds*:123456789012:og:*"
  ]
},
{
  "Sid":"AllowDevTestToModifyInstance",
  "Effect":"Allow",
  "Action":[
    "rds:ModifyDBInstance"
  ],
  "Resource":"arn:aws:rds*:123456789012:db:*",
  "Condition":{"
    "StringEquals":{"
      "rds:db-tag/stage":[
        "development",
        "test"
      ]
    }
  }
}
]
```

## Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
      "Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:my-mysql-instance"
    }
  ]
}
```

### Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "rds:*",
      "Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:mydb"
    }
  ]
}
```

### Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

## Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowMySQLCreate",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql"
        },
        "Bool": {
          "rds:MultiAz": false
        }
      }
    }
  ]
}
```

## Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyLargeCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseClass": [
            "db.r3.8xlarge",
            "db.m4.10xlarge"
          ]
        }
      }
    },
    {
      "Sid": "DenyPIOPSCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "NumericNotEquals": {
          "rds:Piops": "0"
        }
      }
    }
  ]
}
```

**Example 3: Limit the set of tag keys and values that can be used to tag a resource**

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowTagEdits",
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:db-123456",
      "Condition": {
        "StringEquals": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

### Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

#### Note

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a Condition element.

RDS tag identifier	Applies to
db-tag	DB instances, including read replicas
snapshot-tag	DB snapshots
ri-tag	Reserved DB instances
og-tag	DB option groups
pg-tag	DB parameter groups
subgrp-tag	DB subnet groups
es-tag	Event subscriptions
cluster-tag	DB clusters
cluster-pg-tag	DB cluster parameter groups
cluster-snapshot-tag	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":["value"]}} }
```

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

```
"Condition":{"StringEquals":{"rds:db-tag/environment":["production"]}} }
```

For information about creating tags, see [Tagging Amazon Aurora and Amazon RDS resources](#).

### Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions.

For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyTagUpdates",
      "Effect": "Deny",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*"
    }
  ]
}
```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

### Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

#### Note

All examples use the us-west-2 region and contain fictitious account IDs.

### Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

## JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAnySnapshotName",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
    },
    {
      "Sid": "AllowDevTestToCreateSnapshot",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to `development` or `test`.

## JSON

```

{
  "Version": "2012-10-17",
  "Statement": [

```

```

    {
      "Sid": "AllowChangingParameterOptionSecurityGroups",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": [
        "arn:aws:rds:*:123456789012:pg:*",
        "arn:aws:rds:*:123456789012:secgrp:*",
        "arn:aws:rds:*:123456789012:og:*"
      ]
    },
    {
      "Sid": "AllowDevTestToModifyInstance",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}

```

## Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyProductionCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "arn:aws:rds:*:123456789012:pg:*",
      "Condition": {
        "StringEquals": {
          "rds:pg-tag/usage": "prod"
        }
      }
    }
  ]
}
```

**Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name**

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFullDevAccessNoTags",
      "Effect": "Allow",
      "NotAction": [
        "rds:AddTagsToResource",

```

```
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws-cn:rds:*:123456789012:db:${aws:username}*",
      "Condition": {
        "StringEqualsIfExists": {
          "rds:db-tag/stage": "devo"
        }
      }
    }
  ]
}
```

## Grant permission to tag Aurora resources during creation

Some RDS API operations allow you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see [What is ABAC for Amazon?](#) and [Controlling access to Amazon resources using tags](#).

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `rds:CreateDBCluster`. If tags are specified in the create action, RDS performs additional authorization on the `rds:AddTagsToResource` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `rds:AddTagsToResource` action.

In the IAM policy definition for the `rds:AddTagsToResource` action, you can use the `aws:RequestTag` condition key to require tags in a request to tag a resource.

For example, the following policy allows users to create DB instances and apply tags during DB instance creation, but only with specific tag keys (`environment` or `project`):

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance"
      ],

```

```

    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "rds:AddTagsToResource"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "aws:RequestTag/environment": ["production", "development"],
        "aws:RequestTag/project": ["dataanalytics", "webapp"]
      },
      "ForAllValues:StringEquals": {
        "aws:TagKeys": ["environment", "project"]
      }
    }
  }
]
}

```

This policy denies any create DB instance request that includes tags other than the environment or project tags, or that doesn't specify either of these tags. Additionally, users must specify values for the tags that match the allowed values in the policy.

The following policy allows users to create DB clusters and apply any tags during creation except the environment=prod tag:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBCluster"
      ],
      "Resource": "*"
    }
  ]
}

```

```
    "Effect": "Allow",
    "Action": [
        "rds:AddTagsToResource"
    ],
    "Resource": "*",
    "Condition": {
        "StringNotEquals": {
            "aws:RequestTag/environment": "prod"
        }
    }
}
]
```

### Supported RDS API actions for tagging on creation

The following RDS API actions support tagging when you create a resource. For these actions, you can specify tags when you create the resource:

- CreateBlueGreenDeployment
- CreateCustomDBEngineVersion
- CreateDBCluster
- CreateDBClusterEndpoint
- CreateDBClusterParameterGroup
- CreateDBClusterSnapshot
- CreateDBInstance
- CreateDBInstanceReadReplica
- CreateDBParameterGroup
- CreateDBProxy
- CreateDBProxyEndpoint
- CreateDBSecurityGroup
- CreateDBShardGroup
- CreateDBSnapshot
- CreateDBSubnetGroup
- CreateEventSubscription

- `CreateGlobalCluster`
- `CreateIntegration`
- `CreateOptionGroup`
- `CreateTenantDatabase`
- `CopyDBClusterParameterGroup`
- `CopyDBClusterSnapshot`
- `CopyDBParameterGroup`
- `CopyDBSnapshot`
- `CopyOptionGroup`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`
- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceFromS3`
- `RestoreDBInstanceToPointInTime`
- `PurchaseReservedDBInstancesOffering`

If you use the Amazon CLI or API to create a resource with tags, the `Tags` parameter is used to apply tags to resources during creation.

For these API actions, if tagging fails, the resource is not created, and the request fails with an error. This ensures that resources are either created with tags or not created at all, preventing resources from being created without the intended tags.

## Amazon managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use Amazon managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our Amazon managed policies. These policies cover common use cases and are available in your Amazon Web Services account. For more information about Amazon managed policies, see [Amazon managed policies](#) in the *IAM User Guide*.

Amazon Web Services services maintain and update Amazon managed policies. You can't change the permissions in Amazon managed policies. Services occasionally add additional permissions to an Amazon managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an Amazon managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an Amazon managed policy, so policy updates don't break your existing permissions.

Additionally, Amazon supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` Amazon managed policy provides read-only access to all Amazon Web Services services and resources. When a service launches a new feature, Amazon adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [Amazon managed policies for job functions](#) in the *IAM User Guide*.

### Topics

- [Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly](#)
- [Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess](#)
- [Amazon managed policy: AmazonRDSDirectoryServiceAccess](#)
- [Amazon managed policy: AmazonRDSServiceRolePolicy](#)
- [Amazon managed policy: AmazonRDSPreviewServiceRolePolicy](#)
- [Amazon managed policy: AmazonRDSBetaServiceRolePolicy](#)

## Amazon managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the Amazon Web Services Management Console.

### Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSReadOnlyAccess](#) in the *Amazon Managed Policy Reference Guide*.

## Amazon managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the Amazon Web Services Management Console.

### Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

- `outposts` – Allows principals to get Amazon Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSDataFullAccess**

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific Amazon Web Services account. This policy allows the Amazon Web Services account to get the value of a secret from Amazon Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

#### **Permissions details**

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the Amazon Web Services Management Console for multiple Amazon Web Services services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSEnhancedMonitoringRole**

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

#### **Permissions details**

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see [AmazonRDSEnhancedMonitoringRole](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly**

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

#### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsReadOnly](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess**

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

#### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.

- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSDirectoryServiceAccess**

This policy allows Amazon RDS to make calls to the Amazon Directory Service.

#### **Permissions details**

This policy includes the following permission:

- `ds` – Allows principals to describe Amazon Directory Service directories and control authorization to Amazon Directory Service directories.

For more information about this policy, including the JSON policy document, see [AmazonRDSDirectoryServiceAccess](#) in the *Amazon Managed Policy Reference Guide*.

### **Amazon managed policy: AmazonRDSServiceRolePolicy**

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon Aurora](#).

### **Amazon managed policy: AmazonRDSPreviewServiceRolePolicy**

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see [Service-linked role for Amazon RDS Preview](#).

#### **Permissions details**

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSPreviewServiceRolePolicy](#) in the *Amazon Managed Policy Reference Guide*.

## Amazon managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see [Service-linked role permissions for Amazon RDS Beta](#).

### Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSBetaServiceRolePolicy](#) in the *Amazon Managed Policy Reference Guide*.

## Amazon RDS updates to Amazon managed policies

View details about updates to Amazon managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS [Document history](#) page.

Change	Description	Date
<a href="#">Amazon managed policy: AmazonRDSPreviewServiceRolePolicy</a> – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSPreviewServiceRolePolicy of the AWSServiceRoleForRDSPreview service-linked role. For more information, see <a href="#">Amazon managed policy: AmazonRDSPreviewServiceRolePolicy</a> .	August 7, 2024
<a href="#">Amazon managed policy: AmazonRDSBetaServiceRolePolicy</a> – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSBetaServiceRolePolicy of the AWSServiceRoleForRDSBeta service-linked role. For more information, see <a href="#">Amazon managed policy: AmazonRDSBetaServiceRolePolicy</a> .	August 7, 2024
<a href="#">Amazon managed policy: AmazonRDSServiceRolePolicy</a> – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSServiceRolePolicy of the AWSServiceRoleForRDS service-linked role. For more informati	July 2, 2024

<a href="#">Service-linked role permissions for Amazon Aurora</a> – Update to an existing policy	<p>Amazon RDS added new Amazon CloudWatch namespaces to <code>AWSServiceRoleForRDS</code> for <code>PutMetricData</code> .</p> <p>These namespaces are required for Amazon DocumentDB (with MongoDB compatibility) and Amazon Neptune to publish CloudWatch metrics.</p> <p>For more information, see <a href="#">Using condition keys to limit access to CloudWatch namespaces</a> in the <i>Amazon CloudWatch User Guide</i>.</p>	March 4, 2022
Amazon RDS started tracking changes	Amazon RDS started tracking changes for its Amazon managed policies.	October 26, 2021

## Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In Amazon, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, Amazon provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified Amazon account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (\*) for the unknown portions of the ARN. An example is `arn:aws-cn:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws-cn:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- [Granting permissions to publish notifications to an Amazon SNS topic](#)
- [Setting up access to an Amazon S3 bucket](#) (PostgreSQL import)
- [Setting up access to an Amazon S3 bucket](#) (PostgreSQL export)

## IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using Amazon Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (Amazon) JDBC Driver supports IAM database authentication. For more information, see [Amazon IAM Authentication Plugin](#) in the [Amazon Web Services \(Amazon\) JDBC Driver GitHub repository](#).

The Amazon Web Services (Amazon) Python Driver supports IAM database authentication. For more information, see [Amazon IAM Authentication Plugin](#) in the [Amazon Web Services \(Amazon\) Python Driver GitHub repository](#).

Navigate through the following topics to learn the process to set IAM for DB authentication:

- [Enabling and disabling IAM database authentication](#)

- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)
- [Connecting to your DB cluster using IAM authentication](#)

## Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and IAM database authentication, see [Supported Regions and Aurora DB engines for IAM database authentication](#).

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see [Supported DB engines for DB instance classes](#).

## CLI and SDK support

IAM database authentication is available for the [Amazon CLI](#) and for the following language-specific Amazon SDKs:

- [Amazon SDK for .NET](#)
- [Amazon SDK for C++](#)
- [Amazon SDK for Go](#)
- [Amazon SDK for Java](#)
- [Amazon SDK for JavaScript](#)
- [Amazon SDK for PHP](#)
- [Amazon SDK for Python \(Boto3\)](#)
- [Amazon SDK for Ruby](#)

## Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.
- IAM DB authentication requires compute resources on the database cluster. You must have between 300 and 1000 MiB extra memory on your database for reliable connectivity. To see the memory needed for your workload, compare the RES column for RDS processes in the Enhanced Monitoring processlist before and after enabling IAM DB authentication. See [Viewing OS metrics in the RDS console](#).

If you are using a burstable class instance, avoid running out of memory by reducing the memory used by other parameters like buffers and cache by the same amount.

- For Aurora MySQL, you can't use password based authentication for a database user you configure with IAM authentication.
- IAM DB authentication is not supported for RDS on Outposts for any engine.

## Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See [RDS Proxy pricing](#).

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

## Unsupported Amazon global condition context keys

IAM database authentication does not support the following subset of Amazon global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see [Amazon global condition context keys](#) in the *IAM User Guide*.

## Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the Amazon Web Services Management Console, Amazon CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see [Creating an Amazon Aurora DB cluster](#).
- To modify a DB cluster to enable IAM database authentication, see [Modifying an Amazon Aurora DB cluster](#).

- To restore a DB cluster from a snapshot with IAM database authentication enabled, see [Restoring from a DB cluster snapshot](#).
- To restore a DB cluster to a point in time with IAM database authentication enabled, see [Restoring a DB cluster to a specified time](#).

## Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

### To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to modify.

#### Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

4. Choose **Modify**.
5. In the **Database authentication** section, choose **IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. You can also choose to enable publishing IAM DB authentication logs to CloudWatch Logs. Under **Log exports**, choose the **iam-db-auth-error log** option. Publishing your logs to CloudWatch Logs consumes storage and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.
7. Choose **Continue**.
8. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
9. Choose **Modify cluster**.

## Amazon CLI

To create a new DB cluster with IAM authentication by using the Amazon CLI, use the [create-db-cluster](#) command. Specify the `--enable-iam-database-authentication` option.

To update an existing DB cluster to have or not have IAM authentication, use the Amazon CLI command [modify-db-cluster](#). Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

### Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

If you are restoring a DB cluster, use one of the following Amazon CLI commands:

- [restore-db-cluster-to-point-in-time](#)
- [restore-db-cluster-from-db-snapshot](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

## RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation [CreateDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation [ModifyDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Note**

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

If you are restoring a DB cluster, use one of the following API operations:

- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

## Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

**Note**

To learn more about IAM policies, see [Identity and access management for Amazon Aurora](#).

The following example policy allows a user to connect to a DB cluster using IAM database authentication.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
    }
  ],
}
```

```
        "Resource": [
            "arn:aws-cn:rds-db:us-east-2:111122223333:dbuser:db-
            ABCDEFGHIJKL01234/db_user"
        ]
    }
]
```

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:111122223333:dbuser:cluster-
        ABCDEFGHIJKL01234/db_user"
      ]
    }
  ]
}
```

### Important

A user with administrator permissions can access DB clusters without explicit permissions in an IAM policy. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

**Note**

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB cluster.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws-cn:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- *region* is the Amazon Region for the DB cluster. In the example policy, the Amazon Region is `us-east-2`.
- *account-id* is the Amazon account number for the DB cluster. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB cluster.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB cluster and allow your other account to assume the role.

- *DbClusterResourceId* is the identifier for the DB cluster. This identifier is unique to an Amazon Region and never changes. In the example policy, the identifier is `cluster-ABCDEFGHIJKL01234`.

To find a DB cluster resource ID in the Amazon Web Services Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the Amazon CLI command to list the identifiers and resource IDs for all of your DB cluster in the current Amazon Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].
[DBClusterIdentifier,DbClusterResourceId]"
```

### Note

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a database using IAM authentication](#).

- *db-user-name* is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:db-
        ABCDEFGHIJKL01234/jane_doe",
        "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:db-
        ABCDEFGHIJKL01234/mary_roe"
      ]
    }
  ]
}
```

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
        ABCDEFGHIJKL01234/jane_doe",
        "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
        ABCDEFGHIJKL01234/mary_roe"
      ]
    }
  ]
}
```

The following policy uses the "\*" character to match all DB clusters and database accounts for a particular Amazon account and Amazon Region.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:111122223333:dbuser:*/*"
      ]
    }
  ]
}
```

```
    }
  ]
}
```

The following policy matches all of the DB clusters for a particular Amazon account and Amazon Region. However, the policy only grants access to DB clusters that have a `jane_doe` database account.

## JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
      ]
    }
  ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named *dev*, and another database named *test*. If the database user `jane_doe` has access only to *dev*, any users or roles that access that DB cluster with the `jane_doe` user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see [Identity-based policy examples for Amazon Aurora](#).

## Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see [Create and attach your first customer managed policy](#) in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

### Note

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB cluster using the `jane_doe` database account.

## Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

### Note

The user name used for IAM authentication must match the case of the user name in the database.

## Topics

- [Using IAM authentication with Aurora MySQL](#)

- [Using IAM authentication with Aurora PostgreSQL](#)

## Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by `AWSAuthenticationPlugin`—an Amazon-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows Aurora MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#).

### Note

If you see the following message, it means that the Amazon-provided plugin is not available for the current DB cluster.

```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see [Region and version availability](#) and [Enabling and disabling IAM database authentication](#).

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

## Using IAM authentication with Aurora PostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;  
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#). You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the `rds_ad` role. This also applies to nested memberships. For more information, see [Step 7: Create PostgreSQL users for your Kerberos principals](#).

## Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using Amazon signature version 4. (For more information, see [Signature Version 4 signing process](#) in the *Amazon Web Services General Reference*.) The Amazon CLI and an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another Amazon service, such as Amazon Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an Amazon SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3).

For more information, see the following blog posts:

- [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#)
- [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#)

## Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

## Topics

- [Connecting to your DB cluster using IAM authentication with the Amazon drivers](#)
- [Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and mysql client](#)
- [Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and psql client](#)

- [Connecting to your DB cluster using IAM authentication and the Amazon SDK for Python \(Boto3\)](#)

## Connecting to your DB cluster using IAM authentication with the Amazon drivers

The Amazon suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the Amazon drivers, see the corresponding language driver for your [Aurora MySQL](#) or [Aurora PostgreSQL](#) DB cluster.

## Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the Amazon CLI and `mysql` command line tool as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

#### Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#).

