When you invoke an Amazon service such as SageMaker AI or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the Amazon service into a materialized column so that the Amazon service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an Amazon service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.

UPDATE takes a row-level lock that can impact a running application. So you might need to use `SELECT . . . FOR UPDATE SKIP LOCKED`, or use `MATERIALIZED VIEW`.

Analytic queries that operate on a large number of rows in real time can combine batch-mode materialization with real-time processing. To do this, these queries assemble a `UNION ALL` of the pre-materialized results with a query over the rows that don't yet have materialized results. In some cases, such a `UNION ALL` is needed in multiple places, or the query is generated by a third-party application. If so, you can create a `VIEW` to encapsulate the `UNION ALL` operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary `SELECT` statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the `CONCURRENTLY` option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

Monitoring Aurora machine learning

You can monitor the `aws_ml` functions by setting the `track_functions` parameter in your custom DB cluster parameter group to `all`. By default, this parameter is set to `pl` which means that only procedure-language functions are tracked. By changing this to `all`, the `aws_ml` functions are also tracked. For more information, see [Run-time Statistics](#) in the PostgreSQL documentation.

For information about monitoring the performance of the SageMaker AI operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker AI](#) in the *Amazon SageMaker AI Developer Guide*.

With `track_functions` set to `all`, you can query the `pg_stat_user_functions` view to get statistics about the functions that you define and use to invoke Aurora machine learning services. For each function, the view provides the number of calls, `total_time`, and `self_time`.

To view the statistics for the `aws_sagemaker.invoke_endpoint` and the `aws_comprehend.detect_sentiment` functions, you can filter results by schema name using the following query.

```
SELECT * FROM pg_stat_user_functions
```

```
WHERE schemaname  
LIKE 'aws_%';
```

To clear the statistics, do as follows.

```
SELECT pg_stat_reset();
```

You can get the names of your SQL functions that call the `aws_sagemaker.invoke_endpoint` function by querying the PostgreSQL `pg_proc` system catalog. This catalog stores information about functions, procedures, and more. For more information, see [pg_proc](#) in the PostgreSQL documentation. Following is an example of querying the table to get the names of functions (`proname`) whose source (`prosrc`) includes the text `invoke_endpoint`.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

Code examples for Aurora using Amazon SDKs

The following code examples show how to use Aurora with an Amazon software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Aurora

The following code examples show how to get started using Aurora.

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
using Amazon.RDS;
using Amazon.RDS.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace AuroraActions;
```

```
public static class HelloAurora
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
        the
        // Amazon Relational Database Service (Amazon RDS).
        // Use your AWS profile name, or leave it blank to use the default
        profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonRDS>()
            ).Build();

        // Now the client is available for injection. Fetching it directly here
        for example purposes only.
        var rdsClient = host.Services.GetRequiredService<IAmazonRDS>();

        // You can use await and any of the async methods to get a response.
        var response = await rdsClient.DescribeDBClustersAsync(new
        DescribeDBClustersRequest { IncludeShared = true });
        Console.WriteLine($"Hello Amazon RDS Aurora! Let's list some clusters in
        this account:");
        foreach (var cluster in response.DBClusters)
        {
            Console.WriteLine($"\\tCluster: database: {cluster.DatabaseName}
            identifier: {cluster.DBClusterIdentifier}.");
        }
    }
}
```

- For API details, see [DescribeDBClusters](#) in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
project("hello_aurora")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of Aurora with an Amazon SDK

The following code examples show how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using AuroraActions;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
using Microsoft.Extensions.Logging;
using Microsoft.Extensions.Logging.Console;
using Microsoft.Extensions.Logging.Debug;

namespace AuroraScenario;

/// <summary>
/// Scenario for Amazon Aurora examples.
/// </summary>
public class AuroraScenario
{
    /*
    Before running this .NET code example, set up your development environment,
    including your credentials.

    This .NET example performs the following tasks:
    1. Return a list of the available DB engine families for Aurora MySQL using
    the DescribeDBEngineVersionsAsync method.
    2. Select an engine family and create a custom DB cluster parameter group
    using the CreateDBClusterParameterGroupAsync method.
    3. Get the parameter group using the DescribeDBClusterParameterGroupsAsync
    method.
    4. Get some parameters in the group using the
    DescribeDBClusterParametersAsync method.
    5. Parse and display some parameters in the group.
```

6. Modify the `auto_increment_offset` and `auto_increment_increment` parameters using the `ModifyDBClusterParameterGroupAsync` method.
7. Get and display the updated parameters using the `DescribeDBClusterParametersAsync` method with a source of "user".
8. Get a list of allowed engine versions using the `DescribeDBEngineVersionsAsync` method.
9. Create an Aurora DB cluster that contains a MySQL database and uses the parameter group.
using the `CreateDBClusterAsync` method.
10. Wait for the DB cluster to be ready using the `DescribeDBClustersAsync` method.
11. Display and select from a list of instance classes available for the selected engine and version
using the paginated `DescribeOrderableDBInstanceOptions` method.
12. Create a database instance in the cluster using the `CreateDBInstanceAsync` method.
13. Wait for the DB instance to be ready using the `DescribeDBInstances` method.
14. Display the connection endpoint string for the new DB cluster.
15. Create a snapshot of the DB cluster using the `CreateDBClusterSnapshotAsync` method.
16. Wait for DB snapshot to be ready using the `DescribeDBClusterSnapshotsAsync` method.
17. Delete the DB instance using the `DeleteDBInstanceAsync` method.
18. Delete the DB cluster using the `DeleteDBClusterAsync` method.
19. Wait for DB cluster to be deleted using the `DescribeDBClustersAsync` methods.
20. Delete the cluster parameter group using the `DeleteDBClusterParameterGroupAsync`.

Java

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
 * started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
```

```

*
* https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating\_how-
services-use-secrets\_RS.html
*
* This Java example performs the following tasks:
*
* 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
* by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
* 2. Selects an engine family and creates a custom DB cluster parameter group
* by invoking the describeDBClusterParameters method.
* 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
* method.
* 4. Gets parameters in the group by invoking the describeDBClusterParameters
* method.
* 5. Modifies the auto_increment_offset parameter by invoking the
* modifyDbClusterParameterGroupRequest method.
* 6. Gets and displays the updated parameters.
* 7. Gets a list of allowed engine versions by invoking the
* describeDbEngineVersions method.
* 8. Creates an Aurora DB cluster database cluster that contains a MySQL
* database.
* 9. Waits for DB instance to be ready.
* 10. Gets a list of instance classes available for the selected engine.
* 11. Creates a database instance in the cluster.
* 12. Waits for DB instance to be ready.
* 13. Creates a snapshot.
* 14. Waits for DB snapshot to be ready.
* 15. Deletes the DB cluster.
* 16. Deletes the DB cluster group.

Kotlin

SDK for Kotlin

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/**
```

```
Before running this Kotlin code example, set up your development environment, including your credentials.
```

```
For more information, see the following documentation topic:
```

```
https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html
```

```
This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:
```

```
https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating\_how-services-use-secrets\_RS.html
```

```
This Kotlin example performs the following tasks:
```

1. Returns a list of the available DB engines.
2. Creates a custom DB parameter group.
3. Gets the parameter groups.
4. Gets the parameters in the group.

```
5. Modifies the auto_increment_increment parameter.
6. Displays the updated parameter value.
7. Gets a list of allowed engine versions.
8. Creates an Aurora DB cluster database.
9. Waits for DB instance to be ready.
10. Gets a list of instance classes available for the selected engine.
11. Creates a database instance in the cluster.
12. Waits for the database instance in the cluster to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB instance.
16. Deletes the DB cluster.
17. Deletes the DB cluster group.
*/

Actions for Aurora using Amazon SDKs

The following code examples demonstrate how to perform individual Aurora actions with Amazon SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Aurora API and are code excerpts from larger programs that must be run in context. You can see actions in context in [Scenarios for Aurora using Amazon SDKs](#).

The following examples include only the most commonly used actions. For a complete list, see the [Amazon Aurora API Reference](#).

Examples

- [Use CreateDBCluster with an Amazon SDK](#)
- [Use CreateDBClusterParameterGroup with an Amazon SDK](#)
- [Use CreateDBClusterSnapshot with an Amazon SDK](#)
- [Use CreateDBInstance with an Amazon SDK](#)
- [Use DeleteDBCluster with an Amazon SDK](#)

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use CreateDBInstance with an Amazon SDK

The following code examples show how to use CreateDBInstance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Create an Amazon Relational Database Service (Amazon RDS) DB instance
/// with a particular set of properties. Use the action
DescribeDBInstancesAsync
/// to determine when the DB instance is ready to use.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <param name="dbEngine">The engine for the DB instance.</param>
/// <param name="dbEngineVersion">Version for the DB instance.</param>
/// <param name="instanceClass">Class for the DB instance.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> CreateDBInstanceInClusterAsync(
    string dbClusterIdentifier,
    string dbInstanceIdentifier,
    string dbEngine,
    string dbEngineVersion,
    string instanceClass)
{
    // When creating the instance within a cluster, do not specify the name
or size.
    var response = await _amazonRDS.CreateDBInstanceAsync(
        new CreateDBInstanceRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            DBInstanceIdentifier = dbInstanceIdentifier,

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use DeleteDBCluster with an Amazon SDK

The following code examples show how to use DeleteDBCluster.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Delete a particular DB cluster.
/// </summary>
/// <param name="dbClusterIdentifier">DB cluster identifier.</param>
/// <returns>DB cluster object.</returns>
public async Task<DBCluster> DeleteDBClusterByIdentifierAsync(string
dbClusterIdentifier)
{
    var response = await _amazonRDS.DeleteDBClusterAsync(
        new DeleteDBClusterRequest()
        {
            DBClusterIdentifier = dbClusterIdentifier,
            SkipFinalSnapshot = true
        });

    return response.DBCluster;
}
```

- For API details, see [DeleteDBCluster](#) in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

    Aws::RDS::Model::DeleteDBClusterRequest request;
    request.SetDBClusterIdentifier(dbClusterIdentifier);
    request.SetSkipFinalSnapshot(true);

    Aws::RDS::Model::DeleteDBClusterOutcome outcome =
        client.DeleteDBCluster(request);

    if (outcome.IsSuccess()) {
        std::cout << "DB cluster deletion has started."
                  << std::endl;
        clusterDeleting = true;
        std::cout
            << "Waiting for DB cluster to delete before deleting the
parameter group."
            << std::endl;
        std::cout << "This may take a while." << std::endl;
    }
    else {
        std::cerr << "Error with Aurora::DeleteDBCluster. "
                  << outcome.GetError().GetMessage()
                  << std::endl;
        result = false;
    }
}
```

Use `DeleteDBClusterParameterGroup` with an Amazon SDK

The following code examples show how to use `DeleteDBClusterParameterGroup`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

Amazon SDK for .NET

Note

- For API details, see [DeleteDBClusterParameterGroup](#) in *Amazon SDK for Rust API reference*.

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use DeleteDBInstance with an Amazon SDK

The following code examples show how to use DeleteDBInstance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics](#)

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
/// <summary>
/// Delete a particular DB instance.
/// </summary>
/// <param name="dbInstanceIdentifier">DB instance identifier.</param>
/// <returns>DB instance object.</returns>
public async Task<DBInstance> DeleteDBInstanceByIdentifierAsync(string
dbInstanceIdentifier)
{
    var response = await _amazonRDS.DeleteDBInstanceAsync(
        new DeleteDBInstanceRequest()
        {
            DBInstanceIdentifier = dbInstanceIdentifier,
            SkipFinalSnapshot = true,
            DeleteAutomatedBackups = true
        });

    return response.DBInstance;
}
```

- For API details, see [DeleteDBInstance](#) in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

    Aws::RDS::Model::DeleteDBInstanceRequest request;
    request.SetDBInstanceIdentifier(dbInstanceIdentifier);
    request.SetSkipFinalSnapshot(true);
    request.SetDeleteAutomatedBackups(true);

    Aws::RDS::Model::DeleteDBInstanceOutcome outcome =
        client.DeleteDBInstance(request);

    if (outcome.IsSuccess()) {
        std::cout << "DB instance deletion has started."
                  << std::endl;
        instanceDeleting = true;
        std::cout
            << "Waiting for DB instance to delete before deleting the
parameter group."
            << std::endl;
    }
    else {
        std::cerr << "Error with Aurora::DeleteDBInstance. "
                  << outcome.GetError().GetMessage()
                  << std::endl;
        result = false;
    }
}
```

PowerShell

Tools for PowerShell

Example 1: This example lists the DB engine versions that support a specific DB instance class in an Amazon Web Services Region.

```
$params = @{
    Engine = 'aurora-postgresql'
    DBInstanceClass = 'db.r5.large'
    Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

Example 2: This example lists the DB instance classes that are supported for a specific DB engine version in an Amazon Web Services Region.

```
$params = @{
    Engine = 'aurora-postgresql'
    EngineVersion = '13.6'
    Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

Scenarios for Aurora using Amazon SDKs

The following code examples show you how to implement common scenarios in Aurora with Amazon SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Aurora or combined with other Amazon Web Services services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- [Create a lending library REST API](#)
- [Create an Aurora Serverless work item tracker](#)

Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and Amazon Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.
- Use Amazon Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.
- Use Amazon Chalice to deploy a serverless REST API to Amazon API Gateway and Amazon Lambda.
- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

Amazon SDK for .NET

Shows how to use the Amazon SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with Amazon services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the Amazon SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with Amazon Web Services services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

SDK for PHP

Shows how to use the Amazon SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service

(Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with Amazon services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with Amazon Web Services services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an Amazon Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- Aurora

- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of Amazon SDK developer guides and code examples, see [Using this service with an Amazon SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

Database engine	Best practices
Amazon Aurora MySQL	See Best practices with Amazon Aurora MySQL
Amazon Aurora PostgreSQL	See Best practices with Amazon Aurora PostgreSQL

Note

For common recommendations for Aurora, see [Recommendations from Amazon Aurora](#).

Topics

- [Basic operational guidelines for Amazon Aurora](#)
- [DB instance RAM recommendations](#)
- [Amazon database drivers](#)
- [Monitoring Amazon Aurora](#)
- [Working with DB parameter groups and DB cluster parameter groups](#)
- [Amazon Aurora best practices video](#)

Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:

- `VolumeReadIOPS` – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of `VolumeReadIOPS` should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

Tip

If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

- `BufferCacheHitRatio` – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory.

A high hit ratio indicates that your DB instance has enough memory available. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. Investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

For more information, see [Amazon CloudWatch metrics for Amazon Aurora](#).

Amazon database drivers

We recommend the Amazon suite of drivers for application connectivity. The drivers have been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the Amazon suite of drivers is to have built-in support for these service features.

For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

Monitoring Amazon Aurora

Amazon Aurora provides various metrics and insights that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the Amazon Web Services Management Console, Amazon CLI, and CloudWatch API, to view Aurora metrics. You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see [Viewing combined metrics with the Performance Insights dashboard](#).

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information see, [Creating a performance analysis report in Performance Insights](#).

Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see [Backing up and restoring an Amazon Aurora DB cluster](#).

Amazon Aurora best practices video

The Amazon Online Tech Talks channel on YouTube includes a video presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. See [Amazon Aurora best practices for high availability](#).

Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as [Managing performance and scaling for Aurora DB clusters](#), [Amazon Aurora MySQL performance enhancements](#), [Performance and scaling for Amazon Aurora PostgreSQL](#), and [Monitoring DB load with Performance Insights on Amazon Aurora](#).

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your

Amazon representative to see if there are Aurora best practices or case studies for your type of application.

1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as *provisioned*. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the Amazon Database Blog post [How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads](#). Another might be demand-based scaling, described in [Amazon Aurora Auto Scaling with Aurora Replicas](#) in the *Amazon Aurora User Guide*. Others might be performance gains or simplified database operations.

2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. *High velocity* involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 SELECT statements per second. Again depending on workload, such a cluster can process 200,000 INSERT, UPDATE, and DELETE statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 [replicas](#), each of which is on average within 10–20 milliseconds of the primary instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other Amazon services, the Amazon Web Services Management Console, and the Amazon CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

3. Practice with the Amazon Web Services Management Console or Amazon CLI

As a next step, practice with the Amazon Web Services Management Console or the Amazon CLI, to become familiar with these tools and with Aurora.

Practice with the Amazon Web Services Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the Amazon Web Services Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see [Replication with Amazon Aurora](#). Scale the DB instances up or down by changing the Amazon instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the Amazon Web Services Management Console in the beginning. After you understand what you can do with Aurora, you

can progress to automating those operations using the Amazon CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

Practice with the Amazon CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the Amazon CLI if you're not already. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as Amazon CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the Amazon CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see [Update behaviors of stack resources](#) in the *Amazon CloudFormation User Guide*.

4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see [Creating an Amazon Aurora DB cluster](#).

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Turn off **Easy create**. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Use a recent DB engine version. These combinations of database engine and version have wide compatibility with other Aurora features and substantial customer usage for production applications.
 - Aurora MySQL version 3.x (MySQL 8.0 compatibility)
 - Aurora PostgreSQL version 15.x or 16.x
- Choose the **Dev/Test** template. This choice isn't significant for your proof-of-concept activities.
- For **DB instance class**, choose **Memory optimized classes** and one of the **xlarge** instance classes. You can adjust the instance class up or down later.
- Under **Multi-AZ Deployment**, choose **Create an Aurora Replica or Reader node in a different AZ**. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "writer," because different DB instances assume those roles as needed. We recommend using something like `clustername-az-serialnumber`, for example `myprodapddb-a-01`. These pieces uniquely identify the DB instance and its placement.
- Set the backup retention high for the Aurora cluster. With a long retention period, you can do point-in-time recovery (PITR) for a period up to 35 days. You can reset your database to a known state after running tests involving DDL and data manipulation language (DML) statements. You can also recover if you delete or change data by mistake.
- Turn on additional recovery, logging, and monitoring features at cluster creation. Turn on all the choices that are available under **Backtrack**, **Performance Insights**, **Monitoring**, and **Log exports**. With these features enabled, you can test the suitability of features such as backtracking, Enhanced Monitoring, or Performance Insights for your workload. You can also easily investigate performance and perform troubleshooting during the proof of concept.

5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the **Connectivity** tab of the detail page of your cluster. The cluster endpoint is the one labeled **Writer**. The other endpoint, labeled **Reader**, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see [Connecting to an Amazon Aurora DB cluster](#).

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the Amazon Schema Conversion Tool (Amazon SCT) to simplify the process. For details, see the [Amazon Schema Conversion Tool User Guide](#). For general details about migration and porting activities, see the [Migrating Your Databases to Amazon Aurora](#) Amazon whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see [Migrating data to an Amazon Aurora MySQL DB cluster](#) or [Migrating data to Amazon Aurora with PostgreSQL compatibility](#) depending on the database engine you're using in the proof of concept.

Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the Amazon Database Migration Service (Amazon DMS). For details about Amazon DMS, see the [Amazon Database Migration Service User Guide](#).

For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the Amazon SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see [9. Connect to Aurora](#).

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in [Introducing the Aurora storage engine](#) on the Amazon Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see [Amazon Aurora DB cluster and DB instance parameters](#). For the configuration settings that are or aren't applicable to Aurora clusters, see [Aurora MySQL configuration parameters](#) or [Amazon Aurora PostgreSQL parameters](#) depending on your database engine.

9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as SELECT statement, or a write such as a CREATE or INSERT statement.

As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the *primary instance*. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing SELECT statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

 **Note**

Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle SELECT statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.
- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.

- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.

For general information about connection management and endpoints for Aurora, see [Connecting to an Amazon Aurora DB cluster](#). For a deep dive on this subject, see [Aurora MySQL database administrator's handbook – Connection management](#).

10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same Amazon Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on Amazon Regions, see [Regions and Availability Zones](#) in the *Amazon RDS User Guide*. To learn more about the Amazon VPC service, see [What is Amazon VPC?](#) in the *Amazon VPC User Guide*.

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in [8. Specify configuration settings](#).

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different Amazon instance classes, numbers of Amazon Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see [Creating a DB cluster snapshot](#) and [Restoring from a DB cluster snapshot](#).

11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the **Monitoring** tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

To have more choices on the **Monitoring** tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the **Monitoring** tab for that specific instance.

After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To view the throughput and latency metrics, check the **Monitoring** tab for a given Aurora cluster in the [Amazon RDS console](#). The following screenshot shows an example of the **Select Latency**, **DML Latency**, **Select Throughput**, and **DML Throughput** metrics on the **Monitoring** tab.

Select Latency (Milliseconds)

DML Latency (Milliseconds)

Select Throughput (Count/Second)

DML Throughput (Count/Second)

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

Tip

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

Tip

Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the SELECT queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add

DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

 Tip

For a proof of concept, set up all the DB instances in an Aurora cluster with the same Amazon instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your Amazon Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

 Tip

The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.

When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see [Testing Amazon Aurora MySQL using fault injection queries](#).

As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for SELECT queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only SELECT statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other Amazon Regions and restore into other Amazon Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the Amazon whitepaper [Aurora migration handbook](#).

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore Amazon services and features such as Amazon Secrets Manager and Amazon Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see [Managing performance and scaling for Aurora DB clusters](#), [Amazon Aurora MySQL performance enhancements](#), [Performance and scaling for Amazon Aurora PostgreSQL](#), and [Monitoring DB load with Performance Insights on Amazon Aurora](#). If you do additional tuning, make sure that you're familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the Amazon whitepaper [Aurora MySQL database administrator's handbook – Connection management](#).

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other Amazon services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. Amazon services that address such use cases include the following:
 - [Amazon Redshift](#)
 - [Amazon EMR](#)
 - [Amazon Athena](#)
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
 - [Amazon Glue](#)
 - [Amazon DMS](#)
 - [Importing from Amazon S3](#), as described in the *Amazon Aurora User Guide*
 - [Exporting to Amazon S3](#), as described in the *Amazon Aurora User Guide*
 - Many other popular ETL tools

Security in Amazon Aurora

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [Amazon compliance programs](#). To learn about the compliance programs that apply to Amazon Aurora (Aurora), see [Amazon services in scope by compliance program](#).
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other Amazon services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see [Amazon VPC and Amazon Aurora](#) .
- Use Amazon Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

To review IAM policy examples, see [Identity-based policy examples for Amazon Aurora](#) .

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).
- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see [Encrypting Amazon Aurora resources](#).
- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

For information about security with Aurora MySQL, see [Security with Amazon Aurora MySQL](#). For information about security with Aurora PostgreSQL, see [Security with Amazon Aurora PostgreSQL](#).

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the [Amazon RDS user guide](#).

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the Amazon CLI to access the RDS API interactively. Some RDS API operations and Amazon CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see [Amazon RDS API reference](#). For more information about the Amazon CLI, see [Amazon Command Line Interface reference for Amazon RDS](#).

Note

You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, automatic failover, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL and Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics

- [Password authentication](#)
- [IAM database authentication](#)
- [Kerberos authentication](#)

Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database

authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with Amazon Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *Amazon Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *Amazon Secrets Manager User Guide*.

IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication](#).

Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

To use credentials from your self-managed Active Directory, you need to setup a trust relationship to the Amazon Directory Service for Microsoft Active Directory that the DB cluster is joined to.

Aurora PostgreSQL and Aurora MySQL support one-way and two-way forest trust relationships with forest-wide authentication or selective authentication.

In some scenarios, you can configure Kerberos authentication over an external trust relationship. This requires your self-managed Active Directory to have additional settings. This includes but is not limited to [Kerberos Forest Search Order](#).

Aurora supports Kerberos authentication for Aurora MySQL and Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication for Aurora MySQL](#) and [Using Kerberos authentication with Aurora PostgreSQL](#).

