This documentation is for Version 1 of the Amazon CLI only. For documentation related to Version 2 of the Amazon CLI, see the Version 2 User Guide.

What is the Amazon Command Line Interface version 1?

> **Note**
>
> The Amazon CLI version 1 is not the latest version of the Amazon CLI. Some features introduced in Amazon CLI version 2 are not backported to version 1 and you must upgrade to access those features. There are some "breaking" changes from version 1 that might require you to change your scripts. For a list of breaking changes in version 2, see Breaking changes in the *Amazon CLI version 2 User Guide*.

The Amazon Command Line Interface (Amazon CLI) is an open source tool that enables you to interact with Amazon services using commands in your command-line shell. With minimal configuration, the Amazon CLI enables you to start running commands that implement functionality equivalent to that provided by the browser-based Amazon Web Services Management Console from the command prompt in your terminal program:

- **Linux shells** – Use common shell programs such as `bash`, `zsh`, and `tcsh` to run commands in Linux or macOS.
- **Windows command line** – On Windows, run commands at the Windows command prompt or in PowerShell.
- **Remotely** – Run commands on Amazon Elastic Compute Cloud (Amazon EC2) instances through a remote terminal program such as PuTTY or SSH, or with Amazon Systems Manager.

All IaaS (infrastructure as a service) Amazon administration, management, and access functions in the Amazon Web Services Management Console are available in the Amazon API and Amazon CLI. New Amazon IaaS features and services provide full Amazon Web Services Management Console functionality through the API and CLI at launch or within 180 days of launch.

The Amazon CLI provides direct access to the public APIs of Amazon services. You can explore a service's capabilities with the Amazon CLI, and develop shell scripts to manage your resources. In addition to the low-level, API-equivalent commands, several Amazon services provide customizations for the Amazon CLI. Customizations can include higher-level commands that simplify using a service with a complex API.

About Amazon CLI version 1

The Amazon CLI version 1 is the original Amazon CLI, and we continue to support it. However, major new features that are introduced in the Amazon CLI version 2 might not be backported to the Amazon CLI version 1. To use those features, you must install the Amazon CLI version 2. The Amazon CLI version 1 is built using the SDK for Python, and therefore requires you to install a compatible version of Python.

To install the Amazon CLI version 1, see *Install the Amazon CLI*.

To check the currently installed version, use the following command:

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

For version history, see the Amazon CLI version 1 Changelog on *GitHub*.

Maintenance and support for SDK major versions

For information about maintenance and support for SDK major versions and their underlying dependencies, see the following in the Amazon SDKs and Tools Reference Guide:

- Amazon SDKs and tools maintenance policy
- Amazon SDKs and tools version support matrix

About Amazon Web Services

Amazon Web Services (Amazon) is a collection of digital infrastructure services that developers can leverage when developing their applications. The services include computing, storage, database, and application synchronization (messaging and queuing). Amazon uses a pay-as-you-go service model. You are charged only for the services that you—or your applications—use. Also, to make Amazon more approachable as a platform for prototyping and experimentation, Amazon offers a free usage tier. On this tier, services are free below a certain level of usage. For more information about Amazon costs and the Free Tier, see Amazon Free Tier. To obtain an Amazon account, open the Amazon home page and then choose **Create a Free Account**.

About the examples in the Amazon CLI User Guide

The Amazon Command Line Interface (Amazon CLI) examples in this guide are formatted using the following conventions:

- **Prompt** – The command prompt uses the Linux prompt and is displayed as ($). For commands that are Windows specific, `C:\>` is used as the prompt. Do not include the prompt when you type commands.
- **Directory** – When commands must be executed from a specific directory, the directory name is shown before the prompt symbol.
- **User input** – Command text that you enter at the command line is formatted as **`user input`**.
- **Replaceable text** – Variable text, including names of resources that you choose, or IDs generated by Amazon services that you must include in commands, is formatted as *`replaceable text`*. In multiple-line commands or commands where specific keyboard input is required, keyboard commands can also be shown as replaceable text.
- **Output** – Output returned by Amazon services is shown under user input, and is formatted as `computer output`.

The following **`aws configure`** command example demonstrates user input, replaceable text, and output:

1. Enter **`aws configure`** at the command line, and then press **Enter**.
2. The Amazon CLI outputs lines of text, prompting you to enter additional information.
3. Enter each of your access keys in turn, and then press **Enter**.
4. Then, enter an Amazon Region name in the format shown, press **Enter**, and then press **Enter** a final time to skip the output format setting.
5. The final **Enter** command is shown as replaceable text because there is no user input for that line.

```
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: ENTER
```

The following example shows a simple command with output. To use this example, enter the full text of the command (the highlighted text after the prompt), and then press **Enter**. The name of the security group, *my-sg*, is replaceable to your desired security group name. The JSON document, including the curly braces, is output. If you configure your CLI to output in text or table format, the output will be formatted differently. JSON is the default output format.

```
$ aws ec2 create-security-group --group-name my-sg --description "My security group"
{
    "GroupId": "sg-903004f8"
}
```

Additional documentation and resources for the Amazon CLI

Amazon CLI documentation and resources

In addition to this user guide, the following are valuable online resources when you use the Amazon CLI.

- Amazon CLI version 1 reference guide
- Amazon CLI Bash scripting code examples repository. Open source bash scripting examples. Bash scripting examples are hosted in the Amazon Code Examples Repository on *GitHub*.
- Amazon CLI GitHub repository. You can view and fork the source code for the Amazon CLI on *GitHub*. Join the community of users on *GitHub* to provide feedback, request features, and submit your own contributions. This includes viewing and providing commands examples for the Amazon CLI documentation.
- Amazon CLI alias examples repository You can view and fork Amazon CLI alias examples on *GitHub*.
- Amazon CLI version 1 Changelog
- Amazon CLI version 2 Changelog

Other Amazon SDKs and tools

Depending on your use case, you might want to choose one of the Amazon SDKs or tools to better fit your needs:

- Amazon SDKs and Tools Reference Guide

- Amazon SDK for C++
- Amazon SDK for Go
- Amazon SDK for Java
- Amazon SDK for JavaScript
- Amazon SDK for Kotlin
- Amazon SDK for .NET
- Amazon SDK for Python (Boto)
- Amazon SDK for PHP
- Amazon Tools for PowerShell
- Amazon SDK for Ruby
- Amazon SDK for Rust
- Amazon SDK for SAP ABAP
- Amazon SDK for Swift
- Amazon Amplify

Installing, updating, and uninstalling the Amazon CLI

This topic provides links to install, update, and uninstall the original version of the Amazon Command Line Interface (Amazon CLI). The Amazon CLI version 1 is currently supported, but new features added to the Amazon CLI version 2 might not be added to the Amazon CLI version 1. To use those features, you must install the Amazon CLI version 2. For information about how to install version 2, see Installing the Amazon CLI version 2.

Amazon CLI install, update, and uninstall instructions:

- Python version requirements
- Installing, updating, and uninstalling the Amazon CLI version 1 on Amazon Linux
- Installing, updating, and uninstalling the Amazon CLI version 1 on Linux
- Installing, updating, and uninstalling the Amazon CLI version 1 on macOS
- Installing, Updating, and Uninstalling the Amazon CLI version 1 on Windows
- Installing and updating the Amazon CLI version 1 in a virtual environment

Python version requirements

The Amazon CLI version 1 is built using the SDK for Python, and therefore requires you to install a compatible version of Python.

Python version support matrix

Amazon CLI version	Supported Python version
1.32.0 – current	Python 3.8+
1.27.0 – 1.31.x	Python 3.7+
1.20.0 – 1.26.x	Python 3.6+
1.19.0 – 1.19.x	Python 2.7+, Python 3.6+
1.17 – 1.18.x	Python 2.7+, Python 3.4+
1.0 – 1.16.x	Python 2.6 and older, Python 3.3 and older

For information on the latest releases of Amazon CLI, see the Amazon CLI version 2 Changelog on GitHub.

Installing, updating, and uninstalling the Amazon CLI version 1 on Amazon Linux

The Amazon CLI version 1 is preinstalled on Amazon Linux and Amazon Linux 2. Check the currently installed version by using the following command.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

Depending on when you created your Amazon Linux instance, the Amazon CLI version 1 is preinstalled using one of the following package managers:

- pip
- yum

Prerequisites

You must have Python 3.8 or later installed. For installation instructions, see the Downloading Python page in Python's *Beginner Guide*.

Python version support matrix

Amazon CLI version	Supported Python version
1.32.0 – current	Python 3.8+
1.27.0 – 1.31.x	Python 3.7+
1.20.0 – 1.26.x	Python 3.6+
1.19.0 – 1.19.x	Python 2.7+, Python 3.6+
1.17 – 1.18.x	Python 2.7+, Python 3.4+
1.0 – 1.16.x	Python 2.6 and older, Python 3.3 and older

Install, update, or uninstall using pip

Most Amazon Linux instances use pip to preinstall the Amazon CLI version 1.

Install or update the Amazon CLI version 1 on Amazon Linux using pip

To install the latest version of the Amazon CLI version 1 for the current user, use the following instructions.

1. We recommend that if you have Python version 3 or later installed that you use `pip3`. Use `pip3 install` to install or update to the latest version of the Amazon CLI version 1. If you run the command from within a Python virtual environment (venv), you don't need to use the `--user` option.

   ```
   $ pip3 install --upgrade --user awscli
   ```

2. Ensure the folder that contains `aws` is part of your `PATH` variable.

   a. Find your shell's profile script in your user directory. If you're not sure which shell you have, run `echo $SHELL`.

   ```
   $ ls -a ~
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash** – `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh** – `.zshrc`
   - **Tcsh** – `.tcshrc`, `.cshrc` or `.login`

   b. Add an export command at the end of your profile script that's similar to the following example.

   ```
   export PATH=$HOME/.local/bin:$PATH
   ```

   This command inserts the path, `$HOME/.local/bin` in this example, at the front of the existing `$PATH`variable.

   c. Reload the profile into your current session to put those changes into effect.

   ```
   $ source ~/.bash_profile
   ```

3. To verify that you're running the new version, use the `aws --version` command.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

Uninstall the Amazon CLI version 1 using pip

If you need to uninstall the Amazon CLI, use `pip uninstall`.

```
$ pip3 uninstall awscli
```

Install, update, or uninstall using yum

Most Amazon Linux 2 instances use yum to preinstall the Amazon CLI version 1.

Install or update the Amazon CLI version 1 on Amazon Linux using yum

To install the latest version of the Amazon CLI version 1 available on Amazon Linux, run the following command.

```
$ sudo yum install awscli
```

To update to the latest version of the Amazon CLI version 1 available on Amazon Linux, run the following command.

```
$ sudo yum update awscli
```

To verify that you're running the newer version, use the `aws --version` command.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

Uninstall the Amazon CLI version 1 using yum

To uninstall the Amazon CLI, use `yum remove`.

```
$ sudo yum remove awscli
```

Troubleshooting Amazon CLI install and uninstall errors

If you come across issues after installing or uninstalling the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `aws --version` command returns a different version than you installed", and the section called "The `aws --version` command returns a version after uninstalling the Amazon CLI".

Installing, updating, and uninstalling the Amazon CLI version 1 on Linux

You can install the Amazon Command Line Interface (Amazon CLI) version 1 and its dependencies on most Linux distributions by using the `pip` package manager or the bundled installer.

Although the `awscli` package is available in repositories for other package managers such as `apt` and `yum`, these are not produced, managed, or supported by Amazon. We recommend that you install the Amazon CLI from only the official Amazon distribution points, as documented in this guide.

Sections

- Prerequisites
- Install and uninstall the Amazon CLI version 1 on Linux using the bundled installer
- Install and uninstall the Amazon CLI version 1 using pip
- Install and uninstall the Amazon CLI version 1 using Snapcraft
- Add the Amazon CLI version 1 executable to your command line path
- Troubleshooting Amazon CLI install and uninstall errors

Prerequisites

You must have Python 3.8 or later installed. For installation instructions, see the Downloading Python page in Python's *Beginner Guide*.

Python version support matrix

Amazon CLI version	Supported Python version
1.32.0 – current	Python 3.8+
1.27.0 – 1.31.x	Python 3.7+
1.20.0 – 1.26.x	Python 3.6+
1.19.0 – 1.19.x	Python 2.7+, Python 3.6+
1.17 – 1.18.x	Python 2.7+, Python 3.4+
1.0 – 1.16.x	Python 2.6 and older, Python 3.3 and older

Install and uninstall the Amazon CLI version 1 on Linux using the bundled installer

On Linux or macOS, you can use the bundled installer to install version 1 of the Amazon CLI. The bundled installer includes all dependencies and can be used offline.

> **Note**
>
> The bundled installer doesn't support installing to paths that contain spaces.

Topics

- Install the Amazon CLI version 1 using the bundled installer with sudo
- Install the Amazon CLI version 1 using the bundled installer without sudo
- Uninstall the Amazon CLI version 1 bundled installer

Install the Amazon CLI version 1 using the bundled installer with sudo

The following steps enable you to install the Amazon CLI version 1 from the command line on any build of Linux or macOS.

The following is a summary of the installation commands explained below that you can cut and paste to run as a single set of commands.

For the latest version of the Amazon CLI, use the following command block:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-bundle.zip"
unzip awscli-bundle.zip
sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
```

For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
bundle.zip"
unzip awscli-bundle.zip
sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
```

Follow these steps from the command line to install the Amazon CLI version 1 using the bundled installer.

To install the Amazon CLI version 1 using the bundled installer

1. Download the Amazon CLI version 1 bundled installer using one of the the following methods.

   - Download using the `curl` command.

     For the latest version of the Amazon CLI, use the following command block:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-
     bundle.zip"
     ```

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
     bundle.zip"
     ```

   - Download using the direct link.

     For the latest version of the Amazon CLI: https://s3.amazonaws.com/aws-cli/awscli-bundle.zip

For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be awscli-bundle-*1.16.312*.zip resulting in the following url https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip

2. Extract the files from the package. If you don't have unzip to extract the files, use your Linux distribution's built-in package manager to install it.

```
$ unzip awscli-bundle.zip
```

3. Run the install program. The installer installs the Amazon CLI at /usr/local/aws and creates the symlink aws at the /usr/local/bin directory. Using the -b option to create a symlink eliminates the need to specify the install directory in the user's $PATH variable. This should enable all users to call the Amazon CLI by entering aws from any directory.

```
$ sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
```

By default, the install script runs under the system default version of Python. If you have installed an alternative version of Python and want to use that version to install the Amazon CLI, run the install script with that version by absolute path to the Python executable, as follows.

```
$ sudo /usr/local/bin/python3.7 awscli-bundle/install -i /usr/local/aws -b /usr/
local/bin/aws
```

4. Verify that the Amazon CLI installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

If you get an error, see Troubleshooting errors for the Amazon CLI.

Install the Amazon CLI version 1 using the bundled installer without sudo

If you don't have sudo permissions or want to install the Amazon CLI only for the current user, you can use a modified version of the previous commands. The first two commands are the same.

For the latest version of the Amazon CLI, use the following command block:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-bundle.zip"
unzip awscli-bundle.zip
./awscli-bundle/install -b ~/bin/aws
```

For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
bundle.zip"
unzip awscli-bundle.zip
./awscli-bundle/install -b ~/bin/aws
```

To install the Amazon CLI version 1 for current user

1. Download the Amazon CLI version 1 bundled installer in one of the following ways.

   - Download using the `curl` command.

     For the latest version of the Amazon CLI, use the following command block:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-
     bundle.zip"
     ```

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
     bundle.zip"
     ```

   - Download using the direct link.

     For the latest version of the Amazon CLI: https://s3.amazonaws.com/aws-cli/awscli-bundle.zip

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following url https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip

2. Extract the files from the package by using `unzip`. If you don't have `unzip`, use your Linux distribution's built-in package manager to install it.