### Topics

- [Generating an IAM authentication token](#)
- [Connecting to a DB cluster](#)

### Generating an IAM authentication token

The following example shows how to get a signed authentication token using the Amazon CLI.

```
aws rds generate-db-auth-token \  
  --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \  
  --port 3306 \  
  --region us-west-2 \  
  --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB cluster that you want to access

- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

## Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-
cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

For more information, see [TLS connections to Aurora MySQL DB clusters](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.

- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, */sample\_dir/* is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-
west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-
cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----+-----+
| Variable_name | Value
+-----+-----+
| ...           | ...
| Ssl_cipher    | AES256-SHA
+-----+-----+
| ...           | ...
| Ssl_version   | TLSv1.1
+-----+-----+
| ...           | ...
+-----+-----+
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

## Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the Amazon CLI and psql command line tool as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

#### Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#).

### Topics

- [Generating an IAM authentication token](#)
- [Connecting to an Aurora PostgreSQL cluster](#)

### Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the Amazon CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?  
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

## Connecting to an Aurora PostgreSQL cluster

The general format for using `psql` to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full  
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName  
password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB cluster (cluster endpoint) that you want to access
- `port` – The port number used for connecting to your DB cluster
- `sslmode` – The SSL mode to use

When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `sslrootcert` – The full path to the SSL certificate file that contains the public key

For more information, see [Securing Aurora PostgreSQL data with SSL/TLS](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

#### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

The following example shows using `psql` to connect. In the example, `psql` uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

## Connecting to your DB cluster using IAM authentication and the Amazon SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for .NET as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

## Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [Amazon SDK for .NET](#), found on the Amazon site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB cluster, use the .NET database connector for the DB engine, such as `MySqlConnection` for MariaDB or MySQL, or `Npgsql` for PostgreSQL.

This code connects to an Aurora MySQL DB cluster. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB cluster that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB cluster
- `SslMode` – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `SslCa` – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;
```

```
namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
"mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is
generated

            MySqlConnection conn = new
MySqlConnection($"server=mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row
            while (mysqlDataRdr.Read())
                Console.WriteLine(mysqlDataRdr[0]);

            mysqlDataRdr.Close();
            // Close connection
            conn.Close();
        }
    }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB cluster that you want to access
- **User ID** – The database account that you want to access
- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB cluster

- **SSL Mode** – The SSL mode to use

When you use `SSL Mode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
                RDSAuthTokenGenerator.GenerateAuthToken("postgresmycluster.cluster-123456789012.us-
                east-1.rds.amazonaws.com", 5432, "jane_doe");
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is generated

            NpgsqlConnection conn = new
                NpgsqlConnection($"Server=postgresmycluster.cluster-123456789012.us-
                east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL
                Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
            pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();
```

```
        // Read all rows and output the first column in each row
        while (dr.Read())
            Console.WriteLine("{0}\n", dr[0]);

        // Close connection
        conn.Close();
    }
}
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

## Connecting to your DB cluster using IAM authentication and the Amazon SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Go as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

### Examples

To run these code examples, you need the [Amazon SDK for Go](#), found on the Amazon site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB cluster that you want to access

**Note**

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB cluster
- `region` – The Amazon Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Important**

The examples in this section use the following code to provide credentials that access a database from a local environment:

```
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an Amazon service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```
sess := session.Must(session.NewSession())
```

```
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```
"github.com/aws/aws-sdk-go/aws/session"
```

**Topics**

- [Connecting using IAM authentication and the Amazon SDK for Go V2](#)
- [Connecting using IAM authentication and the Amazon SDK for Go V1.](#)

**Connecting using IAM authentication and the Amazon SDK for Go V2**

You can connect to a DB cluster using IAM authentication and the Amazon SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```
package main
```

```
import (  
    "context"  
    "database/sql"  
    "fmt"  
  
    "github.com/aws/aws-sdk-go-v2/config"  
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"  
    _ "github.com/go-sql-driver/mysql"  
)  
  
func main() {  
  
    var dbName string = "DatabaseName"  
    var dbUser string = "DatabaseUser"  
    var dbHost string = "mysqlcluster.cluster-123456789012.us-  
east-1.rds.amazonaws.com"  
    var dbPort int = 3306  
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)  
    var region string = "us-east-1"  
  
    cfg, err := config.LoadDefaultConfig(context.TODO())  
    if err != nil {  
        panic("configuration error: " + err.Error())  
    }  
  
    authenticationToken, err := auth.BuildAuthToken(  
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)  
    if err != nil {  
        panic("failed to create authentication token: " + err.Error())  
    }  
  
    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",  
        dbUser, authenticationToken, dbEndpoint, dbName,  
    )  
  
    db, err := sql.Open("mysql", dsn)  
    if err != nil {  
        panic(err)  
    }  
  
    err = db.Ping()  
    if err != nil {  
        panic(err)  
    }  
}
```

```
}  
}
```

This code connects to an Aurora PostgreSQL DB cluster.

```
package main  
  
import (  
    "context"  
    "database/sql"  
    "fmt"  
  
    "github.com/aws/aws-sdk-go-v2/config"  
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"  
    _ "github.com/lib/pq"  
)  
  
func main() {  
  
    var dbName string = "DatabaseName"  
    var dbUser string = "DatabaseUser"  
    var dbHost string = "postgresmycluster.cluster-123456789012.us-  
east-1.rds.amazonaws.com"  
    var dbPort int = 5432  
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)  
    var region string = "us-east-1"  
  
    cfg, err := config.LoadDefaultConfig(context.TODO())  
    if err != nil {  
        panic("configuration error: " + err.Error())  
    }  
  
    authenticationToken, err := auth.BuildAuthToken(  
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)  
    if err != nil {  
        panic("failed to create authentication token: " + err.Error())  
    }  
  
    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",  
        dbHost, dbPort, dbUser, authenticationToken, dbName,  
    )  
  
    db, err := sql.Open("postgres", dsn)
```

```
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

### Connecting using IAM authentication and the Amazon SDK for Go V1.

You can connect to a DB cluster using IAM authentication and the Amazon SDK for Go V1

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```
package main

import (
    "database/sql"
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/go-sql-driver/mysql"
)

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
```

```

authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
    dbUser, authToken, dbEndpoint, dbName,
)

db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}

```

This code connects to an Aurora PostgreSQL DB cluster.

```

package main

import (
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/lib/pq"
)

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 5432
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
}

```

```
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authToken, dbName,
)

db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

## Connecting to your DB cluster using IAM authentication and the Amazon SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Java as described following.

### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)
- [Set up the Amazon SDK for Java](#)

For examples on how to use the SDK for Java 2.x, see [Amazon RDS examples using SDK for Java 2.x](#). You can also use the Amazon Advanced JDBC Wrapper, see [Amazon Advanced JDBC Wrapper documentation](#).

### Topics

- [Generating an IAM authentication token](#)
- [Manually constructing an IAM authentication token](#)
- [Connecting to a DB cluster](#)

## Generating an IAM authentication token

If you are writing programs using the Amazon SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide Amazon credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first Amazon access key and secret key that it finds in the [default credential provider chain](#). For more information about Amazon access keys, see [Managing access keys for users](#).

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the Amazon Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        System.out.println(generateAuthToken(region, hostname, port, username));
    }
}
```

```
static String generateAuthToken(String region, String hostName, String port, String
username) {

    RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
        .credentials(new DefaultAWSCredentialsProviderChain())
        .region(region)
        .build();

    String authToken = generator.getAuthToken(
        GetIamAuthTokenRequest.builder()
            .hostname(hostName)
            .port(Integer.parseInt(port))
            .userName(username)
            .build());

    return authToken;
}
}
```

## Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using Amazon signature version 4. For more information, see [Signature version 4 signing process](#) in the *Amazon Web Services General Reference*.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
```

```
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIPParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {

        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new
SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
        DefaultAWSCredentialsProviderChain creds = new
DefaultAWSCredentialsProviderChain();
        String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
        String awsSecretKey = creds.getCredentials().getAWSSecretKey();
        String expiryMinutes = "900";

        System.out.println("Step 1: Create a canonical request:");
        String canonicalString = createCanonicalString(username, awsAccessKey, date,
dateTimeStamp, region, expiryMinutes, instanceName, port);
        System.out.println(canonicalString);
        System.out.println();

        System.out.println("Step 2: Create a string to sign:");
```

```

        String stringToSign = createStringToSign(dateTimeStamp, canonicalString,

        md.update(s.getBytes(UTF8));
        return md.digest();
    } catch (Exception e) {
        throw new SdkClientException(
            "Unable to compute hash while signing request: "
                + e.getMessage(), e);
    }
}
}
```

## Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the [Amazon SDK for Java](#), found on the Amazon site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon Aurora that is specific to an Amazon Region. (For more information, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB cluster that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB cluster.
  - `REGION_NAME` – The Amazon Region where the DB cluster is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon Aurora that is specific to an Amazon Region.

To download a certificate for your Amazon Region, see [Using SSL/TLS to encrypt a connection to a DB cluster](#). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains Amazon credentials from the [default credential provider chain](#).

### Note

Specify a password for `DEFAULT_KEY_STORE_PASSWORD` other than the prompt shown here as a security best practice.

```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

### Connecting to your DB cluster using IAM authentication and the Amazon SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Python (Boto3) as described following.

#### Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

In addition, make sure the imported libraries in the sample code exist on your system.

#### Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see [Credentials](#) in the Amazon SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [Amazon SDK for Python \(Boto3\)](#), found on the Amazon site.

Modify the values of the following variables as needed:

- ENDPOINT – The endpoint of the DB cluster that you want to access
- PORT – The port number used for connecting to your DB cluster
- USER – The database account that you want to access
- REGION – The Amazon Region where the DB cluster is running
- DBNAME – The database that you want to access
- SSLCERTIFICATE – The full path to the SSL certificate for Amazon Aurora

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

### Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

This code connects to an Aurora MySQL DB cluster.

Before running this code, install the PyMySQL driver by following the instructions in the [Python Package Index](#).

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
    Region=REGION)
```

```
try:
    conn =
    pymysql.connect(auth_plugin_map={'mysql_clear_password':None},host=ENDPOINT,
    user=USER, password=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE',
    ssl_verify_identity=True, ssl_verify_cert=True)
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install `psycopg2` by following the instructions in [Psycopg2 documentation](#).

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
    password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
```

```
query_results = cur.fetchall()
print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a database using IAM authentication](#).

## Troubleshooting for IAM DB authentication

Following, you can find troubleshooting ideas for some common IAM DB authentication issues and information on CloudWatch logs and metrics for IAM DB authentication.

### Exporting IAM DB authentication error logs to CloudWatch Logs

IAM DB authentication error logs are stored on the database host, and you can export these logs your CloudWatch Logs account. Use the logs and remediation methods in this page to troubleshoot IAM DB authentication issues.

You can enable log exports to CloudWatch Logs from the console, Amazon CLI, and RDS API. For console instructions, see [Publishing database logs to Amazon CloudWatch Logs](#).

To export your IAM DB authentication error logs to CloudWatch Logs when creating a DB cluster from the Amazon CLI, use the following command:

```
aws rds create-db-cluster --db-cluster-identifier mydbinstance \  
--region us-east-1 \  
--engine postgres \  
--engine-version 16 \  
--master-username master \  
--master-user-password password \  
--publicly-accessible \  
--enable-iam-database-authentication \  
--enable-cloudwatch-logs-exports=iam-db-auth-error
```

To export your IAM DB authentication error logs to CloudWatch Logs when modifying a DB cluster from the Amazon CLI, use the following command:

```
aws rds modify-db-cluster --db-cluster-identifier mydbcluster \  
--region us-east-1 \  
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["iam-db-auth-error"]}'
```

To verify if your DB cluster is exporting IAM DB authentication logs to CloudWatch Logs, check if the `EnabledCloudwatchLogsExports` parameter is set to `iam-db-auth-error` in the output for the `describe-db-instances` command.

```
aws rds describe-db-cluster --region us-east-1 --db-cluster-identifier mydbcluster
...
    "EnabledCloudwatchLogsExports": [

```

### IAM DB authentication CloudWatch metrics

Amazon Aurora delivers near-real time metrics about IAM DB authentication to your Amazon CloudWatch account. The following table lists the IAM DB authentication metrics available using CloudWatch:

Metric	Description
<code>IamDbAuthConnectionRequests</code>	Total number of connection requests made with IAM DB authentication.
<code>IamDbAuthConnectionSuccess</code>	Total number of successful IAM DB authentication requests.
<code>IamDbAuthConnectionFailure</code>	Total number of failed IAM DB authentication requests.
<code>IamDbAuthConnectionFailureInvalidToken</code>	Total number of failed IAM DB authentication requests due to invalid token.
<code>IamDbAuthConnectionFailureInsufficientPermissions</code>	Total number of failed IAM DB authentication requests due to incorrect policies or permissions.
<code>IamDbAuthConnectionFailureThrottling</code>	Total number of failed IAM DB authentication requests due to IAM DB authentication throttling.

Metric	Description
IamDbAuthConnectionFailureServerError	Total number of failed IAM DB authentication requests due to an internal server error in the IAM DB authentication feature.

## Common issues and solutions

You might encounter the following issues when using IAM DB authentication. Use the remediation steps in the table to solve the issues:

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authenticate the connection request for user <i>db_user</i> because the provided token is malformed or otherwise invalid. (Status Code: 400, Error Code: InvalidToken)	IamDbAuthConnectionFailure  IamDbAuthConnectionFailureInvalidToken	The IAM DB authentication token in the connection request is either not a valid SigV4a token, or it is not formatted correctly.	Check your token generation strategy in your application. In some cases, make sure you are passing the token with valid formatting. Truncating the token (or incorrect string formatting) will make the token invalid.
[ERROR] Failed to authenticate the connection request for user <i>db_user</i> because the token age is longer than 15 minutes. (Status Code: 400,	IamDbAuthConnectionFailure  IamDbAuthConnectionFailureInvalidToken	The IAM DB authentication token has expired. Tokens are only valid for 15 minutes.	Check your token caching and/or token re-use logic in your application. You should not re-use tokens that are older than 15 minutes.

Error	Metric(s)	Cause	Solution
Error Code:ExpiredToken)			
[ERROR] Failed to authorize the connection request for user <i>db_user</i> because the IAM policy assumed by the caller 'arn:aws:sts::123456789012:assumed-role/<RoleName>/<RoleSession>' is not authorized to perform `rds-db:connect` on the DB instance. (Status Code: 403, Error Code:NotAuthorized)	IamDbAuth Connectio nFailure  IamDbAuth Connectio nFailureI nsufficie ntPermissions	This error might be due to the following reasons: <ul style="list-style-type: none"> <li>The IAM policy assumed by the application does not authorize the <code>rds-db:connect</code> action.</li> <li>You are assuming the incorrect role/policy for <i>db_user</i> to connect to the database.</li> <li>You are assuming the correct policy for <i>db_user</i>, but you are not connecting to the correct database.</li> </ul>	Verify that the IAM role and/or policy you are assuming in your application. Make sure you assume the same policy to generate the token as to connect to the DB.

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authorize the connection request for user <code>db_user</code> due to IAM DB authentication throttling. (Status Code: 429, Error Code: ThrottlingException)	IamDbAuthConnectionFailure  IamDbAuthConnectionFailureThrottling	You are making too many connection requests to your DB in a short amount of time. IAM DB authentication throttling limit is 200 connections per second.	Reduce the rate of establishing new connections with IAM authentication. Consider implementing connection pooling using RDS Proxy in order to reuse established connections in your application.
[ERROR] Failed to authorize the connection request for user <code>db_user</code> due to an internal IAM DB authentication error. (Status Code: 500, Error Code: InternalError)	IamDbAuthConnectionFailure  IamDbAuthConnectionFailureThrottling	There was an internal error while authorizing the DB connection with IAM DB authentication.	Reach out to <a href="http://www.amazonaws.cn/support-plans/">http://www.amazonaws.cn/support-plans/</a> to investigate the issue.

## Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

### Topics

- [I'm not authorized to perform an action in Aurora](#)
- [I'm not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my Amazon account to access my Aurora resources](#)

## I'm not authorized to perform an action in Aurora

If the Amazon Web Services Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a `widget` but does not have `rds:GetWidget` permissions.

```
User: arn:aws-cn:iam::123456789012:user/mateojackson is not authorized to perform:
rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the `my-example-widget` resource using the `rds:GetWidget` action.

## I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Aurora.

Some Amazon services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws-cn:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

## I want to allow people outside of my Amazon account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see [How Amazon Aurora works with IAM](#).
- To learn how to provide access to your resources across Amazon accounts that you own, see [Providing access to an IAM user in another Amazon account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party Amazon accounts, see [Providing access to Amazon accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

## Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your Amazon solutions. You should collect monitoring data from all of the parts of your Amazon solution so that you can more easily debug a multi-point failure if one occurs. Amazon provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

### Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or Amazon Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

## Amazon CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an Amazon service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon Aurora API calls in Amazon CloudTrail](#).

## Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

## Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

## Database Logs

You can view, download, and watch database logs using the Amazon Web Services Management Console, Amazon CLI, or RDS API. For more information, see [Monitoring Amazon Aurora log files](#).

## Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see [Recommendations from Amazon Aurora](#).

## Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an Amazon Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification](#).

## Amazon Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of Amazon customers. Trusted Advisor inspects your Amazon environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All Amazon customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

## Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](#).

For more information about monitoring Aurora see [Monitoring metrics in an Amazon Aurora cluster](#).

# Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple Amazon compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of Amazon services in scope of specific compliance programs, see [Amazon services in scope by compliance program](#). For general information, see [Amazon compliance programs](#).

You can download third-party audit reports using Amazon Artifact. For more information, see [Downloading reports in Amazon Artifact](#).

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. Amazon provides the following resources to help with compliance:

- [Security and compliance quick start guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on Amazon.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use Amazon to create HIPAA-compliant applications.
- [Amazon compliance resources](#) – This collection of workbooks and guides that might apply to your industry and location.
- [Amazon Config](#) – This Amazon service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [Amazon Security Hub CSPM](#) – This Amazon Web Services service provides a comprehensive view of your security state within Amazon. Security Hub CSPM uses security controls to evaluate your Amazon resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub CSPM controls reference](#).

## Resilience in Amazon Aurora

The Amazon global infrastructure is built around Amazon Regions and Availability Zones. Amazon Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about Amazon Regions and Availability Zones, see [Amazon global infrastructure](#).

In addition to the Amazon global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

### Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see [Backing up and restoring an Amazon Aurora DB cluster](#).

### Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the

Availability Zones that a DB cluster spans within an Amazon Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see [Replication with Amazon Aurora](#).

## Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single Amazon Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see [High availability for Amazon Aurora](#).

# Infrastructure security in Amazon Aurora

As a managed service, Amazon Relational Database Service is protected by Amazon global network security. For information about Amazon security services and how Amazon protects infrastructure, see [Amazon Cloud Security](#). To design your Amazon environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar Amazon Well-Architected Framework*.

You use Amazon published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

In addition, Aurora offers features to help support infrastructure security.

## Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see [Controlling access with security groups](#).

## Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see [Hiding a DB cluster in a VPC from the internet](#).

**Note**

If your DB instance is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see [Internet traffic privacy](#).

# Amazon RDS API and interface VPC endpoints (Amazon PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by [Amazon PrivateLink](#).

Amazon PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or Amazon Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces](#) in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see [Interface VPC endpoints \(Amazon PrivateLink\)](#) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](#).

You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see [Scenarios for accessing a DB cluster in a VPC](#).

## Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](#) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using Amazon PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

## Availability

Amazon RDS API currently supports VPC endpoints in the following Amazon Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (Bahrain)

- South America (São Paulo)

## Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the Amazon Command Line Interface (Amazon CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding Amazon Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the Amazon Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) Amazon Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

## Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

### Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
  "Statement": [
    {
      "Principal": "*",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance",
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*"
    }
  ]
}
```