Password management with Amazon Aurora and Amazon Secrets Manager

Amazon Aurora integrates with Secrets Manager to manage master user passwords for your DB clusters.

Topics

- [Region and version availability](#)
- [Limitations for Secrets Manager integration with Amazon Aurora](#)
- [Overview of managing master user passwords with Amazon Secrets Manager](#)
- [Benefits of managing master user passwords with Secrets Manager](#)
- [Permissions required for Secrets Manager integration](#)

- [Managing the master user password for a DB cluster with Secrets Manager](#)
- [Rotating the master user password secret for a DB cluster](#)
- [Viewing the details about a secret for a DB cluster](#)

Region and version availability

Feature availability and support varies across specific versions of each database engine and across Amazon Web Services Regions. For more information about version and Region availability with Secrets Manager integration with Amazon Aurora, see [Supported Regions and Aurora DB engines for Secrets Manager integration](#).

Limitations for Secrets Manager integration with Amazon Aurora

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Amazon RDS Blue/Green Deployments
- DB clusters that are part of an Aurora global database
- Aurora Serverless v1 DB clusters
- Aurora read replicas

Overview of managing master user passwords with Amazon Secrets Manager

With Amazon Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the [Amazon Secrets Manager User Guide](#).

When you store database secrets in Secrets Manager, your Amazon Web Services account incurs charges. For information about pricing, see [Amazon Secrets Manager Pricing](#).

You can specify that Aurora manages the master user password in Secrets Manager for an Amazon Aurora DB cluster when you perform one of the following operations:

- Create a DB cluster
- Modify a DB cluster
- Restore a DB cluster from Amazon S3 (Aurora MySQL only)

When you specify that Aurora manages the master user password in Secrets Manager, Aurora generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

Aurora manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB cluster that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see [Retrieve secrets from Amazon Secrets Manager](#) and [Connect to a SQL database with credentials in an Amazon Secrets Manager secret](#) in the *Amazon Secrets Manager User Guide*.

Benefits of managing master user passwords with Secrets Manager

Managing Aurora master user passwords with Secrets Manager provides the following benefits:

- Aurora automatically generates database credentials.
- Aurora automatically stores and manages database credentials in Amazon Secrets Manager.
- Aurora rotates database credentials regularly, without requiring application changes.

- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with Amazon CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the [Amazon Secrets Manager User Guide](#).

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see [Identity and access management for Amazon Aurora](#).

For create, modify, or restore operations, the user who specifies that Aurora manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

The `kms:DescribeKey` permission is required to access your customer-managed key for the `MasterUserSecretKmsKeyId` and to describe `aws/secretsmanager`.

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`
- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

Enforcing Aurora management of the master user password in Amazon Secrets Manager

You can use IAM condition keys to enforce Aurora management of the master user password in Amazon Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by Aurora in Secrets Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
        "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
      "Resource": "*",
      "Condition": {
        "Bool": {
          "rds:ManageMasterUserPassword": false
        }
      }
    }
  ]
}
```

Note

This policy enforces password management in Amazon Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the cluster.

To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing clusters that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see [Policy condition keys for Aurora](#) and [Example policies: Using condition keys](#).

Managing the master user password for a DB cluster with Secrets Manager

You can configure Aurora management of the master user password in Secrets Manager when you perform the following actions:

- [Creating an Amazon Aurora DB cluster](#)
- [Modifying an Amazon Aurora DB cluster](#)
- [Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster](#)

You can use the RDS console, the Amazon CLI, or the RDS API to perform these actions.

Console

Follow the instructions for creating or modifying a DB cluster with the RDS console:

- [Creating a DB cluster](#)
- [Modifying a DB instance in a DB cluster](#)

In the RDS console, you can modify any DB instance to specify the master user password management settings for the entire DB cluster.

- [Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket](#)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by Aurora in Secrets Manager. To do so when you are creating or restoring a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in Amazon Secrets Manager** setting when you are creating or restoring a DB cluster.

▼ **Credentials Settings**

Master username [Info](#)
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

Manage master credentials in **Secrets Manager**
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password.

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm master password [Info](#)

When you select this option, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

▼ **Credentials Settings**

Master username [Info](#)
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

Manage master credentials in **Secrets Manager**
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

Select the encryption key [Info](#)
You can encrypt using the KMS key that Secrets Manager creates or a customer managed KMS key that you create.

▼

[Add new key](#) 

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see [Settings for Aurora DB clusters](#). For more information about the available settings when you are modifying a DB cluster, see [Settings for Amazon Aurora](#).

Amazon CLI

To specify that Aurora manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- [create-db-cluster](#)
- [modify-db-cluster](#)
- [restore-db-cluster-from-s3](#)

When you specify the `--manage-master-user-password` option in these commands, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see [Settings for Aurora DB clusters](#). For more information about the available settings when you are modifying a DB cluster, see [Settings for Amazon Aurora](#).

This example creates a DB cluster and specifies that Aurora manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier sample-cluster \  
  --engine aurora-mysql \  
  --engine-version 8.0 \  
  --master-username admin \  
  --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier sample-cluster ^  
  --engine aurora-mysql ^  
  --engine-version 8.0 ^  
  --master-username admin ^  
  --manage-master-user-password
```

RDS API

To specify that Aurora manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)
- [RestoreDBClusterFromS3](#)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB cluster

When Aurora rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Aurora changes the master user password for the DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB cluster. For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

You can rotate a master user password secret immediately with the RDS console, the Amazon CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the DB cluster and select **Rotate secret immediately** in **Settings**.

Settings

DB engine version
Version number of the database engine to be used for this database

5.7.mysql_aurora.2.10.2 ▼

DB instance identifier [Info](#)
Type a name for your DB instance. The name must be unique across all DB instances owned by your account in the current Region.

database-1-instance-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

DB cluster identifier
Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your account in the current Region.

database-1

Manage master credentials in **Secrets Manager**
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

Rotate secret immediately
When you rotate a secret, you update the credentials in both the secret and the database.

Follow the instructions for modifying a DB cluster with the RDS console in [Modifying the DB cluster by using the console, CLI, and API](#). You must choose **Apply immediately** on the confirmation page.

Amazon CLI

To rotate a master user password secret using the Amazon CLI, use the [modify-db-cluster](#) command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```

```
--db-cluster-identifier mydbcluster \  
--rotate-master-user-password \  
--apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --rotate-master-user-password ^  
  --apply-immediately
```

RDS API

You can rotate a master user password secret using the [ModifyDBCluster](#) operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB cluster

You can retrieve your secrets using the console (<https://console.amazonaws.cn/secretsmanager/>) or the Amazon CLI ([get-secret-value](#) Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by Aurora in Secrets Manager with the RDS console, the Amazon CLI, or the RDS API.

Console

To view the details about a secret managed by Aurora in Secrets Manager

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster to show its details.
4. Choose the **Configuration** tab.

In **Master Credentials ARN**, you can view the secret ARN.

The screenshot shows the Amazon Aurora console Configuration tab for a database cluster. The 'Configuration' section includes fields for DB cluster role, Regional cluster, Engine version (5.7.mysql_aurora.2.10.2), Resource ID, Amazon Resource Name (ARN), and Network type (IPv4). The 'Capacity type' is Provisioned: single-master, and the 'Availability' section shows IAM DB authentication is Not enabled, Master username is admin, and Multi-AZ is 2 Zones. The 'Master Credentials ARN' field is highlighted with a red box and contains the following text:

```
arn:aws:secretsmanager:ap-south-1:123456789012:secret:rds:cluster-a786cc29-a459-4922-9c03-9442b290c1d1-4TWyUb
```

A link labeled 'Manage in Secrets Manager' is provided below the ARN.

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

Amazon CLI

You can use the RDS Amazon CLI [describe-db-clusters](#) command to find the following information about a secret managed by Aurora in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

The possible status values include the following:

- `creating` – The secret is being created.
- `active` – The secret is available for normal use and rotation.
- `rotating` – The secret is being rotated.
- `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database

credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the [modify-db-cluster](#) command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {  
    "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",  
    "SecretStatus": "active",  
    "KmsKeyId": "arn:aws:kms:eu-  
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"  
}
```

When you have the secret ARN, you can view details about the secret using the [get-secret-value](#) Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \  
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^  
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by Aurora in Secrets Manager using the [DescribeDBClusters](#) RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the [GetSecretValue](#) Secrets Manager operation.

Data protection in Amazon RDS

The Amazon [shared responsibility model](#) applies to data protection in Amazon Relational Database Service. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see the [Data Privacy FAQ](#).

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see [Working with CloudTrail trails](#) in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

Topics

- [Encrypting Amazon Aurora resources](#)
- [Amazon KMS key management](#)
- [Using SSL/TLS to encrypt a connection to a DB cluster](#)
- [Rotating your SSL/TLS certificate](#)

Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.

Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

Note

For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across Amazon Regions.

Topics

- [Overview of encrypting Amazon Aurora resources](#)
- [Encrypting an Amazon Aurora DB cluster](#)
- [Determining whether encryption is turned on for a DB cluster](#)
- [Availability of Amazon Aurora encryption](#)
- [Encryption in transit](#)
- [Limitations of Amazon Aurora encrypted DB clusters](#)

Overview of encrypting Amazon Aurora resources

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest. For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. For more information about the availability and limitations of encryption, see [Availability of Amazon Aurora encryption](#) and [Limitations of Amazon Aurora encrypted DB clusters](#).

Amazon Aurora uses an Amazon Key Management Service key to encrypt these resources. Amazon KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. You can use an Amazon managed key, or you can create customer managed keys.

When you create an encrypted DB cluster, you can choose a customer managed key or the Amazon managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the Amazon managed key for your new DB cluster. Amazon Aurora creates an Amazon managed key for Amazon Aurora for your Amazon account. Your Amazon account has a different Amazon managed key for Amazon Aurora for each Amazon Region.

To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the [Amazon Key Management Service \(Amazon KMS\)](#).

Using Amazon KMS, you can create customer managed keys and define the policies to control the use of these customer managed keys. Amazon KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported Amazon services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with Amazon KMS, see [Amazon Service Integration](#). Some considerations about using KMS keys:

- Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you must change the encryption key for your DB cluster, create a manual snapshot of your cluster and enable encryption while copying the snapshot. For more information, see [re:Post Knowledge article](#).

- If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.
- You can't share a snapshot that has been encrypted using the Amazon managed key of the Amazon account that shared the snapshot.
- Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster.
- You can also encrypt a read replica of an Amazon Aurora encrypted cluster.

Important

Amazon Aurora can lose access to the KMS key for a DB cluster when you disable the KMS key. In these cases, the encrypted DB cluster goes into `inaccessible-encryption-credentials-recoverable` state. The DB cluster remains in this state for seven days, during which the instance is stopped. API calls made to the DB cluster during this time might not succeed. To recover the DB cluster, enable the KMS key and restart this DB cluster. Enable the KMS key from the Amazon Web Services Management Console, Amazon CLI, or RDS API. Restart the DB cluster using the Amazon CLI command [start-db-cluster](#) or Amazon Web Services Management Console.

The `inaccessible-encryption-credentials-recoverable` state only applies to DB clusters that can stop. This recoverable state is not applicable to instances that can't

stop, such as clusters with cross-Region read replicas. For more information, see [the section called "Limitations"](#).

If the DB cluster isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB cluster is not usable anymore and you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups for encrypted DB clusters to guard against the loss of encrypted data in your databases.

During the creation of a DB cluster, Aurora checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB cluster. Revoking the calling principals access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB cluster from the snapshot without specifying a different KMS key, the new cluster uses the KMS key from the source account. Revoking access to the key after you create the DB cluster does not affect the cluster. However, disabling the key impacts all DB clusters encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

For more information about KMS keys, see [Amazon KMS keys](#) in the *Amazon Key Management Service Developer Guide* and [Amazon KMS key management](#).

Encrypting an Amazon Aurora DB cluster

To encrypt a new DB cluster, choose **Enable encryption** on the console. For information on creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#).

If you use the [create-db-cluster](#) Amazon CLI command to create an encrypted DB cluster, set the `--storage-encrypted` parameter. If you use the [CreateDBCluster](#) API operation, set the `StorageEncrypted` parameter to `true`.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

If you use the Amazon CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to

any key identifier for the KMS key. To use a customer managed key in a different Amazon account, specify the key ARN or alias ARN.

Determining whether encryption is turned on for a DB cluster

You can use the Amazon Web Services Management Console, Amazon CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

Console

To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the **Configuration** tab and check the **Encryption** value.

It shows either **Enabled** or **Not enabled**.

The screenshot shows the Amazon RDS console interface for an Aurora MySQL DB cluster named 'aurora-cl-mysql'. The 'Configuration' tab is selected, and the 'Encryption' section is highlighted with a red box, showing 'Encryption Enabled'.

DB identifier	Role	Engine	Region & AZ	Size	Status
aurora-cl-mysql	Regional cluster	Aurora MySQL	us-east-1	2 instances	Available
dbinstance4	Writer instance	Aurora MySQL	us-east-1a	db.t3.medium	Available
dbinstance1	Reader instance	Aurora MySQL	us-east-1b	db.t3.medium	Available

Configuration details:

Configuration	Capacity type	Availability	Encryption
DB cluster role Regional cluster	Provisioned: single-master DB cluster ID aurora-cl-mysql	IAM DB authentication Enabled	Encryption Enabled

Amazon CLI

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon CLI, call the [describe-db-clusters](#) command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "*[].[StorageEncrypted:StorageEncrypted]" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the [DescribeDBClusters](#) operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

Note

Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

Encryption in transit

Encryption at the physical layer

All data flowing across Amazon Web Services Regions over the Amazon global network is automatically encrypted at the physical layer before it leaves Amazon secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section may provide additional protections.

Encryption provided by Amazon VPC peering and Transit Gateway cross-Region peering

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves Amazon secured facilities.

Encryption between instances

Amazon provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
 - **General purpose:** M6i, M6id, M6in, M6idn, M7g
 - **Memory optimized:** R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same Amazon Web Services Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't turn off encryption on an encrypted DB cluster.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
- To copy an encrypted snapshot from one Amazon Region to another, you must specify the KMS key in the destination Amazon Region. This is because KMS keys are specific to the Amazon Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see [Envelope encryption](#) in the *Amazon Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

Amazon KMS key management

Amazon Aurora automatically integrates with [Amazon Key Management Service \(Amazon KMS\)](#) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see [Envelope encryption](#) in the *Amazon Key Management Service Developer Guide*.

You can use two types of Amazon KMS keys to encrypt your DB clusters.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see [Customer managed keys](#) in the *Amazon Key Management Service Developer Guide*.
- *Amazon managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an Amazon service that is integrated with Amazon KMS. By default, the RDS Amazon managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS Amazon managed key. For more information about Amazon managed keys, see [Amazon managed keys](#) in the *Amazon Key Management Service Developer Guide*.

To manage KMS keys used for Amazon Aurora encrypted DB clusters, use the [Amazon Key Management Service \(Amazon KMS\)](#) in the [Amazon KMS console](#), the Amazon CLI, or the Amazon KMS API. To view audit logs of every action taken with an Amazon managed or customer managed key, use [Amazon CloudTrail](#). For more information about key rotation, see [Rotating Amazon KMS keys](#).

Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the [kms:ViaService condition key](#) to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an Amazon service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in Aurora, use the [kms:ViaService condition key](#) with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the [Amazon RDS encryption context](#) as a condition for using the customer managed key for encryption.

For more information, see [Allowing users in other accounts to use a KMS key](#) in the *Amazon Key Management Service Developer Guide* and [Key policies in Amazon KMS](#).

Amazon RDS encryption context

When Aurora uses your KMS key, or when Amazon EBS uses the KMS key on behalf of Aurora, the service specifies an [encryption context](#). The encryption context is [additional authenticated data](#) (AAD) that Amazon KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your [Amazon CloudTrail](#) logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Aurora always uses the DB cluster ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:dbc-id": "cluster-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB cluster for which your KMS key was used.

When your KMS key is used for a specific DB cluster and a specific Amazon EBS volume, both the DB cluster ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:dbc-id": "cluster-BRG7VYS3SVIFQW7234EJQ0M5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate**, for your database. For more information about certificate authorities, see [Certificate authorities](#).
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see [Certificate bundles for specific Amazon Web Services Regions](#).

Note

All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
 - [Security with Amazon Aurora MySQL](#)
 - [Security with Amazon Aurora PostgreSQL](#)

Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	<p>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most Amazon Web Services Regions.</p> <p>In the Amazon GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.</p>	<p>Amazon RDS <i>region-id</i> <i>entifier</i> RSA2048 G1</p>

Certificate authority (CA)	Description	Common name (CN)
	This CA supports automatic server certificate rotation.	

Note

If you are using the Amazon CLI, you can see the validities of the certificate authorities listed above by using [describe-certificates](#).

These CA certificates are included in the regional and global certificate bundle. When you use the `rds-ca-rsa2048-g1` CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

Setting the CA for your database

You can set the CA for a database when you perform the following tasks:

- Create an Aurora DB cluster – You can set the CA for a DB instance in an Aurora cluster when you create the first DB instance in the DB cluster using the Amazon CLI or RDS API. Currently, you can't set the CA for the DB instances in a DB cluster when you create the DB cluster using the RDS console. For instructions, see [Creating an Amazon Aurora DB cluster](#).
- Modify a DB instance – You can set the CA for a DB instance in a DB cluster by modifying it. For instructions, see [Modifying a DB instance in a DB cluster](#).

Note

The default CA is set to `rds-ca-rsa2048-g1`. You can override the default CA for your Amazon Web Services account by using the [modify-certificates](#) command.

The available CAs depend on the DB engine and DB engine version. When you use the Amazon Web Services Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

Certificate authority - optional [Info](#)

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1 (default)

Expiry: May 24, 2061

If you don't select a certificate authority, RDS chooses one for you.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the Amazon CLI, you can set the CA for a DB instance using the [create-db-instance](#) or [modify-db-instance](#) command.

If you're using the Amazon CLI, you can see the available CAs for your account by using the [describe-certificates](#) command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the [describe-db-engine-versions](#) command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
  "DBEngineVersions": [
    {
      "Engine": "postgres",
      "MajorEngineVersion": "13",
      "EngineVersion": "13.4",
      "DBParameterGroupFamily": "postgres13",
      "DBEngineDescription": "PostgreSQL",
      "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
      "ValidUpgradeTarget": [],
      "SupportsLogExportsToCloudwatchLogs": false,
      "SupportsReadReplica": true,
      "SupportedFeatureNames": [
        "Lambda"
      ]
    }
  ]
}
```

```

    ],
    "Status": "available",
    "SupportsParallelQuery": false,
    "SupportsGlobalDatabases": false,

DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](#).

Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.

The screenshot shows the Amazon Aurora console interface. The 'Connectivity & security' tab is selected and highlighted with a red box. Below the tab, the console displays details for the database instance, organized into three columns: Endpoint & port, Networking, and Security. The 'Certificate authority' section in the Security column is highlighted with a red box, showing the following details:

Section	Value
Endpoint & port	Endpoint: mysql-8-0-23. .eu-west-1.rds.amazonaws.com Port: 3306
Networking	Availability Zone: eu-west-1c VPC: vpc-0946fa4490fbdfd65 Subnet group: default-vpc-0946fa4490fbdfd65 Subnets: subnet-0cd82b36ede3b3b8e, subnet-00c5326717b78fe7e, subnet-0bda8129ae376fe70
Security	VPC security groups: default (sg-062c8f43392f87f49) Active Publicly accessible: No Certificate authority: rds-ca-2019 Info Certificate authority date: August 22, 2024, 19:08 (UTC+02:00) DB instance certificate expiration date: August 22, 2024, 19:08 (UTC+02:00)

If you're using the Amazon CLI, you can view the details about the CA for a DB instance by using the [describe-db-instances](#) command.

Download certificate bundles for Aurora

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the Amazon Web Services Region where you host your database.

Certificate bundles for specific Amazon Web Services Regions

To get a certificate bundle for the China (Beijing) Amazon Region or China (Ningxia) Amazon Region, download it from <https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.pem>. If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle from <https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.p7b>.

The bundle contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

To get a certificate bundle, download from the link for the Amazon Region in the following table.

Amazon Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
China (Beijing)	cn-north-1-bundle.pem	cn-north-1-bundle.p7b
China (Ningxia)	cn-northwest-1-bundle.pem	cn-northwest-1-bundle.p7b

Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates `rds-ca-2019` expired in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, consider using the new CA certificate `rds-ca-rsa2048-g1`. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA

certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an Amazon security best practice. For information about the new certificates and the supported Amazon Regions, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

To update the CA certificate for your database, use the following methods:

- [Updating your CA certificate by modifying your DB instance](#)
- [Updating your CA certificate by applying maintenance](#)

Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy and Aurora Serverless v1 use certificates from the Amazon Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](#).
- If you're using Aurora Serverless v1, downloading Amazon RDS certificates isn't required. For more information, see [Using TLS/SSL with Aurora Serverless v1](#).
- If you're using a Go version 1.15 application with a DB instance that was created or updated to the `rds-ca-2019` certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to `rds-ca-rsa2048-g1`.

Use the `modify-db-instance` command, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see [Go GitHub issue #39568](#).

Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from `rds-ca-2019` to `rds-ca-rsa2048-g1`.

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see [Automatic server certificate rotation](#).

To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in [Using SSL/TLS to encrypt a connection to a DB cluster](#).
2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- [Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates](#)
- [Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates](#)

For a sample script that updates a trust store for a Linux operating system, see [Sample script for importing certificates into your trust store](#).

Note

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the Amazon Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the [describe-db-engine-versions](#) command and check the `SupportsCertificateRotationWithoutRestart` flag.

Note

Reboot your Babelfish cluster after modifying to update the CA certificate.

Important

If you are experiencing connectivity issues after certificate expiry, use the `apply immediately` option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the Amazon CLI. By default, this operation is scheduled to run during your next maintenance window.

To set an override for your cluster CA that's different from the default RDS CA, use the [modify-certificates](#) CLI command.

You can use the Amazon Web Services Management Console or the Amazon CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance .

Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

RDS > Databases > database-1 > database-1-instance-1

database-1-instance-1

Related

Filter by databases

DB identifier	Status	Role	Engine	Region & AZ
database-1	Available	Regional cluster	Aurora MySQL	us-west-2
database-1-instance-1	Available	Writer instance	Aurora MySQL	us-west-2a

- In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.

Certificate authority [Info](#)

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1	
rds-ca-2019	
rds-ca-ecc384-g1	
rds-ca-rsa4096-g1	
rds-ca-rsa2048-g1	✓

connect to your
on of connectivity

- Choose **Continue** and check the summary of modifications.
- To apply the changes immediately, choose **Apply immediately**.
- On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

⚠ Important

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

Amazon CLI

To use the Amazon CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance, call the [modify-db-instance](#) or [modify-db-cluster](#) command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

Important

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

Note

If your instance requires reboot, you can use the [modify-db-instance](#) CLI command and specify the `--no-certificate-rotation-restart` option.

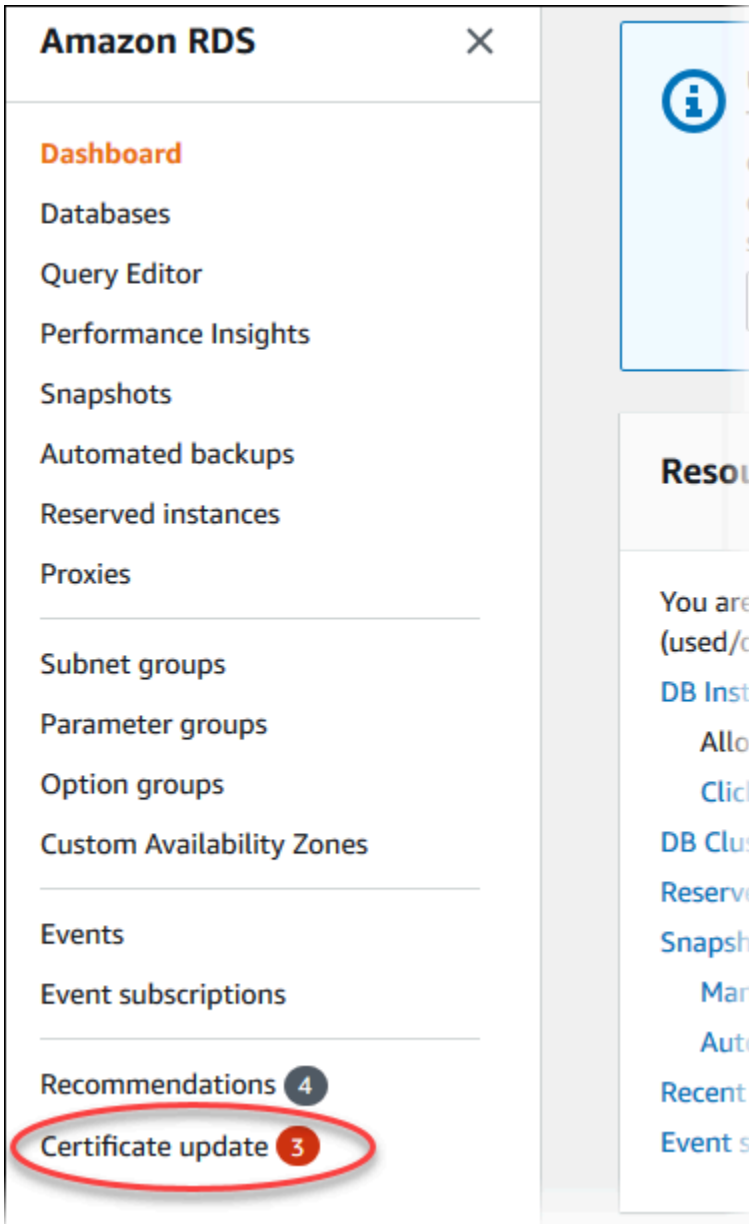

Updating your CA certificate by applying maintenance

Perform the following steps to update your CA certificate by applying maintenance.

Console

To update your CA certificate by applying maintenance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Certificate update**.

The **Databases requiring certificate update** page appears.

RDS > Certificate update

Databases requiring certificate update (2) Refresh Export list Schedule Apply now

Rotate your CA Certificates before expiry date or risk losing SSL/TLS connectivity to your existing DB instances.

Filter by Databases < 1 > Settings

DB identifier ▲	Status ▼	Certificate authority ▼	CA expiration date ▼	Role ▼	Restart Required ▼	Scheduled Changes ▼	Mainten
database-1	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Instance	No	No	March 03
database-2	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Multi-AZ DB cluster	No	No	March 07

Note

This page only shows the DB instances for the current Amazon Web Services Region. If you have databases in more than one Amazon Web Services Region, check this page in each Amazon Web Services Region to see all DB instances with old SSL/TLS certificates.

- Choose the DB instance that you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

Important

If you experience connectivity issues after certificate expiry, use the **Apply now** option.

- If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

Schedule updating your certificates ✕

Select Certificate Authority (CA)
Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

Confirm updating your certificates now ✕

Select Certificate Authority (CA)
Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1 ▼
Expiry: May 24, 2061

 **RDS Certificate Authority**
For more information about the certificate, see [RDS Certificate Authority](#) .
Certificate update **does not require restarting your database.**

Click **Confirm** to apply certificate immediately.

Cancel **Confirm**

 **Important**

Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

- Repeat steps 3 and 4 for each DB instance that you want to update.

Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See [Certificate authorities](#).

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the [describe-db-engine-versions](#) command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see [Setting the CA for your database](#).

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses `keytool`, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit
```

```

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
{split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
'next unless /Subject:;/; s/.*(CN=|CN = )//; print')
echo "Importing $alias"
keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }`
echo " Certificate ${alias} expires in '$expiry'"
done