```
$ unzip awscli-bundle.zip
```

3. Run the install program. The installer installs the Amazon CLI at `/usr/local/aws` and creates the symlink `aws` at the `/usr/local/bin` directory. The command uses the `-b` parameter to specify the directory where the installer places the `aws` symlink file. You must have write permissions to the specified folder.

```
$ ./awscli-bundle/install -b ~/bin/aws
```

This installs the Amazon CLI to the default location (`~/.local/lib/aws`) and creates a symbolic link (symlink) at `~/bin/aws`. Make sure that `~/bin` is in your `PATH` environment variable for the symlink to work.

```
$ echo $PATH | grep ~/bin     // See if $PATH contains ~/bin (output will be empty
 if it doesn't)
$ export PATH=~/bin:$PATH     // Add ~/bin to $PATH if necessary
```

4. Ensure the directory that the Amazon CLI version 1 is part of your `PATH` variable.

   a. Find your shell's profile script in your user folder. If you're not sure which shell you have, run `echo $SHELL`.

```
$ ls -a ~
.  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
```

   - **Bash** – `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh** – `.zshrc`
   - **Tcsh** – `.tcshrc`, `.cshrc` or `.login`

   b. Add an export command at the end of your profile script that's similar to the following example.

```
export PATH=~/.local/bin:$PATH
```

This command inserts the path, `~/.local/bin` in this example, at the front of the existing `PATH` variable.

c. Reload the profile into your current session to put those changes into effect.

```
$ source ~/.bash_profile
```

5. Verify that the Amazon CLI installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

If you get an error, see Troubleshooting errors for the Amazon CLI.

Uninstall the Amazon CLI version 1 bundled installer

1. If you installed the Amazon CLI using the bundled installer, follow these instructions. The bundled installer doesn't put anything outside of the installation directory except the optional symlink, so uninstalling is as simple as deleting those two items.

```
$ sudo rm -rf /usr/local/aws
$ sudo rm -rf /usr/local/bin/aws
```

2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If your user has write permission to this directory, you don't need to use `sudo`.

```
$ sudo rm -r ~/.aws/
```

Install and uninstall the Amazon CLI version 1 using pip

Topics

- Install pip
- Install and update the Amazon CLI version 1 using pip
- Uninstall the Amazon CLI using pip

Install pip

If you don't already have `pip` installed, you can install it by using the script that the *Python Packaging Authority* provides. Run `pip --version` to see if your version of Linux already includes Python and `pip`. We recommend that if you have Python version 3 or later installed, you use the `pip3` command.

1. Use the `curl` command to download the installation script. The following command uses the `-0` (uppercase "O")parameter to specify that the downloaded file is to be stored in the current directory using the same name it has on the remote host.

   ```
   $ curl -O https://bootstrap.pypa.io/get-pip.py
   ```

2. Run the script with the `python` or `python3` command to download and install the latest version of `pip` and other required support packages. When you include the `--user` switch, the script installs `pip` to the path `~/.local/bin`.

   ```
   $ python3 get-pip.py --user
   ```

3. Ensure the directory that contains `pip` is part of your `PATH` variable.

   a. Find your shell's profile script in your user folder. If you're not sure which shell you have, run `echo $SHELL`.

   ```
   $ ls -a ~
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash** – `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh** – `.zshrc`
   - **Tcsh** – `.tcshrc`, `.cshrc` or `.login`

b. Add an export command at the end of your profile script that's similar to the following example.

```
export PATH=~/.local/bin:$PATH
```

This command inserts the path, `~/.local/bin` in this example, at the front of the existing PATH variable.

c. Reload the profile into your current session to put those changes into effect.

```
$ source ~/.bash_profile
```

4. To verify that `pip` or `pip3` is installed correctly, run the following command.

```
$ pip3 --version
pip 24.0 from ~/.local/lib/python3.7/site-packages (python 3.7)
```

Install and update the Amazon CLI version 1 using pip

1. Use the `pip` or `pip3` command to install or update the Amazon CLI. We recommend that if you use Python version 3 or later that you use the `pip3` command. The `--user` switch, `pip` installs the Amazon CLI to `~/.local/bin`.

For the latest version of the Amazon CLI, use the following command block:

```
$ pip3 install awscli --upgrade --user
```

For a specific version of the Amazon CLI, append two equals signs = and the version number to the filename. For this example the filename for version *1.16.312* would be *==1.16.312* resulting in the following command:

```
$ pip3 install awscli==1.16.312 --upgrade --user
```

> **Note**
>
> Use appropriate quoting rules for your terminal. In order to use the = character, you might need to use single or double quotes to escape properly. The following example escapes using single quotes:

```
$ pip3 install 'awscli==1.16.312' --upgrade --user
```

2. Verify that the Amazon CLI installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

If you get an error, see Troubleshooting errors for the Amazon CLI.

Uninstall the Amazon CLI using pip

1. If you installed the Amazon CLI version 1 using `pip`, you must also uninstall using `pip`.

```
$ pip uninstall awscli
```

If you are using version Python 2 or 3, you might need to use the `pip2` or `pip3` command. Use the `aws --version` command to determine the Python version associated with your installed Amazon CLI version 1.

```
$ pip3 uninstall awscli
```

You might need to restart your command prompt window or your computer to remove all files.

2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If your user has write permission to this directory, you don't need to use `sudo`.

```
$ sudo rm -r ~/.aws/
```

Install and uninstall the Amazon CLI version 1 using Snapcraft

Topics

- Install snap
- Install and update the Amazon CLI version 1 using snap
- Uninstall the Amazon CLI using snap

Install snap

If you don't already have `snap` installed, you can install it by using the instructions *Canonical Snapcraft* provides. Run `snap version` to see if your version of Linux already includes `snap`.

1. Install Snapcraft on your platform. For information on installing Snapcraft, see Installing the daemon in the *Snap documentation*.
2. Restart your system so that your PATH variables are updated correctly. If you are having installation issues, follow steps in Fix common issues in the *Snap documentation*.
3. To verify that `snap` is installed correctly, run the following command.

   ```
   $ snap version
   ```

Install and update the Amazon CLI version 1 using snap

1. Run the following `snap install` command for the Amazon CLI version 1.

   ```
   $ snap install aws-cli --channel=v1/stable --classic
   ```

   Depending on your permissions, you may need to add `sudo` to your command.

   ```
   $ sudo snap install aws-cli --channel=v1/stable --classic
   ```

2. Verify that the Amazon CLI installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

If you get an error, see Troubleshooting errors for the Amazon CLI.

Uninstall the Amazon CLI using snap

1. If you installed the Amazon CLI version 1 using `snap`, you must also uninstall using `snap`.

   ```
   $ snap remove aws-cli
   ```

   You might need to restart your command prompt window or your computer to remove all files.
2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

   > **Warning**
   >
   > These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

   The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If you have write permissions to this directory, you don't need to use `sudo`.

   ```
   $ sudo rm -r ~/.aws/
   ```

Add the Amazon CLI version 1 executable to your command line path

After installing with `pip` or `snap`, you might need to add the `aws` executable to your operating system' `PATH` environment variable.

You can verify which folder `pip` installed the Amazon CLI in by running the following command.

```
$ which aws
```

```
/home/username/.local/bin/aws
```

You can reference this as ~/.local/bin/ because /home/username corresponds to ~ in Linux.

If you omitted the --user switch and so didn't install in user mode, the executable might be in the bin folder of your Python installation. If you don't know where Python is installed, run this command.

```
$ which python
/usr/local/bin/python
```

The output might be the path to a symlink, not to the actual executable. Run ls -al to see where it points.

```
$ ls -al /usr/local/bin/python
/usr/local/bin/python -> ~/.local/Python/3.6/bin/python3.6
```

pip installs programs in the same folder that contains the Python application. Add this folder to your PATH variable.

To modify your PATH variable

1. Find your shell's profile script in your user directory. If you're not sure which shell you have, run echo $SHELL.

   ```
   $ ls -a ~
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash** – .bash_profile, .profile, or .bash_login
   - **Zsh** – .zshrc
   - **Tcsh** – .tcshrc, .cshrc, or .login
2. Add an export command to your profile script.

   ```
   export PATH=~/.local/bin:$PATH
   ```

   This command adds a path, ~/.local/bin in this example, to the current PATH variable.
3. Load the updated profile into your current session.

```
$ source ~/.bash_profile
```

Troubleshooting Amazon CLI install and uninstall errors

If you come across issues after installing or uninstalling the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `aws --version` command returns a different version than you installed", and the section called "The `aws --version` command returns a version after uninstalling the Amazon CLI".

Installing, updating, and uninstalling the Amazon CLI version 1 on macOS

You can install the Amazon Command Line Interface (Amazon CLI) version 1 and its dependencies on macOS by using the bundled installer or `pip`.

Sections

- Prerequisites
- Install, update and uninstall the Amazon CLI version 1 on macOS using the bundled installer
- Install, update and uninstall the Amazon CLI version 1 using pip
- Troubleshooting Amazon CLI install and uninstall errors

Prerequisites

Before you can install the Amazon CLI version 1 on macOS, be sure you have Python 3.8 or later installed. For installation instructions, see the Downloading Python page in Python's *Beginner Guide*.

Python version support matrix

Amazon CLI version	Supported Python version
1.32.0 – current	Python 3.8+

Amazon CLI version	Supported Python version
1.27.0 – 1.31.x	Python 3.7+
1.20.0 – 1.26.x	Python 3.6+
1.19.0 – 1.19.x	Python 2.7+, Python 3.6+
1.17 – 1.18.x	Python 2.7+, Python 3.4+
1.0 – 1.16.x	Python 2.6 and older, Python 3.3 and older

Install, update and uninstall the Amazon CLI version 1 on macOS using the bundled installer

On Linux or macOS, you can use the bundled installer to install version 1 of the Amazon Command Line Interface (Amazon CLI). The bundled installer includes all dependencies and can be used offline.

The bundled installer doesn't support installing to paths that contain spaces.

Topics

- Install the Amazon CLI version 1 using the bundled installer with sudo
- Install the Amazon CLI version 1 using the bundled installer without sudo
- Uninstall the Amazon CLI version 1 bundled installer

Install the Amazon CLI version 1 using the bundled installer with sudo

The following steps enable you to install the Amazon CLI version 1 from the command line on any build of macOS.

The following is a summary of the installation commands that you can cut and paste to run as a single set of commands.

For the latest version of the Amazon CLI, use the following command block:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-bundle.zip"
unzip awscli-bundle.zip
```

```
sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
```

For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
bundle.zip"
unzip awscli-bundle.zip
sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
```

To install the Amazon CLI version 1 using the bundled installer

1. Download the Amazon CLI version 1 bundled installer in one of the following ways:

   - Download using the `curl` command.

     For the latest version of the Amazon CLI, use the following command block:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-
     bundle.zip"
     ```

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
     bundle.zip"
     ```

   - Download using the direct link.

     For the latest version of the Amazon CLI: https://s3.amazonaws.com/aws-cli/awscli-bundle.zip

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following url https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip

2. Extract (unzip) the files from the package. If you don't have `unzip`, use your macOs distribution's built-in package manager to install it.

```
$ unzip awscli-bundle.zip
```

3. Run the install program. The installer installs the Amazon CLI at `/usr/local/aws` and creates the symlink `aws` at the `/usr/local/bin` folder. Using the `-b` option to create a symlink eliminates the need to specify the install folder in the user's $PATH variable. This should enable all users to call the Amazon CLI by entering `aws` from any directory.

   ```
   $ sudo ./awscli-bundle/install -i /usr/local/aws -b /usr/local/bin/aws
   ```

   By default, the install script runs under the system default version of Python. If you have installed an alternative version of Python and want to use that to install the Amazon CLI, run the install script with that version by absolute path to the Python executable, as follows.

   ```
   $ sudo /usr/local/bin/python3.7 awscli-bundle/install -i /usr/local/aws -b /usr/
   local/bin/aws
   ```

4. Verify that the Amazon CLI installed correctly.

   ```
   $ aws --version
   aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
   ```

   If you get an error, see Troubleshooting errors for the Amazon CLI.

Install the Amazon CLI version 1 using the bundled installer without sudo

If you don't have sudo permissions or want to install the Amazon CLI only for the current user, you can use a modified version of the previous commands. The first two commands are the same.

For the latest version of the Amazon CLI, use the following command block:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-bundle.zip"
unzip awscli-bundle.zip
./awscli-bundle/install -b ~/bin/aws
```

For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

```
$ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
bundle.zip"
unzip awscli-bundle.zip
./awscli-bundle/install -b ~/bin/aws
```

To install the Amazon CLI version 1 for the current user

1. Download the Amazon CLI version 1 bundled installer using one of the the following methods:

   - Download using the `curl` command.

     For the latest version of the Amazon CLI, use the following command block:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle.zip" -o "awscli-
     bundle.zip"
     ```

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following command:

     ```
     $ curl "https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip" -o "awscli-
     bundle.zip"
     ```

   - Download using the direct link.

     For the latest version of the Amazon CLI: https://s3.amazonaws.com/aws-cli/awscli-bundle.zip

     For a specific version of the Amazon CLI, append a hyphen and the version number to the filename. For this example the filename for version *1.16.312* would be `awscli-bundle-1.16.312.zip` resulting in the following url https://s3.amazonaws.com/aws-cli/awscli-bundle-1.16.312.zip

2. Extract the files from the package. If you don't have `unzip`, use your Linux distribution's built-in package manager to install it.

   ```
   $ unzip awscli-bundle.zip
   ```

3. Run the install program. The installer installs the Amazon CLI at `/usr/local/aws` and creates the symlink `aws` at the `/usr/local/bin` directory. The command uses the `-b` parameter

to specify the directory where the installer places the `aws` symlink file. You must have write permissions to the specified directory.

```
$ ./awscli-bundle/install -b ~/bin/aws
```

This installs the Amazon CLI to the default location (`~/.local/lib/aws`) and creates a symbolic link (symlink) at `~/bin/aws`. Make sure that `~/bin` is in your `$PATH` environment variable for the symlink to work.

```
$ echo $PATH | grep ~/bin     // See if $PATH contains ~/bin (output will be empty
 if it doesn't)
$ export PATH=~/bin:$PATH     // Add ~/bin to $PATH if necessary
```

4. Ensure the folder that the Amazon CLI version 1 is installed in is part of your `$PATH` variable.

   a. Find your shell's profile script in your user folder. If you're not sure which shell you have, run `echo $SHELL`.

   ```
   $ ls -a ~
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash** – `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh** – `.zshrc`
   - **Tcsh** – `.tcshrc`, `.cshrc` or `.login`

   b. Add an export command at the end of your profile script that's similar to the following example.

   ```
   export PATH=~/.local/bin:$PATH
   ```

   This command inserts the path, `~/.local/bin` in this example, at the front of the existing `PATH` variable.

   c. Reload the profile into your current session to put those changes into effect.

   ```
   $ source ~/.bash_profile
   ```

5. Verify that the Amazon CLI installed correctly.

   ```
   $ aws --version
   ```

```
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

If you get an error, see Troubleshooting errors for the Amazon CLI.

Uninstall the Amazon CLI version 1 bundled installer

1. The bundled installer puts everything inside of the installation directory except the optional symlink, so to uninstall, you just need to delete those two items.

```
$ sudo rm -rf /usr/local/aws
$ sudo rm /usr/local/bin/aws
```

2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *~/.aws/*. If your user has write permission to this directory, you don't need to use `sudo`.

```
$ sudo rm ~/.aws/
```

Install, update and uninstall the Amazon CLI version 1 using pip

You can use `pip` directly to install the Amazon CLI.