### Example: VPC endpoint policy that denies all access from a specified Amazon account

The following VPC endpoint policy denies Amazon account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
    }
  ]
}
```

## Security best practices for Amazon Aurora

Use Amazon Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources.

Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual user for each person who manages Amazon Aurora resources, including yourself. Don't use Amazon root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure Amazon Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see [Rotating your Amazon Secrets Manager secrets](#) in the *Amazon Secrets Manager User Guide*. You can also retrieve the credential from Amazon Secrets Manager programmatically. For more information, see [Retrieving the secret value](#) in the *Amazon Secrets Manager User Guide*.

For more information about Amazon Aurora security, see [Security in Amazon Aurora](#) . For more information about IAM, see [Amazon Identity and Access Management](#). For information on IAM best practices, see [IAM best practices](#).

Amazon Security Hub CSPM uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub CSPM to evaluate RDS resources, see [Amazon Relational Database Service controls](#) in the Amazon Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub CSPM. For more information, see [What is Amazon Security Hub CSPM?](#)

Use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes various data sources, including Amazon RDS login activity. It uses threat intelligence feeds and machine learning to identify unexpected, potentially unauthorized, suspicious login behavior, and malicious activity within your Amazon environment.

When Amazon GuardDuty RDS Protection detects a potentially suspicious or anomalous login attempt that indicates a threat to your database, GuardDuty generates a new finding with details

about the potentially compromised database. For more information, see [Monitoring threats with Amazon GuardDuty RDS Protection for Amazon Aurora](#).

## Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

### Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

#### Note

In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

**Note**

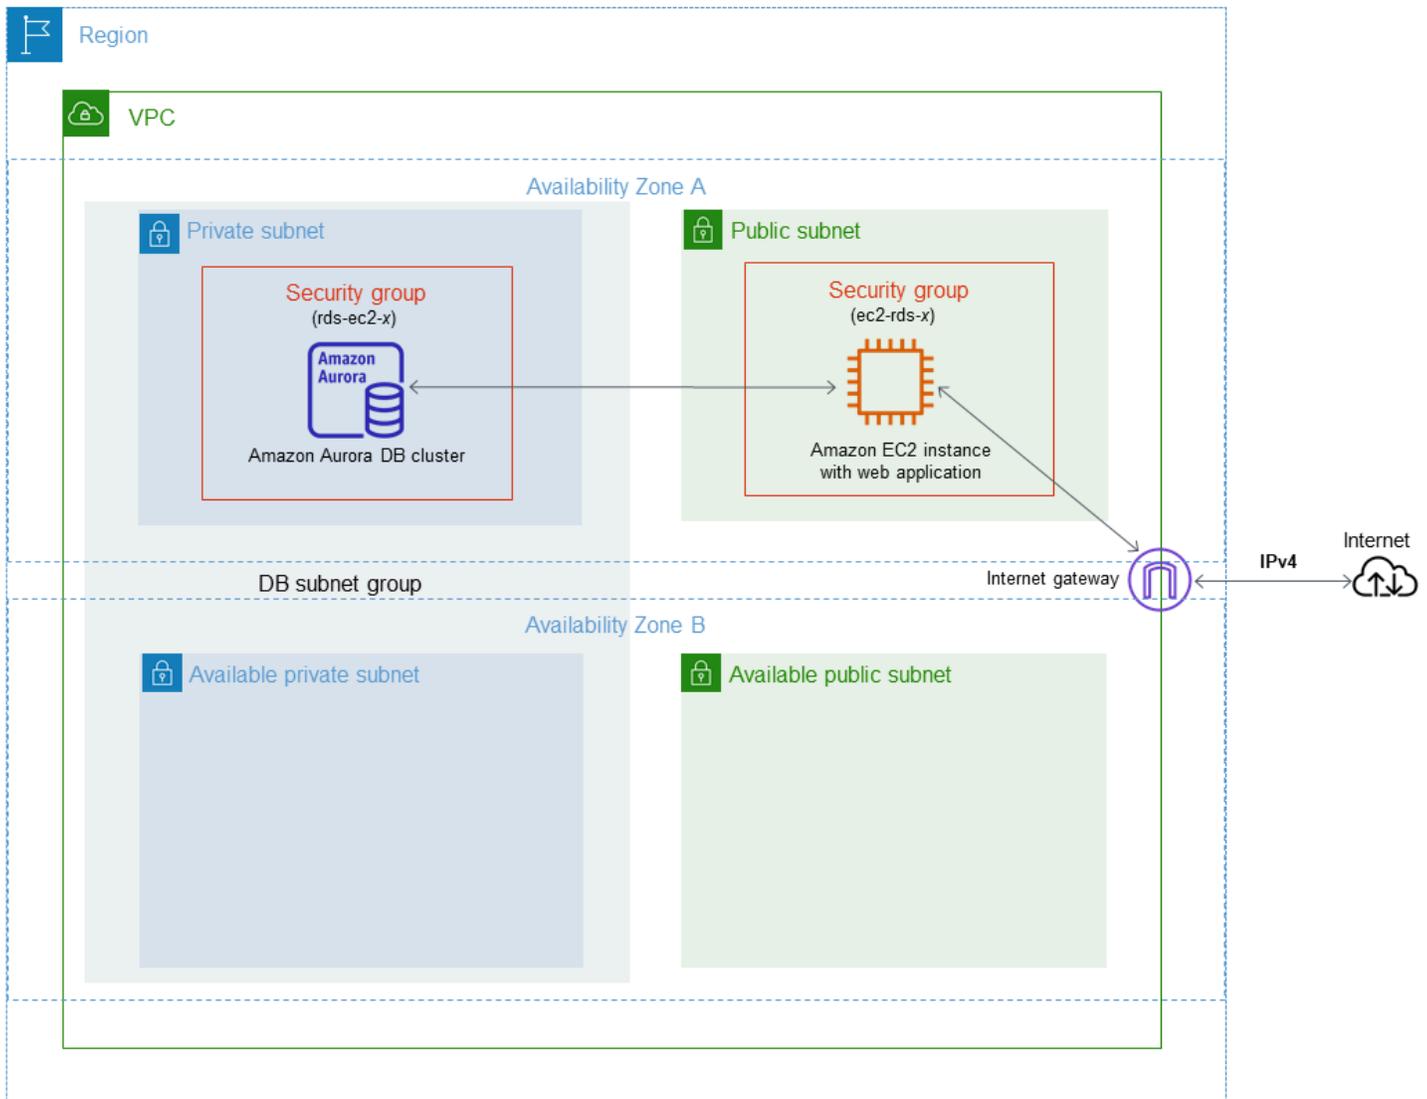

If your DB cluster is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see [Internet traffic privacy](#).

## Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the Amazon Web Services Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB cluster and add the DB cluster to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#) . For more information about using a VPC, see [Amazon VPC and Amazon Aurora](#) .

## Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see [Provide access to the DB cluster in the VPC by creating a security group](#) and [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

## Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using **Modify cluster** on the RDS console, the `ModifyDBCluster` Amazon RDS API, or the `modify-db-cluster` Amazon CLI command.

The following CLI example associates a specific VPC group and removes DB security groups from the DB cluster

```
aws rds modify-db-cluster --db-cluster-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

## Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

### Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
Aurora MySQL	<p>Version 2:</p> <p>ALTER,ALTER ROUTINE, CREATE,CREATE ROUTINE,CREATE TEMPORARY TABLES,CREATE USER,CREATE VIEW,DELETE,DROP, EVENT,EXECUTE,GRANT OPTION,INDEX,INSERT, LOAD FROM S3,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATION CLIENT , REPLICATION SLAVE ,SELECT, SELECT INTO S3,SHOW DATABASES , SHOW VIEW,TRIGGER, UPDATE</p>	—
	<p>Version 3:</p> <p>ALTER,APPLICATION_PASSWORD_ADMIN , ALTER ROUTINE,CONNECTION_ADMIN , CREATE,CREATE ROLE,CREATE ROUTINE,CREATE TEMPORARY TABLES, CREATE USER,CREATE VIEW, DELETE,DROP,DROP ROLE, EVENT,EXECUTE,INDEX, INSERT,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATION CLIENT , REPLICATION SLAVE ,ROLE_ADMIN , SET_USER_ID ,SELECT,SHOW DATABASES ,SHOW VIEW,TRIGGER, UPDATE,XA_RECOVER_ADMIN</p> <p>Starting with Aurora MySQL version 3.04.0, the master user also gets the SHOW_ROUTINE privilege .</p> <p>Starting with Aurora MySQL version 3.09.0, the master user also gets the FLUSH_OPTIMIZER_COSTS ,FLUSH_STATUS ,FLUSH_TABLES , and FLUSH_USER_RESOURCES privileges.</p>	<p>rds_superuser_role</p> <p>For more information about rds_superuser_role, see <a href="#">Role-based privilege model</a> .</p>

Database engine	System privilege	Database role
Aurora PostgreSQL	LOGIN,NOSUPERUSER , INHERIT,CREATEDB, CREATEROLE ,NOREPLICATION ,VALID UNTIL 'infinity'	RDS_SUPERUSER  For more information about RDS_SUPERUSER, see <a href="#">Understanding PostgreSQL roles and permissions</a> .

## Using service-linked roles for Amazon Aurora

Amazon Aurora uses Amazon Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other Amazon services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [Amazon services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

### Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDS` to allow Amazon RDS to call Amazon services on behalf of your DB clusters.

The `AWSServiceRoleForRDS` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see [AmazonRDSServiceRolePolicy](#) in the *Amazon Managed Policy Reference Guide*.

#### Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

**Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws-cn:iam::*:role/aws-service-role/rds.amazonaws.com/
  AWSServiceRoleForRDS",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

### Important

If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see [A new role appeared in my Amazon account](#).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

## Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

## Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

### Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

#### To check whether the service-linked role has an active session in the IAM console

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the `AWSServiceRoleForRDS` role.
3. On the **Summary** page for the chosen role, choose the **Last Accessed** tab.
4. On the **Last Accessed** tab, review recent activity for the service-linked role.

#### Note

If you are unsure whether Amazon Aurora is using the `AWSServiceRoleForRDS` role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the Amazon Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the `AWSServiceRoleForRDS` role, you must first delete *all* of your DB clusters.

### Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

## To delete a cluster (console)

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the **Databases** list, choose the cluster that you want to delete.
3. For **Cluster Actions**, choose **Delete**.
4. Choose **Delete**.

## To delete a cluster (CLI)

See [delete-db-cluster](#) in the *Amazon CLI Command Reference*.

## To delete a cluster (API)

See [DeleteDBCluster](#) in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the `AWSServiceRoleForRDS` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

## Service-linked role permissions for Amazon RDS Beta

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSBeta` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [Amazon managed policy: AmazonRDSBetaServiceRolePolicy](#).

### Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSBetaServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Service-linked role for Amazon RDS Preview

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSPreview` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [Amazon managed policy: AmazonRDSPreviewServiceRolePolicy](#).

### Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
```

```
"Action": "iam:CreateServiceLinkedRole",
"Effect": "Allow",
"Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSPreviewServiceRolePolicy",
"Condition": {
  "StringLike": {
    "iam:AWSServiceName": "custom.rds.amazonaws.com"
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

# Amazon VPC and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch Amazon resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

## Topics

- [Working with a DB cluster in a VPC](#)
- [Scenarios for accessing a DB cluster in a VPC](#)
- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#)

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

## Working with a DB cluster in a VPC

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the Amazon Cloud. Amazon VPC makes it possible for you to launch Amazon resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your Amazon account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC, see [Scenarios for accessing a DB cluster in a VPC](#).

## Topics

- [Working with a DB cluster in a VPC](#)
- [VPC encryption control](#)
- [Working with DB subnet groups](#)
- [Shared subnets](#)
- [Amazon Aurora IP addressing](#)
- [Hiding a DB cluster in a VPC from the internet](#)
- [Creating a DB cluster in a VPC](#)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#)

## Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the Amazon Web Services Region where you want to deploy your DB cluster. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

For more information, see [Scenarios for accessing a DB cluster in a VPC](#).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see [Dedicated instances](#) in the *Amazon Elastic Compute Cloud User Guide*.

### Note

When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn't guarantee that the DB cluster will run on a dedicated host.

## VPC encryption control

VPC encryption controls allow you to enforce encryption-in-transit for all network traffic within your VPCs. Use encryption control to meet regulatory compliance requirements by ensuring that only encryption-capable Nitro-based hardware can be provisioned in designated VPCs. Encryption control also catches compatibility issues at API request time rather than during provisioning. Your existing workloads continue operating and only new incompatible requests are blocked.

Set your VPC encryption controls by setting the VPC control mode to :

- *disabled* (default)
- *monitor*
- *enforced*

To check the current control mode for your VPC, use the Amazon Web Services Management Console or [DescribeVpcs](#) CLI or API command.

If your VPC enforces encryption, you can only provision Nitro-based DB clusters that support encryption in transit in that VPC. For more information see, [DB instance class types](#). For information about Nitro instances, see [Instances built on the Amazon Nitro System](#) in the *Amazon EC2 User Guide*.

**Note**

If you try to provision incompatible DB clusters in an encryption-enforced VPC, Aurora returns a `VpcEncryptionControlViolationException` exception.

For Aurora Serverless for MySQL and PostgreSQL, encryption control requires platform version 3 or higher.

## Working with DB subnet groups

*Subnets* are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the Amazon CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given Amazon Web Services Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet. Aurora always assigns an IP address from a subnet that has free IP address space.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see [Amazon Aurora IP addressing](#) and [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

**Note**

For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

## Shared subnets

You can create a DB cluster in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB cluster from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB cluster.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

## Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora supports both IPv4 and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

### Topics

- [IPv4 addresses](#)
- [IPv6 addresses](#)

- [Dual-stack mode](#)

## IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

## IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see [IP Addressing](#) in the *Amazon VPC User Guide*.

## Dual-stack mode

When a DB cluster can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB cluster over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

### Topics

- [Dual-stack mode and DB subnet groups](#)
- [Working with dual-stack mode DB instances](#)
- [Modifying IPv4-only DB clusters to use dual-stack mode](#)
- [Availability of dual-stack network DB clusters](#)
- [Limitations for dual-stack network DB clusters](#)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#).

### Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB cluster.

To determine whether a DB subnet group supports dual-stack mode by using the Amazon Web Services Management Console, view the **Network type** on the details page of the DB subnet group.

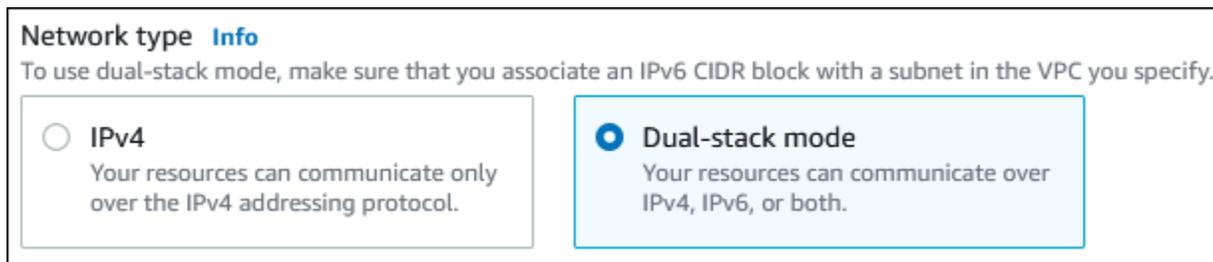

To determine whether a DB subnet group supports dual-stack mode by using the Amazon CLI, run the [describe-db-subnet-groups](#) command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

## Working with dual-stack mode DB instances

When you create or modify a DB cluster, you can specify dual-stack mode to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the Amazon Web Services Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

When you use the Amazon CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

To determine whether a DB cluster is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB cluster.

## Modifying IPv4-only DB clusters to use dual-stack mode

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

It is recommended that you change the network type of your Amazon Aurora DB clusters during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-cluster` command.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. Modifying the DB subnet group of a DB cluster can cause downtime.

If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.

We recommend that you run the [modify-db-cluster](#) API with only the `--network-type` parameter with value `DUAL` to change the network of an Amazon Aurora cluster to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime.

If you can't connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

### To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
  - a. Associate an IPv6 CIDR block with your VPC.

For instructions, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.

- b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

For instructions, see [Add an IPv6 CIDR block to your subnet](#) in the *Amazon VPC User Guide*.

- c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the Amazon Web Services Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

If you are using the Amazon CLI, run the [describe-db-subnet-groups](#) command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual`, `IPv4`.

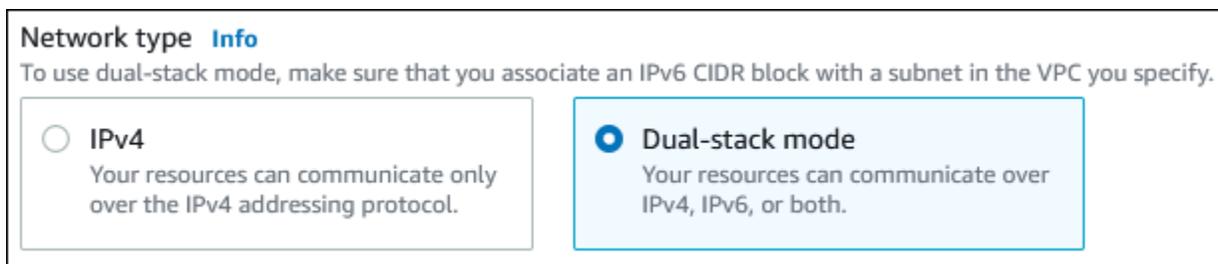

2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

For instructions, see [Security group rules](#) in the *Amazon VPC User Guide*.

3. Modify the DB cluster to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

If you are using the console, make sure that the following settings are correct:

- **Network type – Dual-stack mode**

**Network type** [Info](#)  
To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

**IPv4**  
Your resources can communicate only over the IPv4 addressing protocol.

**Dual-stack mode**  
Your resources can communicate over IPv4, IPv6, or both.

- **DB subnet group** – The DB subnet group that you configured in a previous step
- **Security group** – The security that you configured in a previous step

If you are using the Amazon CLI, make sure that the following settings are correct:

- `--network-type` – `dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-cluster --db-cluster-identifier my-cluster --network-type "DUAL"
```

4. Confirm that the DB cluster supports dual-stack mode.

If you are using the console, choose the **Configuration** tab for the DB cluster. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

If you are using the Amazon CLI, run the [describe-db-clusters](#) command, and make sure that the `NetworkType` value for the DB cluster is `dual`.

Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

## Availability of dual-stack network DB clusters

Dual-stack network DB clusters are available in all Amazon Web Services Regions except for the following:

- Asia Pacific (Hyderabad)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Asia Pacific (Thailand)
- Canada West (Calgary)
- Europe (Spain)
- Europe (Zurich)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (UAE)

The following DB engine versions support dual-stack network DB clusters:

- Aurora MySQL versions:
  - 3.02 and higher 3 versions
  - 2.09.1 and higher 2 versions

For more information about Aurora MySQL versions, see the [Release Notes for Aurora MySQL](#).

- Aurora PostgreSQL versions:

- 15.2 and all higher versions
- 14.3 and higher 14 versions
- 13.7 and higher 13 versions

For more information about Aurora PostgreSQL versions, see the [Release Notes for Aurora PostgreSQL](#).

## Limitations for dual-stack network DB clusters

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB clusters that use dual-stack mode must be private. They can't be publicly accessible.
- You can't use RDS Proxy with dual-stack mode DB clusters.

## Hiding a DB cluster in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an Amazon EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. EC2 instances that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet. In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see [A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC](#).

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance](#)

You can modify a DB cluster to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

For information about modifying a DB instance to set the **Public access** option, see [Modifying a DB instance in a DB cluster](#).

## Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

### Note

If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see [Updating DNS support for your VPC](#).

Follow these steps to create a DB instance in a VPC:

- [Step 1: Create a VPC](#)
- [Step 2: Create a DB subnet group](#)
- [Step 3: Create a VPC security group](#)
- [Step 4: Create a DB instance in the VPC](#)

### Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the Amazon Web Services Region.

For more information, see [Create a VPC with private and public subnets](#), or see [Create a VPC](#) in the *Amazon VPC User Guide*.

### Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the Amazon CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the Amazon Web Services Region. As a best practice,

each DB subnet group should have at least one subnet for every Availability Zone in the Amazon Web Services Region.

For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see [Connect to the internet using an internet gateway](#) in the *Amazon VPC User Guide*.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

### To create a DB subnet group

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

RDS &gt; Subnet groups &gt; Create DB subnet group

## Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

### Subnet group details

#### Name

You won't be able to modify the name after your subnet group has been created.

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

#### Description

#### VPC

Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

### Add subnets

#### Availability Zones

Choose the Availability Zones that include the subnets you want to add.

#### Subnets

Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

#### Subnets selected (2)

Availability zone	Subnet ID	CIDR block
us-east-1a	subnet-079bd4b8953aee1dd	10.0.0.0/24
us-east-1c	subnet-057e85b72c46fdd9a	10.0.1.0/24

## 8. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

### Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see [Create a VPC security group for a private DB cluster](#), or see [Control traffic to resources using security groups](#) in the *Amazon VPC User Guide*.

### Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

#### Note

If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see [DNS attributes for your VPC](#) in the *Amazon VPC User Guide*.

For details on how to create a DB cluster, see [Creating an Amazon Aurora DB cluster](#).

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

#### Note

Updating VPCs isn't currently supported for Aurora DB clusters.

## Scenarios for accessing a DB cluster in a VPC

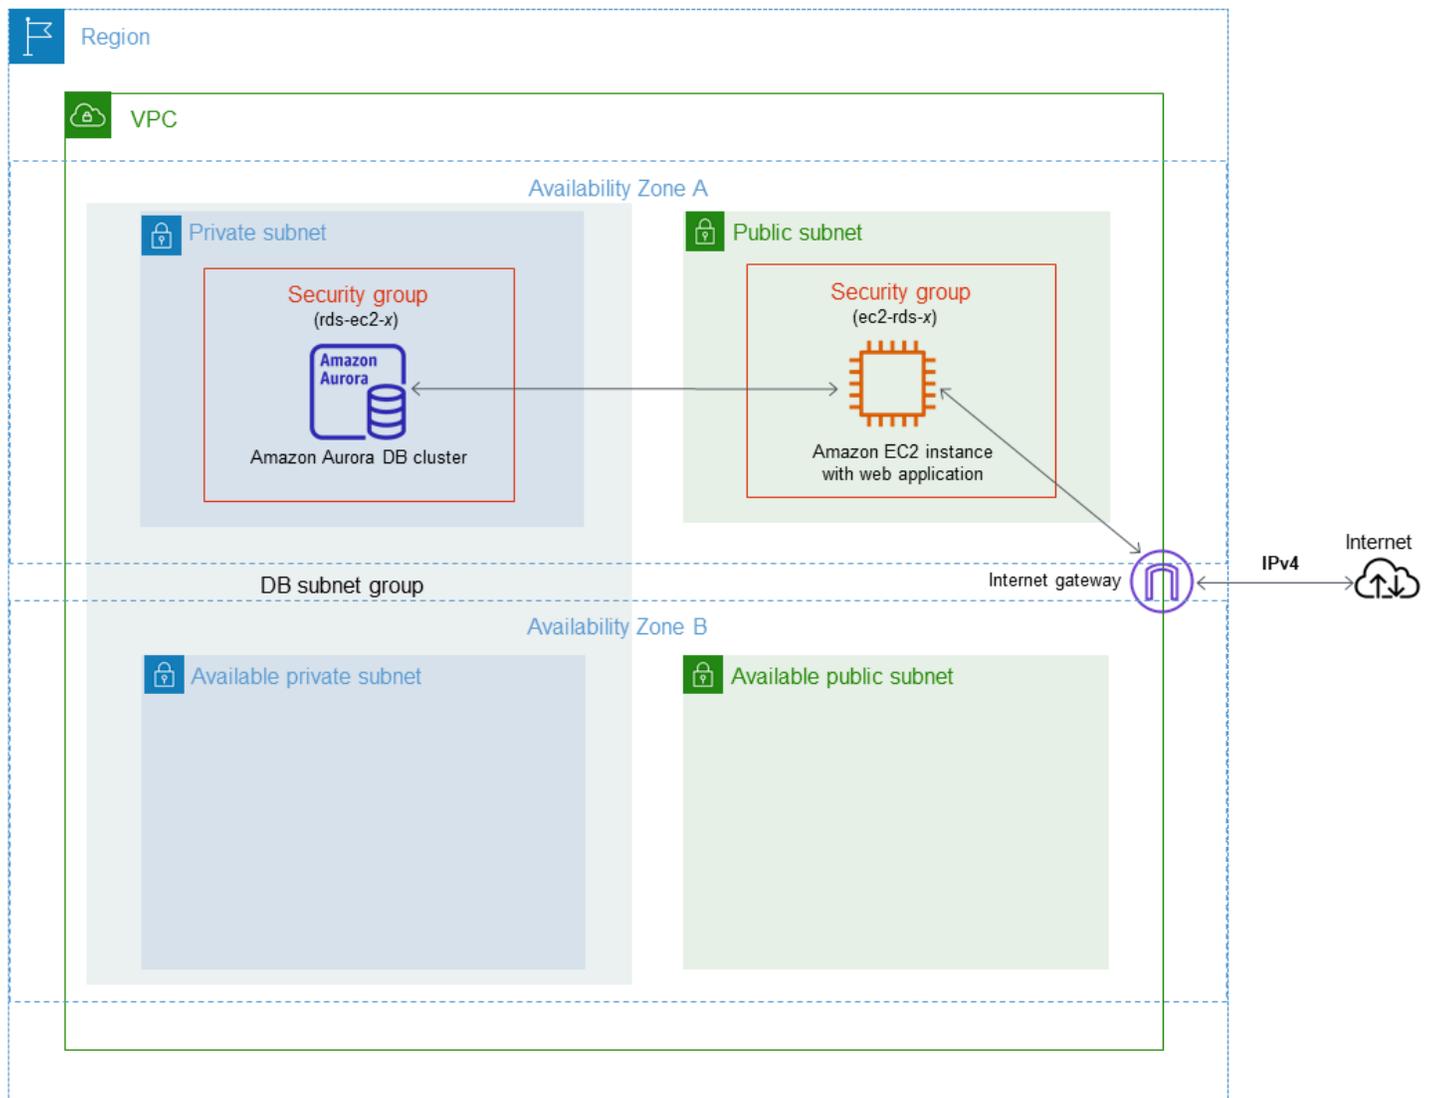

Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- [An Amazon EC2 instance in the same VPC](#)
- [An EC2 instance in a different VPC](#)
- [A client application through the internet](#)
- [A private network](#)

## A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an Amazon EC2 instance in the same VPC.

The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

**To create a rule in a VPC security group that allows connections from another security group, do the following:**

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc>.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB cluster, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

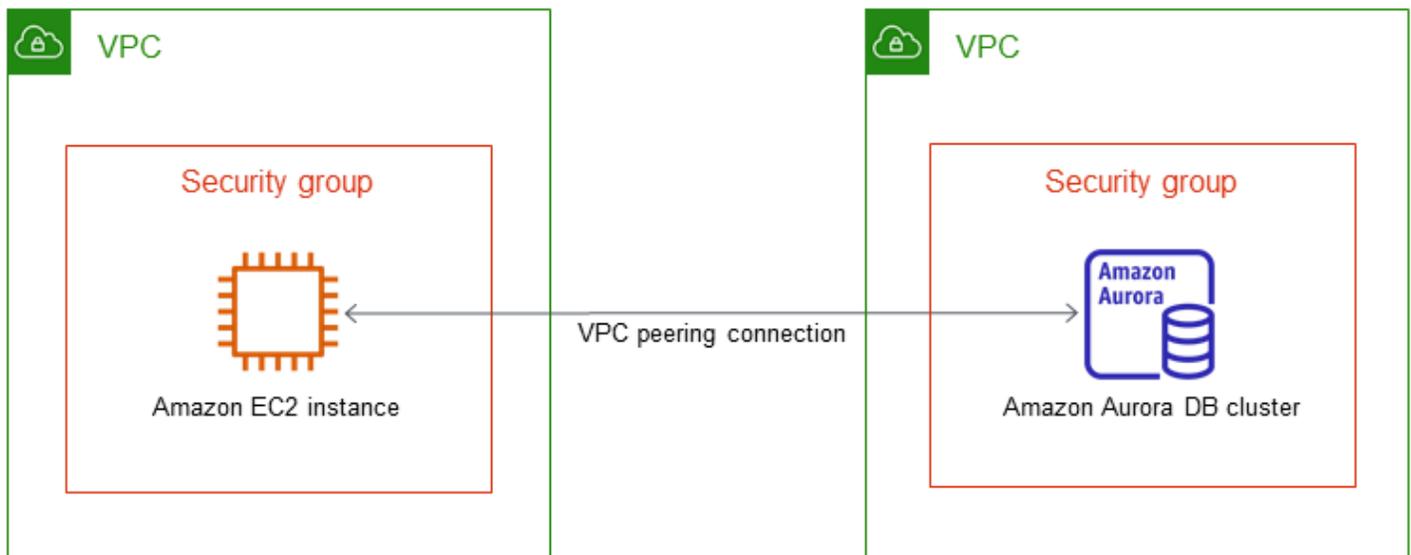

Inbound rules			
Type	Protocol	Port range	Source
MYSQL/Aurora	TCP	3306	sg-00bd2328e37926844 (tutorial-securitygroup)

For more information about connecting to the DB cluster from your EC2 instance, see [Connecting to an Amazon Aurora DB cluster](#).

## A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.

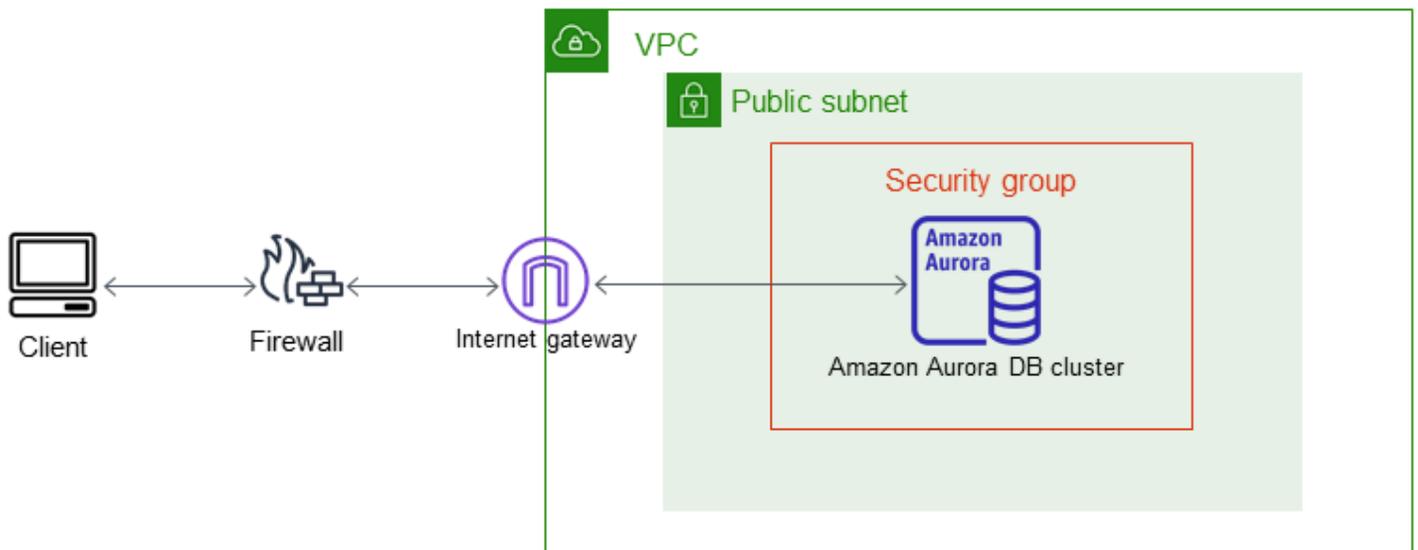

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another Amazon account, or with a VPC in a different Amazon Web Services Region. To learn more about VPC peering, see [VPC peering](#) in the *Amazon Virtual Private Cloud User Guide*.

## A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other Amazon products.
- A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.

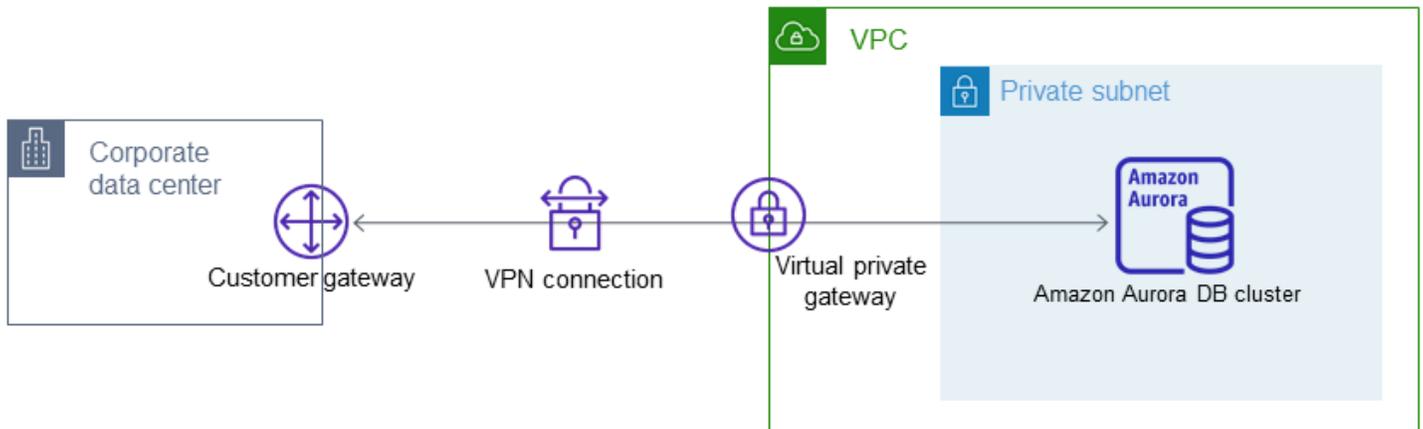

For information about creating a DB clusters in a VPC, see [Creating a DB cluster in a VPC](#).

## A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An Amazon Site-to-Site VPN connection. For more information, see [What is Amazon Site-to-Site VPN?](#)
- An Amazon Direct Connect connection. For more information, see [What is Amazon Direct Connect?](#)
- An Amazon Client VPN connection. For more information, see [What is Amazon Client VPN?](#)

The following diagram shows a scenario with an Amazon Site-to-Site VPN connection.

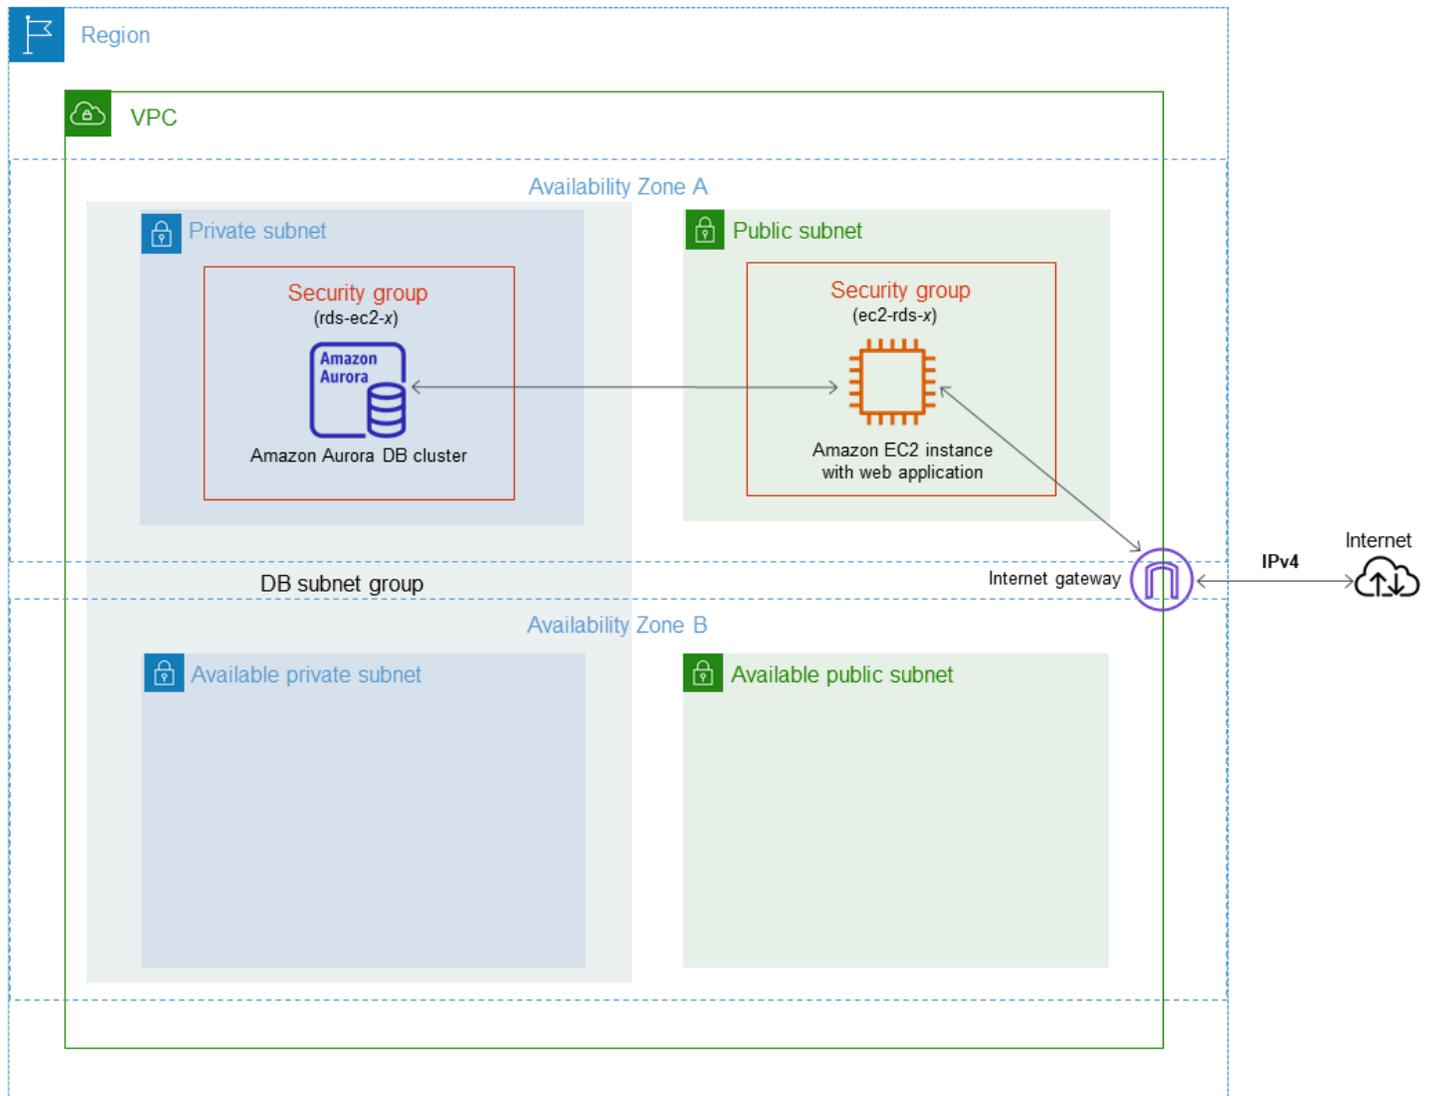

For more information, see [Inter-network traffic privacy](#).

## Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC](#).

Your DB cluster needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see [Tutorial: Create a web server and an Amazon Aurora DB cluster](#). For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

### Tip

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. In the top-right corner of the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:
  - **Name tag auto-generation** – **tutorial**
  - **IPv4 CIDR block** – **10.0.0.0/16**
  - **IPv6 CIDR block** – **No IPv6 CIDR block**
  - **Tenancy** – **Default**
  - **Number of Availability Zones (AZs)** – **2**
  - **Customize AZs** – **Keep the default values.**

- **Number of public subnet** – 2
  - **Number of private subnets** – 2
  - **Customize subnets CIDR blocks** – Keep the default values.
  - **NAT gateways (\$)** – None
  - **VPC endpoints** – None
  - **DNS options** – Keep the default values.
6. Choose **Create VPC**.

## Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-securitygroup**
  - **Description:** **Tutorial Security Group**
  - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier*** (**tutorial-vpc**)
4. Add inbound rules to the security group.
  - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at <https://checkip.amazonaws.com>. An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

**⚠ Warning**

If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- b. In the **Inbound rules** section, choose **Add rule**.
  - c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.
    - **Type:** SSH
    - **Source:** The IP address or range from Step a, for example: **203.0.113.25/32**.
  - d. Choose **Add rule**.
  - e. Set the following values for your new inbound rule to allow HTTP access to your web server:
    - **Type:** HTTP
    - **Source:** **0.0.0.0/0**
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.

3. On the **Create security group** page, set these values:
  - **Security group name:** `tutorial-db-securitygroup`
  - **Description:** `Tutorial DB Instance Security Group`
  - **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier` (`tutorial-vpc`)
4. Add inbound rules to the security group.
  - a. In the **Inbound rules** section, choose **Add rule**.
  - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster. By doing so, you can store and retrieve data from your web application to your database.
    - **Type:** `MySQL/Aurora`
    - **Source:** The identifier of the `tutorial-securitygroup` security group that you created previously in this tutorial, for example: `sg-9edd5cfb`.
5. Choose **Create security group** to create the security group.

## Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Subnets**.
  - c. Note the subnet IDs of the subnets named `tutorial-subnet-private1-us-west-2a` and `tutorial-subnet-private2-us-west-2b`.

You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
  - **Name:** `tutorial-db-subnet-group`
  - **Description:** `Tutorial DB Subnet Group`
  - **VPC:** `tutorial-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

#### Note

If you created this VPC to complete [Tutorial: Create a web server and an Amazon Aurora DB cluster](#), create the DB cluster by following the instructions in [Create an Amazon Aurora DB cluster](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

#### Note

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

## To delete a VPC and related resources

1. Delete the DB subnet group.
  - a. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
  - d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
3. Delete the security groups.
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
  - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
  - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
  - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.
  - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the VPC.
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. Select the VPC you want to delete, such as **tutorial-vpc**.
  - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will

also be deleted, including the subnets associated with it.

- e. On the confirmation page, enter **delete**, and then choose **Delete**.

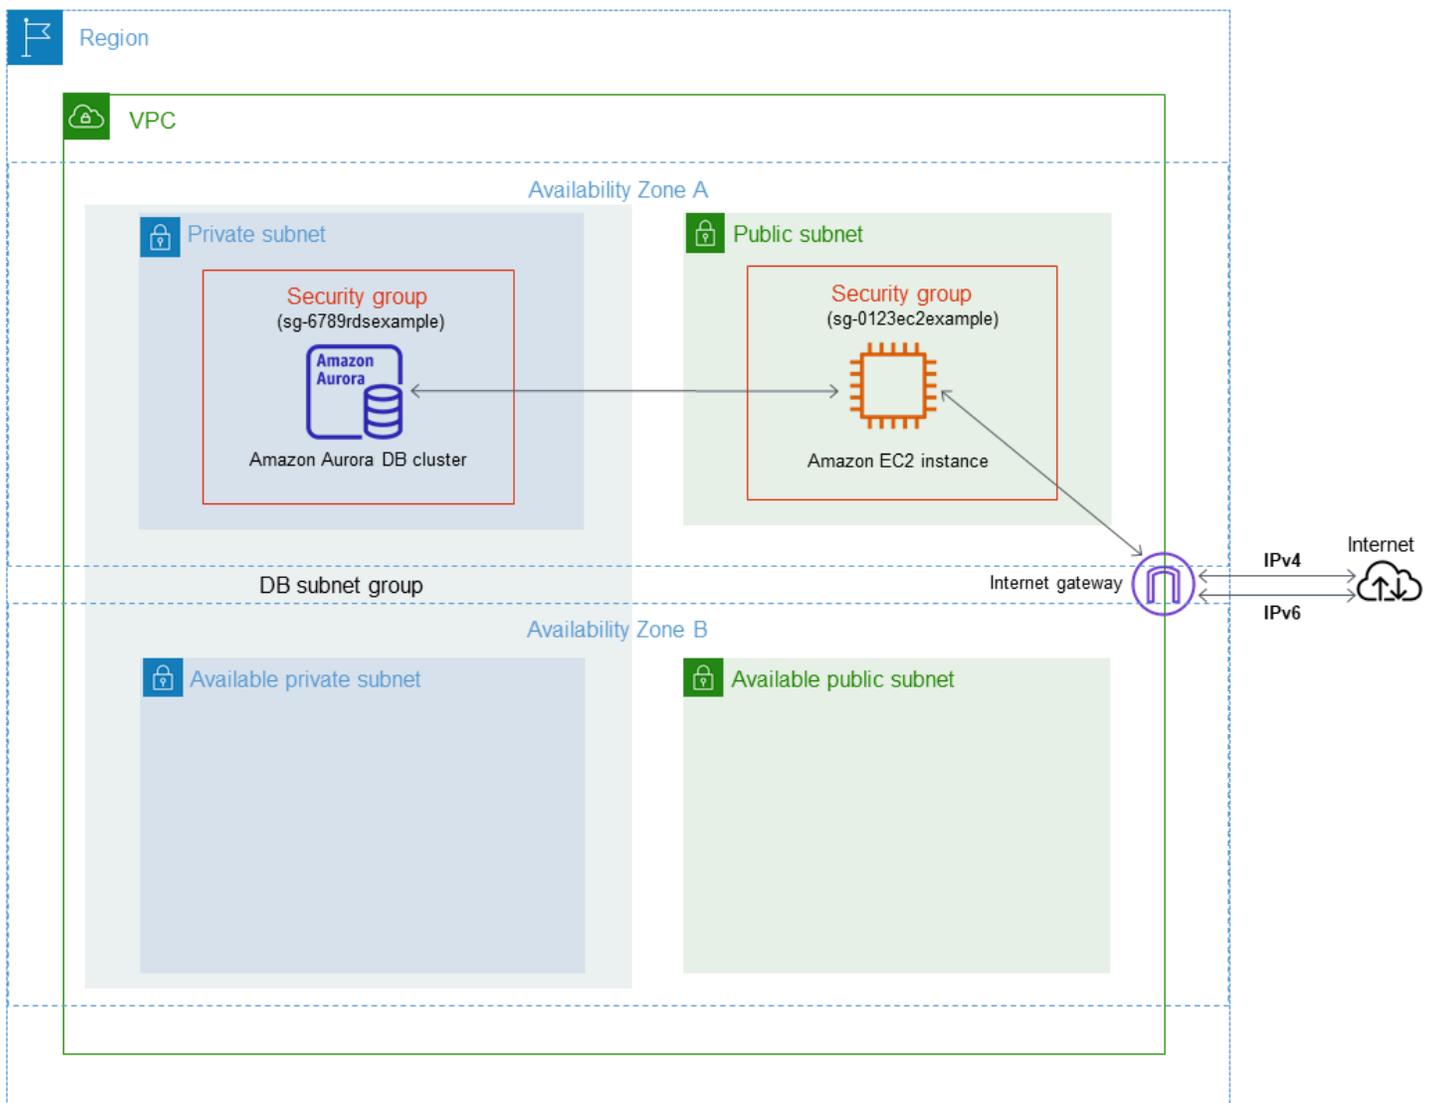

## Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see [Amazon Aurora IP addressing](#).

Dual-stack network clusters are supported in most regions. For more information see [Availability of dual-stack network DB clusters](#). To see the limitations of dual-stack mode, see [Limitations for dual-stack network DB clusters](#).

The following diagram shows this scenario.

For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC](#).

Your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC User Guide](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. In the upper-right corner of the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
  - **Name tag auto-generation** – **tutorial-dual-stack**
  - **IPv4 CIDR block** – **10.0.0.0/16**
  - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
  - **Tenancy** – **Default**
  - **Number of Availability Zones (AZs)** – **2**
  - **Customize AZs** – Keep the default values.
  - **Number of public subnet** – **2**
  - **Number of private subnets** – **2**
  - **Customize subnets CIDR blocks** – Keep the default values.
  - **NAT gateways (\$)** – **None**
  - **Egress only internet gateway** – **No**
  - **VPC endpoints** – **None**
  - **DNS options** – Keep the default values.

**Note**

Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

## Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** `tutorial-dual-stack-securitygroup`
  - **Description:** `Tutorial Dual-Stack Security Group`
  - **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier` (`tutorial-dual-stack-vpc`)
4. Add inbound rules to the security group.
  - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`.

An example of an Internet Protocol version 6 (IPv6) address range is

`2001:db8:1234:1a00::/64`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

**⚠ Warning**

If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

- b. In the **Inbound rules** section, choose **Add rule**.
  - c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:
    - **Type:** SSH
    - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **203.0.113.25/32**. An example of an IPv6 IP address is **2001:DB8::/32**.
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-dual-stack-db-securitygroup**
  - **Description:** **Tutorial Dual-Stack DB Instance Security Group**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group:
    - a. In the **Inbound rules** section, choose **Add rule**.
    - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB cluster. Doing this means that you can send data from your EC2 instance to your database.
      - **Type:** **MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.
  5. To create the security group, choose **Create security group**.

## Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Subnets**.
  - c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
  - **Name:** `tutorial-dual-stack-db-subnet-group`
  - **Description:** `Tutorial Dual-Stack DB Subnet Group`
  - **VPC:** `tutorial-dual-stack-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.  
  
For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

## Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

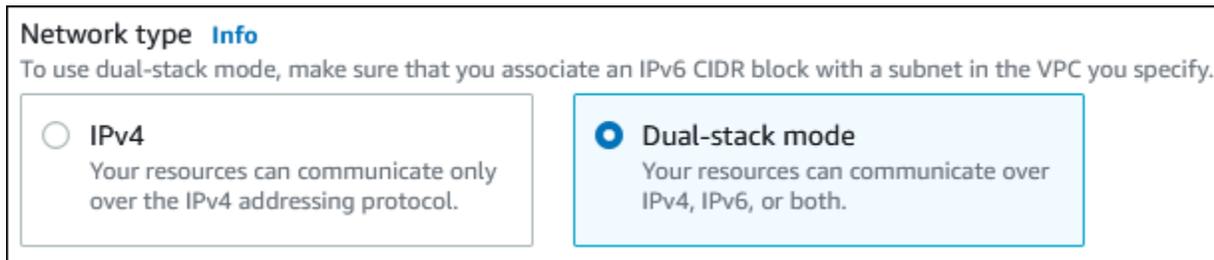

- **Network** – Choose an existing VPC with both public and private subnets, such as `tutorial-dual-stack-vpc (vpc-identifier)` created in [Create a VPC with private and public subnets](#).
- **Subnet** – Choose an existing public subnet, such as `subnet-identifier | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a` created in [Create a VPC security group for a public Amazon EC2 instance](#).
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in [Create a VPC security group for a public Amazon EC2 instance](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

## Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

### To create a DB instance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the upper-right corner of the console, choose the Amazon Web Services Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:
  - **Network type** – Choose **Dual-stack mode**.

**Network type** [Info](#)  
To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

<input type="radio"/> <b>IPv4</b> Your resources can communicate only over the IPv4 addressing protocol.	<input checked="" type="radio"/> <b>Dual-stack mode</b> Your resources can communicate over IPv4, IPv6, or both.
---	---

- **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in [Create a VPC with private and public subnets](#).

The VPC must have subnets in different Availability Zones.

- **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in [Create a DB subnet group](#).
- **Public access** – Choose **No**.
- **VPC security group (firewall)** – Select **Choose existing**.
- **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in [Create a VPC security group for a private DB cluster](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters](#).

## Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide*.

To connect to your Aurora MySQL DB cluster from the Amazon EC2 instance, follow the instructions in [Connect to an Aurora MySQL DB cluster](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB clusters. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group:
  - a. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.

- b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.
  - d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.
3. Delete the security groups:
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
  - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.
  - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
  - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.
  - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the NAT gateway:
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.
  - c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
  - d. For **Actions**, choose **Delete NAT gateway**.
  - e. On the confirmation page, enter **delete**, and then choose **Delete**.
5. Delete the VPC:
  - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.
  - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

6. Release the Elastic IP addresses:
  - a. Open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
  - b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
  - c. Select the Elastic IP address that you want to release.
  - d. For **Actions**, choose **Release Elastic IP addresses**.
  - e. On the confirmation page, choose **Release**.

# Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

## Topics

- [Quotas in Amazon Aurora](#)
- [Naming constraints in Amazon Aurora](#)
- [Amazon Aurora size limits](#)

## Quotas in Amazon Aurora

Each Amazon account has quotas, for each Amazon Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per Amazon Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom endpoints per DB cluster	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of custom endpoints that you can create per Aurora DB cluster in this account in the current Region. This value reflects the highest number of custom endpoints in a DB cluster in the account. Other DB clusters in the account

Name	Default	Adjustable	Description
			might have a lower number of custom endpoints.
Custom engine versions	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	<a href="#">Yes</a>	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of Aurora clusters allowed in this account in the current Region
DB instances	ap-south-1: 20 Each of the other supported Regions: 40	<a href="#">Yes</a>	The maximum number of DB instances allowed in this account in the current Region
DB shard groups	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of DB shard groups for Aurora Limitless Database in this account in the current Region
DB subnet groups	ap-south-1: 20 Each of the other supported Regions: 50	<a href="#">Yes</a>	The maximum number of DB subnet groups

Name	Default	Adjustable	Description
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current Amazon Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.

Name	Default	Adjustable	Description
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current Amazon Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current Amazon Region
Manual DB cluster snapshots	Each supported Region: 100	<a href="#">Yes</a>	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	<a href="#">Yes</a>	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of option groups

Name	Default	Adjustable	Description
Parameter groups	ap-south-1: 20  Each of the other supported Regions: 50	<a href="#">Yes</a>	The maximum number of parameter groups
Proxies	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of proxies allowed in this account in the current Amazon Region
Read replicas per primary	Each supported Region: 15	<a href="#">Yes</a>	The maximum number of read replicas per primary DB instance. This quota can't be adjusted for Amazon Aurora.
Reserved DB instances	ap-south-1: 20  Each of the other supported Regions: 40	<a href="#">Yes</a>	The maximum number of reserved DB instances allowed in this account in the current Amazon Region
Security groups	ap-south-1: 20  Each of the other supported Regions: 25	<a href="#">Yes</a>	The maximum number of DB security groups
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group

Name	Default	Adjustable	Description
Total storage for all DB instances	Each supported Region: 100,000	<a href="#">Yes</a>	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

### Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

If your application requires more DB instances, you can request additional DB instances by opening the [Service Quotas console](#). In the navigation pane, choose **Amazon services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

For RDS for Oracle, you can create up to 15 read replicas per source DB instance in each Region, but we recommend limiting replicas to 5 to minimize replication lag.

Backups managed by Amazon Backup are considered manual DB clustersnapshots, but don't count toward the manual cluster snapshot quota. For information about Amazon Backup, see the [Amazon Backup Developer Guide](#).

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API\_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the [Service Quotas console](#).
- From the Amazon CLI, use the [request-service-quota-increase](#) Amazon CLI command.

For more information, see the [Service Quotas User Guide](#).

## Naming constraints in Amazon Aurora

The naming constraints in Amazon Aurora are as follows:

- DB cluster identifier:
  - Must contain 1–63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Can't end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all DB instances per Amazon account, per Amazon Region.
- Initial database name – Database name constraints differ between Aurora MySQL and Aurora PostgreSQL. For more information, see the available settings when creating each DB cluster.
- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB cluster.
- Master password:
  - The password for the database master user can include any printable ASCII character except /, ', ", @, or a space.
  - The password can contain the following number of printable ASCII characters depending on the DB engine:
    - Aurora MySQL: 8–41
    - Aurora PostgreSQL: 8–99
- DB parameter group:
  - Must contain 1–255 alphanumeric characters.
  - First character must be a letter.
  - Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:

- Must contain 1–255 characters.
- Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

## Amazon Aurora size limits

### Storage size limits

Aurora cluster volume maximum size varies by engine version:

#### 256 TiB maximum:

- Aurora PostgreSQL versions:
  - 17.5 and all higher versions
  - 16.9 and higher
  - 15.13 and higher
- Aurora MySQL version 3.10 (compatible with MySQL 8.0.42) and higher

#### 128 TiB maximum:

- All earlier Aurora PostgreSQL versions
- All available Aurora MySQL 3 versions; Aurora MySQL version 2, versions 2.09 and higher

For more information on automatic storage scaling, see [How Aurora storage automatically resizes](#).

To monitor the remaining storage space, you can use the `AuroraVolumeBytesLeftTotal` metric. For more information, see [Cluster-level metrics for Amazon Aurora](#).

### SQL table size limits

For an Aurora MySQL DB cluster, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

### Table space ID limits

The maximum table space ID for Aurora MySQL is 2147483647. If you frequently create and drop tables, make sure to be aware of your table space IDs and plan to use logical dumps. For more information, see [Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump](#).

# Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

## Topics

- [Can't connect to Amazon RDS DB instance](#)
- [Amazon RDS security issues](#)
- [Resetting the DB instance owner password](#)
- [Amazon RDS DB instance outage or reboot](#)
- [Amazon RDS DB parameter changes not taking effect](#)
- [Freeable memory issues in Amazon Aurora](#)
- [Amazon Aurora MySQL replication issues](#)

For information about debugging problems using the Amazon RDS API, see [Troubleshooting applications on Aurora](#).

## Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

### Note

When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see [Provide access to the DB cluster in the VPC by creating a security group](#).

 **Note**

Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see [Hiding a DB cluster in a VPC from the internet](#).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications because of your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

### To configure an internet gateway for a subnet

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet

gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

- a. Choose the ID of the route table (rtb-xxxxxxx) to navigate to the route table.
- b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

- c. Choose **Save routes**.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB cluster in a VPC](#).

## Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```