```

macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```

mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
'next unless /Subject:;/; s/.*(CN=|CN = )//; print')
echo "Importing $alias"

```

```
keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
  cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*)\n/) { print "$1\n"; }`
  echo " Certificate ${alias} expires in '$expiry'"
done
```

To learn more best practices about using SSL with Amazon RDS, see [Best practices for successful SSL connections to Amazon RDS for Oracle](#).

Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other Amazon resources within the same Amazon Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and Amazon:

- An Amazon Site-to-Site VPN connection. For more information, see [What is Amazon Site-to-Site VPN?](#)
- An Amazon Direct Connect connection. For more information, see [What is Amazon Direct Connect?](#)

You get access to Amazon Aurora through the network by using Amazon-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.

- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [Amazon Security Token Service](#) (Amazon STS) to generate temporary security credentials to sign requests.

Identity and access management for Amazon Aurora

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an Amazon Web Services service that you can use with no additional charge.

Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon Aurora works with IAM](#)
- [Identity-based policy examples for Amazon Aurora](#)
- [Amazon managed policies for Amazon RDS](#)
- [Amazon RDS updates to Amazon managed policies](#)
- [Preventing cross-service confused deputy problems](#)
- [IAM database authentication](#)
- [Troubleshooting Amazon Aurora identity and access](#)

Audience

How you use Amazon Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

Service user – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see [Troubleshooting Amazon Aurora identity and access](#).

Service administrator – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic

concepts of IAM. To learn more about how your company can use IAM with Aurora, see [How Amazon Aurora works with IAM](#).

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see [Identity-based policy examples for Amazon Aurora](#).

Authenticating with identities

Authentication is how you sign in to Amazon using your identity credentials. You must be *authenticated* (signed in to Amazon) as the Amazon Web Services account root user, as an IAM user, or by assuming an IAM role.

If you access Amazon programmatically, Amazon provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use Amazon tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Amazon Signature Version 4 for API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, Amazon recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Amazon Multi-factor authentication in IAM](#) in the *IAM User Guide*.

Amazon account root user

When you create an Amazon Web Services account, you begin with one sign-in identity that has complete access to all Amazon Web Services services and resources in the account. This identity is called the Amazon Web Services account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access Amazon Web Services services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the Amazon Directory Service, or any user that accesses Amazon Web Services services by using credentials provided through an identity source. When federated identities access Amazon Web Services accounts, they assume roles, and the roles provide temporary credentials.

IAM users and groups

An [IAM user](#) is an identity within your Amazon Web Services account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see [Rotate access keys regularly for use cases that require long-term credentials](#) in the *IAM User Guide*.

An [IAM group](#) is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [Use cases for IAM users](#) in the *IAM User Guide*.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see [IAM database authentication](#).

IAM roles

An [IAM role](#) is an identity within your Amazon Web Services account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the Amazon Web Services Management Console by [switching roles](#). You can assume a role by calling an Amazon CLI or Amazon API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some Amazon Web Services services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.
- **Cross-service access** – Some Amazon Web Services services use features in other Amazon Web Services services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
 - **Forward access sessions** – When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).
 - **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an Amazon Web Services service](#) in the *IAM User Guide*.
 - **Service-linked role** – A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making Amazon CLI or Amazon API requests. This is preferable to storing access keys within the EC2 instance. To assign an Amazon role to an EC2 instance and make it available to all of its applications, you create

an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Use an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

Managing access using policies

You control access in Amazon by creating policies and attaching them to IAM identities or Amazon resources. A policy is an object in Amazon that, when associated with an identity or resource, defines their permissions. Amazon evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in Amazon as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

An administrator can use policies to specify who has access to Amazon resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the Amazon Web Services Management Console, the Amazon CLI, or the Amazon API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone

policies that you can attach to multiple permission sets and roles in your Amazon account. Managed policies include Amazon managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

For information about Amazon managed policies that are specific to Amazon Aurora, see [Amazon managed policies for Amazon RDS](#).

Other policy types

Amazon supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in Amazon Organizations. Amazon Organizations is a service for grouping and centrally managing multiple Amazon accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each Amazon Web Services account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *Amazon Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how Amazon determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

How Amazon Aurora works with IAM

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

The following table lists IAM features you can use with Amazon Aurora:

IAM feature	Amazon Aurora support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
Attribute-based access control (ABAC) (tags in policies)	Yes
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how Amazon Aurora and other Amazon services work with IAM, see [Amazon services that work with IAM](#) in the *IAM User Guide*.

Topics

- [Aurora identity-based policies](#)
- [Resource-based policies within Aurora](#)
- [Policy actions for Aurora](#)
- [Policy resources for Aurora](#)
- [Policy condition keys for Aurora](#)
- [Access control lists \(ACLs\) in Aurora](#)
- [Attribute-based access control \(ABAC\) in policies with Aurora tags](#)
- [Using temporary credentials with Aurora](#)
- [Forward access sessions for Aurora](#)
- [Service roles for Aurora](#)
- [Service-linked roles for Aurora](#)

Aurora identity-based policies

Supports identity-based policies: Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see [Identity-based policy examples for Amazon Aurora](#).

Resource-based policies within Aurora

Supports resource-based policies: No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different Amazon Web Services accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Policy actions for Aurora

Supports policy actions: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated Amazon API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: `rds:.` For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [  
  "rds:action1",  
  "rds:action2"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

Policy resources for Aurora

Supports policy resources: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*" 
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\) and Amazon service namespaces](#).

For example, to specify the dbtest DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [  
    "resource1",  
    "resource2"
```

To see a list of Aurora resource types and their ARNs, see [Resources Defined by Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions Defined by Amazon RDS](#).

Policy condition keys for Aurora

Supports service-specific policy condition keys: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or *Condition block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical AND operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](#) in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. To see all Amazon global condition keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all Amazon global condition keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see [Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS](#).

Access control lists (ACLs) in Aurora

Supports access control lists (ACLs): No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Aurora tags

Supports attribute-based access control (ABAC) tags in policies: Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In Amazon, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many Amazon resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [Define permissions with ABAC authorization](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Aurora resources, see [Specifying conditions: Using custom tags](#). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant permission for actions on a resource with a specific tag with two different values](#).

Using temporary credentials with Aurora

Supports temporary credentials: Yes.

Some Amazon Web Services services don't work when you sign in using temporary credentials. For additional information, including which Amazon Web Services services work with temporary credentials, see [Amazon Web Services services that work with IAM](#) in the *IAM User Guide*.

You are using temporary credentials if you sign in to the Amazon Web Services Management Console using any method except a user name and password. For example, when you access Amazon using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switch from a user to an IAM role \(console\)](#) in the *IAM User Guide*.

You can manually create temporary credentials using the Amazon CLI or Amazon API. You can then use those temporary credentials to access Amazon. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#).

Forward access sessions for Aurora

Supports forward access sessions: Yes.

When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service,

combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

Service roles for Aurora

Supports service roles: Yes.

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Create a role to delegate permissions to an Amazon Web Services service](#) in the *IAM User Guide*.

Warning

Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

Service-linked roles for Aurora

Supports service-linked roles: Yes.

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see [Using service-linked roles for Amazon Aurora](#).

Identity-based policy examples for Amazon Aurora

By default, permission sets and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the Amazon Web Services Management Console, Amazon CLI, or Amazon API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see [Creating policies on the JSON tab](#) in the *IAM User Guide*.

Topics

- [Permission policies to create, modify and, delete resources in Aurora](#)
- [Example policies: Using condition keys](#)
- [Specifying conditions: Using custom tags](#)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see [Amazon managed policies](#) or [Amazon managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [Validate policies with IAM Access Analyzer](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Secure API access with MFA](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your Amazon Web Services account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following Amazon managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their Amazon account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in [Managing access using policies](#).

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root Amazon account:

```
AmazonRDSFullAccess
```

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the Amazon CLI or Amazon API.

```
{
  "Version": "2012-10-17",

        "iam:ListGroupPolicies",
        "iam:ListPolicyVersions",
        "iam:ListPolicies",
        "iam:ListUsers"
    ],
    "Resource": "*"
}
]
}

```

Permission policies to create, modify and, delete resources in Aurora

The following sections present examples of permission policies that grant and restrict access to resources:

Allow a user to create DB instances in an Amazon account

The following is an example policy that allows the account with the ID 123456789012 to create DB instances for your Amazon account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the `default` subnet group.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateDBInstanceOnly",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance"
      ],
      "Resource": [
        "arn:aws-cn:rds*:123456789012:db:test*",
        "arn:aws-cn:rds*:123456789012:og:default*",
        "arn:aws-cn:rds*:123456789012:pg:default*",
        "arn:aws-cn:rds*:123456789012:subgrp:default"
      ],
      "Condition": {

```

```
        "StringEquals": {
            "rds:DatabaseEngine": "mysql",
            "rds:DatabaseClass": "db.t2.micro"
        }
    }
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the [CreateDBInstance](#) API operation (this also applies to the [create-db-instance](#) Amazon CLI command and the Amazon Web Services Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resource Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the Amazon Region (* indicates any region in this example), the Amazon account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The `Resource` element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
- The option group for the new DB instance must begin with `default`.
- The DB parameter group for the new DB instance must begin with `default`.
- The subnet group for the new DB instance must be the `default` subnet group.
- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see [Policy condition keys for Aurora](#). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the `Engine` parameter in [CreateDBInstance](#). For information about the valid condition values for `rds:DatabaseClass`, see [Supported DB engines for DB instance classes](#).

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the `Resource` element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRDSDescribe",
      "Effect": "Allow",
      "Action": "rds:Describe*",
      "Resource": "*"
    }
  ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": [
```

```

        "arn:aws-cn:rds:*:*:pg:mydbpg",
        "arn:aws-cn:rds:*:*:subgrp:mydbsubnetgroup"
    ]
}
]
}

```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAnySnapshotName",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
    },
    {
      "Sid": "AllowDevTestToCreateSnapshot",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to `development` or `test`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowChangingParameterOptionSecurityGroups",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": [
        "arn:aws:rds:*:123456789012:pg:*",
        "arn:aws:rds:*:123456789012:secgrp:*",
        "arn:aws:rds:*:123456789012:og:*"
      ]
    },
    {
      "Sid": "AllowDevTestToModifyInstance",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
      "Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:mysql-instance"
    }
  ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "rds:*",
      "Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:mydb"
    }
  ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowMySQLCreate",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql"
        },
        "Bool": {
          "rds:MultiAz": false
        }
      }
    }
  ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

    {
      "Sid": "DenyLargeCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseClass": [
            "db.r3.8xlarge",
            "db.m4.10xlarge"
          ]
        }
      }
    },
    {
      "Sid": "DenyPIOPSCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "NumericNotEquals": {
          "rds:Piops": "0"
        }
      }
    }
  ]
}

```

Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*"
    }
  ]
}

```

```

    "Condition": {
      "streq": {
        "rds:req-tag/stage": [
          "test",
          "qa",
          "production"
        ]
      }
    }
  ]
}

```

Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

Note

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
<code>db-tag</code>	DB instances, including read replicas
<code>snapshot-tag</code>	DB snapshots
<code>ri-tag</code>	Reserved DB instances
<code>og-tag</code>	DB option groups
<code>pg-tag</code>	DB parameter groups
<code>subgrp-tag</code>	DB subnet groups

RDS tag identifier	Applies to
es-tag	Event subscriptions
cluster-tag	DB clusters
cluster-pg-tag	DB cluster parameter groups
cluster-snapshot-tag	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":
["value"]}} }
```

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

```
"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]}} }
```

For information about creating tags, see [Tagging Amazon Aurora and Amazon RDS resources](#).

Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"DenyTagUpdates",
      "Effect":"Deny",
      "Action":[
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
    }
  ],
}
```

```

    "Resource": "*"
  }
]
}

```

To see a list of Aurora actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAnySnapshotName",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBSnapshot"
      ],
      "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
    },
    {
      "Sid": "AllowDevTestToCreateSnapshot",
      "Effect": "Allow",
      "Action": [

```

```

        "rds:CreateDBSnapshot"
    ],
    "Resource": "arn:aws:rds:*:123456789012:db:*",
    "Condition": {
        "StringEquals": {
            "rds:db-tag/stage": [
                "development",
                "test"
            ]
        }
    }
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to `development` or `test`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowChangingParameterOptionSecurityGroups",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": [
        "arn:aws:rds:*:123456789012:pg:*",
        "arn:aws:rds:*:123456789012:secgrp:*",
        "arn:aws:rds:*:123456789012:og:*"
      ]
    },
    {
      "Sid": "AllowDevTestToModifyInstance",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:*",
      "Condition": {
        "StringEquals": {
            "rds:db-tag/stage": [

```

```

        "development",
        "test"
    ]
}
}
}
]
}

```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyProductionCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "arn:aws:rds:*:123456789012:pg:*",
      "Condition": {
        "StringEquals": {
          "rds:pg-tag/usage": "prod"
        }
      }
    }
  ]
}

```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFullDevAccessNoTags",
      "Effect": "Allow",
      "NotAction": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws-cn:rds:*:123456789012:db:${aws:username}*",
      "Condition": {
        "StringEqualsIfExists": {
          "rds:db-tag/stage": "devo"
        }
      }
    }
  ]
}
```

Amazon managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use Amazon managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our Amazon managed policies. These policies cover common use cases and are available in your Amazon Web Services account. For more information about Amazon managed policies, see [Amazon managed policies](#) in the *IAM User Guide*.

Amazon Web Services services maintain and update Amazon managed policies. You can't change the permissions in Amazon managed policies. Services occasionally add additional permissions to an Amazon managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an Amazon managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an Amazon managed policy, so policy updates don't break your existing permissions.

Additionally, Amazon supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` Amazon managed policy provides read-only access to all Amazon Web Services services and resources. When a service launches a new feature, Amazon adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [Amazon managed policies for job functions](#) in the *IAM User Guide*.

Topics

Amazon managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the Amazon Web Services Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSReadOnlyAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the Amazon Web Services Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

- `outposts` – Allows principals to get Amazon Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific Amazon Web Services account. This policy allows the Amazon Web Services account to get the value of a secret from Amazon Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the Amazon Web Services Management Console for multiple Amazon Web Services services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see [AmazonRDSEnhancedMonitoringRole](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsReadOnly](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.

- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the Amazon Directory Service.

Permissions details

This policy includes the following permission:

- `ds` – Allows principals to describe Amazon Directory Service directories and control authorization to Amazon Directory Service directories.

For more information about this policy, including the JSON policy document, see [AmazonRDSDirectoryServiceAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon Aurora](#).

Amazon managed policy: AmazonRDSPreviewServiceRolePolicy

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see [Service-linked role for Amazon RDS Preview](#).

Permissions details

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see [Service-linked role permissions for Amazon RDS Beta](#).

Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSBetaServiceRolePolicy](#) in the *Amazon Managed Policy Reference Guide*.

Amazon RDS updates to Amazon managed policies

View details about updates to Amazon managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS [Document history](#) page.

Change	Description	Date
Amazon managed policy: AmazonRDSPreviewServiceRolePolicy – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSPreviewServiceRolePolicy of the AWSServiceRoleForRDSPreview service-linked role. For more information, see Amazon managed policy: AmazonRDSPreviewServiceRolePolicy .	August 7, 2024
Amazon managed policy: AmazonRDSBetaServiceRolePolicy – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSBetaServiceRolePolicy of the AWSServiceRoleForRDSBeta service-linked role. For more information, see Amazon managed policy: AmazonRDSBetaServiceRolePolicy .	August 7, 2024
Amazon managed policy: AmazonRDSServiceRolePolicy – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSServiceRolePolicy of the AWSServiceRoleForRDS service-linked role. For more informati	July 2, 2024

Amazon RDS started tracking changes	Amazon RDS started tracking changes for its Amazon managed policies.	October 26, 2021

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In Amazon, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, Amazon provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified Amazon account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws-cn:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",

      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- [Granting permissions to publish notifications to an Amazon SNS topic](#)
- [Setting up access to an Amazon S3 bucket](#) (PostgreSQL import)
- [Setting up access to an Amazon S3 bucket](#) (PostgreSQL export)

IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using Amazon Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (Amazon) JDBC Driver supports IAM database authentication. For more information, see [Amazon IAM Authentication Plugin](#) in the [Amazon Web Services \(Amazon\) JDBC Driver GitHub repository](#).

The Amazon Web Services (Amazon) Python Driver supports IAM database authentication. For more information, see [Amazon IAM Authentication Plugin](#) in the [Amazon Web Services \(Amazon\) Python Driver GitHub repository](#).

Navigate through the following topics to learn the process to set IAM for DB authentication:

- [Enabling and disabling IAM database authentication](#)

- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)
- [Connecting to your DB cluster using IAM authentication](#)

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and IAM database authentication, see [Supported Regions and Aurora DB engines for IAM database authentication](#).

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see [Supported DB engines for DB instance classes](#).

CLI and SDK support

IAM database authentication is available for the [Amazon CLI](#) and for the following language-specific Amazon SDKs:

- [Amazon SDK for .NET](#)
- [Amazon SDK for C++](#)
- [Amazon SDK for Go](#)
- [Amazon SDK for Java](#)
- [Amazon SDK for JavaScript](#)
- [Amazon SDK for PHP](#)
- [Amazon SDK for Python \(Boto3\)](#)
- [Amazon SDK for Ruby](#)

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- IAM database authentication throttles connections at 200 connections per second.

Connections that use the same authentication token are not throttled. We recommend that you reuse authentication tokens when possible.

- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see [Amazon global condition context keys](#) in the *IAM User Guide*.

- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For Aurora PostgreSQL, you cannot use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.
- IAM DB authentication requires compute resources on the database cluster. You must have between 300 and 1000 MiB extra memory on your database for reliable connectivity. To see the memory needed for your workload, compare the RES column for RDS processes in the Enhanced Monitoring processlist before and after enabling IAM DB authentication. See [Viewing OS metrics in the RDS console](#).

If you are using a burstable class instance, avoid running out of memory by reducing the memory used by other parameters like buffers and cache by the same amount.

- For Aurora MySQL, you cannot use password based authentication for a database user you configure with IAM authentication.
- IAM DB authentication is not supported for RDS on Outposts for any engine.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See [RDS Proxy pricing](#).

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

Unsupported Amazon global condition context keys

IAM database authentication does not support the following subset of Amazon global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see [Amazon global condition context keys](#) in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the Amazon Web Services Management Console, Amazon CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see [Creating an Amazon Aurora DB cluster](#).
- To modify a DB cluster to enable IAM database authentication, see [Modifying an Amazon Aurora DB cluster](#).
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see [Restoring from a DB cluster snapshot](#).
- To restore a DB cluster to a point in time with IAM database authentication enabled, see [Restoring a DB cluster to a specified time](#).

Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to modify.

Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. You can also choose to enable publishing IAM DB authentication logs to CloudWatch Logs. Under **Log exports**, choose the **iam-db-auth-error log** option. Publishing your logs to CloudWatch Logs consumes storage and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.

7. Choose **Continue**.
8. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
9. Choose **Modify cluster**.

Amazon CLI

To create a new DB cluster with IAM authentication by using the Amazon CLI, use the [create-db-cluster](#) command. Specify the `--enable-iam-database-authentication` option.

To update an existing DB cluster to have or not have IAM authentication, use the Amazon CLI command [modify-db-cluster](#). Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

If you are restoring a DB cluster, use one of the following Amazon CLI commands:

- [restore-db-cluster-to-point-in-time](#)
- [restore-db-cluster-from-db-snapshot](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation [CreateDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation [ModifyDBCluster](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Note

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in [Region and version availability](#).