Topics

- Install pip
- Install and update the Amazon CLI using pip
- Add the Amazon CLI version 1 executable to your macOS command line path

- Uninstall the Amazon CLI using pip

Install pip

If you don't already have `pip` installed, you can install it by using the script that the *Python Packaging Authority* provides. Run `pip --version` to see if your version of Linux already includes Python and `pip`. We recommend that if you have Python version 3 or later installed, you use the `pip3` command.

1. Use the `curl` command to download the installation script. The following command uses the `-O` (uppercase "O") parameter to specify that the downloaded file is to be stored in the current folder using the same name it has on the remote host.

   ```
   $ curl -O https://bootstrap.pypa.io/get-pip.py
   ```

2. Run the script with the `python` or `python3` command to download and install the latest version of `pip` and other required support packages. When you include the `--user` switch, the script installs `pip` to the path `~/.local/bin`.

   ```
   $ python3 get-pip.py --user
   ```

Install and update the Amazon CLI using pip

1. Use the `pip` or `pip3` command to install the Amazon CLI. We recommend that if you use Python version 3 or later, that you use the `pip3` command.

   For the latest version of the Amazon CLI, use the following command block:

   ```
   $ pip3 install awscli --upgrade --user
   ```

   For a specific version of the Amazon CLI, append two equals signs = and the version number to the filename. For this example the filename for version *`1.16.312`* would be *`==1.16.312`* resulting in the following command:

   ```
   $ pip3 install awscli==1.16.312 --upgrade --user
   ```

> **Note**
>
> Use appropriate quoting rules for your terminal. To use the = character, you might need to use single or double quotes to escape properly. The following example escapes using single quotes:
>
> ```
> $ pip3 install 'awscli==1.16.312' --upgrade --user
> ```

2. Verify that the Amazon CLI is installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Darwin/23.3.0 botocore/1.18.6
```

If the program isn't found, add it to your command line path.

Add the Amazon CLI version 1 executable to your macOS command line path

After installing with `pip`, you might need to add the `aws` program to your operating system's `PATH` environment variable. The location of the program depends on where Python is installed.

Example Amazon CLI install location - macOS with Python 3.6 and `pip` (user mode)

```
~/Library/Python/3.7/bin
```

Substitute the version of Python that you have for the version in the previous example.

If you don't know where Python is installed, run `which python`.

```
$ which python
/usr/local/bin/python
```

The output might be the path to a symlink, not the actual program. Run `ls -al` to see where it points.

```
$ ls -al /usr/local/bin/python
~/Library/Python/3.7/bin/python3.7
```

`pip` installs programs in the same folder that contains the Python application. Add this folder to your PATH variable.

To modify your PATH variable

1. Find your shell's profile script in your user directory. If you're not sure which shell you have, run `echo $SHELL`.

   ```
   $ ls -a ~
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash** – `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh** – `.zshrc`
   - **Tcsh** – `.tcshrc`, `.cshrc`, or `.login`
2. Add an export command to your profile script.

   ```
   export PATH=~/.local/bin:$PATH
   ```

   This command adds a path, `~/.local/bin` in this example, to the current PATH variable.
3. Load the updated profile into your current session.

   ```
   $ source ~/.bash_profile
   ```

Uninstall the Amazon CLI using pip

1. If you installed the Amazon CLI version 1 using `pip`, you must also uninstall using `pip`.

   ```
   $ pip uninstall awscli
   ```

   If you are using version Python 2 or 3, you might need to use the `pip2` or `pip3` command. Use the `aws --version` command to determine the Python version associated with your installed Amazon CLI version 1.

   ```
   $ pip3 uninstall awscli
   ```

   You might need to restart your command prompt window or your computer to remove all files.

2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

   > **Warning**
   >
   > These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

   The default location of the `.aws` folder differs between platforms, by default the folder is located in *`~/.aws/`*. If your user has write permission to this directory, you don't need to use `sudo`.

   ```
   $ sudo rm ~/.aws/
   ```

Troubleshooting Amazon CLI install and uninstall errors

If you come across issues after installing or uninstalling the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `aws --version` command returns a different version than you installed", and the section called "The `aws --version` command returns a version after uninstalling the Amazon CLI".

Installing, Updating, and Uninstalling the Amazon CLI version 1 on Windows

You can install version 1 of the Amazon Command Line Interface (Amazon CLI) on Windows by using a standalone installer (recommended) or `pip`, which is a package manager for Python.

Don't include the prompt symbol (`C:\>`) when you type a command. These are included in program listings to differentiate commands that you type from output returned by the Amazon CLI. The rest of this guide uses the generic prompt symbol ($), except in cases where a command is Windows-specific.

Topics

- Install, update, and uninstall the Amazon CLI version 1 using the MSI installer
- Install, update, and uninstall the Amazon CLI version 1 using Python and pip on Windows
- Add the Amazon CLI version 1 executable to your command line path
- Troubleshooting Amazon CLI install and uninstall errors

Install, update, and uninstall the Amazon CLI version 1 using the MSI installer

The Amazon CLI version 1 is supported on Windows XP or later. For Windows users, the MSI installation package offers a familiar and convenient way to install the Amazon CLI version 1 without installing any other prerequisites.

Install and update the Amazon CLI version 1 using the MSI installer

Check the Releases page on GitHub to see when the latest version was released. When updates are released, you must repeat the installation process to get the latest version of the Amazon CLI version 1.

1. Download the appropriate MSI installer:
   - Amazon CLI MSI installer for Windows (64-bit): https://s3.amazonaws.com/aws-cli/AWSCLI64PY3.msi
   - Amazon CLI MSI installer for Windows (32-bit): https://s3.amazonaws.com/aws-cli/AWSCLI32PY3.msi
   - Amazon CLI combined setup file for Windows: https://s3.amazonaws.com/aws-cli/AWSCLISetup.exe (includes both the 32-bit and 64-bit MSI installers, and automatically installs the correct version)
2. Run the downloaded MSI installer or the setup file.
3. Follow the on-screen instructions. By default, the Amazon CLI version 1 installs to `C:\Program Files\Amazon\AWSCLI` (64-bit version) or `C:\Program Files (x86)\Amazon\AWSCLI` (32-bit version).
4. To confirm the installation, use the `aws --version` command at a command prompt (open the **Start** menu and search for `cmd` to start a command prompt).

```
C:\> aws --version
```

```
aws-cli/1.35.20 Python/3.11.6 Windows/10 botocore/1.18.6
```

If Windows is unable to find the program, you might need to close and reopen the command prompt to refresh the path, or add the installation directory to your PATH environment variable manually.

Uninstall the Amazon CLI version 1

To use the following uninstall instructions, you need to have installed the Amazon CLI version 1 with the MSI installer or setup file.

1. Open **Programs and Features** by doing one of the following:
   - Open the **Control Panel**, and then choose **Programs and Features**.
   - Open a command prompt and enter the following command.

     ```
     C:\> appwiz.cpl
     ```
2. Select the entry named **Amazon Command Line Interface**, and then choose **Uninstall** to launch the uninstaller.
3. Confirm that you want to uninstall the Amazon CLI.
4. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

   > **Warning**
   >
   > These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

   The default location of the `.aws` folder differs between platforms, by default the folder is located in *`%UserProfile%\.aws`*.

   ```
   $ rmdir %UserProfile%\.aws
   ```

Install, update, and uninstall the Amazon CLI version 1 using Python and pip on Windows

The Python Software Foundation provides installers for Windows that include `pip`.

Prerequisites

You must have Python 3.8 or later installed. For installation instructions, see the Downloading Python page in Python's *Beginner Guide*.

Install and update the Amazon CLI version 1 using pip

1. To Install the Amazon CLI version 1, use the `pip3` command (if you use Python version 3 or later) or the `pip` command.

   For the latest version of the Amazon CLI, use the following command block:

   ```
   C:\> pip3 install awscli --upgrade --user
   ```

   For a specific version of the Amazon CLI, append a less-than symbol < and the version number to the filename. For this example the filename for version *1.16.312* would be *<1.16.312* resulting in the following command:

   ```
   C:\> pip3 install awscli<1.16.312 --upgrade --user
   ```

2. Verify that the Amazon CLI version 1 is installed correctly. If there is no response, see the Add the Amazon CLI version 1 executable to your command line path section.

   ```
   C:\> aws --version
   aws-cli/1.35.20 Python/3.11.6 Windows/10 botocore/1.18.6
   ```

Uninstall the Amazon CLI version 1 using pip

1. If you installed the Amazon CLI version 1 using `pip`, you must also uninstall using `pip`.

   ```
   C:\> pip uninstall awscli
   ```

If you are using version Python 2 or 3, you might need to use the `pip2` or `pip3` command. Use the `aws --version` command to determine the Python version associated with your installed Amazon CLI version 1.

```
C:\> pip3 uninstall awscli
```

You might need to restart your command prompt window or your computer to remove all files.

2. **(Optional)** Remove the shared Amazon SDK and Amazon CLI settings information in the `.aws` folder.

> **Warning**
>
> These configuration and credentials settings are shared across all Amazon SDKs and the Amazon CLI. If you remove this folder, they cannot be accessed by any Amazon SDKs that are still on your system.

The default location of the `.aws` folder differs between platforms, by default the folder is located in *`%UserProfile%\.aws`*.

```
$ rmdir %UserProfile%\.aws
```

Add the Amazon CLI version 1 executable to your command line path

After installing the Amazon CLI version 1 with `pip`, add the `aws` program to your operating system's PATH environment variable. With an MSI installation, this should happen automatically. But if the `aws` command doesn't run after you install it, you might need to set it manually.

1. Use the `where` command to find the `aws` file location. By default, the `where` command shows where a specified program is found in the system's PATH.

```
C:\> where aws
```

The paths that show up depend on your platform and which method you used to install the Amazon CLI. Folder names that include version numbers can vary. These examples reflect

the use of Python version 3.7. Replace the version with the version number you're using, as needed. Typical paths include the following:

- **Python 3 and pip3** – `C:\Program Files\Python37\Scripts\`
- **Python 3 and pip3 --user option on earlier versions of Windows** – `%USERPROFILE%\AppData\Local\Programs\Python\Python37\Scripts`
- **Python 3 and pip3 --user option on Windows 10** – `%USERPROFILE%\AppData\Roaming\Python\Python37\Scripts`
- **MSI installer (64-bit)** – `C:\Program Files\Amazon\AWSCLI\bin`
- **MSI installer (32-bit)** – `C:\Program Files (x86)\Amazon\AWSCLI\bin`

Use the following steps based on whether a file path is returned.

A file path is returned

```
C:\> where aws
C:\Program Files\Amazon\AWSCLI\bin\aws.exe
```

You can find where the `aws` program is installed by running the following command.

```
C:\> where c:\ aws
C:\Program Files\Python37\Scripts\aws
```

A file path is NOT returned

If the `where` command returns the following error, it's not in the system PATH and you can't run it by entering its name.

```
C:\> where c:\ aws
INFO: Could not find files for the given pattern(s).
```

In that case, run the `where` command with the `/R` *`path`* parameter to tell it to search all folders, and then add the path manually. Use the command line or File Explorer to discover where it's installed on your computer.

```
C:\> where /R c:\ aws
c:\Program Files\Amazon\AWSCLI\bin\aws.exe
```

```
c:\Program Files\Amazon\AWSCLI\bincompat\aws.cmd
c:\Program Files\Amazon\AWSCLI\runtime\Scripts\aws
c:\Program Files\Amazon\AWSCLI\runtime\Scripts\aws.cmd
...
```

2. Press the Windows key and enter **`environment variables`**.
3. Choose **Edit environment variables for your account**.
4. Choose **PATH**, and then choose **Edit**.
5. Add the path you found into the **Variable value** field, for example, ***`C:\Program Files\Amazon\AWSCLI\bin\aws.exe`***.
6. Choose **OK** twice to apply the new settings.
7. Close any running command prompts and reopen the command prompt window.

Troubleshooting Amazon CLI install and uninstall errors

If you come across issues after installing or uninstalling the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `aws --version` command returns a different version than you installed", and the section called "The `aws --version` command returns a version after uninstalling the Amazon CLI".

Installing and updating the Amazon CLI version 1 in a virtual environment

You can avoid requirement version conflicts with other `pip` packages by installing version 1 of the Amazon Command Line Interface (Amazon CLI) in a virtual environment.

Topics

- Prerequisites
- Install and update the Amazon CLI version 1 in a virtual environment
- Troubleshooting Amazon CLI install and uninstall errors

Prerequisites

- Python 3.8 or later. For installation instructions, see the Downloading Python page in Python's *Beginner Guide*.

  Python version support matrix

Amazon CLI version	Supported Python version
1.32.0 – current	Python 3.8+
1.27.0 – 1.31.x	Python 3.7+
1.20.0 – 1.26.x	Python 3.6+
1.19.0 – 1.19.x	Python 2.7+, Python 3.6+
1.17 – 1.18.x	Python 2.7+, Python 3.4+
1.0 – 1.16.x	Python 2.6 and older, Python 3.3 and older

- `pip` or `pip3` is installed.

Install and update the Amazon CLI version 1 in a virtual environment

1. Install `virtualenv` using `pip`.

   ```
   $ pip install --user virtualenv
   ```

2. Create a virtual environment and name it.

   ```
   $ virtualenv ~/cli-ve
   ```

   Alternatively, you can use the `-p` option to specify a version of Python other than the default.

   ```
   $ virtualenv -p /usr/bin/python37 ~/cli-ve
   ```

3. Activate your new virtual environment.

   Linux or macOS

```
$ source ~/cli-ve/bin/activate
```

Windows

```
$ %USERPROFILE%\cli-ve\Scripts\activate
```

The prompt changes to show that your virtual environment is active.

```
(cli-ve)~$
```

4. Install or update the Amazon CLI version 1 into your virtual environment.

```
(cli-ve)~$ pip install --upgrade awscli
```

5. Verify that the Amazon CLI version 1 is installed correctly.

```
$ aws --version
aws-cli/1.35.20 Python/3.11.6 Linux/5.10.205-195.807.amzn2.x86_64 botocore/1.18.6
```

6. You can use the `deactivate` command to exit the virtual environment. Whenever you start a new session, you must reactivate the environment.

Troubleshooting Amazon CLI install and uninstall errors

If you come across issues after installing or uninstalling the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "Command not found errors", the section called "The `aws --version` command returns a different version than you installed", and the section called "The `aws --version` command returns a version after uninstalling the Amazon CLI".

Configuring settings for the Amazon CLI

This section explains how to configure the settings that the Amazon Command Line Interface (Amazon CLI) uses to interact with Amazon. These include the following:

- **Credentials** identify who is calling the API. Access credentials are used to encrypt the request to the Amazon servers to confirm your identity and retrieve associated permissions policies. These permissions determine the actions you can perform. For information on setting up your credentials, see *Authentication and access credentials*.
- **Other configuration details** to tell the Amazon CLI how to process requests, such as the default output format and the default Amazon Region.

> **Note**
>
> Amazon requires that all incoming requests are cryptographically signed. The Amazon CLI does this for you. The "signature" includes a date/time stamp. Therefore, you must ensure that your computer's date and time are set correctly. If you don't, and the date/time in the signature is too far off of the date/time recognized by the Amazon service, Amazon rejects the request.

Configuration and credentials precedence

Credentials and configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. Certain locations take precedence over others. The Amazon CLI credentials and configuration settings take precedence in the following order:

1. **Command line options** – Overrides settings in any other location, such as the `--region`, `--output`, and `--profile` parameters.
2. **Environment variables** – You can store values in your system's environment variables.
3. **Assume role** – Assume the permissions of an IAM role through configuration or the `assume-role` command.
4. **Assume role with web identity** – Assume the permissions of an IAM role using web identity through configuration or the `assume-role-with-web-identity` command.