```
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
open
connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

### Note

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

## Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

## Amazon RDS security issues

To avoid security issues, never use your Amazon Web Services account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see [Creating an IAM user in your Amazon Web Services account](#). For information about creating users in Amazon IAM Identity Center, see [Manage identities in IAM Identity Center](#).

## Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited

for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](#).

## Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the Amazon account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see [Master user account privileges](#).

You can change the DB instance password by using the Amazon RDS console, the Amazon CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) API operation. For more information about modifying a DB instance in a DB cluster, see [Modifying a DB instance in a DB cluster](#).

## Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.

- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

## Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the [RebootDBInstance](#) API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

## Freeable memory issues in Amazon Aurora

*Freeable memory* is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see [Monitoring tools for Amazon Aurora](#).

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see [Amazon Aurora DB instance classes](#).

You can also change the memory settings. For example, on Aurora MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see [How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?](#)

For Aurora Serverless v2, `FreeableMemory` represents the amount of unused memory that's available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. You might have the instance scaled down to relatively low capacity, but it still reports a high value for `FreeableMemory`, because the instance can scale up. That memory isn't available right now, but you can get it if you need it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity, `FreeableMemory` increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can. It's nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance. For more information, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#).

For Aurora Serverless v1, you can change the capacity range to use more ACUs. For more information, see [Modifying an Aurora Serverless v1 DB cluster](#).

## Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

### Topics

- [Diagnosing and resolving lag between read replicas](#)
- [Diagnosing and resolving a MySQL read replication failure](#)
- [Replication stopped error](#)
- [Read replica replication fails to initialize metadata structure](#)

## Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `AuroraBinlogReplicaLag` metric.

The `AuroraBinlogReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MySQL `SHOW REPLICA STATUS` command. For more information, see [SHOW REPLICA STATUS Statement](#) in the MySQL documentation.

When the `AuroraBinlogReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `AuroraBinlogReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see [Diagnosing and resolving a MySQL read replication failure](#). A `AuroraBinlogReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is NULL.

### Note

Previous versions of Aurora MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using Aurora MySQL version 1 or 2, then use `SHOW SLAVE STATUS`. Use `SHOW REPLICA STATUS` for Aurora MySQL version 3 and higher.

The `AuroraBinlogReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `AuroraBinlogReplicaLag` metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `AuroraBinlogReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see [Replication implementation details](#) in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see [Query cache configuration](#).
- Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump \  
-h <endpoint> \  
--port=<port> \  
-u=<username> \  
-p <password> \  
database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^  
-h <endpoint> ^  
--port=<port> ^  
-u=<username> ^  
-p <password> ^  
database_name table1 table2 > /dev/null
```

## Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `ERROR` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045](#), [RDS-EVENT-0046](#), and [RDS-EVENT-0057](#). For more information about events and subscribing to events, see [Working with Amazon RDS event notification](#). If a MySQL error message is returned, check the error in the [MySQL error message documentation](#).

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to `0` to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

You can convert a MyISAM table to InnoDB with the following command:

```
alter table <schema>.<table_name> engine=innodb;
```

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in [Skipping the current replication error](#). Your Aurora MySQL DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see [mysql\\_rds\\_skip\\_repl\\_error](#).
- If you encounter a binary log (binlog) position issue, you can change the replica replay position. You do so with the `mysql.rds_next_master_log` command for Aurora MySQL version 1 and 2. You do so with the `mysql.rds_next_source_log` command for Aurora MySQL version 3 and higher. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see [mysql\\_rds\\_next\\_master\\_log](#).
- If you encounter a temporary performance issue because of high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. This way, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see [Troubleshooting a MySQL read replica problem](#).

## Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error because of binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the [mysql\\_rds\\_set\\_configuration](#) procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

## Read replica replication fails to initialize metadata structure

When you attempted to start replication, you received the following error message:

```
Read Replica Replication Error - SQLError: 13124, reason: Replica failed to initialize applier metadata structure from the repository
```

This error occurs when there is a problem with the metadata structure of the replica. To fix the metadata structure, you must create a new replica.

To prevent this from happening in the future, perform one of the following actions:

- If possible, disable multi-threading on your replicas. Starting with MySQL 8.0.27, multi-threading is enabled by default.
- If you need to use multi-threading on your replicas, then we recommend that you use GTID-based replication. For more information, see [Using GTID-based replication](#).

# Amazon RDS API reference

In addition to the Amazon Web Services Management Console and the Amazon Command Line Interface (Amazon CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see [Actions](#).
- For an alphabetical list of data types, see [Data types](#).
- For a list of common query parameters, see [Common parameters](#).
- For descriptions of the error codes, see [Common errors](#).

For more information about the Amazon CLI, see [Amazon Command Line Interface reference for Amazon RDS](#).

## Topics

- [Using the Query API](#)
- [Troubleshooting applications on Aurora](#)

## Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see [Query requests](#) in the *Amazon EC2 API Reference*.

### Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to [Amazon Relational Database Service \(RDS\)](#) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

## Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either Amazon signature version 4 or signature version 2. For more information, see [Signature Version 4 signing process](#) and [Signature version 2 signing process](#).

## Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

### Topics

- [Retrieving errors](#)
- [Troubleshooting tips](#)

For information about troubleshooting for Amazon RDS DB instances, see [Troubleshooting for Amazon Aurora](#).

## Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the `XML::XPath` module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
 $xp->findvalue("//Error[1]/Code"), "\n", " ",
 $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

## Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the Amazon Region that you're targeting by checking <http://status.www.amazonaws.cn>.
- Check the structure of your request.

Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.

- Check Amazon re:Post.

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [Amazon re:Post](#).

# Document history

**Current API version:** 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the [Amazon Relational Database Service User Guide](#).

## Note

Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see [Document history](#) in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the [What's New with Database?](#) page. For **Products**, choose **Amazon Aurora**. Then search using keywords such as **global database** or **Serverless**.

Change	Description	Date
<a href="#">Aurora PostgreSQL Zero-ETL integrations with Amazon SageMaker support additional Regions</a>	Aurora PostgreSQL Zero-ETL integrations with Amazon SageMaker are now available in additional Regions. For more information, see <a href="#">Supported Regions and Aurora DB engines for zero-ETL integrations</a> .	October 15, 2025

[End-of-life information for Performance Insights](#)

Amazon has announced the end-of-life date for Performance Insights: November 30, 2025. After this date, Amazon RDS will no longer support the Performance Insights console experience, flexible retention periods, and their associated pricing. We recommend upgrading your DB clusters to Database Insights before this date. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).

May 30, 2025

[Aurora PostgreSQL Limitless Database supports CloudWatch Database Insights](#)

You can now use CloudWatch Database Insights to monitor your Amazon Aurora PostgreSQL Limitless Database at scale. For more information, see [Monitoring Amazon Aurora PostgreSQL Limitless Database with CloudWatch Database Insights](#).

May 22, 2025

[Viewing support dates for open source engine major versions](#)

You can now view information about the start and end dates for open source engine major versions in RDS standard support and RDS Extended Support by using the Amazon CLI and the RDS API. For more information, see [Viewing support dates for engine versions in Amazon RDS Extended Support](#).

May 20, 2025

[Aurora PostgreSQL zero-ETL integrations support additional Regions](#)

Aurora PostgreSQL zero-ETL integrations are now available in additional Regions. For more information, see [Supported Regions and Aurora DB engines for zero-ETL integrations with Amazon Redshift](#).

February 17, 2025

[Amazon Aurora is available in the Mexico \(Central\) Region](#)

Amazon Aurora is now available in the Mexico (Central) Region. For more information, see [Regions and Availability Zones](#).

January 14, 2025

[Amazon Aurora is available in the Asia Pacific \(Thailand\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Thailand) Region. For more information, see [Regions and Availability Zones](#).

January 7, 2025

## [End-of-life information for Aurora Serverless v1](#)

Amazon has announced the end-of-life date for Aurora Serverless v1: March 31st, 2025. We strongly recommend upgrading any Aurora Serverless v1 DB clusters to Aurora Serverless v2 before that date. The upgrade can involve a change in the major version number of the database engine. Thus, it's important to plan, test, and implement this switchover before the end-of-life date. Starting January 8th, 2025, customers will no longer be able to create new Aurora Serverless v1 clusters or instances with either the Amazon Web Services Management Console or the CLI. For information about the upgrade procedure from Aurora Serverless v1 to Aurora Serverless v2, see [Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2](#).

December 6, 2024

[Aurora supports CloudWatch Database Insights](#)

You can now use CloudWatch Database Insights to monitor your Amazon Aurora DB clusters at scale. For more information, see [Monitoring Amazon Aurora databases with CloudWatch Database Insights](#).

December 1, 2024

[Amazon Aurora supports the db.r8g instance classes](#)

You can now use the db.r8g instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

November 21, 2024

[Aurora Serverless v2 supports automatic pause and resume](#)

Aurora Serverless v2 DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0 ACUs. For more information, see [Automatic pause and resume for Aurora Serverless v2](#).

November 20, 2024

[Amazon Aurora supports auto-migrating EC2 databases](#)

You can use the RDS console to migrate an EC2 database to Aurora. Aurora uses Amazon Database Migration Service (Amazon DMS) to migrate your source EC2 database. Amazon DMS allows you to migrate relational databases into your Amazon Web Services Cloud. For more information, see [Auto migrating EC2 databases to Amazon Aurora using Amazon Database Migration Service](#).

November 20, 2024

[Amazon Advanced NodeJS Wrapper generally available](#)

The Amazon Web Services (Amazon) Advanced NodeJS Wrapper is complementary to and extends the functionality of an existing NodeJS driver. For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

November 19, 2024

[Amazon Aurora supports the db.r7i instance classes](#)

You can now use the db.r7i instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

November 18, 2024

[RDS Data API for Aurora MySQL supports all Performance Insights views](#)

You can now use the **Top hosts** or **Top applications** views for Performance Insights to monitor SQL operations performed using RDS Data API for Aurora MySQL. For information about Performance Insights support, see [Monitoring RDS Data API queries with Performance Insights](#).

October 31, 2024

[Aurora PostgreSQL Limitless Database](#)

Amazon Aurora PostgreSQL Limitless Database is a new, automated, horizontal scaling (sharding) capability of Amazon Aurora. Aurora PostgreSQL Limitless Database lets you scale beyond the existing Aurora limits for write throughput and storage by distributing a database workload over multiple Aurora writer instances, while maintaining the ability to use it as a single database. For more information, see [Amazon Aurora PostgreSQL Limitless Database](#).

October 31, 2024

[Amazon Aurora MySQL version 2 end of standard support](#)

Aurora MySQL version 2 reached the end of standard support on October 31, 2024. For more information, see [Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support](#).

October 31, 2024

[Amazon Aurora supports cluster-level OS upgrades](#)

You can now apply Aurora operating system upgrades at the DB cluster level. Rolling upgrades automatically apply upgrades to a few reader DB instances at a time, thus preserving read availability. For more information, see [Operating system updates for Aurora DB clusters](#).

October 30, 2024

[Aurora global clusters support tagging](#)

You can now add tags to Aurora global clusters. An Aurora global cluster is the parent resource that contains the primary and secondary DB clusters in an Aurora global database. For general information about tagging, see [Tagging Aurora and Amazon RDS resources](#). For information about tagging with Aurora Global Database, see [Tagging Aurora Global Database resources](#).

October 24, 2024

[Aurora Global Database writer endpoints](#)

Each Aurora Global Database now comes with a writer endpoint that is automatically updated by Aurora to route requests to the current writer instance of the primary DB cluster after an Aurora Global Database switchover and failover operation. To learn more about using the writer endpoint along with Aurora Global Database switchover and failover, see [Using switchover or failover in Amazon Aurora Global Database](#).

October 22, 2024

[Aurora PostgreSQL zero-ETL integrations with Amazon Redshift generally available](#)

Zero-ETL integrations make transactional data available in Amazon Redshift within seconds of it being written to an Aurora PostgreSQL source DB cluster. The feature is now generally available. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

October 15, 2024

[Aurora Serverless v2 supports 256 ACUs](#)

You can now create Aurora Serverless v2 DB clusters with a maximum capacity of 256 Aurora capacity units (ACUs). For more information, see [Aurora Serverless v2 capacity](#).

October 3, 2024

### [Amazon Aurora supports Console-to-Code](#)

You can now use Console-to-Code to generate code from actions that you perform in the RDS console. The generated code can help you write code to automate your use of other Amazon services. For more information, see [Use Console-to-Code to generate code for your Aurora console actions](#).

October 3, 2024

### [RDS Data API supports Performance Insights](#)

You can now use Performance Insights to monitor SQL operations performed using RDS Data API. For information about Performance Insights support, see [Monitoring RDS Data API queries with Performance Insights](#).

September 26, 2024

### [RDS Data API for Aurora Serverless v2 and provisioned is available for Aurora MySQL](#)

RDS Data API is now available for Aurora MySQL clusters that use Aurora Serverless v2 or provisioned instances. For usage information for RDS Data API, see [Using RDS Data API](#). For information about Aurora MySQL version and Amazon Region support for RDS Data API, see [Data API with Aurora MySQL Serverless v2 and provisioned](#).

September 26, 2024

[Amazon Aurora is available in the Asia Pacific \(Malaysia\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Malaysia) Region. For more information, see [Regions and Availability Zones](#).

August 22, 2024

[Update to existing policy](#)

Amazon RDS removed `sns:Publish` permission from the AmazonRDSBetaServiceRolePolicy of the AWSServiceRoleForRDSBeta service-linked role. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 7, 2024

[Update to existing policy](#)

Amazon RDS removed `sns:Publish` permission from the AmazonRDSPreviewServiceRolePolicy of the AWSServiceRoleForRDSPreview service-linked role. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 7, 2024

[Aurora Serverless v2 supports auto-pause \(scale-to-zero\)](#)

Aurora Serverless v2 DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0. For more information, see [Using Aurora Serverless v2](#).

July 25, 2024

[Amazon ODBC Driver for MySQL generally available](#)

The Amazon Web Services (Amazon) ODBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. For more information, see [Connecting to Aurora MySQL with the Amazon Web Services \(Amazon\) ODBC Driver for MySQL](#).

July 18, 2024

[RDS Data API for Aurora Serverless v2 is available in more Regions](#)

RDS Data API is now available for Aurora PostgreSQL in several additional Amazon Regions. For information about Region support for RDS Data API, see [Data API with Aurora PostgreSQL Serverless v2 and provisioned](#).

July 9, 2024

[Amazon Python Driver generally available](#)

The Amazon Web Services (Amazon) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

May 23, 2024

[Zero-ETL integrations available in China Regions](#)

Zero-ETL integrations are now available in the Amazon Web Services Regions China (Beijing) and China (Ningxia). For more information, see [Zero-ETL integrations with Amazon Redshift](#).

May 21, 2024

[RDS Proxy is available in more Regions](#)

RDS Proxy is now available in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary), and Europe (Zurich) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

May 21, 2024

### [Amazon RDS supports fine-grained access for Performance Insights](#)

You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` actions. For more information, see [https://docs.amazonaws.cn/AmazonRDS/latest/UserGuide/USER\\_PerfInsights.access-control.dimensionAccess-policy.html](https://docs.amazonaws.cn/AmazonRDS/latest/UserGuide/USER_PerfInsights.access-control.dimensionAccess-policy.html).

May 21, 2024

### [Amazon RDS Extended Support](#)

Creating or restoring an Aurora MySQL version 2 or 3, or Aurora PostgreSQL version 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the Aurora end of standard support date for your database engine. For more information, see [Using Amazon RDS Extended Support](#).

March 21, 2024

[Data filtering for zero-ETL integrations](#)

Amazon RDS supports data filtering at the database and table level for zero-ETL integrations with Amazon Redshift. For more information, see [Data filtering for Aurora zero-ETL integrations with Amazon Redshift.](#)

March 20, 2024

[Aurora MySQL integrations with Amazon Bedrock](#)

You can now integrate Amazon Aurora MySQL databases with Amazon Bedrock to power generative AI applications. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL.](#)

March 8, 2024

[New Amazon managed policy](#)

Amazon RDS added a new managed policy named AmazonRDS Custom InstanceProfileRolePolicy to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see [Amazon RDS updates to Amazon managed policies.](#)

February 27, 2024

[Amazon RDS support for Amazon Secrets Manager in the Israel \(Tel Aviv\) Region](#)

Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see [Password management with Amazon RDS and Amazon Secrets Manager](#).

February 21, 2024

[Amazon RDS Extended Support](#)

Amazon RDS now automatically enables Amazon RDS Extended Support when Aurora MySQL and Aurora PostgreSQL major engine versions in your DB clusters and global clusters reach the Aurora end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

February 15, 2024

[Aurora PostgreSQL 16.1 supports Babelfish for Aurora PostgreSQL 4.0.0](#)

Aurora PostgreSQL 16.1 supports Babelfish 4.0.0. For a list of new features, see [16.1](#). For a list of features supported in each Babelfish release, see [Supported functionality in Babelfish by version](#). For usage information, see [Working with Babelfish for Aurora PostgreSQL](#).

January 31, 2024

---

<a href="#">Update to default CA Certificate</a>	The default CA certificate is set to <code>rds-ca-rsa2048-g1</code> . For more information, see <a href="#">Using SSL/TLS to encrypt a connection to a DB cluster</a> .	January 26, 2024
<a href="#">RDS Proxy is available in the Europe (Spain) Region</a>	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	January 8, 2024
<a href="#">RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned</a>	You can now use RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned DB clusters. With RDS Data API, you can access your Aurora clusters through a secure HTTP endpoint and run SQL statements without using database drivers or managing connections. For more information, see <a href="#">Using RDS Data API</a> .	December 21, 2023
<a href="#">Aurora PostgreSQL integrations with Amazon Bedrock</a>	You can now integrate Amazon Aurora PostgreSQL databases with Amazon Bedrock to power generative AI applications. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora PostgreSQL</a> .	December 21, 2023

[Amazon Aurora is available in the Canada West \(Calgary\) Region](#)

Amazon Aurora is now available in the Canada West (Calgary) Region. For more information, see [Regions and Availability Zones](#).

December 20, 2023

[Amazon RDS supports viewing and responding to recommendations](#)

Amazon Aurora recommendations now includes threshold based proactive and machine learning based reactive recommendations. For more information, see [Recommendations for Amazon Aurora](#).

December 19, 2023

[Aurora PostgreSQL zero-ETL integrations with Amazon Redshift \(preview\)](#)

You can now create zero-ETL integrations with Amazon Redshift using an Aurora PostgreSQL source DB cluster. For the preview release, you must create all integrations in the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-west-2) Amazon Web Services Region. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

November 28, 2023

[Amazon Aurora PostgreSQL supports global database write forwarding](#)

You can now enable write forwarding on secondary clusters in an Aurora PostgreSQL-based global database. For more information, see [Using write forwarding in an Aurora PostgreSQL global database](#).

November 9, 2023

[Aurora PostgreSQL support for Optimized Reads](#)

You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

November 8, 2023

[Amazon RDS exports Performance Insights metrics to Amazon CloudWatch](#)

Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see [Exporting Performance Insights metrics to CloudWatch](#).

November 8, 2023

[Aurora MySQL zero-ETL integrations with Amazon Redshift general availability](#)

Zero-ETL integrations with Amazon Redshift are now generally available for Aurora MySQL. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

November 7, 2023

[Aurora PostgreSQL support for RDS Blue/Green Deployments](#)

You can now create a blue/green deployment from an Aurora PostgreSQL DB cluster. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

October 26, 2023

[Aurora MySQL supports server-side encryption with Amazon KMS keys \(SSE-KMS\)](#)

In Aurora MySQL version 3.05 and higher, you can use SSE-KMS, including Amazon managed keys and customer managed keys, for server-side encryption of data that you load from or save to Amazon S3. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#) and [Saving data from an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).

October 25, 2023

[Aurora MySQL optimizations reduce database restart time](#)

In Aurora MySQL version 3.05 and higher, we've introduced optimizations that reduce the database restart time. These optimizations provide up to 65% less downtime than without optimizations, and fewer disruptions to your database workloads, after a restart. For more information, see [Optimizations to reduce database restart time](#).

October 25, 2023

[Update to Amazon managed policies](#)

The AmazonRDSPerformanceInsightsReadOnly and AmazonRDSPerformanceInsightsFullAccess managed policies now includes Sid (statement ID) as an identifier in the policy statement. For more information, see [Amazon RDS updates to Amazon managed policies](#).

October 23, 2023

[Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch](#)

The **DB\_PERF\_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see [Creating CloudWatch alarms to monitor Amazon Aurora](#).

September 20, 2023

[Amazon Aurora supports point-in-time recovery \(PITR\) with Amazon Backup](#)

You can now manage Aurora automated (continuous) backups in Amazon Backup and restore to specified times from them. For more information, see [Restoring a DB cluster to a specified time using Amazon Backup](#).

September 7, 2023

## [Amazon RDS Extended Support](#)

Amazon Aurora announces the upcoming ability to continue running Aurora MySQL and Aurora PostgreSQL major engine versions in your DB instances past the Aurora end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

September 1, 2023

## [Amazon Aurora MySQL extends support for Percona XtraBackup](#)

You can now perform physical migrations of MySQL 8.0 databases to Aurora MySQL version 3 DB clusters. For more information, see [Physical migration from MySQL by using Percona XtraBackup and Amazon S3](#).

August 24, 2023

### [Aurora global database supports global database failover](#)

Aurora global database now supports managed global failover, allowing you to more easily recover from a true Regional disaster or complete service-level outage. To learn more about this feature, see [Performing managed failovers for Aurora global databases](#). The feature previously called "managed planned failover" is now called "switchover." For information about switchovers, see [Performing switchovers for Amazon Aurora global databases](#).

August 21, 2023

### [Update to Amazon managed policy permissions](#)

The AmazonRDSFullAccess managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 17, 2023

### [Update to Amazon managed policy permissions](#)

The addition of new permissions to AmazonRDS PerformanceInsight sReadOnly managed policy and addition of new managed policy AmazonRDS PerformanceInsight sFullAccess allows you generate a DB load analysis report for a time period. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 16, 2023

### [Amazon RDS supports DB load time period analysis with Performance Insights](#)

Performance Insights allows you to create performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see [Analyzing DB load for a period of time](#).

August 16, 2023

### [Amazon Aurora supports retaining automated backups for DB clusters](#)

You can now retain automated backups for deleted Aurora clusters and restore them to a specified point in time. For more information, see [Retaining automated backups](#).

August 4, 2023

[Amazon Aurora is available in the Israel \(Tel Aviv\) Region](#)

Amazon Aurora is now available in the Israel (Tel Aviv) Region. For more information, see [Regions and Availability Zones](#).

August 1, 2023

[Amazon Aurora MySQL supports local \(in-cluster\) write forwarding](#)

You can now forward write operations from a reader DB instance to a writer DB instance within an Aurora MySQL DB cluster. For more information, see [Using write forwarding in an Amazon Aurora MySQL DB cluster](#).

July 31, 2023

[Amazon Aurora supports Aurora Serverless v2 in an additional Amazon Web Services Region](#)

You can now create Aurora Serverless v2 DB clusters in the Asia Pacific (Melbourne) Amazon Web Services Region. For information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

June 28, 2023

[Amazon Aurora introduces zero-ETL integrations with Amazon Redshift \(preview\)](#)

Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an Aurora MySQL DB cluster. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

June 28, 2023

[Amazon RDS provides combined Performance Insights and CloudWatch metrics view in the Performance Insights dashboard](#)

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. For more information, see [Viewing combined metrics with the Performance Insights dashboard](#).

May 24, 2023

[Amazon Aurora supports the db.r7g instance classes](#)

You can now use the db.r7g instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

May 11, 2023

[Amazon Aurora supports a new DB cluster storage configuration](#)

With Aurora I/O-Optimized, you pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations. For more information, see [Storage configurations for Amazon Aurora DB clusters](#).

May 11, 2023

[Amazon Aurora supports Aurora Serverless v2 in additional Amazon Web Services Regions](#)

You can now create Aurora Serverless v2 DB clusters in the following Amazon Web Services Regions: Asia Pacific (Hyderabad), Europe (Spain) Europe (Zurich), and Middle East (UAE). For information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

May 4, 2023

---

<a href="#">Aurora Serverless v1 supports conversion to provisioned</a>	You can convert an Aurora Serverless v1 DB cluster directly to a provisioned DB cluster. For more information, see <a href="#">Converting an Aurora Serverless v1 DB cluster to provisioned</a> .	April 27, 2023
<a href="#">Aurora Serverless v1 supports Amazon Aurora PostgreSQL version 13</a>	You can now create Aurora Serverless v1 DB clusters that run Aurora PostgreSQL version 13. For more information, see <a href="#">Aurora Serverless v1</a> .	April 27, 2023
<a href="#">Amazon Aurora support for Amazon Secrets Manager in the China Regions</a>	Amazon Aurora supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see <a href="#">Password management with Amazon Aurora and Amazon Secrets Manager</a> .	April 20, 2023
<a href="#">Amazon Aurora supports publishing events with tags to topic subscribers</a>	Amazon Aurora event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see <a href="#">Amazon RDS event notification tags and attributes</a> .	April 17, 2023