If you are restoring a DB cluster, use one of the following API operations:

- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

Note

To learn more about IAM policies, see [Identity and access management for Amazon Aurora](#).

The following example policy allows a user to connect to a DB cluster using IAM database authentication.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
```

```
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:1234567890:dbuser:cluster-ABCDEFGHIJKL01234/
db_user"
      ]
    }
  ]
}
```

Important

A user with administrator permissions can access DB clusters without explicit permissions in an IAM policy. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:.` You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB cluster.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws-cn:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- *region* is the Amazon Region for the DB cluster. In the example policy, the Amazon Region is `us-east-2`.
- *account-id* is the Amazon account number for the DB cluster. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB cluster.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB cluster and allow your other account to assume the role.

- *DbClusterResourceId* is the identifier for the DB cluster. This identifier is unique to an Amazon Region and never changes. In the example policy, the identifier is `cluster-ABCDEFGHIJKL01234`.

To find a DB cluster resource ID in the Amazon Web Services Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the Amazon CLI command to list the identifiers and resource IDs for all of your DB cluster in the current Amazon Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].
[DBClusterIdentifier,DbClusterResourceId]"
```

Note

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication](#).

- *db-user-name* is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

```
{
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "rds-db:connect"
    ],
    "Resource": [
      "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
      ABCDEFGHIJKL01234/jane_doe",
      "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
      ABCDEFGHIJKL01234/mary_roe"
    ]
  }
]
}

```

The following policy uses the "*" character to match all DB clusters and database accounts for a particular Amazon account and Amazon Region.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws-cn:rds-db:us-east-2:1234567890:dbuser:*/*"
      ]
    }
  ]
}

```

The following policy matches all of the DB clusters for a particular Amazon account and Amazon Region. However, the policy only grants access to DB clusters that have a jane_doe database account.

```

{
  "Version": "2012-10-17",

```

```
"Statement": [  
  {  
    "Effect": "Allow",  
    "Action": [  
      "rds-db:connect"  
    ],  
    "Resource": [  
      "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"  
    ]  
  }  
]
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named *dev*, and another database named *test*. If the database user *jane_doe* has access only to *dev*, any users or roles that access that DB cluster with the *jane_doe* user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see [Identity-based policy examples for Amazon Aurora](#).

Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see [Create and attach your first customer managed policy](#) in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

Note

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB cluster using the `jane_doe` database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

Note

The user name used for IAM authentication must match the case of the user name in the database.

Topics

- [Using IAM authentication with Aurora MySQL](#)
- [Using IAM authentication with Aurora PostgreSQL](#)

Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by `AWSAuthenticationPlugin`—an Amazon-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows Aurora MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for

IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#).

Note

If you see the following message, it means that the Amazon-provided plugin is not available for the current DB cluster.

```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see [Region and version availability](#) and [Enabling and disabling IAM database authentication](#).

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with Aurora PostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;  
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#). You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the `rds_ad` role. This also applies to nested memberships. For more information, see [Step 7: Create PostgreSQL users for your Kerberos principals](#).

Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using Amazon signature version 4. (For more information, see [Signature Version 4 signing process](#) in the *Amazon Web Services General Reference*.) The Amazon CLI and an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another Amazon service, such as Amazon Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an Amazon SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3).

For more information, see the following blog posts:

- [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#)
- [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#)

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

Topics

- [Connecting to your DB cluster using IAM authentication with the Amazon drivers](#)

Connecting to your DB cluster using IAM authentication with the Amazon drivers

The Amazon suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the Amazon drivers, see the corresponding language driver for your [Aurora MySQL](#) or [Aurora PostgreSQL](#) DB cluster.

Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the Amazon CLI and `mysql` command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

Note

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#).

Topics

- [Generating an IAM authentication token](#)
- [Connecting to a DB cluster](#)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the Amazon CLI.

```
aws rds generate-db-auth-token \  
  --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \  
  --port 3306 \  
  --region us-west-2 \  
  --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?  
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-  
cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

For more information, see [TLS connections to Aurora MySQL DB clusters](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.

- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
```

```
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSSHOST --port 3306 --region us-
west-2 --username jane_doe )"

mysql --host=$RDSSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-
cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----+-----+
| Variable_name | Value
+-----+-----+
| ...          | ...
| Ssl_cipher    | AES256-SHA
+-----+-----+
| ...          | ...
| Ssl_version   | TLSv1.1
+-----+-----+
| ...          | ...
+-----+-----+
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the Amazon CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#).

Topics

- [Generating an IAM authentication token](#)
- [Connecting to an Aurora PostgreSQL cluster](#)

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the Amazon CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?  
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

Connecting to an Aurora PostgreSQL cluster

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full  
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName  
password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB cluster (cluster endpoint) that you want to access
- `port` – The port number used for connecting to your DB cluster
- `sslmode` – The SSL mode to use

When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `sslrootcert` – The full path to the SSL certificate file that contains the public key

For more information, see [Securing Aurora PostgreSQL data with SSL/TLS](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

The following example shows using `psql` to connect. In the example, `psql` uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Connecting to your DB cluster using IAM authentication and the Amazon SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for .NET as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [Amazon SDK for .NET](#), found on the Amazon site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB cluster, use

the .NET database connector for the DB engine, such as MySqlConnection for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to an Aurora MySQL DB cluster. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB cluster that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB cluster
- `SslMode` – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `SslCa` – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
"mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
```

```
// for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is
generated

MySQLConnection conn = new
MySQLConnection($"server=mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
conn.Open();

// Define a query
MySQLCommand sampleCommand = new MySQLCommand("SHOW DATABASES;", conn);

// Execute a query
MySQLDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

// Read all rows and output the first column in each row
while (mysqlDataRdr.Read())
    Console.WriteLine(mysqlDataRdr[0]);

mysqlDataRdr.Close();
// Close connection
conn.Close();
}
}
}
```

This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB cluster that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB cluster
- `SSL Mode` – The SSL mode to use

When you use `SSL Mode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- `Root Certificate` – The full path to the SSL certificate for Amazon Aurora

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
                RDSAuthTokenGenerator.GenerateAuthToken("postgresmycluster.cluster-123456789012.us-
                east-1.rds.amazonaws.com", 5432, "jane_doe");
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is generated

            NpgsqlConnection conn = new
                NpgsqlConnection($"Server=postgresmycluster.cluster-123456789012.us-
                east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL
                Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
            pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.WriteLine("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
}
```

```
}
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

Examples

To run these code examples, you need the [Amazon SDK for Go](#), found on the Amazon site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB cluster that you want to access

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB cluster
- `region` – The Amazon Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

⚠ Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

```
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an Amazon service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```
sess := session.Must(session.NewSession())
```

```
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```
"github.com/aws/aws-sdk-go/aws/session"
```

```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)
- [Set up the Amazon SDK for Java](#)

For examples on how to use the SDK for Java 2.x, see [Amazon RDS examples using SDK for Java 2.x](#). You can also use the Amazon Advanced JDBC Wrapper, see [Amazon Advanced JDBC Wrapper documentation](#).

Topics

- [Generating an IAM authentication token](#)
- [Manually constructing an IAM authentication token](#)
- [Connecting to a DB cluster](#)

Generating an IAM authentication token

If you are writing programs using the Amazon SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide Amazon credentials. To do this, you create an instance of the

`DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first Amazon access key and secret key that it finds in the [default credential provider chain](#). For more information about Amazon access keys, see [Managing access keys for users](#).

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the Amazon Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
username) {

        RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
            .credentials(new DefaultAWSCredentialsProviderChain())
            .region(region)
            .build();

        String authToken = generator.getAuthToken(
            GetIamAuthTokenRequest.builder()
```

```
        .hostname(hostName)
        .port(Integer.parseInt(port))
        .userName(username)
        .build());

    return authToken;
}

}
```

Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using Amazon signature version 4. For more information, see [Signature version 4 signing process](#) in the *Amazon Web Services General Reference*.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
```

```
public static String canonicalURIPParameter = "/";
public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();

        return md.digest();
    } catch (Exception e) {
        throw new SdkClientException(
            "Unable to compute hash while signing request: "
            + e.getMessage(), e);
    }
}
}
```

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the [Amazon SDK for Java](#), found on the Amazon site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon Aurora that is specific to an Amazon Region. (For more information, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).) At runtime, the class

loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.

- Modify the values of the following variables as needed:
 - RDS_INSTANCE_HOSTNAME – The host name of the DB cluster that you want to access.
 - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB cluster.
 - REGION_NAME – The Amazon Region where the DB cluster is running.
 - DB_USER – The database account that you want to access.
 - SSL_CERTIFICATE – An SSL certificate for Amazon Aurora that is specific to an Amazon Region.

To download a certificate for your Amazon Region, see [Using SSL/TLS to encrypt a connection to a DB cluster](#). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains Amazon credentials from the [default credential provider chain](#).

 **Note**

Specify a password for DEFAULT_KEY_STORE_PASSWORD other than the prompt shown here as a security best practice.

```
package com.amazonaws.samples;

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see [Credentials](#) in the Amazon SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the [Amazon SDK for Python \(Boto3\)](#), found on the Amazon site.

Modify the values of the following variables as needed:

- ENDPOINT – The endpoint of the DB cluster that you want to access
- PORT – The port number used for connecting to your DB cluster
- USER – The database account that you want to access
- REGION – The Amazon Region where the DB cluster is running
- DBNAME – The database that you want to access
- SSLCERTIFICATE – The full path to the SSL certificate for Amazon Aurora

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](#).

Note

You cannot use a custom Route 53 DNS record or an Aurora custom endpoint instead of the DB cluster endpoint to generate the authentication token.

This code connects to an Aurora MySQL DB cluster.

Before running this code, install the PyMySQL driver by following the instructions in the [Python Package Index](#).

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
Region=REGION)

try:
    conn =
    pymysql.connect(auth_plugin_map={'mysql_clear_password':None},host=ENDPOINT,
user=USER, password=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE',
ssl_verify_identity=True)
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
```

```
print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install `psycopg2` by following the instructions in [Psycopg documentation](#).

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
    Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
        password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB cluster through a proxy, see [Connecting to a proxy using IAM authentication](#).

Troubleshooting for IAM DB authentication

Following, you can find troubleshooting ideas for some common IAM DB authentication issues and information on CloudWatch logs and metrics for IAM DB authentication.

Exporting IAM DB authentication error logs to CloudWatch Logs

IAM DB authentication error logs are stored on the database host, and you can export these logs your CloudWatch Logs account. Use the logs and remediation methods in this page to troubleshoot IAM DB authentication issues.

You can enable log exports to CloudWatch Logs from the console, Amazon CLI, and RDS API. For console instructions, see [Publishing database logs to Amazon CloudWatch Logs](#).

To export your IAM DB authentication error logs to CloudWatch Logs when creating a DB cluster from the Amazon CLI, use the following command:

```
aws rds create-db-cluster --db-cluster-identifier mydbinstance \  
--region us-east-1 \  
--engine postgres \  
--engine-version 16 \  
--master-username master \  
--master-user-password password \  
--publicly-accessible \  
--enable-iam-database-authentication \  
--enable-cloudwatch-logs-exports=iam-db-auth-error
```

To export your IAM DB authentication error logs to CloudWatch Logs when modifying a DB cluster from the Amazon CLI, use the following command:

```
aws rds modify-db-cluster --db-instance-identifier mydbcluster \  
--region us-east-1 \  
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["iam-db-auth-error"]}'
```

To verify if your DB cluster is exporting IAM DB authentication logs to CloudWatch Logs, check if the `EnabledCloudwatchLogsExports` parameter is set to `iam-db-auth-error` in the output for the `describe-db-instances` command.

```
aws rds describe-db-cluster --region us-east-1 --db-cluster-identifier mydbcluster  
...
```

```

    "EnabledCloudwatchLogsExports": [
      "iam-db-auth-error"
    ],
    ...

```

IAM DB authentication CloudWatch metrics

Amazon Aurora delivers near-real time metrics about IAM DB authentication to your Amazon CloudWatch account. The following table lists the IAM DB authentication metrics available using CloudWatch:

Metric	Description
IamDbAuthConnectionRequests	Total number of connection requests made with IAM DB authentication.
IamDbAuthConnectionSuccess	Total number of successful IAM DB authentication requests.
IamDbAuthConnectionFailure	Total number of failed IAM DB authentication requests.
IamDbAuthConnectionFailureInvalidToken	Total number of failed IAM DB authentication requests due to invalid token.
IamDbAuthConnectionFailureInsufficientPermissions	Total number of failed IAM DB authentication requests due to incorrect policies or permissions.
IamDbAuthConnectionFailureThrottling	Total number of failed IAM DB authentication requests due to IAM DB authentication throttling.
IamDbAuthConnectionFailureServerError	Total number of failed IAM DB authentication requests due to an internal server error in the IAM DB authentication feature.

Common issues and solutions

You might encounter the following issues when using IAM DB authentication. Use the remediation steps in the table to solve the issues:

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authenticate the connection request for user <i>db_user</i> because the provided token is malformed or otherwise invalid. (Status Code: 400, Error Code: InvalidToken)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureInvalidToken	The IAM DB authentication token in the connection request is either not a valid SigV4a token, or it is not formatted correctly.	Check your token generation strategy in your application. In some cases, make sure you are passing the token with valid formatting. Truncating the token (or incorrect string formatting) will make the token invalid.
[ERROR] Failed to authenticate the connection request for user <i>db_user</i> because the token age is longer than 15 minutes. (Status Code: 400, Error Code: ExpiredToken)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureInvalidToken	The IAM DB authentication token has expired. Tokens are only valid for 15 minutes.	Check your token caching and/or token re-use logic in your application. You should not re-use tokens that are older than 15 minutes.
[ERROR] Failed to authorize the connection request for user	IamDbAuthConnectionFailure	This error might be due to the following reasons:	Verify that the IAM role and/or policy you are assuming in your applicati

Error	Metric(s)	Cause	Solution
<p><code>db_user</code> because the IAM policy assumed by the caller 'arn:aws:sts::123456789012:assumed-role/<RoleName>/<RoleSession>' is not authorized to perform <code>rds-db:connect`</code> on the DB instance. (Status Code: 403, Error Code:NotAuthorized)</p>	<p>IamDbAuth Connectio nFailureI nsufficie ntPermissions</p>	<ul style="list-style-type: none"> The IAM policy assumed by the application does not authorize the <code>rds-db:connect`</code> action. You are assuming the incorrect role/policy for <code>db_user</code> to connect to the database. You are assuming the correct policy for <code>db_user</code>, but you are not connecting to the correct database. 	<p>on. Make sure you assume the same policy to generate the token as to connect to the DB.</p>
<p>[ERROR] Failed to authorize the connection request for user <code>db_user</code> due to IAM DB authentication throttling. (Status Code: 429, Error Code: ThrottlingException)</p>	<p>IamDbAuth Connectio nFailure IamDbAuth Connectio nFailureT hrottling</p>	<p>You are making too many connection requests to your DB in a short amount of time. IAM DB authentication throttling limit is 200 connections per second.</p>	<p>Reduce the rate of establishing new connections with IAM authentication. Consider implementing connection pooling using RDS Proxy in order to reuse established connections in your application.</p>

Error	Metric(s)	Cause	Solution
[ERROR] Failed to authorize the connection request for user <code>db_user</code> due to an internal IAM DB authentication error. (Status Code: 500, Error Code: InternalError)	IamDbAuth Connectio nFailure IamDbAuth Connectio nFailureT hrottling	There was an internal error while authorizing the DB connection with IAM DB authentication.	Reach out to http://www.amazonaws.cn/support-plans/ to investigate the issue.

Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

Topics

- [I'm not authorized to perform an action in Aurora](#)
- [I'm not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my Amazon account to access my Aurora resources](#)

I'm not authorized to perform an action in Aurora

If the Amazon Web Services Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a `widget` but does not have `rds:GetWidget` permissions.

```
User: arn:aws-cn:iam::123456789012:user/mateojackson is not authorized to perform:
rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *my-example-widget* resource using the `rds:GetWidget` action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Aurora.

Some Amazon services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws-cn:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I want to allow people outside of my Amazon account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see [How Amazon Aurora works with IAM](#).
- To learn how to provide access to your resources across Amazon accounts that you own, see [Providing access to an IAM user in another Amazon account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party Amazon accounts, see [Providing access to Amazon accounts owned by third parties](#) in the *IAM User Guide*.

- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your Amazon solutions. You should collect monitoring data from all of the parts of your Amazon solution so that you can more easily debug a multi-point failure if one occurs. Amazon provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or Amazon Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

Amazon CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an Amazon service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon Aurora API calls in Amazon CloudTrail](#).

Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance

Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#) .

Database Logs

You can view, download, and watch database logs using the Amazon Web Services Management Console, Amazon CLI, or RDS API. For more information, see [Monitoring Amazon Aurora log files](#) .

Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see [Recommendations from Amazon Aurora](#) .

Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an Amazon Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification](#) .

Amazon Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of Amazon customers. Trusted Advisor inspects your Amazon environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All Amazon customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](#) .

For more information about monitoring Aurora see [Monitoring metrics in an Amazon Aurora cluster](#) .

Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple Amazon compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of Amazon services in scope of specific compliance programs, see [Amazon services in scope by compliance program](#). For general information, see [Amazon compliance programs](#).

You can download third-party audit reports using Amazon Artifact. For more information, see [Downloading reports in Amazon Artifact](#).

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. Amazon provides the following resources to help with compliance:

- [Security and compliance quick start guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on Amazon.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use Amazon to create HIPAA-compliant applications.
- [Amazon compliance resources](#) – This collection of workbooks and guides that might apply to your industry and location.
- [Amazon Config](#) – This Amazon service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [Amazon Security Hub](#) – This Amazon Web Services service provides a comprehensive view of your security state within Amazon. Security Hub uses security controls to evaluate your Amazon resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](#).

Resilience in Amazon Aurora

The Amazon global infrastructure is built around Amazon Regions and Availability Zones. Amazon Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about Amazon Regions and Availability Zones, see [Amazon global infrastructure](#).

In addition to the Amazon global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see [Backing up and restoring an Amazon Aurora DB cluster](#).

Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the

Availability Zones that a DB cluster spans within an Amazon Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see [Replication with Amazon Aurora](#).

Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single Amazon Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see [High availability for Amazon Aurora](#).

Infrastructure security in Amazon Aurora

As a managed service, Amazon Relational Database Service is protected by Amazon global network security. For information about Amazon security services and how Amazon protects infrastructure, see [Amazon Cloud Security](#). To design your Amazon environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar Amazon Well-Architected Framework*.

You use Amazon published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [Amazon Security Token Service](#) (Amazon STS) to generate temporary security credentials to sign requests.

In addition, Aurora offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see [Controlling access with security groups](#).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see [Hiding a DB cluster in a VPC from the internet](#).

 **Note**

If your DB instance is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see [Internet network traffic privacy](#).

Amazon RDS API and interface VPC endpoints (Amazon PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by [Amazon PrivateLink](#).

Amazon PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or Amazon Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces](#) in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see [Interface VPC endpoints \(Amazon PrivateLink\)](#) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](#).

You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see [Scenarios for accessing a DB cluster in a VPC](#).

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](#) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using Amazon PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

Availability

Amazon RDS API currently supports VPC endpoints in the following Amazon Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- South America (São Paulo)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the Amazon Command Line Interface (Amazon CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding Amazon Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the Amazon Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) Amazon Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
  "Statement": [
```

```

    {
      "Principal": "*",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance",
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*"
    }
  ]
}

```

Example: VPC endpoint policy that denies all access from a specified Amazon account

The following VPC endpoint policy denies Amazon account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```

{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
    }
  ]
}

```

Security best practices for Amazon Aurora

Use Amazon Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources. Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual user for each person who manages Amazon Aurora resources, including yourself. Don't use Amazon root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure Amazon Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see [Rotating your Amazon Secrets Manager secrets](#) in the *Amazon Secrets Manager User Guide*. You can also retrieve the credential from Amazon Secrets Manager programmatically. For more information, see [Retrieving the secret value](#) in the *Amazon Secrets Manager User Guide*.

For more information about Amazon Aurora security, see [Security in Amazon Aurora](#) . For more information about IAM, see [Amazon Identity and Access Management](#). For information on IAM best practices, see [IAM best practices](#).

Amazon Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see [Amazon Relational Database Service controls](#) in the Amazon Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see [What is Amazon Security Hub?](#).

Use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes various data sources, including Amazon RDS login activity. It uses threat intelligence feeds and machine learning to identify unexpected, potentially unauthorized, suspicious login behavior, and malicious activity within your Amazon environment.

When Amazon GuardDuty RDS Protection detects a potentially suspicious or anomalous login attempt that indicates a threat to your database, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see [Monitoring threats with Amazon GuardDuty RDS Protection for Amazon Aurora](#) .

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

Note

In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

Note

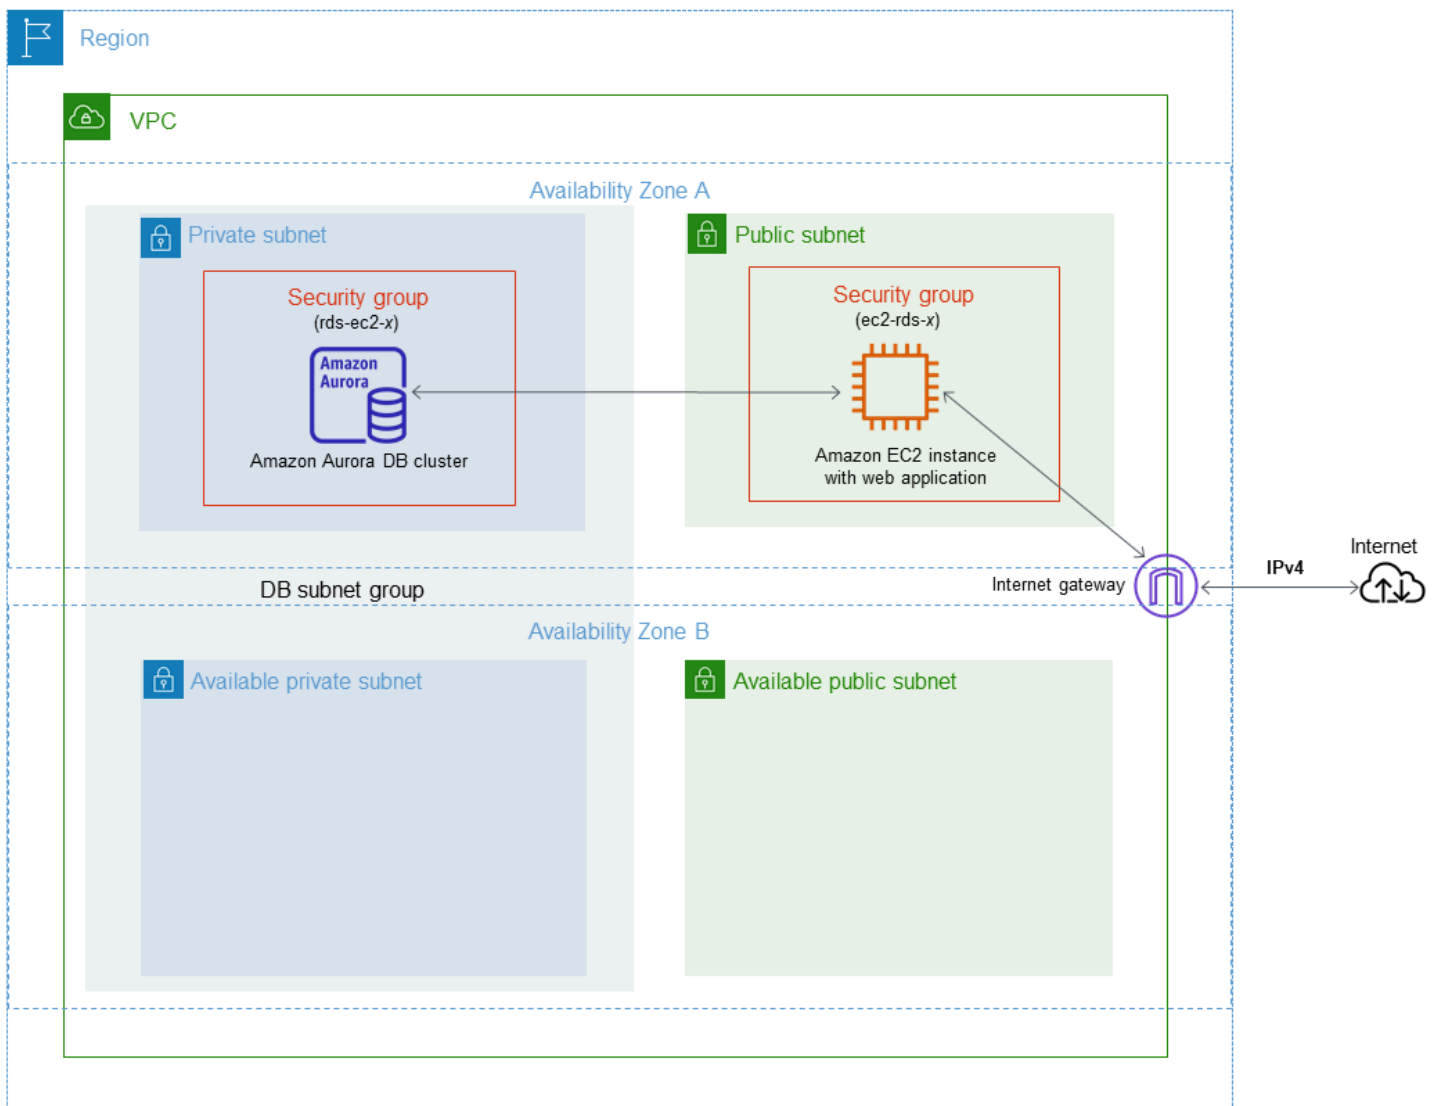

If your DB cluster is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see [Internet network traffic privacy](#).

Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the Amazon Web Services Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB cluster and add the DB cluster to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#) . For more information about using a VPC, see [Amazon VPC and Amazon Aurora](#) .

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see [Provide access to the DB cluster in the VPC by creating a security group](#) and [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using **Modify cluster** on the RDS console, the `ModifyDBCluster` Amazon RDS API, or the `modify-db-cluster` Amazon CLI command.

The following CLI example associates a specific VPC group and removes DB security groups from the DB cluster

```
aws rds modify-db-cluster --db-cluster-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
Aurora MySQL	<p>Version 2:</p> <p>ALTER,ALTER ROUTINE, CREATE,CREATE ROUTINE,CREATE TEMPORARY TABLES,CREATE USER,CREATE VIEW,DELETE,DROP, EVENT,EXECUTE,GRANT OPTION,INDEX,INSERT, LOAD FROM S3,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATI ON CLIENT , REPLICATION SLAVE ,SELECT, SELECT INTO S3,SHOW DATABASES , SHOW VIEW,TRIGGER, UPDATE</p>	—
	<p>Version 3:</p> <p>ALTER,APPLICATION_PASSWORD_ADMIN , ALTER ROUTINE,CONNECTION_ADMIN , CREATE,CREATE ROLE,CREATE ROUTINE,CREATE TEMPORARY TABLES, CREATE USER,CREATE VIEW, DELETE,DROP,DROP ROLE, EVENT,EXECUTE,INDEX, INSERT,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATION CLIENT , REPLICATI ON SLAVE ,ROLE_ADMIN , SET_USER_ID ,SELECT,SHOW DATABASES ,SHOW VIEW,TRIGGER, UPDATE,XA_RECOVER_ADMIN</p> <p>Starting with Aurora MySQL version 3.04.0, the master user also gets the SHOW_ROUTINE privilege .</p> <p>Starting with Aurora MySQL version 3.09.0, the master user also gets the FLUSH_OPTIMIZER_COSTS ,FLUSH_STATUS ,FLUSH_TABLES , and FLUSH_USER_RESOURCES privileges.</p>	<p>rds_superuser_role</p> <p>For more information about rds_superuser_role, see Role-based privilege model .</p>

Database engine	System privilege	Database role
Aurora PostgreSQL	LOGIN,NOSUPERUSER , INHERIT,CREATEDB, CREATEROLE ,NOREPLICATION ,VALID UNTIL 'infinity'	RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions .

Using service-linked roles for Amazon Aurora

Amazon Aurora uses Amazon Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other Amazon services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [Amazon services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDS` to allow Amazon RDS to call Amazon services on behalf of your DB clusters.

The `AWSServiceRoleForRDS` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see [AmazonRDSServiceRolePolicy](#) in the *Amazon Managed Policy Reference Guide*.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws-cn:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

Important

If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the `AWSServiceRoleForRDS` role in your account. To learn more, see [A new role appeared in my Amazon account](#).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the `AWSServiceRoleForRDS` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the Amazon Web Services Management Console and open the IAM console at <https://console.amazonaws.cn/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the `AWSServiceRoleForRDS` role.
3. On the **Summary** page for the chosen role, choose the **Last Accessed** tab.
4. On the **Last Accessed** tab, review recent activity for the service-linked role.

Note

If you are unsure whether Amazon Aurora is using the `AWSServiceRoleForRDS` role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the Amazon Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the `AWSServiceRoleForRDS` role, you must first delete *all* of your DB clusters.

Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

To delete a cluster (console)

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the **Databases** list, choose the cluster that you want to delete.
3. For **Cluster Actions**, choose **Delete**.
4. Choose **Delete**.

To delete a cluster (CLI)

See [delete-db-cluster](#) in the *Amazon CLI Command Reference*.

To delete a cluster (API)

See [DeleteDBCluster](#) in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the `AWSServiceRoleForRDS` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Beta

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSBeta` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [Amazon managed policy: AmazonRDSBetaServiceRolePolicy](#).

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSBetaServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Service-linked role for Amazon RDS Preview

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSPreview` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [Amazon managed policy: AmazonRDSPreviewServiceRolePolicy](#).

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
```

```
"Action": "iam:CreateServiceLinkedRole",
"Effect": "Allow",
"Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSPreviewServiceRolePolicy",
"Condition": {
  "StringLike": {
    "iam:AWSServiceName": "custom.rds.amazonaws.com"
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

Amazon VPC and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch Amazon resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

Topics

- [Working with a DB cluster in a VPC](#)
- [Scenarios for accessing a DB cluster in a VPC](#)
- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#)

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

Working with a DB cluster in a VPC

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the Amazon Cloud. Amazon VPC makes it possible for you to launch Amazon resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your Amazon account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC, see [Scenarios for accessing a DB cluster in a VPC](#).

Topics

- [Working with a DB cluster in a VPC](#)
- [Working with DB subnet groups](#)
- [Shared subnets](#)
- [Amazon Aurora IP addressing](#)
- [Hiding a DB cluster in a VPC from the internet](#)
- [Creating a DB cluster in a VPC](#)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#)
- [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#)

Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the Amazon Web Services Region where you want to deploy your DB cluster. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

For more information, see [Scenarios for accessing a DB cluster in a VPC](#).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see [Dedicated instances](#) in the *Amazon Elastic Compute Cloud User Guide*.

Note

When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn't guarantee that the DB cluster will run on a dedicated host.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the Amazon CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given Amazon Web Services Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet. Aurora always assigns an IP address from a subnet that has free IP address space.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it.

For more information, see [Amazon Aurora IP addressing](#) and [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

Note

For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

Shared subnets

You can create a DB cluster in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB cluster from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB cluster.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora supports both IPv4 and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC.

Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

- [IPv4 addresses](#)
- [IPv6 addresses](#)
- [Dual-stack mode](#)

IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.

- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see [IP Addressing](#) in the *Amazon VPC User Guide*.

Dual-stack mode

When a DB cluster can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB cluster over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

Topics

- [Dual-stack mode and DB subnet groups](#)
- [Working with dual-stack mode DB instances](#)
- [Modifying IPv4-only DB clusters to use dual-stack mode](#)
- [Availability of dual-stack network DB clusters](#)
- [Limitations for dual-stack network DB clusters](#)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see [Tutorial: Create a VPC for use with a DB cluster \(dual-stack mode\)](#).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB cluster.

To determine whether a DB subnet group supports dual-stack mode by using the Amazon Web Services Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the Amazon CLI, run the [describe-db-subnet-groups](#) command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB cluster, you can specify dual-stack mode to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the Amazon Web Services Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

The screenshot shows the 'Network type' section in the AWS console. It includes a title 'Network type' with an 'Info' link, a note 'To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.', and two radio button options: 'IPv4' (unselected) and 'Dual-stack mode' (selected). The 'Dual-stack mode' option is highlighted with a blue border.

Network type [Info](#)
To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

IPv4
Your resources can communicate only over the IPv4 addressing protocol.

Dual-stack mode
Your resources can communicate over IPv4, IPv6, or both.

When you use the Amazon CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

To determine whether a DB cluster is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB cluster.

Modifying IPv4-only DB clusters to use dual-stack mode

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

It is recommended that you change the network type of your Amazon Aurora DB clusters during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-cluster` command.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. Modifying the DB subnet group of a DB cluster can cause downtime.

If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.

We recommend that you run the [modify-db-cluster](#) API with only the `--network-type` parameter with value `DUAL` to change the network of an Amazon Aurora cluster to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime.

If you can't connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:
 - a. Associate an IPv6 CIDR block with your VPC.

For instructions, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.

- b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

For instructions, see [Add an IPv6 CIDR block to your subnet](#) in the *Amazon VPC User Guide*.

- c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the Amazon Web Services Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

If you are using the Amazon CLI, run the [describe-db-subnet-groups](#) command, and make sure that the SupportedNetworkType value for the DB instance is Dual, IPv4.

2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

For instructions, see [Security group rules](#) in the *Amazon VPC User Guide*.

3. Modify the DB cluster to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

If you are using the console, make sure that the following settings are correct:

- **Network type – Dual-stack mode**

The screenshot shows a 'Network type' configuration panel. At the top, it says 'Network type Info' and provides a note: 'To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.' Below this, there are two radio button options. The first is 'IPv4' with the description 'Your resources can communicate only over the IPv4 addressing protocol.' The second is 'Dual-stack mode' with the description 'Your resources can communicate over IPv4, IPv6, or both.' The 'Dual-stack mode' option is selected, indicated by a blue circle and a blue border around its box.

- **DB subnet group** – The DB subnet group that you configured in a previous step
- **Security group** – The security that you configured in a previous step

If you are using the Amazon CLI, make sure that the following settings are correct:

- `--network-type` – dual
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-cluster --db-cluster-identifier my-cluster --network-type "DUAL"
```

4. Confirm that the DB cluster supports dual-stack mode.

If you are using the console, choose the **Configuration** tab for the DB cluster. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

If you are using the Amazon CLI, run the [describe-db-clusters](#) command, and make sure that the `NetworkType` value for the DB cluster is `dual`.

Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

Availability of dual-stack network DB clusters

Dual-stack network DB clusters are available in all Amazon Web Services Regions except for the following:

- Asia Pacific (Hyderabad)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Canada West (Calgary)
- Europe (Spain)
- Europe (Zurich)
- Israel (Tel Aviv)
- Middle East (UAE)

The following DB engine versions support dual-stack network DB clusters:

- Aurora MySQL versions:
 - 3.02 and higher 3 versions

- 2.09.1 and higher 2 versions

For more information about Aurora MySQL versions, see the [Release Notes for Aurora MySQL](#).

- Aurora PostgreSQL versions:
 - 15.2 and all higher versions
 - 14.3 and higher 14 versions
 - 13.7 and higher 13 versions

For more information about Aurora PostgreSQL versions, see the [Release Notes for Aurora PostgreSQL](#).

Limitations for dual-stack network DB clusters

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB clusters that use dual-stack mode must be private. They can't be publicly accessible.
- You can't use RDS Proxy with dual-stack mode DB clusters.

Hiding a DB cluster in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an Amazon EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. EC2 instances that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet. In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see [A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC](#).

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC.

Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance](#)

You can modify a DB cluster to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

Connectivity G

For information about modifying a DB instance to set the **Public access** option, see [Modifying a DB instance in a DB cluster](#).

Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

Note

If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see [Updating DNS support for your VPC](#).

Follow these steps to create a DB instance in a VPC:

- [Step 1: Create a VPC](#)
- [Step 2: Create a DB subnet group](#)
- [Step 3: Create a VPC security group](#)
- [Step 4: Create a DB instance in the VPC](#)

Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the Amazon Web Services Region.

For more information, see [Create a VPC with private and public subnets](#), or see [Create a VPC](#) in the *Amazon VPC User Guide*.

Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the Amazon CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the Amazon Web Services Region. As a best practice,

each DB subnet group should have at least one subnet for every Availability Zone in the Amazon Web Services Region.

For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see [Connect to the internet using an internet gateway](#) in the *Amazon VPC User Guide*.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

Subnet group details

Name

You won't be able to modify the name after your subnet group has been created.

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Description

VPC

Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

Add subnets

Availability Zones

Choose the Availability Zones that include the subnets you want to add.

Subnets

Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Subnets selected (2)

Availability zone	Subnet ID	CIDR block
us-east-1a	subnet-079bd4b8953aee1dd	10.0.0.0/24
us-east-1c	subnet-057e85b72c46fdd9a	10.0.1.0/24

Cancel

Create

8. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see [Create a VPC security group for a private DB cluster](#), or see [Control traffic to resources using security groups](#) in the *Amazon VPC User Guide*.

Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

Note

If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see [DNS attributes for your VPC](#) in the *Amazon VPC User Guide*.

For details on how to create a DB cluster, see [Creating an Amazon Aurora DB cluster](#).

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

Note

Updating VPCs isn't currently supported for Aurora DB clusters.

Scenarios for accessing a DB cluster in a VPC

Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- [An Amazon EC2 instance in the same VPC](#)
- [An EC2 instance in a different VPC](#)
- [A client application through the internet](#)
- [A private network](#)

A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an Amazon EC2 instance in the same VPC.

The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see [Tutorial: Create a VPC for use with a DB cluster \(IPv4 only\)](#).

Tip

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at <https://console.amazonaws.cn/vpc>.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB cluster, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

Type	Protocol	Port range	Source
MYSQL/Aurora	TCP	3306	sg-00bd2328e37926844 (tutorial-securitygroup)

For more information about connecting to the DB cluster from your EC2 instance, see [Connecting to an Amazon Aurora DB cluster](#).

A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another Amazon account, or with a VPC in a different Amazon Web Services Region. To learn more about VPC peering, see [VPC peering](#) in the *Amazon Virtual Private Cloud User Guide*.

A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other Amazon products.
- A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.

For information about creating a DB clusters in a VPC, see [Creating a DB cluster in a VPC](#).

A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An Amazon Site-to-Site VPN connection. For more information, see [What is Amazon Site-to-Site VPN?](#)
- An Amazon Direct Connect connection. For more information, see [What is Amazon Direct Connect?](#)
- An Amazon Client VPN connection. For more information, see [What is Amazon Client VPN?](#)

The following diagram shows a scenario with an Amazon Site-to-Site VPN connection.

For more information, see [Inter-network traffic privacy](#).

Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC](#).

Your DB cluster needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see [Tutorial: Create a web server and an Amazon Aurora DB cluster](#). For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

Tip

You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. In the top-right corner of the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:
 - **Name tag auto-generation** – **tutorial**
 - **IPv4 CIDR block** – **10.0.0.0/16**
 - **IPv6 CIDR block** – **No IPv6 CIDR block**
 - **Tenancy** – **Default**
 - **Number of Availability Zones (AZs)** – **2**
 - **Customize AZs** – **Keep the default values.**

- **Number of public subnet** – 2
 - **Number of private subnets** – 2
 - **Customize subnets CIDR blocks** – Keep the default values.
 - **NAT gateways (\$)** – None
 - **VPC endpoints** – None
 - **DNS options** – Keep the default values.
6. Choose **Create VPC**.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
 - **Security group name:** **tutorial-securitygroup**
 - **Description:** **Tutorial Security Group**
 - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**
4. Add inbound rules to the security group.
 - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at <https://checkip.amazonaws.com>. An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

⚠ Warning

If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- b. In the **Inbound rules** section, choose **Add rule**.
 - c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.
 - **Type:** SSH
 - **Source:** The IP address or range from Step a, for example: **203.0.113.25/32**.
 - d. Choose **Add rule**.
 - e. Set the following values for your new inbound rule to allow HTTP access to your web server:
 - **Type:** HTTP
 - **Source:** **0.0.0.0/0**
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.

3. On the **Create security group** page, set these values:
 - **Security group name:** `tutorial-db-securitygroup`
 - **Description:** **Tutorial DB Instance Security Group**
 - **VPC:** Choose the VPC that you created earlier, for example: `vpc-identifier` (`tutorial-vpc`)
4. Add inbound rules to the security group.
 - a. In the **Inbound rules** section, choose **Add rule**.
 - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster. By doing so, you can store and retrieve data from your web application to your database.
 - **Type:** **MySQL/Aurora**
 - **Source:** The identifier of the `tutorial-securitygroup` security group that you created previously in this tutorial, for example: `sg-9edd5cfb`.
5. Choose **Create security group** to create the security group.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **Subnets**.
 - c. Note the subnet IDs of the subnets named `tutorial-subnet-private1-us-west-2a` and `tutorial-subnet-private2-us-west-2b`.

You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
 - **Name:** `tutorial-db-subnet-group`
 - **Description:** `Tutorial DB Subnet Group`
 - **VPC:** `tutorial-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

Note

If you created this VPC to complete [Tutorial: Create a web server and an Amazon Aurora DB cluster](#), create the DB cluster by following the instructions in [Create an Amazon Aurora DB cluster](#).

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

Note

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group.
 - a. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
 - b. In the navigation pane, choose **Subnet groups**.
 - c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
 - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **VPCs**.
 - c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
 - d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
3. Delete the security groups.
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
 - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
 - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
 - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.
 - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the VPC.
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **VPCs**.
 - c. Select the VPC you want to delete, such as **tutorial-vpc**.
 - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will

also be deleted, including the subnets associated with it.

- e. On the confirmation page, enter **delete**, and then choose **Delete**.

Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see [Amazon Aurora IP addressing](#).

Dual-stack network clusters are supported in most regions. For more information see [Availability of dual-stack network DB clusters](#). To see the limitations of dual-stack mode, see [Limitations for dual-stack network DB clusters](#).

The following diagram shows this scenario.

For information about other scenarios, see [Scenarios for accessing a DB cluster in a VPC](#).

Your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster](#). For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](#).

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see [Amazon VPC User Guide](#).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. In the upper-right corner of the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
 - **Name tag auto-generation** – **tutorial-dual-stack**
 - **IPv4 CIDR block** – **10.0.0.0/16**
 - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
 - **Tenancy** – **Default**
 - **Number of Availability Zones (AZs)** – **2**
 - **Customize AZs** – Keep the default values.
 - **Number of public subnet** – **2**
 - **Number of private subnets** – **2**
 - **Customize subnets CIDR blocks** – Keep the default values.
 - **NAT gateways (\$)** – **None**
 - **Egress only internet gateway** – **No**
 - **VPC endpoints** – **None**
 - **DNS options** – Keep the default values.

Note

Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose Create VPC.**Create a VPC security group for a public Amazon EC2 instance**

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
 - **Security group name:** **tutorial-dual-stack-securitygroup**
 - **Description:** **Tutorial Dual-Stack Security Group**
 - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier*** (**tutorial-dual-stack-vpc**)
4. Add inbound rules to the security group.
 - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`.

An example of an Internet Protocol version 6 (IPv6) address range is

`2001:db8:1234:1a00::/64`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

⚠ Warning

If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

- b. In the **Inbound rules** section, choose **Add rule**.
 - c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:
 - **Type:** SSH
 - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **203.0.113.25/32**. An example of an IPv6 IP address is **2001:DB8::/32**.
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
 - **Security group name:** **tutorial-dual-stack-db-securitygroup**
 - **Description:** **Tutorial Dual-Stack DB Instance Security Group**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group:
 - a. In the **Inbound rules** section, choose **Add rule**.
 - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB cluster. Doing this means that you can send data from your EC2 instance to your database.
 - **Type:** **MySQL/Aurora**
 - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.
 5. To create the security group, choose **Create security group**.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **Subnets**.
 - c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
 - **Name:** `tutorial-dual-stack-db-subnet-group`
 - **Description:** `Tutorial Dual-Stack DB Subnet Group`
 - **VPC:** `tutorial-dual-stack-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as `tutorial-dual-stack-vpc (vpc-identifier)` created in [Create a VPC with private and public subnets](#).
- **Subnet** – Choose an existing public subnet, such as `subnet-identifier | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a` created in [Create a VPC security group for a public Amazon EC2 instance](#).
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in [Create a VPC security group for a public Amazon EC2 instance](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

To create a DB instance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the upper-right corner of the console, choose the Amazon Web Services Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:
 - **Network type** – Choose **Dual-stack mode**.

Network type **Info**
To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

IPv4
Your resources can communicate only over the IPv4 addressing protocol.

Dual-stack mode
Your resources can communicate over IPv4, IPv6, or both.

- **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in [Create a VPC with private and public subnets](#).

The VPC must have subnets in different Availability Zones.

- **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in [Create a DB subnet group](#).
- **Public access** – Choose **No**.
- **VPC security group (firewall)** – Select **Choose existing**.
- **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in [Create a VPC security group for a private DB cluster](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters](#).

Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide*.

To connect to your Aurora MySQL DB cluster from the Amazon EC2 instance, follow the instructions in [Connect to an Aurora MySQL DB cluster](#).

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB clusters. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group:
 - a. Open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
 - b. In the navigation pane, choose **Subnet groups**.
 - c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
 - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.

- b. Choose **VPC Dashboard**, and then choose **VPCs**.
 - c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.
 - d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.
3. Delete the security groups:
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
 - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.
 - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
 - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.
 - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the NAT gateway:
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.
 - c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
 - d. For **Actions**, choose **Delete NAT gateway**.
 - e. On the confirmation page, enter **delete**, and then choose **Delete**.
5. Delete the VPC:
 - a. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
 - b. Choose **VPC Dashboard**, and then choose **VPCs**.
 - c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.
 - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

6. Release the Elastic IP addresses:
 - a. Open the Amazon EC2 console at <https://console.amazonaws.cn/ec2/>.
 - b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
 - c. Select the Elastic IP address that you want to release.
 - d. For **Actions**, choose **Release Elastic IP addresses**.
 - e. On the confirmation page, choose **Release**.

Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

Topics

- [Quotas in Amazon Aurora](#)
- [Naming constraints in Amazon Aurora](#)
- [Amazon Aurora size limits](#)

Quotas in Amazon Aurora

Each Amazon account has quotas, for each Amazon Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per Amazon Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom endpoints per DB cluster	Each supported Region: 5	Yes	The maximum number of custom endpoints that you can create per Aurora DB cluster in this account in the current Region. This value reflects the highest number of custom endpoints in a DB cluster in the account. Other DB clusters in the account

Name	Default	Adjustable	Description
			might have a lower number of custom endpoints.
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	Yes	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed in this account in the current Region
DB instances	ap-south-1: 20 Each of the other supported Regions: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB shard groups	Each supported Region: 5	Yes	The maximum number of DB shard groups for Aurora Limitless Database in this account in the current Region
DB subnet groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of DB subnet groups

Name	Default	Adjustable	Description
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current Amazon Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.