5. **Credentials file** – The `credentials` and `config` file are updated when you run the command `aws configure`. The `credentials` file is located at `~/.aws/credentials` on Linux or macOS, or at `C:\Users\USERNAME\.aws\credentials` on Windows.
6. **Custom process** – Get your credentials from an external source.
7. **Configuration file** – The `credentials` and `config` file are updated when you run the command `aws configure`. The `config` file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\USERNAME\.aws\config` on Windows.
8. **Container credentials** – You can associate an IAM role with each of your Amazon Elastic Container Service (Amazon ECS) task definitions. Temporary credentials for that role are then available to that task's containers. For more information, see IAM Roles for Tasks in the *Amazon Elastic Container Service Developer Guide*.
9. **Amazon EC2 instance profile credentials** – You can associate an IAM role with each of your Amazon Elastic Compute Cloud (Amazon EC2) instances. Temporary credentials for that role are then available to code running in the instance. The credentials are delivered through the Amazon EC2 metadata service. For more information, see IAM Roles for Amazon EC2 in the *Amazon EC2 User Guide* and Using Instance Profiles in the *IAM User Guide*.

Additional topics in this section

- the section called “Configuration settings”
- the section called “Environment Variables”
- the section called “Command line options”
- the section called “ Command completion”
- the section called “Retries”
- the section called “HTTP proxies”

Configuration and credential file settings in the Amazon CLI

You can save your frequently used configuration settings and credentials in files that are maintained by the Amazon CLI.

The files are divided into `profiles`. By default, the Amazon CLI uses the settings found in the profile named `default`. To use alternate settings, you can create and reference additional profiles.

You can override an individual setting by either setting one of the supported environment variables, or by using a command line parameter. For more information on configuration setting precedence, see Configuring settings for the Amazon CLI.

> **Note**
>
> For information on setting up your credentials, see *Authentication and access credentials*.

Topics

- Format of the configuration and credential files
- Where are configuration settings stored?
- Using named profiles
- Set and view configuration settings using commands
- Setting new configuration and credentials command examples
- Supported config file settings

Format of the configuration and credential files

The `config` and `credentials` files are organized into sections. Sections include *profiles* and *services*. A section is a named collection of settings, and continues until another section definition line is encountered. Multiple profiles and sections can be stored in the `config` and `credentials` files.

These files are plaintext files that use the following format:

- Section names are enclosed in brackets [ ] such as `[default]`, `[profile user1]`, and `[sso-session]`.
- All entries in a section take the general form of `setting_name=value`.
- Lines can be commented out by starting the line with a hash character (#).

The config and credentials files contain the following section types:

- Section type: profile
- Section type: services

Section type: `profile`

Depending on the file, profile section names use the following format:

- **Config file:** `[default]` `[profile user1]`
- **Credentials file:** `[default]` `[user1]`

  Do ***not*** use the word `profile` when creating an entry in the `credentials` file.

Each profile can specify different credentials and can also specify different Amazon Regions and output formats. When naming the profile in a `config` file, include the prefix word "`profile`", but do not include it in the `credentials` file.

The following examples show a `credentials` and `config` file with two profiles, region, and output specified. The first *[default]* is used when you run a Amazon CLI command with no profile specified. The second is used when you run a Amazon CLI command with the `--profile user1` parameter.

Short-term credentials

This example is for the short-term credentials from Amazon Identity and Access Management. For more information, see the section called “Short-term credentials”.

Credentials file

```
[default]
aws_access_key_id=ASIAIOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
aws_session_token
 = IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONGSTRINGEXAMPLE

[user1]
aws_access_key_id=ASIAI44QH8DHBEXAMPLE
aws_secret_access_key=je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY
aws_session_token
 = fcZib3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONGSTRINGEXAMPLE
```

Config file

```
[default]
```

```
region=us-west-2
output=json

[profile user1]
region=us-east-1
output=text
```

IAM role

This example is for assuming an IAM role. Profiles that use IAM roles pull credentials from another profile, and then apply IAM role permissions. In the following examples, `default` is the source profile for credentials and `user1` borrows the same credentials then assumes a new role. For more information, see the section called “IAM roles”.

Credentials file

The `credentials` file depends on what authentication your source profile uses. For the following example, the source profile uses short-term credentials.

```
[default]
aws_access_key_id=ASIAIOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
aws_session_token
 = IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONGSTRINGEXAMPLE
```

Config file

```
[default]
region=us-west-2
output=json

[profile user1]
role_arn=arn:aws-cn:iam::777788889999:role/user1role
source_profile=default
role_session_name=session_user1
region=us-east-1
output=text
```

Amazon EC2 instance metadata credentials

This example is for the credentials obtained from the hosting Amazon EC2 instance metadata. For more information, see the section called “Amazon EC2 metadata”.

Credentials file

The `credentials` file is not used for this authentication method.

Config file

```
[default]
role_arn=arn:aws-cn:iam::123456789012:role/defaultrole
credential_source=Ec2InstanceMetadata
region=us-west-2
output=json

[profile user1]
role_arn=arn:aws-cn:iam::777788889999:role/user1role
credential_source=Ec2InstanceMetadata
region=us-east-1
output=text
```

Long-term credentials

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as Amazon IAM Identity Center.

This example is for the long-term credentials from Amazon Identity and Access Management. For more information, see the section called “IAM users”.

Credentials file

```
[default]
aws_access_key_id=AKIAIOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

[user1]
aws_access_key_id=AKIAI44QH8DHBEXAMPLE
aws_secret_access_key=je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY
```

Config file

```
[default]
region=us-west-2
output=json

[profile user1]
region=us-east-1
output=text
```

For more information and additional authorization and credential methods see, see the section called “IAM users”.

Section type: `services`

The `services` section is a group of settings that configures custom endpoints for Amazon Web Services service requests. A profile then is linked to a `services` section.

```
[profile dev]
services = my-services
```

The `services` section is separated into subsections by <SERVICE> = lines, where <SERVICE> is the Amazon Web Services service identifier key. The Amazon Web Services service identifier is based on the API model's `serviceId` by replacing all spaces with underscores and lowercasing all letters. For a list of all service identifier keys to use in the `services` section, see Using endpoints in the Amazon CLI. The service identifier key is followed by nested settings with each on its own line and indented by two spaces.

The following example configures the endpoint to use for requests made to the Amazon DynamoDB service in the *my-services* section that is used in the *dev* profile. Any immediately following lines that are indented are included in that subsection and apply to that service.

```
[profile dev]
services = my-services

[services my-services]
dynamodb =
  endpoint_url = http://localhost:8000
```

For more information on service-specific endpoints, see Using endpoints in the Amazon CLI.

If your profile has role-based credentials configured through a `source_profile` parameter for IAM assume role functionality, the SDK only uses service configurations for the specified profile. It does not use profiles that are role chained to it. For example, using the following shared `config` file:

```
[profile A]
credential_source = Ec2InstanceMetadata
endpoint_url = https://profile-a-endpoint.aws/

[profile B]
source_profile = A
role_arn = arn:aws:iam::123456789012:role/roleB
services = profileB

[services profileB]
ec2 =
  endpoint_url = https://profile-b-ec2-endpoint.aws
```

If you use profile B and make a call in your code to Amazon EC2, the endpoint resolves as `https://profile-b-ec2-endpoint.aws`. If your code makes a request to any other service, the endpoint resolution will not follow any custom logic. The endpoint does not resolve to the global endpoint defined in profile A. For a global endpoint to take effect for profile B, you would need to set `endpoint_url` directly within profile B.

Where are configuration settings stored?

The Amazon CLI stores sensitive credential information that you specify with `aws configure` in a local file named `credentials`, in a folder named `.aws` in your home directory. The less sensitive configuration options that you specify with `aws configure` are stored in a local file named `config`, also stored in the `.aws` folder in your home directory.

> **Storing credentials in the config file**
>
> You can keep all of your profile settings in a single file as the Amazon CLI can read credentials from the `config` file. If there are credentials in both files for a profile sharing the same name, the keys in the credentials file take precedence. We suggest keeping credentials in the `credentials` files. These files are also used by the various language software development kits (SDKs). If you use one of the SDKs in addition to the Amazon CLI, confirm if the credentials should be stored in their own file.

Where you find your home directory location varies based on the operating system, but is referred to using the environment variables `%UserProfile%` in Windows and `$HOME` or `~` (tilde) in Unix-based systems. You can specify a non-default location for the files by setting the `AWS_CONFIG_FILE` and `AWS_SHARED_CREDENTIALS_FILE` environment variables to another local path. See Configuring environment variables for the Amazon CLI for details.

When you use a shared profile that specifies an Amazon Identity and Access Management (IAM) role, the Amazon CLI calls the Amazon STS `AssumeRole` operation to retrieve temporary credentials. These credentials are then stored (in `~/.aws/cli/cache`). Subsequent Amazon CLI commands use the cached temporary credentials until they expire, and at that point the Amazon CLI automatically refreshes the credentials.

Using named profiles

If no profile is explicitly defined, the `default` profile is used.

To use a named profile, add the `--profile` *`profile-name`* option to your command. The following example lists all of your Amazon EC2 instances using the credentials and settings defined in the `user1` profile.

```
$ aws ec2 describe-instances --profile user1
```

To use a named profile for multiple commands, you can avoid specifying the profile in every command by setting the `AWS_PROFILE` environment variable as the default profile. You can override this setting by using the `--profile` parameter.

Linux or macOS

```
$ export AWS_PROFILE=user1
```

Windows

```
C:\> setx AWS_PROFILE user1
```

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.

Using `setx` to set an environment variable changes the value in all command shells that you create after running the command. It does ***not*** affect any command shell that is already running

at the time you run the command. Close and restart the command shell to see the effects of the change.

Setting the environment variable changes the default profile until the end of your shell session, or until you set the variable to a different value. You can make environment variables persistent across future sessions by putting them in your shell's startup script. For more information, see Configuring environment variables for the Amazon CLI.

Set and view configuration settings using commands

There are several ways to view and set your configuration settings using commands.

`aws configure`

Run this command to quickly set and view your credentials, Region, and output format. The following example shows sample values.

```
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

`aws configure set`

You can set any credentials or configuration settings using `aws configure set`. Specify the profile that you want to view or modify with the `--profile` setting.

For example, the following command sets the `region` in the profile named `integ`.

```
$ aws configure set region us-west-2 --profile integ
```

To remove a setting, manually delete the setting in your `config` and `credentials` files in a text editor.

`aws configure get`

You can retrieve any credentials or configuration settings you've set using `aws configure get`. Specify the profile that you want to view or modify with the `--profile` setting.

For example, the following command retrieves the `region` setting in the profile named `integ`.

```
$ aws configure get region --profile integ
us-west-2
```

If the output is empty, the setting is not explicitly set and uses the default value.

`aws configure list`

To list configuration data, use the `aws configure list` command. This command lists the profile, access key, secret key, and region configuration information used for the specified profile. For each configuration item, it shows the value, where the configuration value was retrieved, and the configuration variable name.

For example, if you provide the Amazon Web Services Region in an environment variable, this command shows you the name of the region you've configured, that this value came from an environment variable, and the name of the environment variable.

For temporary credential methods such as roles and IAM Identity Center, this command displays the temporarily cached access key and secret access key is displayed.

```
$ aws configure list
      Name                    Value             Type    Location
      ----                    -----             ----    --------
   profile                <not set>             None    None
access_key     ****************ABCD  shared-credentials-file
secret_key     ****************ABCD  shared-credentials-file
    region                us-west-2             env    AWS_DEFAULT_REGION
```

Setting new configuration and credentials command examples

The following examples show configuring a default profile with credentials, region, and output specified for different authentication methods.

Short-term credentials

This example is for the short-term credentials from Amazon Identity and Access Management. The aws configure wizard is used to set initial values and then the `aws configure set` command assigns the last value needed. For more information, see the section called “Short-term credentials”.

```
$ aws configure
```

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
$ aws configure set
 aws_session_token fcZib3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONG
```

IAM role

This example is for assuming an IAM role. Profiles that use IAM roles pull credentials from another profile, and then apply IAM role permissions. In the following examples, `default` is the source profile for credentials and `user1` borrows the same credentials then assumes a new role. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “IAM roles”.

```
$ aws configure set role_arn arn:aws-cn:iam::123456789012:role/defaultrole
$ aws configure set source_profile default
$ aws configure set role_session_name session_user1
$ aws configure set region us-west-2
$ aws configure set output json
```

Amazon EC2 instance metadata credentials

This example is for the credentials obtained from the hosting Amazon EC2 instance metadata. There is no wizard for this process, therefore each value is set using the `aws configure set` command. For more information, see the section called “Amazon EC2 metadata”.

```
$ aws configure set role_arn arn:aws-cn:iam::123456789012:role/defaultrole
$ aws configure set credential_source Ec2InstanceMetadata
$ aws configure set region us-west-2
$ aws configure set output json
```

Long-term credentials

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as Amazon IAM Identity Center.

This example is for the long-term credentials from Amazon Identity and Access Management. For more information, see the section called "IAM users".

```
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

Supported `config` file settings

Topics

- Global settings
- S3 Custom command settings

The following settings are supported in the `config` file. The values listed in the specified (or default) profile are used unless they are overridden by the presence of an environment variable with the same name, or a command line option with the same name. For more information on what order settings take precendence, see Configuring settings for the Amazon CLI

Global settings

`account_id_endpoint_mode`

Specifies whether to use Amazon account-based endpoint IDs for calls to supported Amazon Web Services services. For more information on account-based endpoints, see the section called "Account-based endpoints".

This setting can be set to the following:

- **(default) `preferred`** – The endpoint should include account ID if available.
- **`disabled`** – A resolved endpoint doesn't include account ID.
- **`required`** – The endpoint must include account ID. If the account ID isn't available, the SDK throws an error.

Can be overridden by the `AWS_ACCOUNT_ID_ENDPOINT_MODE` environment variable. To use account-based endpoints, the ID must be set in the `AWS_ACCOUNT_ID` environment variable or `aws_account_id` setting.

```
account_id_endpoint_mode = preferred
```

Endpoint precedence

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called “Endpoint configuration and settings precedence”.

`api_versions`

Some Amazon services maintain multiple API versions to support backward compatibility. By default, Amazon CLI commands use the latest available API version. You can specify an API version to use for a profile by including the `api_versions` setting in the `config` file.

This is a "nested" setting that is followed by one or more indented lines that each identify one Amazon service and the API version to use. See the documentation for each service to understand which API versions are available.

The following example shows how to specify an API version for two Amazon services. These API versions are used only for commands that run under the profile that contains these settings.

```
api_versions =
    ec2 = 2015-03-01
    cloudfront = 2015-09-017
```

This setting does not have an environment variable or command line parameter equivalent.

`aws_access_key_id`

Specifies the Amazon access key used as part of the credentials to authenticate the command request. Although this can be stored in the `config` file, we recommend that you store this in the `credentials` file.

Can be overridden by the `AWS_ACCESS_KEY_ID` environment variable. You can't specify the access key ID as a command line option.

```
aws_access_key_id = AKIAIOSFODNN7EXAMPLE
```

aws_account_id

Specifies the Amazon account-based endpoint ID to use for calls to supported Amazon Web Services services. For more information on account-based endpoints, see the section called "Account-based endpoints".

Can be overridden by the AWS_ACCOUNT_ID environment variable. The AWS_ACCOUNT_ID_ENDPOINT_MODE environment variable or account_id_endpoint_mode setting must be set to `preferred` or `required` to use this setting.

```
aws_account_id = 123456789EXAMPLE
```

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

aws_secret_access_key

Specifies the Amazon secret key used as part of the credentials to authenticate the command request. Although this can be stored in the `config` file, we recommend that you store this in the `credentials` file.

Can be overridden by the AWS_SECRET_ACCESS_KEY environment variable. You can't specify the secret access key as a command line option.