[Update to IAM service-linked role permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see [Amazon RDS updates to Amazon managed policies](#).

March 30, 2023

[Amazon Aurora supports global databases in the Asia Pacific \(Melbourne\) Region](#)

You can now create Aurora global databases in the Asia Pacific (Melbourne) Region. For information about Aurora global databases, see [Using Amazon Aurora global databases](#).

March 22, 2023

[Update to Amazon managed policy permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to Amazon CloudWatch. For more information, see [Amazon RDS updates to Amazon managed policies](#).

March 16, 2023

[RDS Proxy is available in the China Regions](#)

RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 15, 2023

[Amazon Aurora supports Aurora Serverless v2 in the China Regions](#)

Aurora Serverless v2 is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see [Aurora Serverless v2](#).

March 15, 2023

[RDS Proxy is available in the Asia Pacific \(Jakarta\) Region](#)

RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 8, 2023

[Amazon Aurora MySQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB clusters. For more information, see [Using Kerberos authentication for Aurora MySQL](#).

March 8, 2023

[Amazon Aurora supports global databases in additional Amazon Web Services Regions](#)

You can now create Aurora global databases in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about Aurora global databases, see [Using Amazon Aurora global databases](#).

March 6, 2023

[Amazon Aurora supports copying DB cluster snapshots in additional Amazon Web Services Regions](#)

You can now copy DB cluster snapshots in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Asia Pacific (Melbourne), Europe (Milan), Europe (Spain), Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about copying DB cluster snapshots, see [Copying a DB cluster snapshot](#).

March 6, 2023

[Amazon DevOps Guru for RDS supports proactive insights](#)

Amazon DevOps Guru for RDS publishes proactive insights with recommendations to help you address issues in your Aurora databases before they are predicted to happen. For more information, see [How DevOps Guru for RDS works](#).

February 28, 2023

[Amazon Aurora MySQL version 1 is deprecated](#)

Aurora MySQL version 1 (compatible with MySQL 5.6) has been deprecated. For more information, see [How long Amazon Aurora major versions remain available](#).

February 28, 2023

[Aurora Serverless v1 supports setting the DB cluster maintenance window](#)

You can now set the maintenance window for Aurora Serverless v1 DB clusters. For more information, see [Adjusting the preferred DB cluster maintenance window](#).

February 27, 2023

[Amazon Aurora supports Database Activity Streams in the Asia Pacific \(Hyderabad\), Europe \(Spain\), and Middle East \(UAE\) Regions.](#)

For more information, see [Database Activity Streams](#).

January 27, 2023

[Amazon Aurora is available in the Asia Pacific \(Melbourne\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Melbourne) Region. For more information, see [Regions and Availability Zones](#).

January 23, 2023

[Specify certificate authority \(CA\) during DB cluster creation](#)

You can now specify which CA to use for a DB cluster's server certificate during DB cluster creation. For more information, see [Certificate authorities](#).

January 5, 2023

[Aurora MySQL 3.\\* support for backtracking](#)

Aurora MySQL 3.\* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see [Backtracking an Aurora DB cluster](#).

January 4, 2023

[Use Amazon RDS Blue/Green Deployments available in additional Amazon Web Services Regions](#)

The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

December 22, 2022

[Update to IAM service-linked role permissions](#)

The AmazonRDSServiceRolePolicy policy now grants additional permissions to Amazon Secrets Manager. For more information, see [Amazon RDS updates to Amazon managed policies](#).

December 22, 2022

[Amazon Aurora integrates with Amazon Secrets Manager for password management](#)

Aurora can manage the master user password for a DB cluster in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#).

December 22, 2022

[Amazon Aurora supports Aurora Serverless v2 in additional Amazon Web Services Regions](#)

Aurora Serverless v2 is now available in the Africa (Cape Town) and Europe (Milan) Regions. For more information, see [Aurora Serverless v2](#).

December 21, 2022

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 14](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 14 DB cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

December 13, 2022

[Amazon Aurora alerts you to recent anomalies detected by Amazon DevOps Guru](#)

The database details page of the console alerts you both to current and anomalies that occurred in the past 24 hours. For more information, see [How DevOps Guru for RDS works](#).

December 13, 2022

[Amazon RDS Proxy supports global databases](#)

You can now use RDS Proxy with Aurora global databases . For more information, see [Using RDS Proxy with Aurora global databases](#).

December 7, 2022

[Aurora PostgreSQL DB clusters support Trusted Language Extensions for PostgreSQL](#)

Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

November 30, 2022

[Amazon GuardDuty RDS Protection monitors for access threats](#)

When you turn on GuardDuty RDS Protection, GuardDuty consumes RDS login events from your Aurora databases, monitors these events, and profiles them for potential insider threats or external actors. When GuardDuty RDS Protection detects a potential threat, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see [Monitoring threats with GuardDuty RDS Protection](#).

November 30, 2022

[Use Amazon RDS Blue/Green Deployments for database updates](#)

You can make changes to a DB cluster in a staging environment and test the changes without affecting your production DB cluster. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

November 27, 2022

[Amazon Aurora is available in the Asia Pacific \(Hyderabad\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Hyderabad) Region. For more information, see [Regions and Availability Zones](#).

November 22, 2022

[Amazon Aurora is available in the Europe \(Spain\) Region](#)

Amazon Aurora is now available in the Europe (Spain) Region. For more information, see [Regions and Availability Zones](#).

November 16, 2022

[Amazon Aurora is available in the Europe \(Zurich\) Region](#)

Amazon Aurora is now available in the Europe (Zurich) Region. For more information, see [Regions and Availability Zones](#).

November 9, 2022

[Amazon Aurora supports exporting data to Amazon S3 from DB clusters](#)

You can now export Aurora cluster data directly to S3, without having to create a snapshot first. For more information, see [Exporting DB cluster data to Amazon S3](#).

October 27, 2022

[Amazon Aurora MySQL supports faster exports to Amazon S3](#)

You can now see up to 10x faster performance for exporting DB cluster snapshot data to S3 for MySQL 5.7- and 8.0-compatible Aurora MySQL clusters. For more information, see [Exporting DB cluster snapshot data to Amazon S3](#).

October 20, 2022

[Amazon Aurora supports automatically setting up connectivity between an Aurora DB cluster and an EC2 instance](#)

You can use the Amazon Web Services Management Console to set up connectivity between an existing Aurora DB cluster and an EC2 instance. For more information, see [Connecting an EC2 instance and an Aurora DB cluster automatically](#).

October 14, 2022

[Amazon JDBC Driver for PostgreSQL generally available](#)

The Amazon JDBC Driver for PostgreSQL is a client driver designed for Aurora PostgreSQL. The Amazon JDBC Driver for PostgreSQL is now generally available. For more information, see [Connecting with the Amazon JDBC Driver for PostgreSQL](#).

October 6, 2022

[Amazon Aurora supports in-place upgrade for MySQL 5.7-compatible Aurora MySQL](#)

You can perform an in-place upgrade to change an existing MySQL 5.7-compatible Aurora MySQL cluster into a MySQL 8.0-compatible Aurora MySQL cluster. For more information, see [Upgrading from Aurora MySQL 2.x to 3.x](#).

September 26, 2022

[Performance Insights shows the top 25 SQL queries](#)

In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see [Overview of the Top SQL tab](#).

September 13, 2022

[Aurora MySQL supports a new DB instance class](#)

You can now use the db.r6i DB instance class for Aurora MySQL DB clusters. For more information, see [DB instance classes](#).

September 13, 2022

[Amazon Aurora is available in the Middle East \(UAE\) Region](#)

Amazon Aurora is now available in the Middle East (UAE) Region. For more information, see [Regions and Availability Zones](#).

August 30, 2022

[Amazon Aurora supports automatically setting up connectivity with an EC2 instance](#)

When you create an Aurora DB cluster, you can use the Amazon Web Services Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

August 22, 2022

[Amazon Aurora supports dual-stack mode](#)

DB clusters can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB cluster over IPv4, IPv6, or both. For more information, see [Amazon Aurora IP addressing](#).

August 17, 2022

[Amazon Aurora supports in-place upgrade for PostgreSQL 10-compatible Aurora Serverless v1](#)

You can perform an in-place upgrade for a PostgreSQL 10-compatible Aurora Serverless v1 cluster to change an existing cluster into a PostgreSQL 11-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see [Modifying an Aurora Serverless v1 DB cluster](#).

August 8, 2022

[Performance Insights supports the Asia Pacific \(Jakarta\) Region](#)

Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more information, see [Amazon Web Services Region support for Performance Insights](#).

July 21, 2022

[Amazon Aurora supports a new DB instance class](#)

You can now use the db.r6i DB instance class for Aurora PostgreSQL DB clusters. For more information, see [DB instance classes](#).

July 14, 2022

[RDS Performance Insights supports additional retention periods](#)

Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance data for longer than 7 days, you can specify from 1–24 months. For more information, see [Pricing and data retention for Performance Insights](#).

July 1, 2022

[Amazon Aurora supports in-place upgrade for MySQL-compatible Aurora Serverless v1](#)

You can perform an in-place upgrade for a MySQL 5.6-compatible Aurora Serverless v1 cluster to change an existing cluster into a MySQL 5.7-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see [Modifying an Aurora Serverless v1 DB cluster](#).

June 16, 2022

[Aurora supports turning on Amazon DevOps Guru in the RDS console](#)

You can turn on DevOps Guru coverage for your Aurora databases from within the RDS console. For more information, see [Setting up DevOps Guru for RDS](#).

June 9, 2022

[Amazon Aurora supports publishing events to encrypted Amazon SNS topics](#)

Amazon Aurora can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see [Subscribing to Amazon RDS event notification](#).

June 1, 2022

---

<a href="#">Amazon RDS publishes usage metrics to Amazon CloudWatch</a>	The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see <a href="#">Amazon CloudWatch usage metrics for Amazon Aurora</a> .	April 28, 2022
<a href="#">Data API result sets in JSON format</a>	An optional parameter for the ExecuteStatement function causes the query result set to be returned as a string in JSON format. The JSON result set is simple and convenient to transform into a data structure in your application's language. For more information, see <a href="#">Processing query results in JSON format</a> .	April 27, 2022
<a href="#">Amazon Aurora Serverless v2 is now generally available</a>	Amazon Aurora Serverless v2 is generally available for all users. For more information, see <a href="#">Using Aurora Serverless v2</a> .	April 21, 2022
<a href="#">Aurora MySQL supports configurable cipher suites</a>	With Aurora MySQL, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For more information, see <a href="#">Configuring cipher suites for connections to Aurora MySQL DB clusters</a> .	April 15, 2022

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 13](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 13 DB cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

April 4, 2022

[Release Notes for Aurora PostgreSQL](#)

There is now a separate guide for the Amazon Aurora PostgreSQL release notes. For more information, see [Release Notes for Aurora PostgreSQL](#).

March 22, 2022

[Release Notes for Aurora MySQL](#)

There is now a separate guide for the Amazon Aurora MySQL release notes. For more information, see [Release Notes for Aurora MySQL](#).

March 22, 2022

[Aurora PostgreSQL supports multi-major version upgrades](#)

You can now perform version upgrades of Aurora PostgreSQL DB clusters across multiple major versions. For more information, see [How to perform a major version upgrade](#).

March 4, 2022

[Aurora PostgreSQL supports configurable cipher suites](#)

With Aurora PostgreSQL versions 11.8 and higher, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For information about using configurable cipher suites with Aurora PostgreSQL, see [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters](#).

March 4, 2022

[Amazon JDBC Driver for MySQL generally available](#)

The Amazon JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The Amazon JDBC Driver for MySQL is now generally available. For more information, see [Connecting with the Amazon Web Services JDBC Driver for MySQL](#).

March 2, 2022

[Aurora PostgreSQL 13.5 supports Babelfish for Aurora PostgreSQL 1.1.0](#)

Aurora PostgreSQL 13.5 supports Babelfish 1.1.0. For a list of new features, see [13.5](#). For a list of features supported in each Babelfish release, see [Supported functionality in Babelfish by version](#). For usage information, see [Working with Babelfish for Aurora PostgreSQL](#).

February 28, 2022

[Amazon Aurora supports Database Activity Streams in the Asia Pacific \(Jakarta\) Region](#)

For more information, see [Support for Amazon Web Services Regions for database activity streams](#).

February 16, 2022

[Performance Insights supports new API operations](#)

Performance Insights now supports the following API operations: `GetResourceMetadata` , `ListAvailableResourceDimensions` , and `ListAvailableResourceMetrics` . For more information, see [Retrieving metrics with the Performance Insights API](#) in this manual and the [Amazon RDS Performance Insights API Reference](#).

January 12, 2022

[Amazon RDS Proxy supports events](#)

RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see [Working with RDS Proxy events](#).

January 11, 2022

[RDS Proxy available in additional Amazon Web Services Regions](#)

RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

January 5, 2022

[Amazon Aurora is available in the Asia Pacific \(Jakarta\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Jakarta) Region. For more information, see [Regions and Availability Zones](#).

December 13, 2021

[DevOps Guru for Amazon RDS provides detailed insights and recommendations for Amazon Aurora](#)

DevOps Guru for RDS mines Performance Insights for performance-related data. Using this data, the service analyzes the performance of your Amazon Aurora DB instances and can help you resolve performance issues. To learn more, see [Analyzing performance anomalies with DevOps Guru for RDS](#) in this guide and see [Overview of DevOps Guru for RDS](#) in the *Amazon DevOps Guru User Guide*.

December 1, 2021

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 12](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 12 database cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

November 22, 2021

[Aurora supports Amazon Graviton2 instance classes for Database Activity Streams](#)

You can use database activity streams with the db.r6g instance class for Aurora MySQL and Aurora PostgreSQL. For more information, see [Supported DB instance classes](#).

November 3, 2021

[Amazon Aurora support for cross-account Amazon KMS keys](#)

You can use a KMS key from a different Amazon Web Services account for encryption when exporting DB snapshots to Amazon S3. For more information, see [Exporting DB snapshot data to Amazon S3](#).

November 3, 2021

[Amazon Aurora supports Babelfish for Aurora PostgreSQL](#)

Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see [Working with Babelfish for Aurora PostgreSQL](#).

October 28, 2021

[Aurora Serverless v1 can require SSL for connections](#)

The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL are supported now for Aurora Serverless v1. For more information, see [Using TLS/SSL with Aurora Serverless v1](#).

October 26, 2021

[Amazon Aurora supports Performance Insights in additional Amazon Web Services Regions](#)

Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see [Amazon Web Services Region support for Performance Insights](#).

October 5, 2021

[Configurable autoscaling timeout for Aurora Serverless v1](#)

You can choose how long Aurora Serverless v1 waits to find an autoscaling point. If no autoscaling point is found during that period, Aurora Serverless v1 cancels the scaling event or forces the capacity change, depending on the timeout action that you selected. For more information, see [Autoscaling for Aurora Serverless v1](#).

September 10, 2021

[Aurora supports X2g and T4g instance classes](#)

Both Aurora MySQL and Aurora PostgreSQL can now use X2g and T4g instance classes. The instance classes that you can use depend on the version of Aurora MySQL or Aurora PostgreSQL. For information about supported instance types, see [DB instance classes](#).

September 10, 2021

[Amazon RDS supports RDS Proxy in a shared VPC](#)

You can now create an RDS Proxy in a shared virtual private cloud (VPC). For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora User Guide](#).

August 6, 2021

[Aurora version policy page](#)

The *Amazon Aurora User Guide* now includes a section with general information about Aurora versions and associated policies. For details, see [Amazon Aurora versions](#).

July 14, 2021

[Exclude Data API events from an Amazon CloudTrail trail](#)

You can exclude Data API events from a CloudTrail trail. For more information, see [Excluding Data API events from an Amazon CloudTrail trail](#).

July 2, 2021

---

<a href="#">Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions</a>	Newly supported extensions include <code>pg_bigm</code> , <code>pg_cron</code> , <code>pg_partman</code> , and <code>pg_proctab</code> . For more information, see <a href="#">Extension versions for Amazon Aurora PostgreSQL-Compatible Edition</a> .	June 17, 2021
<a href="#">Cloning for Aurora Serverless clusters</a>	You can now create cloned clusters that are Aurora Serverless. For information about cloning, see <a href="#">Cloning a volume for an Aurora DB cluster</a> .	June 16, 2021
<a href="#">Aurora global databases available in China (Beijing) and China (Ningxia) Regions</a>	You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see <a href="#">Working with Amazon Aurora global databases</a> .	May 19, 2021
<a href="#">FIPS 140-2 support for Data API</a>	The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see <a href="#">Data API availability</a> .	May 14, 2021

[Amazon JDBC Driver for PostgreSQL \(preview\)](#)

The Amazon JDBC Driver for PostgreSQL, now available in preview, is a client driver designed for the high availability of Aurora PostgreSQL. For more information, see [Connecting with the Amazon Web Services JDBC Driver for PostgreSQL \(preview\)](#).

April 27, 2021

[The Data API available in additional Amazon Web Services Regions](#)

The Data API is now available in the Asia Pacific (Seoul) and Canada (Central) Regions. For more information, see [Availability of the Data API](#).

April 9, 2021

[Amazon Aurora supports the Graviton2 DB instance classes](#)

You can now use the Graviton2 DB instance classes db.r6g.x to create DB clusters running MySQL or PostgreSQL. For more information, see [DB instance class types](#).

March 12, 2021

### [RDS Proxy endpoint enhancements](#)

You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora user guide](#).

March 8, 2021

### [Amazon Aurora is available in the Asia Pacific \(Osaka\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Osaka) Region. For more information, see [Regions and Availability Zones](#).

March 1, 2021

### [Aurora PostgreSQL supports enabling both IAM and Kerberos authentication on the same DB cluster](#)

Aurora PostgreSQL now supports enabling both IAM authentication and Kerberos authentication on the same DB cluster. For more information, see [Database authentication with Amazon Aurora](#).

February 24, 2021

[Aurora global database now supports managed planned failover](#)

Aurora global database now supports managed planned failover, allowing you to more easily change the primary Amazon Region of your Aurora global database. You can use managed planned failover with healthy Aurora global databases only. To learn more, see [Disaster recovery and Amazon Aurora global databases](#). For reference information, see [FailoverGlobalCluster](#) in the *Amazon RDS API Reference*.

February 11, 2021

[Data API for Aurora Serverless now supports more data types](#)

With the Data API for Aurora Serverless, you can now use UUID and JSON data types as input to your database. Also with the Data API for Aurora Serverless, you can now have a LONG type value returned from your database as a STRING value. To learn more, see [Calling the Data API](#). For reference information about supported data types, see [SqlParameter](#) in the *Amazon RDS Data Service API Reference*.

February 2, 2021

[Aurora PostgreSQL supports major version upgrades to PostgreSQL 12](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to major version 12. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

January 28, 2021

[Aurora MySQL supports in-place upgrade](#)

You can upgrade your Aurora MySQL 1.x cluster to Aurora MySQL 2.x, preserving the DB instances, endpoints, and so on of the original cluster. This in-place upgrade technique avoids the inconvenience of setting up a whole new cluster by restoring a snapshot. It also avoids the overhead of copying all your table data into a new cluster. For more information, see [Upgrading the major version of an Aurora MySQL DB cluster from 1.x to 2.x](#).

January 11, 2021

[Amazon JDBC Driver for MySQL \(preview\)](#)

The Amazon JDBC Driver for MySQL, now available in preview, is a client driver designed for the high availability of Aurora MySQL. For more information, see [Connecting with the Amazon Web Services JDBC Driver for MySQL \(preview\)](#).

January 7, 2021

[Aurora supports database activity streams on secondary clusters of a global database](#)

You can start a database a database activity stream on a primary or secondary cluster of Aurora PostgreSQL or Aurora MySQL. For supported engine versions, see [Limitations of Aurora global databases](#).

December 22, 2020

[Multi-master clusters with 4 DB instances](#)

The maximum number of DB instances in an Aurora MySQL multi-master cluster is now four. Formerly, the maximum was two DB instances. For more information, see [Working with Aurora Multi-Master Clusters](#).

December 17, 2020

[Aurora PostgreSQL supports Amazon Lambda functions](#)

You can now invoke Amazon Lambda function for your Aurora PostgreSQL DB clusters. For more information, see [Invoking a Lambda function from an Aurora PostgreSQL DB cluster](#).

December 11, 2020

[Amazon Aurora supports the Graviton2 DB instance classes in preview](#)

You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see [DB instance class types](#).

December 11, 2020

[Amazon Aurora Serverless v2 is now available in preview.](#)

Amazon Aurora Serverless v2 is available in preview. To work with Amazon Aurora Serverless v2, apply for access. For more information, see the [Aurora Serverless v2 page](#).

December 1, 2020

[Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions.](#)

Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions. You can now choose to run Aurora PostgreSQL Serverless v1 in the same Amazon Web Services Regions that offer Aurora MySQL Serverless v1. Additional Amazon Web Services Regions with Aurora Serverless support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless, see [Supported Regions and Aurora DB engines for Aurora Serverless v1](#). Amazon RDS Data API for Aurora Serverless is also now available in these same Amazon Web Services Regions. For a list of all Regions with support for the Data API for Aurora Serverless, see [Data API with Aurora MySQL Serverless v1](#)

November 24, 2020

[Amazon RDS Performance Insights introduces new dimensions](#)

You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session\_type.name (PostgreSQL). For more information, see [Top load table](#).

November 24, 2020

[Aurora Serverless supports Aurora PostgreSQL version 10.12](#)

Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the Amazon Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see [Supported Regions and Aurora DB engines for Aurora Serverless v1](#).

November 4, 2020

[The Data API now supports tag-based authorization](#)

The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see [Authorizing access to the Data API](#).

October 27, 2020

[Amazon Aurora extends support for exporting snapshots to Amazon S3](#)

You can now export DB snapshot data to Amazon S3 in all commercial Amazon Web Services Regions. For more information, see [Exporting DB snapshot data to Amazon S3](#).

October 22, 2020

[Aurora global database supports cloning](#)