Name	Default	Adjustable	Description
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed in this account in the current Amazon Region
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current Amazon Region
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups

Name	Default	Adjustable	Description
Parameter groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current Amazon Region
Read replicas per primary	Each supported Region: 15	Yes	The maximum number of read replicas per primary DB instance. This quota can't be adjusted for Amazon Aurora.
Reserved DB instances	Each supported Region: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current Amazon Region
Security groups	ap-south-1: 20 Each of the other supported Regions: 25	Yes	The maximum number of DB security groups
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group

Name	Default	Adjustable	Description
Total storage for all DB instances	Each supported Region: 100,000 Gigabytes	Yes	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

If your application requires more DB instances, you can request additional DB instances by opening the [Service Quotas console](#). In the navigation pane, choose **Amazon services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

For RDS for Oracle, you can create up to 15 read replicas per source DB instance in each Region, but we recommend limiting replicas to 5 to minimize replication lag.

Backups managed by Amazon Backup are considered manual DB clustersnapshots, but don't count toward the manual cluster snapshot quota. For information about Amazon Backup, see the [Amazon Backup Developer Guide](#).

Note that the default quota for cross-Region automated backups is 20 for an Amazon Web Services account, and the default quota for the number of snapshot copy requests is 20 for each Region for an Amazon Web Services account.

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the [Service Quotas console](#).
- From the Amazon CLI, use the [request-service-quota-increase](#) Amazon CLI command.

For more information, see the [Service Quotas User Guide](#).

Naming constraints in Amazon Aurora

The naming constraints in Amazon Aurora are as follows:

- DB cluster identifier:
 - Must contain 1–63 alphanumeric characters or hyphens.
 - First character must be a letter.
 - Can't end with a hyphen or contain two consecutive hyphens.
 - Must be unique for all DB instances per Amazon account, per Amazon Region.
- Initial database name – Database name constraints differ between Aurora MySQL and Aurora PostgreSQL. For more information, see the available settings when creating each DB cluster.
- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB cluster.
- Master password:
 - The password for the database master user can include any printable ASCII character except /, ', ", @, or a space.
 - The password can contain the following number of printable ASCII characters depending on the DB engine:
 - Aurora MySQL: 8–41
 - Aurora PostgreSQL: 8–99
- DB parameter group:

- Must contain 1–255 alphanumeric characters.
- First character must be a letter.
- Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:
 - Must contain 1–255 characters.
 - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Amazon Aurora size limits

Storage size limits

An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB) for the following engine versions:

- All available Aurora MySQL version 3 versions; Aurora MySQL version 2, versions 2.09 and higher
- All available Aurora PostgreSQL versions

For lower engine versions, the maximum size of an Aurora cluster volume is 64 TiB. For more information, see [How Aurora storage automatically resizes](#).

To monitor the remaining storage space, you can use the `AuroraVolumeBytesLeftTotal` metric. For more information, see [Cluster-level metrics for Amazon Aurora](#).

SQL table size limits

For an Aurora MySQL DB cluster, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

Table space ID limits

The maximum table space ID for Aurora MySQL is 2147483647. If you frequently create and drop tables, make sure to be aware of your table space IDs and plan to use logical dumps. For more information, see [Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump](#).

Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

- [Can't connect to Amazon RDS DB instance](#)
- [Amazon RDS security issues](#)
- [Resetting the DB instance owner password](#)
- [Amazon RDS DB instance outage or reboot](#)
- [Amazon RDS DB parameter changes not taking effect](#)
- [Freeable memory issues in Amazon Aurora](#)
- [Amazon Aurora MySQL replication issues](#)

For information about debugging problems using the Amazon RDS API, see [Troubleshooting applications on Aurora](#).

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

Note

When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see [Provide access to the DB cluster in the VPC by creating a security group](#).

 **Note**

Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see [Hiding a DB cluster in a VPC from the internet](#).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications because of your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

To configure an internet gateway for a subnet

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at <https://console.amazonaws.cn/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at <https://console.amazonaws.cn/vpc/>.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet

gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

- a. Choose the ID of the route table (rtb-xxxxxxx) to navigate to the route table.
- b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.

- c. Choose **Save routes**.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB cluster in a VPC](#).

Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```

```
Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
open
connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

Note

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

Amazon RDS security issues

To avoid security issues, never use your Amazon Web Services account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see [Creating an IAM user in your Amazon Web Services account](#). For information about creating users in Amazon IAM Identity Center, see [Manage identities in IAM Identity Center](#).

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited

for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](#).

Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the Amazon account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see [Master user account privileges](#).

You can change the DB instance password by using the Amazon RDS console, the Amazon CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) API operation. For more information about modifying a DB instance in a DB cluster, see [Modifying a DB instance in a DB cluster](#).

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.

- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the [RebootDBInstance](#) API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see [Modifying parameters in a DB parameter group in Amazon Aurora](#).

Freeable memory issues in Amazon Aurora

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see [Monitoring tools for Amazon Aurora](#).

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see [Amazon Aurora DB instance classes](#).

You can also change the memory settings. For example, on Aurora MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see [How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?](#)

For Aurora Serverless v2, `FreeableMemory` represents the amount of unused memory that's available when the Aurora Serverless v2 DB instance is scaled to its maximum capacity. You might have the instance scaled down to relatively low capacity, but it still reports a high value for `FreeableMemory`, because the instance can scale up. That memory isn't available right now, but you can get it if you need it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity, `FreeableMemory` increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of 0, the DB instance has scaled up as much as it can. It's nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of 0 on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance. For more information, see [Important Amazon CloudWatch metrics for Aurora Serverless v2](#).

For Aurora Serverless v1, you can change the capacity range to use more ACUs. For more information, see [Modifying an Aurora Serverless v1 DB cluster](#).

Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

Topics

- [Diagnosing and resolving lag between read replicas](#)
- [Diagnosing and resolving a MySQL read replication failure](#)
- [Replication stopped error](#)
- [Read replica replication fails to initialize metadata structure](#)

Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `AuroraBinlogReplicaLag` metric.

The `AuroraBinlogReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MySQL `SHOW REPLICA STATUS` command. For more information, see [SHOW REPLICA STATUS Statement](#) in the MySQL documentation.

When the `AuroraBinlogReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `AuroraBinlogReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see [Diagnosing and resolving a MySQL read replication failure](#). A `AuroraBinlogReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is NULL.

Note

Previous versions of Aurora MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using Aurora MySQL version 1 or 2, then use `SHOW SLAVE STATUS`. Use `SHOW REPLICA STATUS` for Aurora MySQL version 3 and higher.

The `AuroraBinlogReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `AuroraBinlogReplicaLag` metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `AuroraBinlogReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see [Replication implementation details](#) in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see [Query cache configuration](#).
- Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump \  
  -h <endpoint> \  
  --port=<port> \  
  -u=<username> \  
  -p <password> \  
  database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^  
  -h <endpoint> ^  
  --port=<port> ^  
  -u=<username> ^  
  -p <password> ^  
  database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `ERROR` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045](#), [RDS-EVENT-0046](#), and [RDS-EVENT-0057](#). For more information about events and subscribing to events, see [Working with Amazon RDS event notification](#). If a MySQL error message is returned, check the error in the [MySQL error message documentation](#).

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to `0` to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

You can convert a MyISAM table to InnoDB with the following command:

```
alter table <schema>.<table_name> engine=innodb;
```

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in [Skipping the current replication error](#). Your Aurora MySQL DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see [mysql_rds_skip_repl_error](#).
- If you encounter a binary log (binlog) position issue, you can change the replica replay position. You do so with the `mysql.rds_next_master_log` command for Aurora MySQL version 1 and 2. You do so with the `mysql.rds_next_source_log` command for Aurora MySQL version 3 and higher. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see [mysql_rds_next_master_log](#).
- If you encounter a temporary performance issue because of high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. This way, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see [Troubleshooting a MySQL read replica problem](#).

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error because of binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the [mysql_rds_set_configuration](#) procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica replication fails to initialize metadata structure

When you attempted to start replication, you received the following error message:

```
Read Replica Replication Error - SQLError: 13124, reason: Replica failed to initialize applier metadata structure from the repository
```

This error occurs when there is a problem with the metadata structure of the replica. To fix the metadata structure, you must create a new replica.

To prevent this from happening in the future, perform one of the following actions:

- If possible, disable multi-threading on your replicas. Starting with MySQL 8.0.27, multi-threading is enabled by default.
- If you need to use multi-threading on your replicas, then we recommend that you use GTID-based replication. For more information, see [Using GTID-based replication](#).

Amazon RDS API reference

In addition to the Amazon Web Services Management Console and the Amazon Command Line Interface (Amazon CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see [Actions](#).
- For an alphabetical list of data types, see [Data types](#).
- For a list of common query parameters, see [Common parameters](#).
- For descriptions of the error codes, see [Common errors](#).

For more information about the Amazon CLI, see [Amazon Command Line Interface reference for Amazon RDS](#).

Topics

- [Using the Query API](#)
- [Troubleshooting applications on Aurora](#)

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see [Query requests](#) in the *Amazon EC2 API Reference*.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to [Amazon Relational Database Service \(RDS\)](#) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either Amazon signature version 4 or signature version 2. For more information, see [Signature Version 4 signing process](#) and [Signature version 2 signing process](#).

Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- [Retrieving errors](#)
- [Troubleshooting tips](#)

For information about troubleshooting for Amazon RDS DB instances, see [Troubleshooting for Amazon Aurora](#).

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the `XML::XPath` module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
 $xp->findvalue("//Error[1]/Code"), "\n", " ",
 $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the Amazon Region that you're targeting by checking <http://status.www.amazonaws.cn>.
- Check the structure of your request.

Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.

- Check Amazon re:Post.

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [Amazon re:Post](#).

Document history

Current API version: 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the [Amazon Relational Database Service User Guide](#).

Note

Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see [Document history](#) in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the [What's New with Database?](#) page. For **Products**, choose **Amazon Aurora**. Then search using keywords such as **global database** or **Serverless**.

Change	Description	Date
Aurora PostgreSQL zero-ETL integrations support additional Regions	Aurora PostgreSQL zero-ETL integrations are now available in additional Regions. For more information, see Supported Regions and Aurora DB engines for zero-ETL integrations with Amazon Redshift .	February 17, 2025
End-of-life information for Aurora Serverless v1	Amazon has announced the end-of-life date for Aurora Serverless v1: March 31st, 2025. We strongly recommend upgrading any Aurora Serverless v1 DB clusters to Aurora Serverless	December 6, 2024

s v2 before that date. The upgrade can involve a change in the major version number of the database engine. Thus, it's important to plan, test, and implement this switchover before the end-of-life date. Starting January 8th, 2025, customers will no longer be able to create new Aurora Serverless v1 clusters or instances with either the Amazon Web Services Management Console or the CLI. For information about the upgrade procedure from Aurora Serverless v1 to Aurora Serverless v2, see [Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2](#).

[Aurora supports CloudWatch Database Insights](#)

You can now use CloudWatch Database Insights to monitor your Amazon Aurora DB clusters at scale. For more information, see [Monitoring Amazon Aurora databases with CloudWatch Database Insights](#).

December 1, 2024

[Amazon Aurora supports the db.r8g instance classes](#)

You can now use the db.r8g instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

November 21, 2024

[Aurora Serverless v2 supports automatic pause and resume](#)

Aurora Serverless v2 DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0 ACUs. For more information, see [Automatic pause and resume for Aurora Serverless v2](#).

November 20, 2024

[Amazon Aurora supports auto-migrating EC2 databases](#)

You can use the RDS console to migrate an EC2 database to Aurora. Aurora uses Amazon Database Migration Service (Amazon DMS) to migrate your source EC2 database. Amazon DMS allows you to migrate relational databases into your Amazon Web Services Cloud. For more information, see [Auto migrating EC2 databases to Amazon Aurora using Amazon Database Migration Service](#).

November 20, 2024

[Amazon Advanced NodeJS Wrapper generally available](#)

The Amazon Web Services (Amazon) Advanced NodeJS Wrapper is complementary to and extends the functionality of an existing NodeJS driver. For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

November 19, 2024

[Amazon Aurora supports the db.r7i instance classes](#)

You can now use the db.r7i instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

November 18, 2024

[RDS Data API for Aurora MySQL supports all Performance Insights views](#)

You can now use the **Top hosts** or **Top applications** views for Performance Insights to monitor SQL operations performed using RDS Data API for Aurora MySQL. For information about Performance Insights support, see [Monitoring RDS Data API queries with Performance Insights](#).

October 31, 2024

[Aurora PostgreSQL Limitless Database](#)

Amazon Aurora PostgreSQL Limitless Database is a new, automated, horizontal scaling (sharding) capability of Amazon Aurora. Aurora PostgreSQL Limitless Database lets you scale beyond the existing Aurora limits for write throughput and storage by distributing a database workload over multiple Aurora writer instances, while maintaining the ability to use it as a single database. For more information, see [Amazon Aurora PostgreSQL Limitless Database](#).

October 31, 2024

[Amazon Aurora MySQL version 2 end of standard support](#)

Aurora MySQL version 2 reached the end of standard support on October 31, 2024. For more information, see [Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support](#).

October 31, 2024

[Amazon Aurora supports cluster-level OS upgrades](#)

You can now apply Aurora operating system upgrades at the DB cluster level. Rolling upgrades automatically apply upgrades to a few reader DB instances at a time, thus preserving read availability. For more information, see [Operating system updates for Aurora DB clusters](#).

October 30, 2024

[Aurora global clusters support tagging](#)

You can now add tags to Aurora global clusters. An Aurora global cluster is the parent resource that contains the primary and secondary DB clusters in an Aurora global database. For general information about tagging, see [Tagging Aurora and Amazon RDS resources](#). For information about tagging with Aurora Global Database, see [Tagging Aurora Global Database resources](#).

October 24, 2024

[Aurora Global Database writer endpoints](#)

Each Aurora Global Database now comes with a writer endpoint that is automatically updated by Aurora to route requests to the current writer instance of the primary DB cluster after an Aurora Global Database switchover and failover operation. To learn more about using the writer endpoint along with Aurora Global Database switchover and failover, see [Using switchover or failover in Amazon Aurora Global Database](#).

October 22, 2024

[Aurora PostgreSQL zero-ETL integrations with Amazon Redshift generally available](#)

Zero-ETL integrations make transactional data available in Amazon Redshift within seconds of it being written to an Aurora PostgreSQL source DB cluster. The feature is now generally available. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

October 15, 2024

[Aurora Serverless v2 supports 256 ACUs](#)

You can now create Aurora Serverless v2 DB clusters with a maximum capacity of 256 Aurora capacity units (ACUs). For more information, see [Aurora Serverless v2 capacity](#).

October 3, 2024

[Amazon Aurora supports Console-to-Code](#)

You can now use Console-to-Code to generate code from actions that you perform in the RDS console. The generated code can help you write code to automate your use of other Amazon services. For more information, see [Use Console-to-Code to generate code for your Aurora console actions](#).

October 3, 2024

[RDS Data API supports Performance Insights](#)

You can now use Performance Insights to monitor SQL operations performed using RDS Data API. For information about Performance Insights support, see [Monitoring RDS Data API queries with Performance Insights](#).

September 26, 2024

[RDS Data API for Aurora Serverless v2 and provisioned is available for Aurora MySQL](#)

RDS Data API is now available for Aurora MySQL clusters that use Aurora Serverless v2 or provisioned instances. For usage information for RDS Data API, see [Using RDS Data API](#). For information about Aurora MySQL version and Amazon Region support for RDS Data API, see [Data API with Aurora MySQL Serverless v2 and provisioned](#).

September 26, 2024

[Amazon Aurora is available in the Asia Pacific \(Malaysia\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Malaysia) Region. For more information, see [Regions and Availability Zones](#).

August 22, 2024

[Update to existing policy](#)

Amazon RDS removed `sns:Publish` permission from the AmazonRDSBetaServiceRolePolicy of the AWSServiceRoleForRDSBeta service-linked role. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 7, 2024

[Update to existing policy](#)

Amazon RDS removed `sns:Publish` permission from the AmazonRDSPreviewServiceRolePolicy of the AWSServiceRoleForRDSPreview service-linked role. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 7, 2024

[Aurora Serverless v2 supports auto-pause \(scale-to-zero\)](#)

Aurora Serverless v2 DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0. For more information, see [Using Aurora Serverless v2](#).

July 25, 2024

[Amazon ODBC Driver for MySQL generally available](#)

The Amazon Web Services (Amazon) ODBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. For more information, see [Connecting to Aurora MySQL with the Amazon Web Services \(Amazon\) ODBC Driver for MySQL](#).

July 18, 2024

[RDS Data API for Aurora Serverless v2 is available in more Regions](#)

RDS Data API is now available for Aurora PostgreSQL in several additional Amazon Regions. For information about Region support for RDS Data API, see [Data API with Aurora PostgreSQL Serverless v2 and provisioned](#).

July 9, 2024

[Amazon Python Driver generally available](#)

The Amazon Web Services (Amazon) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more information, see [Connecting to Aurora DB clusters with the Amazon drivers](#).

May 23, 2024

[Zero-ETL integrations available in China Regions](#)

Zero-ETL integrations are now available in the Amazon Web Services Regions China (Beijing) and China (Ningxia). For more information, see [Zero-ETL integrations with Amazon Redshift](#).

May 21, 2024

[RDS Proxy is available in more Regions](#)

RDS Proxy is now available in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary), and Europe (Zurich) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

May 21, 2024

[Amazon RDS supports fine-grained access for Performance Insights](#)

You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` actions. For more information, see https://docs.amazonaws.cn/AmazonRDS/latest/UserGuide/USER_PerfInsights.access-control.dimensionAccess-policy.html.

May 21, 2024

[Amazon RDS Extended Support](#)

Creating or restoring an Aurora MySQL version 2 or 3, or Aurora PostgreSQL version 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the Aurora end of standard support date for your database engine. For more information, see [Using Amazon RDS Extended Support](#).

March 21, 2024

[Data filtering for zero-ETL integrations](#)

Amazon RDS supports data filtering at the database and table level for zero-ETL integrations with Amazon Redshift. For more information, see [Data filtering for Aurora zero-ETL integrations with Amazon Redshift.](#)

March 20, 2024

[Aurora MySQL integrations with Amazon Bedrock](#)

You can now integrate Amazon Aurora MySQL databases with Amazon Bedrock to power generative AI applications. For more information, see [Using Amazon Aurora machine learning with Aurora MySQL.](#)

March 8, 2024

[New Amazon managed policy](#)

Amazon RDS added a new managed policy named AmazonRDS Custom InstanceProfileRolePolicy to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see [Amazon RDS updates to Amazon managed policies.](#)

February 27, 2024

[Amazon RDS support for Amazon Secrets Manager in the Israel \(Tel Aviv\) Region](#)

Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see [Password management with Amazon RDS and Amazon Secrets Manager](#).

February 21, 2024

[Amazon RDS Extended Support](#)

Amazon RDS now automatically enables Amazon RDS Extended Support when Aurora MySQL and Aurora PostgreSQL major engine versions in your DB clusters and global clusters reach the Aurora end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

February 15, 2024

[Aurora PostgreSQL 16.1 supports Babelfish for Aurora PostgreSQL 4.0.0](#)

Aurora PostgreSQL 16.1 supports Babelfish 4.0.0. For a list of new features, see [16.1](#). For a list of features supported in each Babelfish release, see [Supported functionality in Babelfish by version](#). For usage information, see [Working with Babelfish for Aurora PostgreSQL](#).

January 31, 2024

Update to default CA Certificate	The default CA certificate is set to <code>rds-ca-rsa2048-g1</code> . For more information, see Using SSL/TLS to encrypt a connection to a DB cluster .	January 26, 2024
RDS Proxy is available in the Europe (Spain) Region	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see Using Amazon RDS Proxy .	January 8, 2024
RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned	You can now use RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned DB clusters. With RDS Data API, you can access your Aurora clusters through a secure HTTP endpoint and run SQL statements without using database drivers or managing connections. For more information, see Using RDS Data API .	December 21, 2023
Aurora PostgreSQL integrations with Amazon Bedrock	You can now integrate Amazon Aurora PostgreSQL databases with Amazon Bedrock to power generative AI applications. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL .	December 21, 2023

[Amazon Aurora is available in the Canada West \(Calgary\) Region](#)

Amazon Aurora is now available in the Canada West (Calgary) Region. For more information, see [Regions and Availability Zones](#).

December 20, 2023

[Amazon RDS supports viewing and responding to recommendations](#)

Amazon Aurora recommendations now includes threshold based proactive and machine learning based reactive recommendations. For more information, see [Recommendations for Amazon Aurora](#).

December 19, 2023

[Aurora PostgreSQL zero-ETL integrations with Amazon Redshift \(preview\)](#)

You can now create zero-ETL integrations with Amazon Redshift using an Aurora PostgreSQL source DB cluster. For the preview release, you must create all integrations in the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-west-2) Amazon Web Services Region. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

November 28, 2023

[Amazon Aurora PostgreSQL supports global database write forwarding](#)

You can now enable write forwarding on secondary clusters in an Aurora PostgreSQL-based global database. For more information, see [Using write forwarding in an Aurora PostgreSQL global database](#).

November 9, 2023

[Aurora PostgreSQL support for Optimized Reads](#)

You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

November 8, 2023

[Amazon RDS exports Performance Insights metrics to Amazon CloudWatch](#)

Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see [Exporting Performance Insights metrics to CloudWatch](#).

November 8, 2023

[Aurora MySQL zero-ETL integrations with Amazon Redshift general availability](#)

Zero-ETL integrations with Amazon Redshift are now generally available for Aurora MySQL. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

November 7, 2023

[Aurora PostgreSQL support for RDS Blue/Green Deployments](#)

You can now create a blue/green deployment from an Aurora PostgreSQL DB cluster. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

October 26, 2023

[Aurora MySQL supports server-side encryption with Amazon KMS keys \(SSE-KMS\)](#)

In Aurora MySQL version 3.05 and higher, you can use SSE-KMS, including Amazon managed keys and customer managed keys, for server-side encryption of data that you load from or save to Amazon S3. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#) and [Saving data from an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).

October 25, 2023

[Aurora MySQL optimizations reduce database restart time](#)

In Aurora MySQL version 3.05 and higher, we've introduced optimizations that reduce the database restart time. These optimizations provide up to 65% less downtime than without optimizations, and fewer disruptions to your database workloads, after a restart. For more information, see [Optimizations to reduce database restart time](#).

October 25, 2023

[Update to Amazon managed policies](#)

The AmazonRDSPerformanceInsightsReadOnly and AmazonRDSPerformanceInsightsFullAccess managed policies now includes Sid (statement ID) as an identifier in the policy statement. For more information, see [Amazon RDS updates to Amazon managed policies](#).

October 23, 2023

[Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch](#)

The **DB_PERF_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see [Creating CloudWatch alarms to monitor Amazon Aurora](#).

September 20, 2023

[Amazon Aurora supports point-in-time recovery \(PITR\) with Amazon Backup](#)

You can now manage Aurora automated (continuous) backups in Amazon Backup and restore to specified times from them. For more information, see [Restoring a DB cluster to a specified time using Amazon Backup](#).

September 7, 2023

[Amazon RDS Extended Support](#)

Amazon Aurora announces the upcoming ability to continue running Aurora MySQL and Aurora PostgreSQL major engine versions in your DB instances past the Aurora end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

September 1, 2023

[Amazon Aurora MySQL extends support for Percona XtraBackup](#)

You can now perform physical migrations of MySQL 8.0 databases to Aurora MySQL version 3 DB clusters. For more information, see [Physical migration from MySQL by using Percona XtraBackup and Amazon S3](#).

August 24, 2023

[Aurora global database supports global database failover](#)

Aurora global database now supports managed global failover, allowing you to more easily recover from a true Regional disaster or complete service-level outage. To learn more about this feature, see [Performing managed failovers for Aurora global databases](#).

The feature previously called "managed planned failover" is now called "switchover." For information about switchovers, see [Performing switchovers for Amazon Aurora global databases](#).

August 21, 2023

[Update to Amazon managed policy permissions](#)

The AmazonRDSFullAccess managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 17, 2023

[Update to Amazon managed policy permissions](#)

The addition of new permissions to AmazonRDS PerformanceInsight sReadOnly managed policy and addition of new managed policy AmazonRDS PerformanceInsight sFullAccess allows you generate a DB load analysis report for a time period. For more information, see [Amazon RDS updates to Amazon managed policies](#).

August 16, 2023

[Amazon RDS supports DB load time period analysis with Performance Insights](#)

Performance Insights allows you to create performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see [Analyzing DB load for a period of time](#).

August 16, 2023

[Amazon Aurora supports retaining automated backups for DB clusters](#)

You can now retain automated backups for deleted Aurora clusters and restore them to a specified point in time. For more information, see [Retaining automated backups](#).

August 4, 2023

[Amazon Aurora is available in the Israel \(Tel Aviv\) Region](#)

Amazon Aurora is now available in the Israel (Tel Aviv) Region. For more information, see [Regions and Availability Zones](#).

August 1, 2023

[Amazon Aurora MySQL supports local \(in-cluster\) write forwarding](#)

You can now forward write operations from a reader DB instance to a writer DB instance within an Aurora MySQL DB cluster. For more information, see [Using write forwarding in an Amazon Aurora MySQL DB cluster](#).

July 31, 2023

[Amazon Aurora supports Aurora Serverless v2 in an additional Amazon Web Services Region](#)

You can now create Aurora Serverless v2 DB clusters in the Asia Pacific (Melbourne) Amazon Web Services Region. For information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

June 28, 2023

[Amazon Aurora introduces zero-ETL integrations with Amazon Redshift \(preview\)](#)

Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an Aurora MySQL DB cluster. For more information, see [Working with Aurora zero-ETL integrations with Amazon Redshift](#).

June 28, 2023

[Amazon RDS provides combined Performance Insights and CloudWatch metrics view in the Performance Insights dashboard](#)

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. For more information, see [Viewing combined metrics with the Performance Insights dashboard](#).

May 24, 2023

[Amazon Aurora supports the db.r7g instance classes](#)

You can now use the db.r7g instance classes to create Aurora DB clusters. For more information, see [Aurora DB instance classes](#).

May 11, 2023

[Amazon Aurora supports a new DB cluster storage configuration](#)

With Aurora I/O-Optimized, you pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations. For more information, see [Storage configurations for Amazon Aurora DB clusters](#).

May 11, 2023

[Amazon Aurora supports Aurora Serverless v2 in additional Amazon Web Services Regions](#)

You can now create Aurora Serverless v2 DB clusters in the following Amazon Web Services Regions: Asia Pacific (Hyderabad), Europe (Spain) Europe (Zurich), and Middle East (UAE). For information about Aurora Serverless v2, see [Using Aurora Serverless v2](#).

May 4, 2023

Aurora Serverless v1 supports conversion to provisioned	You can convert an Aurora Serverless v1 DB cluster directly to a provisioned DB cluster. For more information, see Converting an Aurora Serverless v1 DB cluster to provisioned .	April 27, 2023
Aurora Serverless v1 supports Amazon Aurora PostgreSQL version 13	You can now create Aurora Serverless v1 DB clusters that run Aurora PostgreSQL version 13. For more information, see Aurora Serverless v1 .	April 27, 2023
Amazon Aurora support for Amazon Secrets Manager in the China Regions	Amazon Aurora supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see Password management with Amazon Aurora and Amazon Secrets Manager .	April 20, 2023
Amazon Aurora supports publishing events with tags to topic subscribers	Amazon Aurora event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see Amazon RDS event notification tags and attributes .	April 17, 2023

[Update to IAM service-linked role permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see [Amazon RDS updates to Amazon managed policies](#).

March 30, 2023

[Amazon Aurora supports global databases in the Asia Pacific \(Melbourne\) Region](#)

You can now create Aurora global databases in the Asia Pacific (Melbourne) Region. For information about Aurora global databases, see [Using Amazon Aurora global databases](#).

March 22, 2023

[Update to Amazon managed policy permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to Amazon CloudWatch. For more information, see [Amazon RDS updates to Amazon managed policies](#).

March 16, 2023

[RDS Proxy is available in the China Regions](#)

RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 15, 2023

[Amazon Aurora supports Aurora Serverless v2 in the China Regions](#)

Aurora Serverless v2 is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see [Aurora Serverless v2](#).

March 15, 2023

[RDS Proxy is available in the Asia Pacific \(Jakarta\) Region](#)

RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 8, 2023

[Amazon Aurora MySQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB clusters. For more information, see [Using Kerberos authentication for Aurora MySQL](#).

March 8, 2023

[Amazon Aurora supports global databases in additional Amazon Web Services Regions](#)

You can now create Aurora global databases in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about Aurora global databases, see [Using Amazon Aurora global databases](#).

March 6, 2023

[Amazon Aurora supports copying DB cluster snapshots in additional Amazon Web Services Regions](#)

You can now copy DB cluster snapshots in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Asia Pacific (Melbourne), Europe (Milan), Europe (Spain), Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about copying DB cluster snapshots, see [Copying a DB cluster snapshot](#).

March 6, 2023

[Amazon DevOps Guru for RDS supports proactive insights](#)

Amazon DevOps Guru for RDS publishes proactive insights with recommendations to help you address issues in your Aurora databases before they are predicted to happen. For more information, see [How DevOps Guru for RDS works](#).

February 28, 2023

[Amazon Aurora MySQL version 1 is deprecated](#)

Aurora MySQL version 1 (compatible with MySQL 5.6) has been deprecated. For more information, see [How long Amazon Aurora major versions remain available](#).

February 28, 2023

[Aurora Serverless v1 supports setting the DB cluster maintenance window](#)

You can now set the maintenance window for Aurora Serverless v1 DB clusters. For more information, see [Adjusting the preferred DB cluster maintenance window](#).

February 27, 2023

[Amazon Aurora supports Database Activity Streams in the Asia Pacific \(Hyderabad\), Europe \(Spain\), and Middle East \(UAE\) Regions.](#)

For more information, see [Database Activity Streams](#).

January 27, 2023

[Amazon Aurora is available in the Asia Pacific \(Melbourne\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Melbourne) Region. For more information, see [Regions and Availability Zones](#).

January 23, 2023

[Specify certificate authority \(CA\) during DB cluster creation](#)

You can now specify which CA to use for a DB cluster's server certificate during DB cluster creation. For more information, see [Certificate authorities](#).

January 5, 2023

[Aurora MySQL 3.* support for backtracking](#)

Aurora MySQL 3.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see [Backtracking an Aurora DB cluster](#).

January 4, 2023

[Use Amazon RDS Blue/Green Deployments available in additional Amazon Web Services Regions](#)

The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

December 22, 2022

[Update to IAM service-linked role permissions](#)

The AmazonRDSServiceRolePolicy policy now grants additional permissions to Amazon Secrets Manager. For more information, see [Amazon RDS updates to Amazon managed policies](#).

December 22, 2022

[Amazon Aurora integrates with Amazon Secrets Manager for password management](#)

Aurora can manage the master user password for a DB cluster in Secrets Manager. For more information, see [Password management with Amazon Aurora and Amazon Secrets Manager](#).

December 22, 2022

[Amazon Aurora supports Aurora Serverless v2 in additional Amazon Web Services Regions](#)

Aurora Serverless v2 is now available in the Africa (Cape Town) and Europe (Milan) Regions. For more information, see [Aurora Serverless v2](#).

December 21, 2022

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 14](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 14 DB cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

December 13, 2022

[Amazon Aurora alerts you to recent anomalies detected by Amazon DevOps Guru](#)

The database details page of the console alerts you both to current and anomalies that occurred in the past 24 hours. For more information, see [How DevOps Guru for RDS works](#).

December 13, 2022

[Amazon RDS Proxy supports global databases](#)

You can now use RDS Proxy with Aurora global databases . For more information, see [Using RDS Proxy with Aurora global databases](#).

December 7, 2022

[Aurora PostgreSQL DB clusters support Trusted Language Extensions for PostgreSQL](#)

Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

November 30, 2022

[Amazon GuardDuty RDS Protection monitors for access threats](#)

When you turn on GuardDuty RDS Protection, GuardDuty consumes RDS login events from your Aurora databases, monitors these events, and profiles them for potential insider threats or external actors. When GuardDuty RDS Protection detects a potential threat, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see [Monitoring threats with GuardDuty RDS Protection](#).

November 30, 2022

[Use Amazon RDS Blue/Green Deployments for database updates](#)

You can make changes to a DB cluster in a staging environment and test the changes without affecting your production DB cluster. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

November 27, 2022

[Amazon Aurora is available in the Asia Pacific \(Hyderabad\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Hyderabad) Region. For more information, see [Regions and Availability Zones](#).

November 22, 2022

[Amazon Aurora is available in the Europe \(Spain\) Region](#)

Amazon Aurora is now available in the Europe (Spain) Region. For more information, see [Regions and Availability Zones](#).

November 16, 2022

[Amazon Aurora is available in the Europe \(Zurich\) Region](#)

Amazon Aurora is now available in the Europe (Zurich) Region. For more information, see [Regions and Availability Zones](#).

November 9, 2022

[Amazon Aurora supports exporting data to Amazon S3 from DB clusters](#)

You can now export Aurora cluster data directly to S3, without having to create a snapshot first. For more information, see [Exporting DB cluster data to Amazon S3](#).

October 27, 2022

[Amazon Aurora MySQL supports faster exports to Amazon S3](#)

You can now see up to 10x faster performance for exporting DB cluster snapshot data to S3 for MySQL 5.7- and 8.0-compatible Aurora MySQL clusters. For more information, see [Exporting DB cluster snapshot data to Amazon S3](#).

October 20, 2022

[Amazon Aurora supports automatically setting up connectivity between an Aurora DB cluster and an EC2 instance](#)

You can use the Amazon Web Services Management Console to set up connectivity between an existing Aurora DB cluster and an EC2 instance. For more information, see [Connecting an EC2 instance and an Aurora DB cluster automatically](#).

October 14, 2022

[Amazon JDBC Driver for PostgreSQL generally available](#)

The Amazon JDBC Driver for PostgreSQL is a client driver designed for Aurora PostgreSQL. The Amazon JDBC Driver for PostgreSQL is now generally available. For more information, see [Connecting with the Amazon JDBC Driver for PostgreSQL](#).

October 6, 2022

[Amazon Aurora supports in-place upgrade for MySQL 5.7-compatible Aurora MySQL](#)

You can perform an in-place upgrade to change an existing MySQL 5.7-compatible Aurora MySQL cluster into a MySQL 8.0-compatible Aurora MySQL cluster. For more information, see [Upgrading from Aurora MySQL 2.x to 3.x](#).

September 26, 2022

[Performance Insights shows the top 25 SQL queries](#)

In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see [Overview of the Top SQL tab](#).

September 13, 2022

[Aurora MySQL supports a new DB instance class](#)

You can now use the db.r6i DB instance class for Aurora MySQL DB clusters. For more information, see [DB instance classes](#).

September 13, 2022

[Amazon Aurora is available in the Middle East \(UAE\) Region](#)

Amazon Aurora is now available in the Middle East (UAE) Region. For more information, see [Regions and Availability Zones](#).

August 30, 2022

[Amazon Aurora supports automatically setting up connectivity with an EC2 instance](#)

When you create an Aurora DB cluster, you can use the Amazon Web Services Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

August 22, 2022

[Amazon Aurora supports dual-stack mode](#)

DB clusters can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB cluster over IPv4, IPv6, or both. For more information, see [Amazon Aurora IP addressing](#).

August 17, 2022

[Amazon Aurora supports in-place upgrade for PostgreSQL 10-compatible Aurora Serverless v1](#)

You can perform an in-place upgrade for a PostgreSQL 10-compatible Aurora Serverless v1 cluster to change an existing cluster into a PostgreSQL 11-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see [Modifying an Aurora Serverless v1 DB cluster](#).

August 8, 2022

[Performance Insights supports the Asia Pacific \(Jakarta\) Region](#)

Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more information, see [Amazon Web Services Region support for Performance Insights](#).

July 21, 2022

[Amazon Aurora supports a new DB instance class](#)

You can now use the db.r6i DB instance class for Aurora PostgreSQL DB clusters. For more information, see [DB instance classes](#).

July 14, 2022

[RDS Performance Insights supports additional retention periods](#)

Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance data for longer than 7 days, you can specify from 1–24 months. For more information, see [Pricing and data retention for Performance Insights](#).

July 1, 2022

[Amazon Aurora supports in-place upgrade for MySQL-compatible Aurora Serverless v1](#)

You can perform an in-place upgrade for a MySQL 5.6-compatible Aurora Serverless v1 cluster to change an existing cluster into a MySQL 5.7-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see [Modifying an Aurora Serverless v1 DB cluster](#).

June 16, 2022

[Aurora supports turning on Amazon DevOps Guru in the RDS console](#)

You can turn on DevOps Guru coverage for your Aurora databases from within the RDS console. For more information, see [Setting up DevOps Guru for RDS](#).

June 9, 2022

[Amazon Aurora supports publishing events to encrypted Amazon SNS topics](#)

Amazon Aurora can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see [Subscribing to Amazon RDS event notification](#).

June 1, 2022

Amazon RDS publishes usage metrics to Amazon CloudWatch	The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon Aurora .	April 28, 2022
Data API result sets in JSON format	An optional parameter for the ExecuteStatement function causes the query result set to be returned as a string in JSON format. The JSON result set is simple and convenient to transform into a data structure in your application's language. For more information, see Processing query results in JSON format .	April 27, 2022
Amazon Aurora Serverless v2 is now generally available	Amazon Aurora Serverless v2 is generally available for all users. For more information, see Using Aurora Serverless v2 .	April 21, 2022
Aurora MySQL supports configurable cipher suites	With Aurora MySQL, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For more information, see Configuring cipher suites for connections to Aurora MySQL DB clusters .	April 15, 2022

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 13](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 13 DB cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

April 4, 2022

[Release Notes for Aurora PostgreSQL](#)

There is now a separate guide for the Amazon Aurora PostgreSQL release notes. For more information, see [Release Notes for Aurora PostgreSQL](#).

March 22, 2022

[Release Notes for Aurora MySQL](#)

There is now a separate guide for the Amazon Aurora MySQL release notes. For more information, see [Release Notes for Aurora MySQL](#).

March 22, 2022

[Aurora PostgreSQL supports multi-major version upgrades](#)

You can now perform version upgrades of Aurora PostgreSQL DB clusters across multiple major versions. For more information, see [How to perform a major version upgrade](#).

March 4, 2022

[Aurora PostgreSQL supports configurable cipher suites](#)

With Aurora PostgreSQL versions 11.8 and higher, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For information about using configurable cipher suites with Aurora PostgreSQL, see [Configuring cipher suites for connections to Aurora PostgreSQL DB clusters](#).

March 4, 2022

[Amazon JDBC Driver for MySQL generally available](#)

The Amazon JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The Amazon JDBC Driver for MySQL is now generally available. For more information, see [Connecting with the Amazon Web Services JDBC Driver for MySQL](#).

March 2, 2022

[Aurora PostgreSQL 13.5 supports Babelfish for Aurora PostgreSQL 1.1.0](#)

Aurora PostgreSQL 13.5 supports Babelfish 1.1.0. For a list of new features, see [13.5](#). For a list of features supported in each Babelfish release, see [Supported functionality in Babelfish by version](#). For usage information, see [Working with Babelfish for Aurora PostgreSQL](#).

February 28, 2022

[Amazon Aurora supports Database Activity Streams in the Asia Pacific \(Jakarta\) Region](#)

For more information, see [Support for Amazon Web Services Regions for database activity streams](#).