```
aws_secret_access_key = wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

`aws_session_token`

Specifies an Amazon session token. A session token is required only if you manually specify temporary security credentials. Although this can be stored in the `config` file, we recommend that you store this in the `credentials` file.

Can be overridden by the `AWS_SESSION_TOKEN` environment variable. You can't specify the session token as a command line option.

```
aws_session_token = AQoEXAMPLEH4aoAH0gNCAPyJxz4BlCFFxWNE1OPTgk5TthT
+FvwqnKwRcOIfrRh3c/LTo6UDdyJwOOvEVPvLXCrrrUtdnniCEXAMPLE/
IvU1dYUg2RVAJBanLiHb4IgRmpRV3zrkuWJOgQs8IZZaIv2BXIa2R4Olgk
```

`ca_bundle`

Specifies a CA certificate bundle (a file with the `.pem` extension) that is used to verify SSL certificates.

Can be overridden by the `AWS_CA_BUNDLE` environment variable or the `--ca-bundle` command line option.

```
ca_bundle = dev/apps/ca-certs/cabundle-2019mar05.pem
```

`cli_follow_urlparam`

Specifies whether the Amazon CLI attempts to follow URL links in command line parameters that begin with `http://` or `https://`. When enabled, the retrieved content is used as the parameter value instead of the URL.

- **true** – This is the default value. If specified, any string parameters that begin with `http://` or `https://` are fetched and any downloaded content is used as the parameter value for the command.
- **false** – If specified, the Amazon CLI does not treat parameter string values that begin with `http://` or `https://` differently from other strings.

This entry does not have an equivalent environment variable or command line option.

```
cli_follow_urlparam = false
```

`cli_history`

Disabled by default. This setting enables command history for the Amazon CLI. After enabling this setting, the Amazon CLI records the history of `aws` commands.

```
cli_history = enabled
```

You can list your history using the `aws history list` command, and use the resulting `command_ids` in the `aws history show` command for details. For more information see `aws history` in the *Amazon CLI reference guide*.

`cli_timestamp_format`

Specifies the format of timestamp values included in the output. You can specify either of the following values:

- **iso8601** – The default value for the Amazon CLI version 2. If specified, the Amazon CLI reformats all timestamps according to ISO 8601.

  ISO 8601 formatted timestamps look like the following examples. The first example shows the time in Coordinated Universal Time (UTC) by including a `Z` after the time. The date and the time are separated by a `T`.

  ```
  2019-10-31T22:21:41Z
  ```

  To specify a different time zone, instead of the `Z`, specify a `+` or `-` and the number of hours the desired time zone is ahead of or behind UTC, as a two-digit value. The following example shows the same time as the previous example but adjusted to Pacific Standard time, which is eight hours behind UTC.

  ```
  2019-10-31T14:21:41-08
  ```

- **wire** – The default value for the Amazon CLI version 1. If specified, the Amazon CLI displays all timestamp values exactly as received in the HTTP query response.

This entry does not have an equivalent environment variable or command line option.

```
cli_timestamp_format = iso8601
```

credential_process

Specifies an external command that the Amazon CLI runs to generate or retrieve authentication credentials to use for this command. The command must return the credentials in a specific format. For more information about how to use this setting, see Sourcing credentials with an external process in the Amazon CLI.

This entry does not have an equivalent environment variable or command line option.

```
credential_process = /opt/bin/awscreds-retriever --username susan
```

credential_source

Used within Amazon EC2 instances or containers to specify where the Amazon CLI can find credentials to use to assume the role you specified with the `role_arn` parameter. You cannot specify both `source_profile` and `credential_source` in the same profile.

This parameter can have one of three values:

- **Environment** – Specifies that the Amazon CLI is to retrieve source credentials from environment variables.
- **Ec2InstanceMetadata** – Specifies that the Amazon CLI is to use the IAM role attached to the EC2 instance profile to get source credentials.
- **EcsContainer** – Specifies that the Amazon CLI is to use the IAM role attached to the ECS container as source credentials.

```
credential_source = Ec2InstanceMetadata
```

duration_seconds

Specifies the maximum duration of the role session, in seconds. The value can range from 900 seconds (15 minutes) up to the maximum session duration setting for the role (which can be a maximum of 43200). This is an optional parameter and by default, the value is set to 3600 seconds.

endpoint_url

Specifies the endpoint that is used for all service requests. If this setting is used in the `services` section of the `config` file, then the endpoint is used only for the specified service.

For more information, see the section called "Set global endpoint for all Amazon Web Services services".

The following example uses the global endpoint `http://localhost:1234` and a service-specific endpoint of `http://localhost:4567` for Amazon S3.

```
[profile dev]
endpoint_url = http://localhost:1234
services = s3-specific

[services s3-specific]
s3 =
  endpoint_url = http://localhost:4567
```

Endpoint precedence

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

`ignore_configure_endpoint_urls`

If enabled, the Amazon CLI ignores all custom endpoint configurations specified in the `config` file. Valid values are **`true`** and **`false`**.

```
ignore_configure_endpoint_urls = true
```

Endpoint precedence

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the

endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

external_id

Specifies a unique identifier that is used by third parties to assume a role in their customers' accounts. This maps to the `ExternalId` parameter in the `AssumeRole` operation. This parameter is needed only if the trust policy for the role specifies a value for `ExternalId`. For more information, see How to use an external ID when granting access to your Amazon resources to a third party in the *IAM User Guide*.

max_attempts

Specifies a value of maximum retry attempts the Amazon CLI retry handler uses, where the initial call counts toward the `max_attempts` value that you provide.

You can override this value by using the `AWS_MAX_ATTEMPTS` environment variable.

```
max_attempts = 3
```

mfa_serial

The identification number of an MFA device to use when assuming a role. This is mandatory only if the trust policy of the role being assumed includes a condition that requires MFA authentication. The value can be either a serial number for a hardware device (such as `GAHT12345678`) or an Amazon Resource Name (ARN) for a virtual MFA device (such as `arn:aws:iam::123456789012:mfa/user`).

output

Specifies the default output format for commands requested using this profile. You can specify any of the following values:

- **json** – The output is formatted as a JSON string.
- **text** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like `grep`, `sed`, or `awk`.
- **table** – The output is formatted as a table using the characters +|- to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

Can be overridden by the `AWS_DEFAULT_OUTPUT` environment variable or the `--output` command line option.

```
output = table
```

`parameter_validation`

Specifies whether the Amazon CLI client attempts to validate parameters before sending them to the Amazon service endpoint.

- **true** – This is the default value. If specified, the Amazon CLI performs local validation of command line parameters.
- **false** – If specified, the Amazon CLI does not validate command line parameters before sending them to the Amazon service endpoint.

This entry does not have an equivalent environment variable or command line option.

```
parameter_validation = false
```

`region`

Specifies the Amazon Web Services Region to send requests to for commands requested using this profile.

- You can specify any of the Region codes available for the chosen service as listed in Amazon Regions and Endpoints in the *Amazon Web Services General Reference*.
- `aws_global` enables you to specify the global endpoint for services that support a global endpoint in addition to Regional endpoints, such as Amazon Security Token Service (Amazon STS) and Amazon Simple Storage Service (Amazon S3).

You can override this value by using the `AWS_DEFAULT_REGION` environment variable, or the `--region` command line option.

```
region = us-west-2
```

`request_checksum_calculation`

Specifies when a checksum is calculated for request payloads, and has the following options:

- `when_supported` – **(Default)** The request payload checksum is calculated when an operation either specifies a checksum algorithm in its service model or requires request checksums.

- `when_required` – The request payload checksum is calculated when an operation requires request checksums or when a user provides a `requestAlgorithmMember` that is modeled by the Amazon Web Services service.

```
request_checksum_calculation = when_supported
```

The environment variable `AWS_REQUEST_CHECKSUM_CALCULATION` overrides this setting.

`response_checksum_validation`

Specifies when checksum validation is performed for response payloads, and has the following options:

- `when_supported` – **(Default)** The response payload checksum validation is performed when an operation specifies a response algorithm in its service model that the Amazon CLI supports.
- `when_required` – The response payload checksum validation is performed when an operation specifies a response algorithm in its service model that the Amazon CLI supports, and you set the modeled `requestValidationModeMember` to `ENABLED` in the operation input.

```
response_checksum_validation = when_supported
```

The environment variable `AWS_RESPONSE_CHECKSUM_VALIDATION` overrides this setting.

`retry_mode`

Specifies which retry mode Amazon CLI uses. There are three retry modes available: legacy (default), standard, and adaptive. For more information on retries, see Amazon CLI retries in the Amazon CLI.

You can override this value by using the `AWS_RETRY_MODE` environment variable.

```
retry_mode = standard
```

`role_arn`

Specifies the Amazon Resource Name (ARN) of an IAM role that you want to use to run the Amazon CLI commands. You must also specify one of the following parameters to identify the credentials that have permission to assume this role:

- source_profile

- credential_source

```
role_arn = arn:aws:iam::123456789012:role/role-name
```

The environment variable AWS_ROLE_ARN overrides this setting.

For more information on using web identities, see the section called "Assume role with web identity".

role_session_name

Specifies the name to attach to the role session. This value is provided to the RoleSessionName parameter when the Amazon CLI calls the AssumeRole operation, and becomes part of the assumed role user ARN: arn:aws:sts::*123456789012*:assumed-role/*role_name*/*role_session_name*. This is an optional parameter. If you do not provide this value, a session name is generated automatically. This name appears in Amazon CloudTrail logs for entries associated with this session.

```
role_session_name = maria_garcia_role
```

The environment variable AWS_ROLE_SESSION_NAME overrides this setting.

For more information on using web identities, see the section called "Assume role with web identity".

services

Specifies the service configuration to use for your profile.

```
[profile dev-s3-specific-and-global]
endpoint_url = http://localhost:1234
services = s3-specific

[services s3-specific]
s3 =
  endpoint_url = http://localhost:4567
```

For more information on the services section, see the section called "services".

The environment variable AWS_ROLE_SESSION_NAME overrides this setting.

For more information on using web identities, see the section called "Assume role with web identity".

sdk_ua_app_id

A single Amazon Web Services account can be used by multiple customer applications to make calls to Amazon Web Services services. Application ID identifies which source application made a set of calls using an Amazon Web Services service. Amazon SDKs and services don't use or interpret this value other than to surface it back in customer communications. For example, this value can be included in operational emails to uniquely identify which of your applications is associated with the notification.

The Application ID is a string with maximum length of 50 characters. Letters, numbers and the following special characters are allowed: ! $ % & * + - . , ^ _ ` | ~ By default, no value is assigned.

```
sdk_ua_app_id = prod1
```

This setting can be overwritten by using the AWS_SDK_UA_APP_ID environment variable. You can't set this value as a command line parameter.

sigv4a_signing_region_set

Specifies the regions to use when signing with SigV4a using a comma-delimited list. If this variable is not set, the Amazon CLI uses the default used by the Amazon Web Services service. If the Amazon Web Services service has no default, the request signature becomes valid in all regions using a value of *.

```
sigv4a_signing_region_set = us-west-2, us-east-1
```

For more information on SigV4a, see Amazon Signature Version 4 for API requests in the *IAM User Guide*

This setting can be overwritten by using the AWS_SIGV4A_SIGNING_REGION_SET environment variable. You can't set this value as a command line parameter.

source_profile

Specifies a named profile with long-term credentials that the Amazon CLI can use to assume a role that you specified with the `role_arn` parameter. You cannot specify both `source_profile` and `credential_source` in the same profile.

```
source_profile = production-profile
```

`sts_regional_endpoints`

Specifies how the Amazon CLI determines the Amazon service endpoint that the Amazon CLI client uses to talk to the Amazon Security Token Service (Amazon STS). The default value for Amazon CLI version 1 is `legacy`.

You can specify one of two values:

- **`legacy`** – Uses the global STS endpoint, `sts.amazonaws.com`, for the following Amazon Regions: `ap-northeast-1`, `ap-south-1`, `ap-southeast-1`, `ap-southeast-2`, `aws-global`, `ca-central-1`, `eu-central-1`, `eu-north-1`, `eu-west-1`, `eu-west-2`, `eu-west-3`, `sa-east-1`, `us-east-1`, `us-east-2`, `us-west-1`, and `us-west-2`. All other Regions automatically use their respective Regional endpoint.
- **`regional`** – The Amazon CLI always uses the Amazon STS endpoint for the currently configured Region. For example, if the client is configured to use `us-west-2`, all calls to Amazon STS are made to the Regional endpoint `sts.us-west-2.amazonaws.com` instead of the global `sts.amazonaws.com` endpoint. To send a request to the global endpoint while this setting is enabled, you can set the Region to `aws-global`.

This setting can be overwritten by using the `AWS_STS_REGIONAL_ENDPOINTS` environment variable. You can't set this value as a command line parameter.

`use_dualstack_endpoint`

Enables the use of dual-stack endpoints to send Amazon requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see Using Amazon S3 dual-stack endpoints in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or Amazon Web Services Region, the request fails. Valid settings are `true` and `false`. This is disabled by default. For more information, see the section called “Set to use dual-stack endpoints for all Amazon Web Services services”.

This is mutually exclusive with the `use_accelerate_endpoint` setting.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the

endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

`use_fips_endpoint`

Some Amazon services offer endpoints that support Federal Information Processing Standard (FIPS) 140-2 in some Amazon Web Services Regions. When the Amazon service supports FIPS, this setting specifies what FIPS endpoint the Amazon CLI should use . Unlike standard Amazon endpoints, FIPS endpoints use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government. For more information see, the section called "Set to use FIPs endpoints for all Amazon Web Services services".

If this setting is enabled, but a FIPS endpoint does not exist for the service in your Amazon Web Services Region, the Amazon command may fail. In this case, manually specify the endpoint to use in the command using the `--endpoint-url` option or use service-specific endpoints.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

`web_identity_token_file`

Specifies the path to a file that contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by an identity provider. The Amazon CLI loads the contents of this file and passes it as the `WebIdentityToken` argument to the `AssumeRoleWithWebIdentity` operation.

The environment variable `AWS_WEB_IDENTITY_TOKEN_FILE` overrides this setting.

For more information on using web identities, see the section called "Assume role with web identity".

`tcp_keepalive`

Specifies whether the Amazon CLI client uses TCP keep-alive packets.

This entry does not have an equivalent environment variable or command line option.

```
tcp_keepalive = false
```

S3 Custom command settings

Amazon S3 supports several settings that configure how the Amazon CLI performs Amazon S3 operations. Some apply to all S3 commands in both the `s3api` and `s3` namespaces. Others are specifically for the S3 "custom" commands that abstract common operations and do more than a one-to-one mapping to an API operation. The `aws s3` transfer commands `cp`, `sync`, `mv`, and `rm` have additional settings you can use to control S3 transfers.

All of these options can be configured by specifying the `s3` nested setting in your `config` file. Each setting is then indented on its own line.

> **Note**
>
> These settings are entirely optional. You should be able to successfully use the `aws s3` transfer commands without configuring any of these settings. These settings are provided to enable you to tune for performance or to account for the specific environment where you are running these `aws s3` commands.

These settings are all set under a top-level `s3` key in the `config` file, as shown in the following example for the `development` profile.

```
[profile development]
s3 =
  max_concurrent_requests = 20
  max_queue_size = 10000
  multipart_threshold = 64MB
  multipart_chunksize = 16MB
  max_bandwidth = 50MB/s
  use_accelerate_endpoint = true
  addressing_style = path
```

The following settings apply to any S3 command in the `s3` or `s3api` namespaces.

`addressing_style`

Specifies which addressing style to use. This controls whether the bucket name is in the hostname or is part of the URL. Valid values are: `path`, `virtual`, and `auto`. The default value is `auto`.