You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the Amazon Web Services Management Console and choosing the **Create clone** menu option. You can also use the Amazon CLI and run the `restore-db-cluster-to-point-in-time` command with the `--restore-type copy-on-write` option. Using the Amazon Web Services Management Console or the Amazon CLI, you can also clone DB clusters from your Aurora global databases across Amazon accounts. For more information about cloning, see [Cloning an Aurora DB cluster volume](#).

October 19, 2020

[Amazon Aurora supports dynamic resizing for the cluster volume](#)

Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as `DROP TABLE`. To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see [Managing Performance and Scaling for Aurora DB Clusters](#).

October 13, 2020

[Amazon Aurora supports volume sizes up to 128 TiB](#)

New and existing Aurora cluster volumes can now grow to a maximum size of 128 terabytes (TiB). For more information, see [How Aurora storage grows](#).

September 22, 2020

[Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China \(Ningxia\) Region](#)

You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see [DB instance classes](#).

September 3, 2020

## [Aurora parallel query enhancements](#)

September 2, 2020

Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature . Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the DYNAMIC row format. Parallel query clusters can use Amazon Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the READ COMMITTED

isolation level. You can also now create parallel query clusters in additional Amazon Web Services Regions. For more information about the parallel query feature and these enhancements, see [Parallel query for Aurora MySQL](#).

[Changes to Aurora MySQL parameter `binlog\_rows\_query\_log\_events`](#)

You can now change the value of the Aurora MySQL configuration parameter `binlog_rows_query_log_events`. Formerly, this parameter wasn't modifiable.

August 26, 2020

[Support for automatic minor version upgrades for Aurora MySQL](#)

With Aurora MySQL, the setting **Enable auto minor version upgrade** now takes effect when you specify it for an Aurora MySQL DB cluster. When you enable auto minor version upgrade, Aurora automatically upgrades to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database. For Aurora MySQL, this feature applies only to Aurora MySQL version 2, which is compatible with MySQL 5.7. Initially, the automatic upgrade procedure brings Aurora MySQL DB clusters to version 2.07.2. For more information about how this feature works with Aurora MySQL, see [Database Upgrades and Patches for Amazon Aurora MySQL](#).

August 3, 2020

[Aurora PostgreSQL supports major version upgrades to PostgreSQL version 11](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to major version 11. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

July 28, 2020

[Amazon Aurora supports Amazon PrivateLink](#)

Amazon Aurora now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Aurora in the Amazon network. For more information, see [Amazon Aurora and interface VPC endpoints \(Amazon PrivateLink\)](#). July 9, 2020

[RDS Proxy generally available](#)

RDS Proxy is now generally available. You can use RDS Proxy with RDS for MySQL, Aurora MySQL, RDS for PostgreSQL, and Aurora PostgreSQL for production workloads. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora user guide](#). June 30, 2020

[Aurora global database write forwarding](#)

You can now enable write capability on secondary clusters in a global database. With write forwarding, you issue DML statements on a secondary cluster, Aurora forwards the write to the primary cluster, and the updated data is replicated to all the secondary clusters. For more information, see [Write forwarding for secondary Amazon Web Services Regions with an Aurora global database](#).

June 18, 2020

[Aurora supports integration with Amazon Backup](#)

You can use Amazon Backup to manage backups of Aurora DB clusters. For more information, see [Overview of backing up and restoring an Aurora DB cluster](#).

June 10, 2020

[Aurora PostgreSQL supports db.t3.large DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.t3.large DB instance classes. For more information, see [DB instance classes](#).

June 5, 2020

[Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective \(RPO\)](#)

You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see [Cross-Region Disaster Recovery for Aurora global databases](#).

June 4, 2020

[Aurora MySQL supports database monitoring with database activity streams](#)

Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see [Using database activity streams](#).

June 2, 2020

[The query editor available in additional Amazon Web Services Regions](#)

The query editor for Aurora Serverless is now available in additional Amazon Web Services Regions. For more information, see [Availability of the query editor](#).

May 28, 2020

[The Data API available in additional Amazon Web Services Regions](#)

The Data API is now available in additional Amazon Web Services Regions. For more information, see [Availability of the Data API](#).

May 28, 2020

[RDS Proxy available in Canada \(Central\) Region](#)

You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see [Managing connections with Amazon RDS proxy \(preview\)](#).

May 28, 2020

[Aurora global database and cross-Region read replicas](#)

For an Aurora global database, you can now create an Aurora MySQL cross-Region read replica from the primary cluster in the same region as a secondary cluster. For more information about Aurora Global Database and cross-Region read replicas, see [Working with Amazon Aurora global database and Replicating Amazon Aurora MySQL DB](#).

May 18, 2020

[RDS Proxy available in more Amazon Web Services Regions](#)

You can now use the RDS Proxy preview in the US West (N. California) Region, the Europe (London) Region, the Europe (Frankfurt) Region, the Asia Pacific (Seoul) Region, the Asia Pacific (Mumbai) Region, the Asia Pacific (Singapore) Region, and the Asia Pacific (Sydney) Region. For more information about RDS Proxy, see [Managing connections with Amazon RDS proxy \(preview\)](#).

May 13, 2020

[Aurora PostgreSQL-Compatible Edition supports on-premises or self-hosted Microsoft active directory](#)

You can now use an on-premises or self-hosted Active Directory for Kerberos authentication of users when they connect to your Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication with Aurora PostgreSQL](#).

May 7, 2020

[Aurora MySQL multi-master clusters available in more Amazon Web Services Regions](#)

You can now create Aurora multi-master clusters in the Asia Pacific (Seoul) Region, the Asia Pacific (Tokyo) Region, the Asia Pacific (Mumbai) Region, and the Europe (Frankfurt) Region. For more information about multi-master clusters, see [Working with Aurora multi-master clusters](#).

May 7, 2020

[Performance Insights supports analyzing statistics of running Aurora MySQL queries](#)

You can now analyze statistics of running queries with Performance Insights for Aurora MySQL DB instances. For more information, see [Analyzing statistics of running queries](#).

May 5, 2020

[Java client library for Data API generally available](#)

The Java client library for the Data API is now generally available. You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see [Using the Java client library for Data API](#).

April 30, 2020

[Amazon Aurora is available in the Europe \(Milan\) Region](#)

Amazon Aurora is now available in the Europe (Milan) Region. For more information, see [Regions and Availability Zones](#).

April 28, 2020

[Amazon Aurora is available in the Europe \(Milan\) Region](#)

Amazon Aurora is now available in the Europe (Milan) Region. For more information, see [Regions and Availability Zones](#).

April 27, 2020

[Amazon Aurora is available in the Africa \(Cape Town\) Region](#)

Amazon Aurora is now available in the Africa (Cape Town) Region. For more information, see [Regions and Availability Zones](#).

April 22, 2020

[Aurora PostgreSQL now supports db.r5.16xlarge and db.r5.8xlarge DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters running PostgreSQL that use the db.r5.16xlarge and db.r5.8xlarge DB instance classes. For more information, see [Hardware specifications for DB instance classes for Aurora](#).

April 8, 2020

[Amazon RDS proxy for PostgreSQL](#)

Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your cluster and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

April 8, 2020

[Aurora global databases now support Aurora PostgreSQL](#)

You can now create Aurora global databases for the PostgreSQL database engine. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see [Working with Amazon Aurora global database](#).

March 10, 2020

[Support for major version upgrades for Aurora PostgreSQL](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to a major version. By doing so, you can skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

March 4, 2020

[Aurora PostgreSQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication with Aurora PostgreSQL](#).

February 28, 2020

[The Data API supports Amazon PrivateLink](#)

The Data API now supports creating Amazon VPC endpoints for Data API calls to keep traffic between applications and the Data API in the Amazon network. For more information, see [Creating an Amazon VPC endpoint \(Amazon PrivateLink\) for the Data API](#).

February 6, 2020

[Aurora machine learning support in Aurora PostgreSQL](#)

The `aws_ml` Aurora PostgreSQL extension provides functions you use in your database queries to call Amazon Comprehend for sentiment analysis and SageMaker AI to run your own machine learning models. For more information, see [Using machine learning \(ML\) capabilities with Aurora](#).

February 5, 2020

[Aurora PostgreSQL supports exporting data to Amazon S3](#)

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. For more information, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).

February 5, 2020

[Support for exporting DB snapshot data to Amazon S3](#)

Amazon Aurora supports exporting DB snapshot data to Amazon S3 for MySQL and PostgreSQL. For more information, see [Exporting DB snapshot data to Amazon S3](#).

January 9, 2020

[Aurora MySQL release notes in document history](#)

This section now includes history entries for Aurora MySQL-Compatible Edition release notes for versions released after August 31, 2018. For the full release notes for a specific version, choose the link in the first column of the history entry.

December 13, 2019

[Amazon RDS proxy](#)

You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the Aurora MySQL database engine. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

December 3, 2019

[Data API for Aurora Serverless v1 supports data type mapping hints](#)

You can now use a hint to instruct the Data API for Aurora Serverless v1 to send a `String` value to the database as a different type. For more information, see [Calling the data API](#).

November 26, 2019

[Data API for Aurora Serverless v1 supports a Java client library \(preview\)](#)

You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see [Using the Java client library for Data API](#).

November 26, 2019

[Aurora PostgreSQL is FedRAMP HIGH eligible](#)

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about Amazon and compliance efforts, see [Amazon services in scope by compliance program](#).

November 26, 2019

[READ COMMITTED isolation level enabled for Amazon Aurora MySQL replicas](#)

You can now enable the READ COMMITTED isolation level on Aurora MySQL Replicas. Doing so requires enabling the `aurora_read_replica_read_committed_isolation_enabled` configuration setting at the session level. Using the READ COMMITTED isolation level for long-running queries on OLTP clusters can help address issues with history list length. Before enabling this setting, be sure to understand how the isolation behavior on Aurora Replicas differs from the usual MySQL implementation of READ COMMITTED. For more information, see [Aurora MySQL isolation levels](#).

November 25, 2019

[Performance Insights supports analyzing statistics of running Aurora PostgreSQL queries](#)

You can now analyze statistics of running queries with Performance Insights for Aurora PostgreSQL DB instances. For more information, see [Analyzing statistics of running queries](#).

November 25, 2019

### [More clusters in an Aurora global database](#)

You can now add multiple secondary regions to an Aurora global database. You can take advantage of low latency global reads and disaster recovery across a wider geographic area. For more information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

November 25, 2019

### [Aurora machine learning support in Aurora MySQL](#)

In Aurora MySQL 2.07 and higher, you can call Amazon Comprehend for sentiment analysis and SageMaker AI for a wide variety of machine learning algorithms. You use the results directly in your database application by embedding calls to stored functions in your queries. For more information, see [Using machine learning \(ML\) capabilities with Aurora](#).

November 25, 2019

### [Aurora global database no longer requires engine mode setting](#)

You no longer need to specify `--engine-mode=global` when creating a cluster that is intended to be part of an Aurora global database. All Aurora clusters that meet the compatibility requirements are eligible to be part of a global database. For example, the cluster currently must use Aurora MySQL version 1 with MySQL 5.6 compatibility. For information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

November 25, 2019

### [Aurora global database is available for Aurora MySQL version 2](#)

Starting in Aurora MySQL 2.07, you can create an Aurora global database with MySQL 5.7 compatibility. You don't need to specify the `global` engine mode for the primary or secondary clusters. You can add any new provisioned cluster with Aurora MySQL 2.07 or higher to an Aurora Global Database. For information about Aurora Global Database, see [Working with Amazon Aurora global database](#).

November 25, 2019

[Aurora MySQL hot row contention optimization available without lab mode](#)

The hot row contention optimization is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page. The improvement involves changing the lock release algorithm used by Aurora MySQL.

November 19, 2019

[Aurora MySQL hash joins available without lab mode](#)

The hash join feature is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information about using this feature, see [Working with hash joins in Aurora MySQL](#).

November 19, 2019

[Aurora MySQL 2.\\* support for more db.r5 instance classes](#)

Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see [Choosing the DB instance class](#).

November 19, 2019

### [Aurora MySQL 2.\\* support for backtracking](#)

Aurora MySQL 2.\* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see [Backtracking an Aurora DB cluster](#).

November 19, 2019

### [Billing tag support for Aurora](#)

You can now use tags to keep track of cost allocation for resources such as Aurora clusters, DB instances within Aurora clusters, I/O, backups, snapshots, and so on. You can see costs associated with each tag using Amazon Cost Explorer. For more information about using tags with Aurora, see [Tagging Amazon RDS resources](#). For general information about tags and ways to use them for cost analysis, see [Using cost allocation tags](#) and [User-defined cost allocation tags](#).

October 23, 2019

## [Data API for Aurora PostgreSQL](#)

Aurora PostgreSQL now supports using the Data API with Amazon Aurora Serverless v1 DB clusters. For more information, see [Using the Data API for Aurora Serverless v1](#).

September 23, 2019

## [Aurora PostgreSQL supports uploading database logs to CloudWatch logs](#)

You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](#).

August 9, 2019

## [Multi-master clusters for Aurora MySQL](#)

You can set up Aurora MySQL multi-master clusters. In these clusters, each DB instance has read/write capability. For more information, see [Working with Aurora multi-master clusters](#).

August 8, 2019

[Aurora PostgreSQL supports Aurora Serverless v1](#)

You can now use Amazon Aurora Serverless v1 with Aurora PostgreSQL. An Aurora Serverless DB cluster automatically starts up, shuts down, and scales up or down its compute capacity based on your application's needs. For more information, see [Using Amazon Aurora Serverless v1](#).

July 9, 2019

[Cross-account cloning for Aurora MySQL](#)

You can now clone the cluster volume for an Aurora MySQL DB cluster between Amazon accounts. You authorize the sharing through Amazon Resource Access Manager (Amazon RAM). The cloned cluster volume uses a copy-on-write mechanism, which only requires additional storage for new or changed data. For more information about cloning for Aurora, see [Cloning databases in an Aurora DB cluster](#).

July 2, 2019

[Aurora PostgreSQL supports db.t3 DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

June 20, 2019

[Support for importing data from Amazon S3 for Aurora PostgreSQL](#)

You can now import data from an Amazon S3 file into a table in an Aurora PostgreSQL DB cluster. For more information, see [Importing Amazon S3 data into an Aurora PostgreSQL DB cluster](#).

June 19, 2019

[Aurora PostgreSQL now provides fast failover recovery with cluster cache management](#)

Aurora PostgreSQL now provides cluster cache management to ensure fast recovery of the primary DB instance in the event of a failover. For more information, see [Fast recovery after failover with cluster cache management](#).

June 11, 2019

[Data API for Aurora Serverless v1 generally available](#)

You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see [Using the Data API for Aurora Serverless v1](#).

May 30, 2019

[Aurora PostgreSQL supports database monitoring with database activity streams](#)

Aurora PostgreSQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see [Using database activity streams](#).

May 30, 2019

[Amazon Aurora recommendations](#)

Amazon Aurora now provides automated recommendations for Aurora resources. For more information, see [Using Amazon Aurora recommendations](#).

May 22, 2019

[Performance Insights support for Aurora global database](#)

You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see [Using Amazon RDS performance insights](#). For information about Aurora global databases, see [Working with Aurora global database](#).

May 13, 2019

[Performance Insights is available for Aurora MySQL 5.7](#)

Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see [Using Amazon RDS performance insights](#).

May 3, 2019

[Aurora global databases available in more Amazon Web Services Regions](#)

You can now create Aurora global databases in most Amazon Web Services Regions where Aurora is available. For information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

April 30, 2019

### [Minimum capacity of 1 for Aurora Serverless v1](#)

The minimum capacity setting you can use for an Aurora Serverless v1 cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see [Setting the capacity of an Aurora Serverless v1 DB cluster](#). April 29, 2019

### [Aurora Serverless v1 timeout action](#)

You can now specify the action to take when an Aurora Serverless v1 capacity change times out. For more information, see [Timeout action for capacity changes](#). April 29, 2019

### [Per-second billing](#)

Amazon RDS is now billed in 1-second increments in all Amazon Web Services Regions except Amazon GovCloud (US) for on-demand instances. For more information, see [DB instance billing for Aurora](#). April 25, 2019

### [Sharing Aurora Serverless v1 snapshots across Amazon Web Services Regions](#)

With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across Amazon Web Services Regions. For information about snapshots of Aurora Serverless v1 DB clusters, see [Aurora Serverless v1 and snapshots](#). April 17, 2019

[Restore MySQL 5.7 backups from Amazon S3](#)

You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see [Migrating data from an external MySQL database to an Aurora MySQL DB cluster](#).

April 17, 2019

[Sharing Aurora Serverless v1 snapshots across regions](#)

With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless v1 DB clusters, see [Aurora Serverless and snapshots](#).

April 16, 2019

[Aurora proof-of-concept tutorial](#)

You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see [Performing an Aurora proof of concept](#).

April 16, 2019

[Aurora Serverless v1 supports restoring from an Amazon S3 backup](#)

You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see [Migrating data from MySQL by using an Amazon S3 bucket](#).

April 16, 2019

## [New modifiable parameters for Aurora Serverless v1](#)

You can now modify the following DB parameters for an Aurora Serverless v1 cluster: `innodb_file_format` , `innodb_file_per_table` , `innodb_large_prefix` , `innodb_lock_wait_timeout` , `innodb_monitor_disable` , `innodb_monitor_enable` , `innodb_monitor_reset` , `innodb_monitor_reset_all` , `innodb_print_all_deadlocks` , `log_warnings` , `net_read_timeout` , `net_retry_count` , `net_write_timeout` , `sql_mode`, and `tx_isolation` . For more information about configuration parameters for Aurora Serverless v1 clusters, see [Aurora Serverless v1 and parameter groups](#).

April 4, 2019

## [Aurora PostgreSQL supports db.r5 DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

April 4, 2019

### [Aurora PostgreSQL logical replication](#)

You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see [Using PostgreSQL logical replication](#).

March 28, 2019

### [GTID support for Aurora MySQL 2.04](#)

You can now use replication with the global transaction ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication between Aurora MySQL and an external MySQL 5.7-compatible database. The replication can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see [Using GTID-based replication for Aurora MySQL](#).

March 25, 2019

### [Uploading Aurora Serverless v1 logs to Amazon CloudWatch](#)

You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless v1 cluster. For more information, see [Viewing Aurora Serverless DB clusters](#). As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see [Working with DB parameter groups and DB cluster parameter groups](#).

February 25, 2019

### [Aurora MySQL supports db.t3 DB instance classes](#)

You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

February 25, 2019

### [Aurora MySQL supports db.r5 DB instance classes](#)

You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

February 25, 2019

[Performance Insights counters for Aurora MySQL](#)

You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see [Performance Insights dashboard components](#).

February 19, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Aurora MySQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora MySQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

February 6, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Aurora PostgreSQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora PostgreSQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

January 24, 2019

[Aurora backup billing](#)

You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled` , `SnapshotStorageUsed` , and `BackupRetentionPeriodStorageUsed` to monitor the space usage of your Aurora backups. For more information about how to use CloudWatch metrics, see [Overview of monitoring](#). For more information about how to manage storage for backup data, see [Understanding Aurora backup storage usage](#).

January 3, 2019

[Performance Insights counters](#)

You can now add performance counters to your Performance Insights charts. For more information, see [Performance Insights dashboard components](#).

December 6, 2018

[Aurora global database](#)

You can now create Aurora global databases. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see [Working with Amazon Aurora global database](#).

---

<a href="#">Query plan management in Aurora PostgreSQL</a>	Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see <a href="#">Managing query execution plans for Aurora PostgreSQL</a> .	November 20, 2018
<a href="#">Query editor for Aurora Serverless v1 (beta)</a>	You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see <a href="#">Using the query editor for Aurora Serverless v1</a> .	November 20, 2018
<a href="#">Data API for Aurora Serverless v1 (beta)</a>	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see <a href="#">Using the Data API for Aurora Serverless</a> .	November 20, 2018
<a href="#">TLS support for Aurora Serverless v1</a>	Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see <a href="#">TLS/SSL for Aurora Serverless</a> .	November 19, 2018

[Custom endpoints](#)

You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see [Amazon Aurora endpoints](#).

November 12, 2018

[IAM authentication support in Aurora PostgreSQL](#)

Aurora PostgreSQL now supports IAM authentication. For more information see [IAM database authentication](#).

November 8, 2018

[Custom parameter groups for restore and point in time recovery](#)

You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see [Restoring from a DB cluster snapshot](#) and [Restoring a DB cluster to a specified time](#).

October 15, 2018

[Deletion protection for Aurora DB clusters](#)

When you enable deletion protection for a DB cluster, the database cannot be deleted by any user. For more information, see [Deleting a DB cluster](#).

September 26, 2018

[Stop/Start feature Aurora](#)

You can now stop or start an entire Aurora cluster with a single operation. For more information, see [Stopping and starting an Aurora cluster](#).

September 24, 2018

[Parallel query feature for Aurora MySQL](#)

Aurora MySQL now offers an option to parallelize I/O work for queries across the Aurora storage infrastructure. This feature speeds up data-intensive analytic queries, which are often the most time-consuming operations in a workload. For more information, see [Parallel query for Aurora MySQL](#).