February 16, 2022

[Performance Insights supports new API operations](#)

Performance Insights now supports the following API operations: `GetResourceMetadata` , `ListAvailableResourceDimensions` , and `ListAvailableResourceMetrics` . For more information, see [Retrieving metrics with the Performance Insights API](#) in this manual and the [Amazon RDS Performance Insights API Reference](#).

January 12, 2022

[Amazon RDS Proxy supports events](#)

RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see [Working with RDS Proxy events](#).

January 11, 2022

[RDS Proxy available in additional Amazon Web Services Regions](#)

RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

January 5, 2022

[Amazon Aurora is available in the Asia Pacific \(Jakarta\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Jakarta) Region. For more information, see [Regions and Availability Zones](#).

December 13, 2021

[DevOps Guru for Amazon RDS provides detailed insights and recommendations for Amazon Aurora](#)

DevOps Guru for RDS mines Performance Insights for performance-related data. Using this data, the service analyzes the performance of your Amazon Aurora DB instances and can help you resolve performance issues. To learn more, see [Analyzing performance anomalies with DevOps Guru for RDS](#) in this guide and see [Overview of DevOps Guru for RDS](#) in the *Amazon DevOps Guru User Guide*.

December 1, 2021

[Aurora PostgreSQL supports RDS Proxy with PostgreSQL 12](#)

You can now create an RDS Proxy with an Aurora PostgreSQL 12 database cluster. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

November 22, 2021

[Aurora supports Amazon Graviton2 instance classes for Database Activity Streams](#)

You can use database activity streams with the db.r6g instance class for Aurora MySQL and Aurora PostgreSQL. For more information, see [Supported DB instance classes](#).

November 3, 2021

[Amazon Aurora support for cross-account Amazon KMS keys](#)

You can use a KMS key from a different Amazon Web Services account for encryption when exporting DB snapshots to Amazon S3. For more information, see [Exporting DB snapshot data to Amazon S3](#).

November 3, 2021

[Amazon Aurora supports Babelfish for Aurora PostgreSQL](#)

Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see [Working with Babelfish for Aurora PostgreSQL](#).

October 28, 2021

[Aurora Serverless v1 can require SSL for connections](#)

The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL are supported now for Aurora Serverless v1. For more information, see [Using TLS/SSL with Aurora Serverless v1](#).

October 26, 2021

[Amazon Aurora supports Performance Insights in additional Amazon Web Services Regions](#)

Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see [Amazon Web Services Region support for Performance Insights](#).

October 5, 2021

[Configurable autoscaling timeout for Aurora Serverless v1](#)

You can choose how long Aurora Serverless v1 waits to find an autoscaling point. If no autoscaling point is found during that period, Aurora Serverless v1 cancels the scaling event or forces the capacity change, depending on the timeout action that you selected. For more information, see [Autoscaling for Aurora Serverless v1](#).

September 10, 2021

Aurora supports X2g and T4g instance classes	Both Aurora MySQL and Aurora PostgreSQL can now use X2g and T4g instance classes. The instance classes that you can use depend on the version of Aurora MySQL or Aurora PostgreSQL. For information about supported instance types, see DB instance classes .	September 10, 2021
Amazon RDS supports RDS Proxy in a shared VPC	You can now create an RDS Proxy in a shared virtual private cloud (VPC). For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora User Guide .	August 6, 2021
Aurora version policy page	The <i>Amazon Aurora User Guide</i> now includes a section with general information about Aurora versions and associated policies. For details, see Amazon Aurora versions .	July 14, 2021
Exclude Data API events from an Amazon CloudTrail trail	You can exclude Data API events from a CloudTrail trail. For more information, see Excluding Data API events from an Amazon CloudTrail trail .	July 2, 2021

Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions	Newly supported extensions include <code>pg_bigm</code> , <code>pg_cron</code> , <code>pg_partman</code> , and <code>pg_proctab</code> . For more information, see Extension versions for Amazon Aurora PostgreSQL-Compatible Edition .	June 17, 2021
Cloning for Aurora Serverless clusters	You can now create cloned clusters that are Aurora Serverless. For information about cloning, see Cloning a volume for an Aurora DB cluster .	June 16, 2021
Aurora global databases available in China (Beijing) and China (Ningxia) Regions	You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see Working with Amazon Aurora global databases .	May 19, 2021
FIPS 140-2 support for Data API	The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see Data API availability .	May 14, 2021

[Amazon JDBC Driver for PostgreSQL \(preview\)](#)

The Amazon JDBC Driver for PostgreSQL, now available in preview, is a client driver designed for the high availability of Aurora PostgreSQL. For more information, see [Connecting with the Amazon Web Services JDBC Driver for PostgreSQL \(preview\)](#).

April 27, 2021

[The Data API available in additional Amazon Web Services Regions](#)

The Data API is now available in the Asia Pacific (Seoul) and Canada (Central) Regions. For more information, see [Availability of the Data API](#).

April 9, 2021

[Amazon Aurora supports the Graviton2 DB instance classes](#)

You can now use the Graviton2 DB instance classes db.r6g.x to create DB clusters running MySQL or PostgreSQL. For more information, see [DB instance class types](#).

March 12, 2021

[RDS Proxy endpoint enhancements](#)

You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora user guide](#).

March 8, 2021

[Amazon Aurora is available in the Asia Pacific \(Osaka\) Region](#)

Amazon Aurora is now available in the Asia Pacific (Osaka) Region. For more information, see [Regions and Availability Zones](#).

March 1, 2021

[Aurora PostgreSQL supports enabling both IAM and Kerberos authentication on the same DB cluster](#)

Aurora PostgreSQL now supports enabling both IAM authentication and Kerberos authentication on the same DB cluster. For more information, see [Database authentication with Amazon Aurora](#).

February 24, 2021

[Aurora global database now supports managed planned failover](#)

Aurora global database now supports managed planned failover, allowing you to more easily change the primary Amazon Region of your Aurora global database. You can use managed planned failover with healthy Aurora global databases only. To learn more, see [Disaster recovery and Amazon Aurora global databases](#). For reference information, see [FailoverGlobalCluster](#) in the *Amazon RDS API Reference*.

February 11, 2021

[Data API for Aurora Serverless now supports more data types](#)

With the Data API for Aurora Serverless, you can now use UUID and JSON data types as input to your database. Also with the Data API for Aurora Serverless, you can now have a LONG type value returned from your database as a STRING value. To learn more, see [Calling the Data API](#). For reference information about supported data types, see [SqlParameter](#) in the *Amazon RDS Data Service API Reference*.

February 2, 2021

[Aurora PostgreSQL supports major version upgrades to PostgreSQL 12](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to major version 12. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

January 28, 2021

[Aurora MySQL supports in-place upgrade](#)

You can upgrade your Aurora MySQL 1.x cluster to Aurora MySQL 2.x, preserving the DB instances, endpoints, and so on of the original cluster. This in-place upgrade technique avoids the inconvenience of setting up a whole new cluster by restoring a snapshot. It also avoids the overhead of copying all your table data into a new cluster. For more information, see [Upgrading the major version of an Aurora MySQL DB cluster from 1.x to 2.x](#).

January 11, 2021

[Amazon JDBC Driver for MySQL \(preview\)](#)

The Amazon JDBC Driver for MySQL, now available in preview, is a client driver designed for the high availability of Aurora MySQL. For more information, see [Connecting with the Amazon Web Services JDBC Driver for MySQL \(preview\)](#).

January 7, 2021

[Aurora supports database activity streams on secondary clusters of a global database](#)

You can start a database a database activity stream on a primary or secondary cluster of Aurora PostgreSQL or Aurora MySQL. For supported engine versions, see [Limitations of Aurora global databases](#).

December 22, 2020

[Multi-master clusters with 4 DB instances](#)

The maximum number of DB instances in an Aurora MySQL multi-master cluster is now four. Formerly, the maximum was two DB instances. For more information, see [Working with Aurora Multi-Master Clusters](#).

December 17, 2020

[Aurora PostgreSQL supports Amazon Lambda functions](#)

You can now invoke Amazon Lambda function for your Aurora PostgreSQL DB clusters. For more information, see [Invoking a Lambda function from an Aurora PostgreSQL DB cluster](#).

December 11, 2020

[Amazon Aurora supports the Graviton2 DB instance classes in preview](#)

You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see [DB instance class types](#).

December 11, 2020

[Amazon Aurora Serverless v2 is now available in preview.](#)

Amazon Aurora Serverless v2 is available in preview. To work with Amazon Aurora Serverless v2, apply for access. For more information, see the [Aurora Serverless v2 page](#).

December 1, 2020

[Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions.](#)

Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions. You can now choose to run Aurora PostgreSQL Serverless v1 in the same Amazon Web Services Regions that offer Aurora MySQL Serverless v1. Additional Amazon Web Services Regions with Aurora Serverless support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless, see [Supported Regions and Aurora DB engines for Aurora Serverless v1](#). Amazon RDS Data API for Aurora Serverless is also now available in these same Amazon Web Services Regions. For a list of all Regions with support for the Data API for Aurora Serverless, see [Data API with Aurora MySQL Serverless v1](#)

November 24, 2020

[Amazon RDS Performance Insights introduces new dimensions](#)

You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see [Top load table](#).

November 24, 2020

[Aurora Serverless supports Aurora PostgreSQL version 10.12](#)

Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the Amazon Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see [Supported Regions and Aurora DB engines for Aurora Serverless v1](#).

November 4, 2020

[The Data API now supports tag-based authorization](#)

The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see [Authorizing access to the Data API](#).

October 27, 2020

[Amazon Aurora extends support for exporting snapshots to Amazon S3](#)

You can now export DB snapshot data to Amazon S3 in all commercial Amazon Web Services Regions. For more information, see [Exporting DB snapshot data to Amazon S3](#).

October 22, 2020

[Aurora global database supports cloning](#)

You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the Amazon Web Services Management Console and choosing the **Create clone** menu option. You can also use the Amazon CLI and run the `restore-db-cluster-to-point-in-time` command with the `--restore-type copy-on-write` option. Using the Amazon Web Services Management Console or the Amazon CLI, you can also clone DB clusters from your Aurora global databases across Amazon accounts. For more information about cloning, see [Cloning an Aurora DB cluster volume](#).

October 19, 2020

[Amazon Aurora supports dynamic resizing for the cluster volume](#)

Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as `DROP TABLE`. To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see [Managing Performance and Scaling for Aurora DB Clusters](#).

October 13, 2020

[Amazon Aurora supports volume sizes up to 128 TiB](#)

New and existing Aurora cluster volumes can now grow to a maximum size of 128 terabytes (TiB). For more information, see [How Aurora storage grows](#).

September 22, 2020

[Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China \(Ningxia\) Region](#)

You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see [DB instance classes](#).

September 3, 2020

[Aurora parallel query enhancements](#)

September 2, 2020

Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature . Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the DYNAMIC row format. Parallel query clusters can use Amazon Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the READ COMMITTED

isolation level. You can also now create parallel query clusters in additional Amazon Web Services Regions. For more information about the parallel query feature and these enhancements, see [Parallel query for Aurora MySQL](#).

[Changes to Aurora MySQL parameter `binlog_rows_query_log_events`](#)

You can now change the value of the Aurora MySQL configuration parameter `binlog_rows_query_log_events`. Formerly, this parameter wasn't modifiable.

August 26, 2020

[Support for automatic minor version upgrades for Aurora MySQL](#)

With Aurora MySQL, the setting **Enable auto minor version upgrade** now takes effect when you specify it for an Aurora MySQL DB cluster. When you enable auto minor version upgrade, Aurora automatically upgrades to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database. For Aurora MySQL, this feature applies only to Aurora MySQL version 2, which is compatible with MySQL 5.7. Initially, the automatic upgrade procedure brings Aurora MySQL DB clusters to version 2.07.2. For more information about how this feature works with Aurora MySQL, see [Database Upgrades and Patches for Amazon Aurora MySQL](#).

August 3, 2020

[Aurora PostgreSQL supports major version upgrades to PostgreSQL version 11](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to major version 11. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

July 28, 2020

[Amazon Aurora supports Amazon PrivateLink](#)

Amazon Aurora now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Aurora in the Amazon network. For more information, see [Amazon Aurora and interface VPC endpoints \(Amazon PrivateLink\)](#). July 9, 2020

[RDS Proxy generally available](#)

RDS Proxy is now generally available. You can use RDS Proxy with RDS for MySQL, Aurora MySQL, RDS for PostgreSQL, and Aurora PostgreSQL for production workloads. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora user guide](#). June 30, 2020

[Aurora global database write forwarding](#)

You can now enable write capability on secondary clusters in a global database. With write forwarding, you issue DML statements on a secondary cluster, Aurora forwards the write to the primary cluster, and the updated data is replicated to all the secondary clusters. For more information, see [Write forwarding for secondary Amazon Web Services Regions with an Aurora global database](#).

June 18, 2020

[Aurora supports integration with Amazon Backup](#)

You can use Amazon Backup to manage backups of Aurora DB clusters. For more information, see [Overview of backing up and restoring an Aurora DB cluster](#).

June 10, 2020

[Aurora PostgreSQL supports db.t3.large DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.t3.large DB instance classes. For more information, see [DB instance classes](#).

June 5, 2020

[Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective \(RPO\)](#)

You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see [Cross-Region Disaster Recovery for Aurora global databases](#).

June 4, 2020

[Aurora MySQL supports database monitoring with database activity streams](#)

Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see [Using database activity streams](#).

June 2, 2020

[The query editor available in additional Amazon Web Services Regions](#)

The query editor for Aurora Serverless is now available in additional Amazon Web Services Regions. For more information, see [Availability of the query editor](#).

May 28, 2020

[The Data API available in additional Amazon Web Services Regions](#)

The Data API is now available in additional Amazon Web Services Regions. For more information, see [Availability of the Data API](#).

May 28, 2020

[RDS Proxy available in Canada \(Central\) Region](#)

You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see [Managing connections with Amazon RDS proxy \(preview\)](#).

May 28, 2020

[Aurora global database and cross-Region read replicas](#)

For an Aurora global database, you can now create an Aurora MySQL cross-Region read replica from the primary cluster in the same region as a secondary cluster. For more information about Aurora Global Database and cross-Region read replicas, see [Working with Amazon Aurora global database and Replicating Amazon Aurora MySQL DB](#).

May 18, 2020

[RDS Proxy available in more Amazon Web Services Regions](#)

You can now use the RDS Proxy preview in the US West (N. California) Region, the Europe (London) Region, the Europe (Frankfurt) Region, the Asia Pacific (Seoul) Region, the Asia Pacific (Mumbai) Region, the Asia Pacific (Singapore) Region, and the Asia Pacific (Sydney) Region. For more information about RDS Proxy, see [Managing connections with Amazon RDS proxy \(preview\)](#).

May 13, 2020

[Aurora PostgreSQL-Compatible Edition supports on-premises or self-hosted Microsoft active directory](#)

You can now use an on-premises or self-hosted Active Directory for Kerberos authentication of users when they connect to your Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication with Aurora PostgreSQL](#).

May 7, 2020

[Aurora MySQL multi-master clusters available in more Amazon Web Services Regions](#)

You can now create Aurora multi-master clusters in the Asia Pacific (Seoul) Region, the Asia Pacific (Tokyo) Region, the Asia Pacific (Mumbai) Region, and the Europe (Frankfurt) Region. For more information about multi-master clusters, see [Working with Aurora multi-master clusters](#).

May 7, 2020

[Performance Insights supports analyzing statistics of running Aurora MySQL queries](#)

You can now analyze statistics of running queries with Performance Insights for Aurora MySQL DB instances. For more information, see [Analyzing statistics of running queries](#).

May 5, 2020

[Java client library for Data API generally available](#)

The Java client library for the Data API is now generally available. You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see [Using the Java client library for Data API](#).

April 30, 2020

[Amazon Aurora is available in the Europe \(Milan\) Region](#)

Amazon Aurora is now available in the Europe (Milan) Region. For more information, see [Regions and Availability Zones](#).

April 28, 2020

[Amazon Aurora is available in the Europe \(Milan\) Region](#)

Amazon Aurora is now available in the Europe (Milan) Region. For more information, see [Regions and Availability Zones](#).

April 27, 2020

[Amazon Aurora is available in the Africa \(Cape Town\) Region](#)

Amazon Aurora is now available in the Africa (Cape Town) Region. For more information, see [Regions and Availability Zones](#).

April 22, 2020

[Aurora PostgreSQL now supports db.r5.16xlarge and db.r5.8xlarge DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters running PostgreSQL that use the db.r5.16xlarge and db.r5.8xlarge DB instance classes. For more information, see [Hardware specifications for DB instance classes for Aurora](#).

April 8, 2020

[Amazon RDS proxy for PostgreSQL](#)

Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your cluster and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

April 8, 2020

[Aurora global databases now support Aurora PostgreSQL](#)

You can now create Aurora global databases for the PostgreSQL database engine. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see [Working with Amazon Aurora global database](#).

March 10, 2020

[Support for major version upgrades for Aurora PostgreSQL](#)

With Aurora PostgreSQL, you can now upgrade the DB engine to a major version. By doing so, you can skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](#).

March 4, 2020

[Aurora PostgreSQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Aurora PostgreSQL DB clusters. For more information, see [Using Kerberos authentication with Aurora PostgreSQL](#).

February 28, 2020

[The Data API supports Amazon PrivateLink](#)

The Data API now supports creating Amazon VPC endpoints for Data API calls to keep traffic between applications and the Data API in the Amazon network. For more information, see [Creating an Amazon VPC endpoint \(Amazon PrivateLink\) for the Data API](#).

February 6, 2020

[Aurora machine learning support in Aurora PostgreSQL](#)

The `aws_ml` Aurora PostgreSQL extension provides functions you use in your database queries to call Amazon Comprehend for sentiment analysis and SageMaker AI to run your own machine learning models. For more information, see [Using machine learning \(ML\) capabilities with Aurora](#).

February 5, 2020

[Aurora PostgreSQL supports exporting data to Amazon S3](#)

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. For more information, see [Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3](#).

February 5, 2020

[Support for exporting DB snapshot data to Amazon S3](#)

Amazon Aurora supports exporting DB snapshot data to Amazon S3 for MySQL and PostgreSQL. For more information, see [Exporting DB snapshot data to Amazon S3](#).

January 9, 2020

[Aurora MySQL release notes in document history](#)

This section now includes history entries for Aurora MySQL-Compatible Edition release notes for versions released after August 31, 2018. For the full release notes for a specific version, choose the link in the first column of the history entry.

December 13, 2019

[Amazon RDS proxy](#)

You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the Aurora MySQL database engine. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

December 3, 2019

[Data API for Aurora Serverless v1 supports data type mapping hints](#)

You can now use a hint to instruct the Data API for Aurora Serverless v1 to send a String value to the database as a different type. For more information, see [Calling the data API](#).

November 26, 2019

[Data API for Aurora Serverless v1 supports a Java client library \(preview\)](#)

You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see [Using the Java client library for Data API](#).

November 26, 2019

[Aurora PostgreSQL is FedRAMP HIGH eligible](#)

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about Amazon and compliance efforts, see [Amazon services in scope by compliance program](#).

November 26, 2019

[READ COMMITTED isolation level enabled for Amazon Aurora MySQL replicas](#)

You can now enable the READ COMMITTED isolation level on Aurora MySQL Replicas. Doing so requires enabling the `aurora_read_replica_read_committed_isolation_enabled` configuration setting at the session level. Using the READ COMMITTED isolation level for long-running queries on OLTP clusters can help address issues with history list length. Before enabling this setting, be sure to understand how the isolation behavior on Aurora Replicas differs from the usual MySQL implementation of READ COMMITTED. For more information, see [Aurora MySQL isolation levels](#).

November 25, 2019

[Performance Insights supports analyzing statistics of running Aurora PostgreSQL queries](#)

You can now analyze statistics of running queries with Performance Insights for Aurora PostgreSQL DB instances. For more information, see [Analyzing statistics of running queries](#).

November 25, 2019

[More clusters in an Aurora global database](#)

You can now add multiple secondary regions to an Aurora global database. You can take advantage of low latency global reads and disaster recovery across a wider geographic area. For more information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

November 25, 2019

[Aurora machine learning support in Aurora MySQL](#)

In Aurora MySQL 2.07 and higher, you can call Amazon Comprehend for sentiment analysis and SageMaker AI for a wide variety of machine learning algorithms. You use the results directly in your database application by embedding calls to stored functions in your queries. For more information, see [Using machine learning \(ML\) capabilities with Aurora](#).

November 25, 2019

[Aurora global database no longer requires engine mode setting](#)

You no longer need to specify `--engine-mode=global` when creating a cluster that is intended to be part of an Aurora global database. All Aurora clusters that meet the compatibility requirements are eligible to be part of a global database. For example, the cluster currently must use Aurora MySQL version 1 with MySQL 5.6 compatibility. For information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

November 25, 2019

[Aurora global database is available for Aurora MySQL version 2](#)

Starting in Aurora MySQL 2.07, you can create an Aurora global database with MySQL 5.7 compatibility. You don't need to specify the `global` engine mode for the primary or secondary clusters. You can add any new provisioned cluster with Aurora MySQL 2.07 or higher to an Aurora Global Database. For information about Aurora Global Database, see [Working with Amazon Aurora global database](#).

November 25, 2019

[Aurora MySQL hot row contention optimization available without lab mode](#)

The hot row contention optimization is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page. The improvement involves changing the lock release algorithm used by Aurora MySQL.

November 19, 2019

[Aurora MySQL hash joins available without lab mode](#)

The hash join feature is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information about using this feature, see [Working with hash joins in Aurora MySQL](#).

November 19, 2019

[Aurora MySQL 2.* support for more db.r5 instance classes](#)

Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see [Choosing the DB instance class](#).

November 19, 2019

[Aurora MySQL 2.* support for backtracking](#)

Aurora MySQL 2.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see [Backtracking an Aurora DB cluster](#).

November 19, 2019

[Billing tag support for Aurora](#)

You can now use tags to keep track of cost allocation for resources such as Aurora clusters, DB instances within Aurora clusters, I/O, backups, snapshots, and so on. You can see costs associated with each tag using Amazon Cost Explorer. For more information about using tags with Aurora, see [Tagging Amazon RDS resources](#). For general information about tags and ways to use them for cost analysis, see [Using cost allocation tags](#) and [User-defined cost allocation tags](#).

October 23, 2019

[Data API for Aurora PostgreSQL](#)

Aurora PostgreSQL now supports using the Data API with Amazon Aurora Serverless v1 DB clusters. For more information, see [Using the Data API for Aurora Serverless v1](#).

September 23, 2019

[Aurora PostgreSQL supports uploading database logs to CloudWatch logs](#)

You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs](#).

August 9, 2019

[Multi-master clusters for Aurora MySQL](#)

You can set up Aurora MySQL multi-master clusters. In these clusters, each DB instance has read/write capability. For more information, see [Working with Aurora multi-master clusters](#).

August 8, 2019

[Aurora PostgreSQL supports Aurora Serverless v1](#)

You can now use Amazon Aurora Serverless v1 with Aurora PostgreSQL. An Aurora Serverless DB cluster automatically starts up, shuts down, and scales up or down its compute capacity based on your application's needs. For more information, see [Using Amazon Aurora Serverless v1](#).

July 9, 2019

[Cross-account cloning for Aurora MySQL](#)

You can now clone the cluster volume for an Aurora MySQL DB cluster between Amazon accounts. You authorize the sharing through Amazon Resource Access Manager (Amazon RAM). The cloned cluster volume uses a copy-on-write mechanism, which only requires additional storage for new or changed data. For more information about cloning for Aurora, see [Cloning databases in an Aurora DB cluster](#).

July 2, 2019

[Aurora PostgreSQL supports db.t3 DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

June 20, 2019

[Support for importing data from Amazon S3 for Aurora PostgreSQL](#)

You can now import data from an Amazon S3 file into a table in an Aurora PostgreSQL DB cluster. For more information, see [Importing Amazon S3 data into an Aurora PostgreSQL DB cluster](#).

June 19, 2019

[Aurora PostgreSQL now provides fast failover recovery with cluster cache management](#)

Aurora PostgreSQL now provides cluster cache management to ensure fast recovery of the primary DB instance in the event of a failover. For more information, see [Fast recovery after failover with cluster cache management](#).

June 11, 2019

[Data API for Aurora Serverless v1 generally available](#)

You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see [Using the Data API for Aurora Serverless v1](#).

May 30, 2019

[Aurora PostgreSQL supports database monitoring with database activity streams](#)

Aurora PostgreSQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see [Using database activity streams](#).

May 30, 2019

[Amazon Aurora recommendations](#)

Amazon Aurora now provides automated recommendations for Aurora resources. For more information, see [Using Amazon Aurora recommendations](#).

May 22, 2019

[Performance Insights support for Aurora global database](#)

You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see [Using Amazon RDS performance insights](#). For information about Aurora global databases, see [Working with Aurora global database](#).

May 13, 2019

[Performance Insights is available for Aurora MySQL 5.7](#)

Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see [Using Amazon RDS performance insights](#).

May 3, 2019

[Aurora global databases available in more Amazon Web Services Regions](#)

You can now create Aurora global databases in most Amazon Web Services Regions where Aurora is available. For information about Aurora global databases, see [Working with Amazon Aurora global databases](#).

April 30, 2019

[Minimum capacity of 1 for Aurora Serverless v1](#)

The minimum capacity setting you can use for an Aurora Serverless v1 cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see [Setting the capacity of an Aurora Serverless v1 DB cluster](#). April 29, 2019

[Aurora Serverless v1 timeout action](#)

You can now specify the action to take when an Aurora Serverless v1 capacity change times out. For more information, see [Timeout action for capacity changes](#). April 29, 2019

[Per-second billing](#)

Amazon RDS is now billed in 1-second increments in all Amazon Web Services Regions except Amazon GovCloud (US) for on-demand instances. For more information, see [DB instance billing for Aurora](#). April 25, 2019

[Sharing Aurora Serverless v1 snapshots across Amazon Web Services Regions](#)

With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across Amazon Web Services Regions. For information about snapshots of Aurora Serverless v1 DB clusters, see [Aurora Serverless v1 and snapshots](#). April 17, 2019

[Restore MySQL 5.7 backups from Amazon S3](#)

You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see [Migrating data from an external MySQL database to an Aurora MySQL DB cluster](#).

April 17, 2019

[Sharing Aurora Serverless v1 snapshots across regions](#)

With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless v1 DB clusters, see [Aurora Serverless and snapshots](#).

April 16, 2019

[Aurora proof-of-concept tutorial](#)

You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see [Performing an Aurora proof of concept](#).

April 16, 2019

[Aurora Serverless v1 supports restoring from an Amazon S3 backup](#)

You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see [Migrating data from MySQL by using an Amazon S3 bucket](#).

April 16, 2019

[New modifiable parameters for Aurora Serverless v1](#)

You can now modify the following DB parameters for an Aurora Serverless v1 cluster: `innodb_file_format` , `innodb_file_per_table` , `innodb_large_prefix` , `innodb_lock_wait_timeout` , `innodb_monitor_disable` , `innodb_monitor_enable` , `innodb_monitor_reset` , `innodb_monitor_reset_all` , `innodb_print_all_deadlocks` , `log_warnings` , `net_read_timeout` , `net_retry_count` , `net_write_timeout` , `sql_mode`, and `tx_isolation` . For more information about configuration parameters for Aurora Serverless v1 clusters, see [Aurora Serverless v1 and parameter groups](#).

April 4, 2019

[Aurora PostgreSQL supports db.r5 DB instance classes](#)

You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

April 4, 2019

[Aurora PostgreSQL logical replication](#)

You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see [Using PostgreSQL logical replication](#).

March 28, 2019

[GTID support for Aurora MySQL 2.04](#)

You can now use replication with the global transaction ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication between Aurora MySQL and an external MySQL 5.7-compatible database. The replication can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see [Using GTID-based replication for Aurora MySQL](#).

March 25, 2019

[Uploading Aurora Serverless v1 logs to Amazon CloudWatch](#)

You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless v1 cluster. For more information, see [Viewing Aurora Serverless DB clusters](#). As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see [Working with DB parameter groups and DB cluster parameter groups](#).

February 25, 2019

[Aurora MySQL supports db.t3 DB instance classes](#)

You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

February 25, 2019

[Aurora MySQL supports db.r5 DB instance classes](#)

You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

February 25, 2019

[Performance Insights counters for Aurora MySQL](#)

You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see [Performance Insights dashboard components](#).

February 19, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Aurora MySQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora MySQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

February 6, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Aurora PostgreSQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora PostgreSQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

January 24, 2019

[Aurora backup billing](#)

You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled` , `SnapshotStorageUsed` , and `BackupRetentionPeriodStorageUsed` to monitor the space usage of your Aurora backups. For more information about how to use CloudWatch metrics, see [Overview of monitoring](#). For more information about how to manage storage for backup data, see [Understanding Aurora backup storage usage](#).

January 3, 2019

[Performance Insights counters](#)

You can now add performance counters to your Performance Insights charts. For more information, see [Performance Insights dashboard components](#).

December 6, 2018

[Aurora global database](#)

You can now create Aurora global databases. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see [Working with Amazon Aurora global database](#).

November 28, 2018

[Query plan management in Aurora PostgreSQL](#)

Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see [Managing query execution plans for Aurora PostgreSQL](#).

November 20, 2018

[Query editor for Aurora Serverless v1 \(beta\)](#)

You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see [Using the query editor for Aurora Serverless v1](#).

November 20, 2018

[Data API for Aurora Serverless v1 \(beta\)](#)

You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see [Using the Data API for Aurora Serverless](#).

November 20, 2018

[TLS support for Aurora Serverless v1](#)

Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see [TLS/SSL for Aurora Serverless](#).

November 19, 2018

[Custom endpoints](#)

You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see [Amazon Aurora endpoints](#).

November 12, 2018

[IAM authentication support in Aurora PostgreSQL](#)

Aurora PostgreSQL now supports IAM authentication. For more information see [IAM database authentication](#).

November 8, 2018

[Custom parameter groups for restore and point in time recovery](#)

You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see [Restoring from a DB cluster snapshot](#) and [Restoring a DB cluster to a specified time](#).

October 15, 2018

[Deletion protection for Aurora DB clusters](#)

When you enable deletion protection for a DB cluster, the database cannot be deleted by any user. For more information, see [Deleting a DB cluster](#).

September 26, 2018

[Stop/Start feature Aurora](#)

You can now stop or start an entire Aurora cluster with a single operation. For more information, see [Stopping and starting an Aurora cluster](#).

September 24, 2018

[Parallel query feature for Aurora MySQL](#)

Aurora MySQL now offers an option to parallelize I/O work for queries across the Aurora storage infrastructure. This feature speeds up data-intensive analytic queries, which are often the most time-consuming operations in a workload. For more information, see [Parallel query for Aurora MySQL](#).

September 20, 2018

[New guide](#)

This is the first release of the *Amazon Aurora User Guide*.

August 31, 2018

Amazon Glossary

For the latest Amazon terminology, see the [Amazon glossary](#) in the *Amazon Web Services Glossary Reference*.