There are two styles of constructing an Amazon S3 endpoint. The first is called `virtual` and includes the bucket name as part of the hostname. For example: `https://`*`bucketname`*`.s3.amazonaws.com`. Alternatively, with the `path` style, you treat the bucket name as if it is a path in the URI; for example, `https://s3.amazonaws.com/`*`bucketname`*. The default value in the CLI is to use `auto`, which attempts to use the `virtual` style where it can, but will fall back to `path` style when required. For example, if your bucket name is not DNS compatible, the bucket name cannot be part of the hostname and must be in the path. With `auto`, the CLI will detect this condition and automatically switch to `path` style for you. If you set the addressing style to `path`, you must then ensure that the Amazon Region you configured in the Amazon CLI matches the Region of your bucket.

`payload_signing_enabled`

Specifies whether to SHA256 sign sigv4 payloads. By default, this is disabled for streaming uploads (`UploadPart` and `PutObject`) when using HTTPS. By default, this is set to `false` for streaming uploads (`UploadPart` and `PutObject`), but only if a `ContentMD5` is present (it is generated by default) and the endpoint uses HTTPS.

If set to true, S3 requests receive additional content validation in the form of a SHA256 checksum which is calculated for you and included in the request signature. If set to false, the checksum isn't calculated. Disabling this can be useful to reduce the performance overhead created by the checksum calculation.

`use_accelerate_endpoint`

Use the Amazon S3 Accelerate endpoint for all `s3` and `s3api` commands. The default value is false. This is mutually exclusive with the `use_dualstack_endpoint` setting.

If set to true, the Amazon CLI directs all Amazon S3 requests to the `S3 Accelerate` endpoint at `s3-accelerate.amazonaws.com`. To use this endpoint, you must enable your bucket to use `S3 Accelerate`. All requests are sent using the virtual style of bucket addressing: *`my-bucket`*`.s3-accelerate.amazonaws.com`. Any `ListBuckets`, `CreateBucket`,

and `DeleteBucket` requests aren't sent to the S3 Accelerate endpoint as that endpoint doesn't support those operations. This behavior can also be set if the `--endpoint-url` parameter is set to `https://s3-accelerate.amazonaws.com` or `http://s3-accelerate.amazonaws.com` for any `s3` or `s3api` command.

`use_dualstack_endpoint`

Enables the use of dual-stack endpoints to send `s3` and `s3api` requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see Using Amazon S3 dual-stack endpoints in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or Amazon Web Services Region, the request fails. Valid settings are `true` and `false`. This is disabled by default. For more information, see the section called “Set to use dual-stack endpoints for all Amazon Web Services services”.

This is mutually exclusive with the `use_accelerate_endpoint` setting.

The following settings apply only to commands in the `s3` namespace command set.

`max_bandwidth`

Specifies the maximum bandwidth that can be consumed for uploading and downloading data to and from Amazon S3. The default is no limit.

This limits the maximum bandwidth that the S3 commands can use to transfer data to and from Amazon S3. This value applies to only uploads and downloads; it doesn't apply to copies or deletes. The value is expressed as bytes per second. The value can be specified as:

- An integer. For example, `1048576` sets the maximum bandwidth usage to 1 megabyte per second.
- An integer followed by a rate suffix. You can specify rate suffixes using: `KB/s`, `MB/s`, or `GB/s`. For example, `300KB/s`, `10MB/s`.

In general, we recommend that you first try to lower bandwidth consumption by lowering `max_concurrent_requests`. If that doesn't adequately limit bandwidth consumption to the desired rate, you can use the `max_bandwidth` setting to further limit bandwidth consumption. This is because `max_concurrent_requests` controls how many threads are currently running. If you instead first lower `max_bandwidth` but leave a high `max_concurrent_requests` setting, it can result in threads having to wait unnecessarily. This can lead to excess resource consumption and connection timeouts.

`max_concurrent_requests`

Specifies the maximum number of concurrent requests. The default value is 10.

The `aws s3` transfer commands are multithreaded. At any given time, multiple Amazon S3 requests can be running. For example, when you use the command `aws s3 cp localdir s3://bucket/ --recursive` to upload files to an S3 bucket, the Amazon CLI can upload the files `localdir/file1`, `localdir/file2`, and `localdir/file3` in parallel. The setting `max_concurrent_requests` specifies the maximum number of transfer operations that can run at the same time.

You might need to change this value for a few reasons:

- Decreasing this value – On some environments, the default of 10 concurrent requests can overwhelm a system. This can cause connection timeouts or slow the responsiveness of the system. Lowering this value makes the S3 transfer commands less resource intensive. The tradeoff is that S3 transfers can take longer to complete. Lowering this value might be necessary if you use a tool to limit bandwidth.
- Increasing this value – In some scenarios, you might want the Amazon S3 transfers to complete as quickly as possible, using as much network bandwidth as necessary. In this scenario, the default number of concurrent requests might not be sufficient to use all of the available network bandwidth. Increasing this value can improve the time it takes to complete an Amazon S3 transfer.

`max_queue_size`

Specifies the maximum number of tasks in the task queue. The default value is 1000.

The Amazon CLI internally uses a model where it queues up Amazon S3 tasks that are then executed by consumers whose numbers are limited by `max_concurrent_requests`.
A task generally maps to a single Amazon S3 operation. For example, a task could be a `PutObjectTask`, or a `GetObjectTask`, or an `UploadPartTask`. The rate at which tasks are added to the queue can be much faster than the rate at which consumers finish the tasks. To avoid unbounded growth, the task queue size is capped to a specific size. This setting changes the value of that maximum number.

You generally don't need to change this setting. This setting also corresponds to the number of tasks that the Amazon CLI is aware of that need to be run. This means that by default the Amazon CLI can only see 1000 tasks ahead. Increasing this value means that the Amazon CLI can more quickly know the total number of tasks needed, assuming that the queuing rate is

quicker than the rate of task completion. The tradeoff is that a larger max_queue_size requires more memory.

`multipart_chunksize`

Specifies the chunk size that the Amazon CLI uses for multipart transfers of individual files. The default value is 8 MB, with a minimum of 5 MB.

When a file transfer exceeds the `multipart_threshold`, the Amazon CLI divides the file into chunks of this size. This value can be specified using the same syntax as `multipart_threshold`, either as the number of bytes as an integer, or by using a size and a suffix.

`multipart_threshold`

Specifies the size threshold the Amazon CLI uses for multipart transfers of individual files. The default value is 8 MB.

When uploading, downloading, or copying a file, the Amazon S3 commands switch to multipart operations if the file exceeds this size. You can specify this value in one of two ways:

- The file size in bytes. For example, `1048576`.
- The file size with a size suffix. You can use `KB`, `MB`, `GB`, or `TB`. For example: `10MB`, `1GB`.

> **Note**
>
> S3 can impose constraints on valid values that can be used for multipart operations. For more information, see the S3 Multipart Upload documentation in the *Amazon Simple Storage Service User Guide*.

Configuring environment variables for the Amazon CLI

Environment variables provide another way to specify configuration options and credentials, and can be useful for scripting.

Precedence of options

- If you specify an option by using one of the environment variables described in this topic, it overrides any value loaded from a profile in the configuration file.

- If you specify an option by using a parameter on the Amazon CLI command line, it overrides any value from either the corresponding environment variable or a profile in the configuration file.

For more information about precedence and how the Amazon CLI determines which credentials to use, see Configuring settings for the Amazon CLI.

Topics

- How to set environment variables
- Amazon CLI supported environment variables

How to set environment variables

The following examples show how you can configure environment variables for the default user.

Linux or macOS

```
$ export AWS_ACCESS_KEY_ID=AKIAIOSFODNN7EXAMPLE
$ export AWS_SECRET_ACCESS_KEY=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
$ export AWS_DEFAULT_REGION=us-west-2
```

Setting the environment variable changes the value used until the end of your shell session, or until you set the variable to a different value. You can make the variables persistent across future sessions by setting them in your shell's startup script.

Windows Command Prompt

To set for all sessions

```
C:\> setx AWS_ACCESS_KEY_ID AKIAIOSFODNN7EXAMPLE
C:\> setx AWS_SECRET_ACCESS_KEY wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
C:\> setx AWS_DEFAULT_REGION us-west-2
```

Using `setx` to set an environment variable changes the value used in both the current command prompt session and all command prompt sessions that you create after running the command. It does ***not*** affect other command shells that are already running at the time you run the command. You may need to restart you terminal for settings to load.

To set for current session only

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.

```
C:\> set AWS_ACCESS_KEY_ID=AKIAIOSFODNN7EXAMPLE
C:\> set AWS_SECRET_ACCESS_KEY=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
C:\> set AWS_DEFAULT_REGION=us-west-2
```

PowerShell

```
PS C:\> $Env:AWS_ACCESS_KEY_ID="AKIAIOSFODNN7EXAMPLE"
PS C:\> $Env:AWS_SECRET_ACCESS_KEY="wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY"
PS C:\> $Env:AWS_DEFAULT_REGION="us-west-2"
```

If you set an environment variable at the PowerShell prompt as shown in the previous examples, it saves the value for only the duration of the current session. To make the environment variable setting persistent across all PowerShell and Command Prompt sessions, store it by using the **System** application in **Control Panel**. Alternatively, you can set the variable for all future PowerShell sessions by adding it to your PowerShell profile. See the PowerShell documentation for more information about storing environment variables or persisting them across sessions.

Amazon CLI supported environment variables

The Amazon CLI supports the following environment variables.

`AWS_ACCESS_KEY_ID`

Specifies an Amazon access key associated with an IAM account.

If defined, this environment variable overrides the value for the profile setting `aws_access_key_id`. You can't specify the access key ID by using a command line option.

`AWS_ACCOUNT_ID`

Specifies the Amazon account-based endpoint ID to use for calls to supported Amazon Web Services services. For more information on account-based endpoints, see the section called "Account-based endpoints".

This setting overrides the `aws_account_id` setting. The `AWS_ACCOUNT_ID_ENDPOINT_MODE` environment variable or `account_id_endpoint_mode` setting must be set to `preferred` or `required` to use this setting.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

`AWS_ACCOUNT_ID_ENDPOINT_MODE`

Specifies whether to use Amazon account-based endpoint IDs for calls to supported Amazon Web Services services. For more information on account-based endpoints, see the section called "Account-based endpoints".

This setting can be set to the following:

- **(default) `preferred`** – The endpoint should include account ID if available.
- **`disabled`** – A resolved endpoint doesn't include account ID.
- **`required`** – The endpoint must include account ID. If the account ID isn't available, the SDK throws an error.

This setting overrides the `account_id_endpoint_mode` setting. To use account-based endpoints, the ID must be set in the `AWS_ACCOUNT_ID` environment variable or `aws_account_id` setting.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

AWS_CA_BUNDLE

Specifies the path to a certificate bundle to use for HTTPS certificate validation.

If defined, this environment variable overrides the value for the profile setting `ca_bundle`. You can override this environment variable by using the `--ca-bundle` command line parameter.

AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS

If the source and destination buckets are the same when using the `s3 mv` command, the source file or object can be moved onto itself, which can result in accidental deletion of your source file or object. The `AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS` environment variable and `--validate-same-s3-paths` option specifies whether to validate your access point ARNs or access point aliases in your Amazon S3 source or destination URIs.

> **Note**
>
> Path validation for `s3 mv` requires additional API calls.

AWS_CONFIG_FILE

Specifies the location of the file that the Amazon CLI uses to store configuration profiles. The default path is `~/.aws/config`.

You can't specify this value in a named profile setting or by using a command line parameter.

AWS_DATA_PATH

A list of additional directories to check outside of the built-in search path of `~/.aws/models` when loading Amazon CLI data. Setting this environment variable indicates additional directories to check first before falling back to the built-in search path. Multiple entries should be separated with the `os.pathsep` character, which is `:` on Linux or macOS and `;` on Windows.

AWS_DEFAULT_OUTPUT

Specifies the output format to use.

If defined, this environment variable overrides the value for the profile setting `output`. You can override this environment variable by using the `--output` command line parameter.

AWS_DEFAULT_REGION

The `Default region name` identifies the Amazon Region whose servers you want to send your requests to by default. This is typically the Region closest to you, but it can be any Region. For example, you can type `us-west-2` to use US West (Oregon). This is the Region that all later requests are sent to, unless you specify otherwise in an individual command.

> **Note**
>
> You must specify an Amazon Region when using the Amazon CLI, either explicitly or by setting a default Region. For a list of the available Regions, see Regions and Endpoints. The Region designators used by the Amazon CLI are the same names that you see in Amazon Web Services Management Console URLs and service endpoints.

If defined, this environment variable overrides the value for the profile setting `region`. You can override this environment variable by using the `--region` command line parameter.

AWS_EC2_METADATA_DISABLED

Disables the use of the Amazon EC2 instance metadata service (IMDS).

If set to true, user credentials or configuration (like the Region) are not requested from IMDS.

AWS_ENDPOINT_URL

Specifies the endpoint that is used for all service requests. For more information, see the section called “Set global endpoint for all Amazon Web Services services”.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called “Endpoint configuration and settings precedence”.

AWS_ENDPOINT_URL_<SERVICE>

Specifies a custom endpoint that is used for a specific service, where <SERVICE> is replaced with the Amazon Web Services service identifier. For example, Amazon DynamoDB has a `serviceId` of DynamoDB. For this service, the endpoint URL environment variable is `AWS_ENDPOINT_URL_DYNAMODB`.

For a list of all service-specific environment variables, see List of service-specific identifiers.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

AWS_IGNORE_CONFIGURED_ENDPOINT_URLS

If enabled, the Amazon CLI ignores all custom endpoint configurations. Valid values are **`true`** and **`false`**. For more information, see the section called "Set global endpoint for all Amazon Web Services services".

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. For endpoint precedence, see the section called "Endpoint configuration and settings precedence".

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

AWS_MAX_ATTEMPTS

Specifies a value of maximum retry attempts the Amazon CLI retry handler uses, where the initial call counts toward the value that you provide. For more information on retries, see Amazon CLI retries in the Amazon CLI.

If defined, this environment variable overrides the value for the profiles setting `max_attempts`.

AWS_METADATA_SERVICE_NUM_ATTEMPTS

When attempting to retrieve credentials on an Amazon EC2 instance that has been configured with an IAM role, the Amazon CLI attempts to retrieve credentials once from the instance metadata service before stopping. If you know your commands will run on an Amazon EC2 instance, you can increase this value to make Amazon CLI retry multiple times before giving up.

AWS_METADATA_SERVICE_TIMEOUT

The number of seconds before a connection to the instance metadata service should time out. When attempting to retrieve credentials on an Amazon EC2 instance that is configured with an IAM role, a connection to the instance metadata service times out after 1 second by default. If you know you're running on an Amazon EC2 instance with an IAM role configured, you can increase this value if needed.

AWS_PROFILE

Specifies the name of the Amazon CLI profile with the credentials and options to use. This can be the name of a profile stored in a `credentials` or `config` file, or the value `default` to use the default profile.

If defined, this environment variable overrides the behavior of using the profile named `[default]` in the configuration file. You can override this environment variable by using the `--profile` command line parameter.

AWS_REQUEST_CHECKSUM_CALCULATION

Specifies when a checksum is calculated for request payloads, and has the following options:

- `when_supported` – **(Default)** The request payload checksum is calculated when an operation either specifies a checksum algorithm in its service model or requires request checksums.
- `when_required` – The request payload checksum is calculated when an operation requires request checksums or when a user provides a `requestAlgorithmMember` that is modeled by the Amazon Web Services service.

If defined, this environment variable overrides the value for the profiles setting `request_checksum_calculation`.

`AWS_RESPONSE_CHECKSUM_VALIDATION`

Specifies when checksum validation is performed for response payloads, and has the following options:

- `when_supported` – **(Default)** The response payload checksum validation is performed when an operation specifies a response algorithm in its service model that the Amazon CLI supports.
- `when_required` – The response payload checksum validation is performed when an operation specifies a response algorithm in its service model that the Amazon CLI supports, and you set the modeled `requestValidationModeMember` to `ENABLED` in the operation input.

If defined, this environment variable overrides the value for the profiles setting `response_checksum_validation`.

`AWS_RETRY_MODE`

Specifies which retry mode Amazon CLI uses. There are three retry modes available: legacy (default), standard, and adaptive. For more information on retries, see Amazon CLI retries in the Amazon CLI.

If defined, this environment variable overrides the value for the profiles setting `retry_mode`.

`AWS_ROLE_ARN`

Specifies the Amazon Resource Name (ARN) of an IAM role with a web identity provider that you want to use to run the Amazon CLI commands.

Used with the `AWS_WEB_IDENTITY_TOKEN_FILE` and `AWS_ROLE_SESSION_NAME` environment variables.

If defined, this environment variable overrides the value for the profile setting `role_arn`. You can't specify a role session name as a command line parameter.

> **Note**
>
> This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

For more information on using web identities, see the section called "Assume role with web identity".

AWS_ROLE_SESSION_NAME

Specifies the name to attach to the role session. This value is provided to the `RoleSessionName` parameter when the Amazon CLI calls the `AssumeRole` operation, and becomes part of the assumed role user ARN: `arn:aws:sts::123456789012:assumed-role/role_name/role_session_name`. This is an optional parameter. If you do not provide this value, a session name is generated automatically. This name appears in Amazon CloudTrail logs for entries associated with this session.

If defined, this environment variable overrides the value for the profile setting `role_session_name`.

Used with the `AWS_ROLE_ARN` and `AWS_WEB_IDENTITY_TOKEN_FILE` environment variables.

For more information on using web identities, see the section called "Assume role with web identity".

> **Note**
>
> This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

AWS_SDK_UA_APP_ID

A single Amazon Web Services account can be used by multiple customer applications to make calls to Amazon Web Services services. Application ID identifies which source application made a set of calls using an Amazon Web Services service. Amazon SDKs and services don't use or interpret this value other than to surface it back in customer communications. For example, this value can be included in operational emails to uniquely identify which of your applications is associated with the notification.

By default, there is no value.

The Application ID is a string with maximum length of 50 characters. Letters, numbers and the following special characters are allowed:

```
! $ % & * + - . , ^ _ ` | ~
```

If defined, this environment variable overrides the value for the profile setting `sdk_ua_app_id`. You can't specify Application ID as a command line option.

`AWS_SECRET_ACCESS_KEY`

Specifies the secret key associated with the access key. This is essentially the "password" for the access key.

If defined, this environment variable overrides the value for the profile setting `aws_secret_access_key`. You can't specify the secret access key ID as a command line option.

`AWS_SESSION_TOKEN`

Specifies the session token value that is required if you are using temporary security credentials that you retrieved directly from Amazon STS operations. For more information, see the Output section of the assume-role command in the *Amazon CLI Command Reference*.

If defined, this environment variable overrides the value for the profile setting `aws_session_token`.

`AWS_SHARED_CREDENTIALS_FILE`

Specifies the location of the file that the Amazon CLI uses to store access keys. The default path is `~/.aws/credentials`.

You can't specify this value in a named profile setting or by using a command line parameter.

`AWS_SIGV4A_SIGNING_REGION_SET`

Specifies the regions to use when signing with SigV4a using a comma-delimited list. If this variable is not set, the Amazon CLI uses the default used by the Amazon Web Services service. If the Amazon Web Services service has no default, the request signature becomes valid in all regions using a value of `*`.

For more information on SigV4a, see Amazon Signature Version 4 for API requests in the *IAM User Guide*

If defined, this environment variable overrides the value for the profile setting `sigv4a_signing_region_set`.

`AWS_STS_REGIONAL_ENDPOINTS`

Specifies how the Amazon CLI determines the Amazon service endpoint that the Amazon CLI client uses to talk to the Amazon Security Token Service (Amazon STS). The default value for Amazon CLI version 1 is `legacy`.

You can specify one of two values:

- **`legacy`** – Uses the global STS endpoint, `sts.amazonaws.com`, for the following Amazon Regions: `ap-northeast-1`, `ap-south-1`, `ap-southeast-1`, `ap-southeast-2`, `aws-global`, `ca-central-1`, `eu-central-1`, `eu-north-1`, `eu-west-1`, `eu-west-2`, `eu-west-3`, `sa-east-1`, `us-east-1`, `us-east-2`, `us-west-1`, and `us-west-2`. All other Regions automatically use their respective Regional endpoint.
- **`regional`** – The Amazon CLI always uses the Amazon STS endpoint for the currently configured Region. For example, if the client is configured to use `us-west-2`, all calls to Amazon STS are made to the Regional endpoint `sts.us-west-2.amazonaws.com` instead of the global `sts.amazonaws.com` endpoint. To send a request to the global endpoint while this setting is enabled, you can set the Region to `aws-global`.

`AWS_USE_DUALSTACK_ENDPOINT`

Enables the use of dual-stack endpoints to send Amazon requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see Using Amazon S3 dual-stack endpoints in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or Amazon Web Services Region, the request fails. This is disabled by default. For more information, see the section called “Set to use dual-stack endpoints for all Amazon Web Services services”.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called “Endpoint configuration and settings precedence”.

AWS_USE_FIPS_ENDPOINT

Some Amazon services offer endpoints that support Federal Information Processing Standard (FIPS) 140-2 in some Amazon Web Services Regions. When the Amazon service supports FIPS, this setting specifies what FIPS endpoint the Amazon CLI should use . Unlike standard Amazon endpoints, FIPS endpoints use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government. For more information see, the section called "Set to use FIPs endpoints for all Amazon Web Services services".

If this setting is enabled, but a FIPS endpoint does not exist for the service in your Amazon Web Services Region, the Amazon command may fail. In this case, manually specify the endpoint to use in the command using the `--endpoint-url` option or use service-specific endpoints.

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called "Endpoint configuration and settings precedence".

AWS_WEB_IDENTITY_TOKEN_FILE

Specifies the path to a file that contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by an identity provider. The Amazon CLI loads the contents of this file and passes it as the `WebIdentityToken` argument to the `AssumeRoleWithWebIdentity` operation.

Used with the `AWS_ROLE_ARN` and `AWS_ROLE_SESSION_NAME` environment variables.

If defined, this environment variable overrides the value for the profile setting `web_identity_token_file`.

For more information on using web identities, see the section called "Assume role with web identity".

> **Note**
>
> This environment variable only applies to an assumed role with web identity provider it does not apply to the general assume role provider configuration.

Command line options in the Amazon CLI

In the Amazon CLI, command line options are global parameters you can use to override the default configuration settings, any corresponding profile setting, or environment variable setting for that single command. You can't use command line options to directly specify credentials, although you can specify which profile to use.

Topics

- How to use command line options
- Amazon CLI supported global command line options
- Common uses of command line options

How to use command line options

Most command line options are simple strings, such as the profile name `profile1` in the following example:

```
$ aws s3 ls --profile profile1
amzn-s3-demo-bucket1
amzn-s3-demo-bucket2
...
```

Each option that takes an argument requires a space or equals sign (=) separating the argument from the option name. If the argument value is a string that contains a space, you must use quotation marks around the argument. For details on argument types and formatting for parameters, see Specifying parameter values in the Amazon CLI.

Amazon CLI supported global command line options

In the Amazon CLI you can use the following command line options to override the default configuration settings, any corresponding profile setting, or environment variable setting for that single command.

--ca-bundle *<string>*

Specifies the certificate authority (CA) certificate bundle to use when verifying SSL certificates.

If defined, this option overrides the value for the profile setting `ca_bundle` and the `AWS_CA_BUNDLE` environment variable.

--cli-connect-timeout *<integer>*

Specifies the maximum socket connect time in seconds. If the value is set to zero (0), the socket connect waits indefinitely (is blocking) and doesn't timeout.

--cli-read-timeout *<integer>*

Specifies the maximum socket read time in seconds. If the value is set to zero (0) the socket read waits indefinitely (is blocking) and doesn't timeout.

--color *<string>*

Specifies support for color output. Valid values are on, `off`, and `auto`. The default value is `auto`.

--debug

A Boolean switch that enables debug logging. The Amazon CLI by default provides cleaned up information regarding any successes or failures regarding command outcomes in the command output. The `--debug` option provides the full Python logs. This includes additional `stderr` diagnostic information about the operation of the command that can be useful when troubleshooting why a command provides unexpected results. To easily view debug logs, we suggest sending the logs to a file to more easily search the information. You can do this by using one of the following.

To send **only** the `stderr` diagnostic information, append `2> debug.txt` where `debug.txt` is the name you want to use for your debug file:

```
$ aws servicename commandname options --debug 2> debug.txt
```

To send **both** the output and `stderr` diagnostic information, append `&> debug.txt` where `debug.txt` is the name you want to use for your debug file:

```
$ aws servicename commandname options --debug &> debug.txt
```

--endpoint-url *<string>*

Specifies the URL to send the request to. For most commands, the Amazon CLI automatically determines the URL based on the selected service and the specified Amazon Region. However, some commands require that you specify an account-specific URL. You can also configure some Amazon services to host an endpoint directly within your private VPC, which might then need to be specified.

The following command example uses a custom Amazon S3 endpoint URL.

```
$ aws s3 ls --endpoint-url http://localhost:4567
```

> **Endpoint precedence**
>
> Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI checks these endpoint settings in a particular order, and uses the endpoint setting with the highest precedence. For the endpoint precedence list, see the section called “Endpoint configuration and settings precedence”.

--no-paginate

A Boolean switch that disables the multiple calls the automatically Amazon CLI makes to receive all command results that creates pagination of the output. This means only the first page of your output is displayed.

--no-sign-request

A Boolean switch that disables signing the HTTP requests to the Amazon service endpoint. This prevents credentials from being loaded.

--no-verify-ssl

By default, the Amazon CLI uses SSL when communicating with Amazon services. For each SSL connection and call, the Amazon CLI verifies the SSL certificates. Using this option overrides the default behavior of verifying SSL certificates.

> **Warning**
>
> This option is **not** best practice. If you use `--no-verify-ssl`, your traffic between your client and Amazon services is no longer secured. This means your traffic is a security risk and vulnerable to man-in-the-middle exploits. If you're having issues with certificates, it's best to resolve those issues instead. For certificate troubleshooting steps, see the section called “SSL certificate errors”.

--output *<string>*

Specifies the output format to use for this command. You can specify any of the following values:

- **`json`** – The output is formatted as a JSON string.
- **`text`** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like `grep`, `sed`, or `awk`.
- **`table`** – The output is formatted as a table using the characters +|- to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

--profile *<string>*

Specifies the named profile to use for this command. To set up additional named profiles, you can use the `aws configure` command with the `--profile` option.

```
$ aws configure --profile <profilename>
```

--query *<string>*

Specifies a JMESPath query to use in filtering the response data. For more information, see Filtering output in the Amazon CLI.

--region *<string>*

Specifies which Amazon Region to send this command's Amazon request to. For a list of all of the Regions that you can specify, see Amazon Regions and Endpoints in the *Amazon Web Services General Reference*.

--version

A Boolean switch that displays the current version of the Amazon CLI program that is running.

Common uses of command line options

Common uses for command line options include checking your resources in multiple Amazon Regions, and changing the output format for legibility or ease of use when scripting. In the following examples, we run the **describe-instances** command against each Region until we find which Region our instance is in.

```
$ aws ec2 describe-instances --output table --region us-west-1
-------------------
|DescribeInstances|
+-----------------+
$ aws ec2 describe-instances --output table --region us-west-2
-----------------------------------------------------------------------------
|                            DescribeInstances                              |
+---------------------------------------------------------------------------+
||                              Reservations                                 ||
|+-----------------------------------+-----------------------------------+|
||  OwnerId                          |  012345678901                     ||
||  ReservationId                    |  r-abcdefgh                       ||
|+-----------------------------------+-----------------------------------+|
|||                               Instances                               |||
||+-------------------------+-------------------------------------------+||
|||  AmiLaunchIndex         |  0                                        |||
|||  Architecture           |  x86_64                                   |||
...
```

Configuring command completion in the Amazon CLI

The Amazon Command Line Interface (Amazon CLI) includes a bash-compatible command-completion feature that enables you to use the **Tab** key to complete a partially entered command. On most systems you need to configure this manually.

Topics

- How it works
- Configuring command completion on Linux or macOS
- Configuring command completion on Windows

How it works

When you partially enter a command, parameter, or option, the command-completion feature either automatically completes your command or displays a suggested list of commands. To prompt command completion, you partially enter in a command and press the completion key, which is typically *Tab* in most shells.

The following examples show different ways that you can use command completion:

- Partially enter a command and press *Tab* to display a suggested list of commands.

```
$ aws dynamodb dTAB
delete-backup                       describe-global-table
delete-item                         describe-global-table-settings
delete-table                        describe-limits
describe-backup                     describe-table
describe-continuous-backups         describe-table-replica-auto-scaling
describe-contributor-insights       describe-time-to-live
describe-endpoints
```

- Partially enter a parameter and press *Tab* to display a suggested list of parameters.

```
$ aws dynamodb delete-table --TAB
--ca-bundle              --endpoint-url           --profile
--cli-connect-timeout    --generate-cli-skeleton  --query
--cli-input-json         --no-paginate            --region
--cli-read-timeout       --no-sign-request        --table-name
--color                  --no-verify-ssl          --version
--debug                  --output
```

- Enter a parameter and press *Tab* to display a suggested list of resource values. This feature is available only in the Amazon CLI version 2.

```
$ aws dynamodb delete-table --table-name TAB
```

```
Table 1                 Table 2                 Table 3
```

Configuring command completion on Linux or macOS

To configure command completion on Linux or macOS, you must know the name of the shell you're using and the location of the `aws_completer` script.

> **Note**
>
> Command completion is automatically configured and enabled by default on Amazon EC2 instances that run Amazon Linux.

Topics

- Confirm the completer's folder is in your path
- Enable command completion
- Verify command completion

Confirm the completer's folder is in your path

For the Amazon completer to work successfully, the `aws_completer` needs to be in your shell's path. The `which` command can check if the completer is in your path.

```
$ which aws_completer
/usr/local/bin/aws_completer
```

If the which command can't find the completer, then use the following steps to add the completer's folder to your path.

Step 1: Locate the Amazon completer

The location of the Amazon completer can vary depending on the installation method used.

- **Package Manager** - Programs such as `pip`, `yum`, `brew`, and `apt-get` typically install the Amazon completer (or a symlink to it) to a standard path location.
  - If you used `pip` **without** the `--user` parameter, the default path is `/usr/local/bin/aws_completer`.

- If you used `pip` **with** the `--user` parameter the default path is `/home/`*`username`*`/.local/bin/aws_completer`.
- **Bundled Installer** - If you used the bundled installer, the default path is `/usr/local/bin/aws_completer`.

If all else fails, you can use the `find` command to search your file system for the Amazon completer.

```
$ find / -name aws_completer
/usr/local/bin/aws_completer
```

Step 2: Identify your shell

To identify which shell you're using, you can use one of the following commands.

- **echo $SHELL** – Displays the shell's program file name. This usually matches the name of the in-use shell, unless you launched a different shell after logging in.

  ```
  $ echo $SHELL
  /bin/bash
  ```

- **ps** – Displays the processes running for the current user. One of them is the shell.

  ```
  $ ps
    PID TTY          TIME CMD
   2148 pts/1    00:00:00 bash
   8756 pts/1    00:00:00 ps
  ```

Step 3: Add the completer to your path

1. Find your shell's profile script in your user folder.

   ```
   $ ls -a ~/
   .  ..  .bash_logout  .bash_profile  .bashrc  Desktop  Documents  Downloads
   ```

   - **Bash**– `.bash_profile`, `.profile`, or `.bash_login`
   - **Zsh**– `.zshrc`
   - **Tcsh**– `.tcshrc`, `.cshrc`, or `.login`

2. Add an export command at the end of your profile script that's similar to the following example. Replace */usr/local/bin/* with the folder that you discovered in the previous section.

```
export PATH=/usr/local/bin/:$PATH
```

3. Reload the profile into the current session to put those changes into effect. Replace *.bash_profile* with the name of the shell script you discovered in the first section.

```
$ source ~/.bash_profile
```

Enable command completion

After confirming the completer is in your path, enable command completion by running the appropriate command for the shell that you're using. You can add the command to your shell's profile to run it each time you open a new shell. In each command, replace the */usr/local/bin/* path with the one found on your system in Confirm the completer's folder is in your path.

- **bash** – Use the built-in command `complete`.

```
$ complete -C '/usr/local/bin/aws_completer' aws
```

  Add the previous command to `~/.bashrc` to run it each time you open a new shell. Your `~/.bash_profile` should source `~/.bashrc` to ensure that the command is also run in login shells.

- **zsh** – To run command completion, you need to run `bashcompinit` by adding the following autoload line at the end of your `~/.zshrc` profile script.

```
$ autoload bashcompinit && bashcompinit
$ autoload -Uz compinit && compinit
```

  To enable command completion, use the built-in command `complete`.

```
$ complete -C '/usr/local/bin/aws_completer' aws
```

  Add the previous commands to `~/.zshrc` to run it each time you open a new shell.

- **tcsh** – Complete for `tcsh` takes a word type and pattern to define the completion behavior.

```
> complete aws 'p/*/`aws_completer`/'
```

Add the previous command to `~/.tschrc` to run it each time you open a new shell.

After you've enabled command completion, Verify command completion is working.

Verify command completion

After enabling command completion, reload your shell, enter a partial command, and press **Tab** to see the available commands.

```
$ aws sTAB
s3              ses             sqs             sts             swf
s3api           sns             storagegateway  support
```

Configuring command completion on Windows

> **Note**
>
> For information on how PowerShell handles their completion, including their various completion keys, see about_Tab_Expansion in the *Microsoft PowerShell Docs*.

To enable command completion for PowerShell on Windows, complete the following steps in PowerShell.

1. Open your `$PROFILE` with the following command.

   ```
   PS C:\> Notepad $PROFILE
   ```

   If you do not have a `$PROFILE`, create a user profile using the following command.

   ```
   PS C:\> if (!(Test-Path -Path $PROFILE ))
   { New-Item -Type File -Path $PROFILE -Force }
   ```

   For more information on PowerShell profiles, see How to Use Profiles in Windows PowerShell ISE on the *Microsoft Docs* website.

2. To enable command completion, add the following code block to your profile, save, and then close the file.

```
Register-ArgumentCompleter -Native -CommandName aws -ScriptBlock {
    param($commandName, $wordToComplete, $cursorPosition)
        $env:COMP_LINE=$wordToComplete
        if ($env:COMP_LINE.Length -lt $cursorPosition){
            $env:COMP_LINE=$env:COMP_LINE + " "
        }
        $env:COMP_POINT=$cursorPosition
        aws_completer.exe | ForEach-Object {
            [System.Management.Automation.CompletionResult]::new($_, $_,
 'ParameterValue', $_)
        }
        Remove-Item Env:\COMP_LINE
        Remove-Item Env:\COMP_POINT
}
```

3. After enabling command completion, reload your shell, enter a partial command, and press **Tab** to cycle through the available commands.

```
$ aws sTab
```

```
$ aws s3
```

To see all available commands available to your completion, enter a partial command and press **Ctrl** + **Space**.

```
$ aws sCtrl + Space
s3              ses             sqs             sts             swf
s3api           sns             storagegateway  support
```

Amazon CLI retries in the Amazon CLI

This topic describes how the Amazon CLI might see calls to Amazon services fail due to unexpected issues. These issues can occur on the server side or might fail due to rate limiting from the Amazon service you're attempting to call. These kinds of failures usually don't require special handling and the call is automatically made again, often after a brief waiting period. The Amazon CLI provides

many features to assist in retrying client calls to Amazon services when these kinds of errors or exceptions are experienced.

Topics

- Available retry modes
- Configuring a retry mode
- Viewing logs of retry attempts

Available retry modes

The Amazon CLI has multiple modes to choose from depending on your version:

- Legacy retry mode
- Standard retry mode
- Adaptive retry mode

Legacy retry mode

Legacy mode is the default mode used by the Amazon CLI version 1. Legacy mode uses an older retry handler that has limited functionality which includes:

- A default value of 4 for maximum retry attempts, making a total of 5 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.
- DynamoDB has a default value of 9 for maximum retry attempts, making a total of 10 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.
- Retry attempts for the following limited number of errors/exceptions:
  - General socket/connection errors:
    - `ConnectionError`
    - `ConnectionClosedError`
    - `ReadTimeoutError`
    - `EndpointConnectionError`
  - Service-side throttling/limit errors and exceptions:
    - `Throttling`
    - `ThrottlingException`

    - `ThrottledException`
    - `RequestThrottledException`
    - `ProvisionedThroughputExceededException`
- Retry attempts on several HTTP status codes, including 429, 500, 502, 503, 504, and 509.
- Any retry attempt will include an exponential backoff by a base factor of 2.

Standard retry mode

Standard mode is a standard set of retry rules across the Amazon SDKs with more functionality than legacy. Standard mode was created for the Amazon CLI version 2 and is backported to Amazon CLI version 1. Standard mode's functionality includes:

- A default value of 2 for maximum retry attempts, making a total of 3 call attempts. This value can be overwritten through the `max_attempts` configuration parameter.
- Retry attempts for the following expanded list of errors/exceptions:
    - Transient errors/exceptions
        - `RequestTimeout`
        - `RequestTimeoutException`
        - `PriorRequestNotComplete`
        - `ConnectionError`
        - `HTTPClientError`
    - Service-side throttling/limit errors and exceptions:
        - `Throttling`
        - `ThrottlingException`
        - `ThrottledException`
        - `RequestThrottledException`
        - `TooManyRequestsException`
        - `ProvisionedThroughputExceededException`
        - `TransactionInProgressException`
        - `RequestLimitExceeded`
        - `BandwidthLimitExceeded`
        - `LimitExceededException`

- `RequestThrottled`
- `SlowDown`
- `EC2ThrottledException`

- Retry attempts on nondescriptive, transient error codes. Specifically, these HTTP status codes: 500, 502, 503, 504.
- Any retry attempt will include an exponential backoff by a base factor of 2 for a maximum backoff time of 20 seconds.

Adaptive retry mode

> **Warning**
>
> Adaptive mode is an experimental mode and is subject to change, both in features and behavior.

Adaptive retry mode is an experimental retry mode that includes all the features of standard mode. In addition to the standard mode features, adaptive mode also introduces client-side rate limiting through the use of a token bucket and rate-limit variables that are dynamically updated with each retry attempt. This mode offers flexibility in client-side retries that adapts to the error/exception state response from an Amazon service.

With each new retry attempt, adaptive mode modifies the rate-limit variables based on the error, exception, or HTTP status code presented in the response from the Amazon service. These rate-limit variables are then used to calculate a new call rate for the client. Each exception/error or non-success HTTP response (provided in the list above) from an Amazon service updates the rate-limit variables as retries occur until success is reached, the token bucket is exhausted, or the configured maximum attempts value is reached.

Configuring a retry mode

The Amazon CLI includes a variety of both retry configurations as well as configuration methods to consider when creating your client object.

Available configuration methods

In the Amazon CLI, users can configure retries in the following ways:

- Environment variables
- Amazon CLI configuration file

Users can customize the following retry options:

- Retry mode - Specifies which retry mode the Amazon CLI uses. As described previously, there are three retry modes available: legacy, standard, and adaptive. The default value for the Amazon CLI version 1 is legacy.
- Max attempts - Specifies the value of maximum retry attempts the Amazon CLI retry handler uses, where the initial call counts toward the value that you provide. The default value is based on your retry mode.

Defining a retry configuration in your environment variables

To define your retry configuration for the Amazon CLI, update your operating system's environment variables.

The retry environment variables are:

- `AWS_RETRY_MODE`
- `AWS_MAX_ATTEMPTS`

For more information on environment variables, see Configuring environment variables for the Amazon CLI.

Viewing logs of retry attempts

The Amazon CLI uses Boto3's retry methodology and logging. You can use the `--debug` option on any command to receive debug logs. For more information on how to use the `--debug` option, see Command line options in the Amazon CLI.

If you search for "retry" in your debug logs, you'll find the retry information you need. The client log entries for retry attempts depend on which retry mode you've enabled.

Legacy mode:

Retry messages are generated by botocore.retryhandler. You'll see one of three messages:

- `No retry needed`
- `Retry needed, action of: <action_name>`
- `Reached the maximum number of retry attempts: <attempt_number>`

Standard or adaptive mode:

Retry messages are generated by botocore.retries.standard. You'll see one of three messages:

- `No retrying request`
- `Retry needed, retrying request after delay of: <delay_value>`
- `Retry needed but retry quota reached, not retrying request`

For the full definition file of botocore retries, see _retry.json on the *botocore GitHub Repository*.

Using an HTTP proxy for the Amazon CLI

To access Amazon through proxy servers, you can configure the HTTP_PROXY and HTTPS_PROXY environment variables with either the DNS domain names or IP addresses and port numbers that your proxy servers use.

Topics

- Using the examples
- Authenticating to a proxy
- Using a proxy on Amazon EC2 instances
- Troubleshooting

Using the examples

> **Note**
>
> The following examples show the environment variable name in all uppercase letters. However, if you specify a variable twice using different cases, the lowercase letters take

precedence. We recommend that you define each variable only once to avoid system confusion and unexpected behavior.

The following examples show how you can use either the explicit IP address of your proxy or a DNS name that resolves to the IP address of your proxy. Either can be followed by a colon and the port number to which queries should be sent.

Linux or macOS

```
$ export HTTP_PROXY=http://10.15.20.25:1234
$ export HTTP_PROXY=http://proxy.example.com:1234
$ export HTTPS_PROXY=http://10.15.20.25:5678
$ export HTTPS_PROXY=http://proxy.example.com:5678
```

Windows Command Prompt

To set for all sessions

```
C:\> setx HTTP_PROXY http://10.15.20.25:1234
C:\> setx HTTP_PROXY http://proxy.example.com:1234
C:\> setx HTTPS_PROXY http://10.15.20.25:5678
C:\> setx HTTPS_PROXY http://proxy.example.com:5678
```

Using `setx` to set an environment variable changes the value used in both the current command prompt session and all command prompt sessions that you create after running the command. It does ***not*** affect other command shells that are already running at the time you run the command.

To set for current session only

Using `set` to set an environment variable changes the value used until the end of the current command prompt session, or until you set the variable to a different value.

```
C:\> set HTTP_PROXY=http://10.15.20.25:1234
C:\> set HTTP_PROXY=http://proxy.example.com:1234
C:\> set HTTPS_PROXY=http://10.15.20.25:5678
C:\> set HTTPS_PROXY=http://proxy.example.com:5678
```

Authenticating to a proxy

> **Note**
>
> The Amazon CLI doesn't support NTLM proxies. If you use an NTLM or Kerberos protocol proxy, you might be able to connect through an authentication proxy like Cntlm.

The Amazon CLI supports HTTP Basic authentication. Specify the username and password in the proxy URL, as follows.

Linux or macOS

```
$ export HTTP_PROXY=http://username:password@proxy.example.com:1234
$ export HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

Windows Command Prompt

To set for all sessions

```
C:\> setx HTTP_PROXY http://username:password@proxy.example.com:1234
C:\> setx HTTPS_PROXY http://username:password@proxy.example.com:5678
```

To set for current session only

```
C:\> set HTTP_PROXY=http://username:password@proxy.example.com:1234
C:\> set HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

Using a proxy on Amazon EC2 instances

If you configure a proxy on an Amazon EC2 instance launched with an attached IAM role, ensure that you exempt the address used to access the instance metadata. To do this, set the NO_PROXY environment variable to the IP address of the instance metadata service, 169.254.169.254. This address does not vary.

Linux or macOS

```
$ export NO_PROXY=169.254.169.254
```

Windows Command Prompt

To set for all sessions

```
C:\> setx NO_PROXY 169.254.169.254
```

To set for current session only

```
C:\> set NO_PROXY=169.254.169.254
```

Troubleshooting

If you come across issues with the Amazon CLI, see *Troubleshoot errors* for troubleshooting steps. For the most relevant troubleshooting steps, see the section called "SSL certificate errors".

Using endpoints in the Amazon CLI

To connect programmatically to an Amazon Web Services service, you use an endpoint. An *endpoint* is the URL of the entry point for an Amazon web service. The Amazon Command Line Interface (Amazon CLI) automatically uses the default endpoint for each service in an Amazon Web Services Region, but you can specify an alternate endpoint for your API requests.

Endpoint topics

- Set endpoint for a single command
- Set global endpoint for all Amazon Web Services services
- Set to use FIPs endpoints for all Amazon Web Services services
- Set to use dual-stack endpoints for all Amazon Web Services services
- Set service-specific endpoints
  - Service-specific endpoints: Environment variables
  - Service-specific endpoints: Shared config file
  - Service-specific endpoints: List of service-specific identifiers
- Account-based endpoints
- Endpoint configuration and settings precedence

Set endpoint for a single command

To override any endpoint settings or environment variables for a single command, use the `--endpoint-url` command line option. The following command example uses a custom Amazon S3 endpoint URL.

```
$ aws s3 ls --endpoint-url http://localhost:4567
```

Set global endpoint for all Amazon Web Services services

To route requests for all services to a custom endpoint URL, use one of the following settings:

- Environment variables:
  - `AWS_IGNORE_CONFIGURED_ENDPOINT_URLS` - Ignore configured endpoint URLs.

    Linux or macOS

    ```
    $ export AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
    ```

    Windows Command Prompt

    To set for all sessions

    ```
    C:\> setx AWS_IGNORE_CONFIGURED_ENDPOINT_URLS true
    ```

    To set for current session only

    ```
    C:\> set AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
    ```

    PowerShell

    ```
    PS C:\> $Env:AWS_IGNORE_CONFIGURED_ENDPOINT_URLS="true"
    ```

  - `AWS_ENDPOINT_URL` - Set global endpoint URL.

    Linux or macOS

    ```
    $ export AWS_ENDPOINT_URL=http://localhost:4567
    ```

Windows Command Prompt

To set for all sessions

```
C:\> setx AWS_ENDPOINT_URL http://localhost:4567
```

To set for current session only

```
C:\> set AWS_ENDPOINT_URL=http://localhost:4567
```

PowerShell

```
PS C:\> $Env:AWS_ENDPOINT_URL="http://localhost:4567"
```

- The `config` file:
  - `ignore_configure_endpoint_urls` - Ignore configured endpoint URLs.

    ```
    ignore_configure_endpoint_urls = true
    ```

  - `endpoint_url` - Set global endpoint URL.

    ```
    endpoint_url = http://localhost:4567
    ```

Service-specific endpoints and the `--endpoint-url` command line option override any global endpoints.

Set to use FIPs endpoints for all Amazon Web Services services

To route requests for all services to use FIPs endpoints, use one of the following:

- `AWS_USE_FIPS_ENDPOINT` environment variable.

  Linux or macOS

  ```
  $ export AWS_USE_FIPS_ENDPOINT=true
  ```

  Windows Command Prompt

  To set for all sessions

```
C:\> setx AWS_USE_FIPS_ENDPOINT true
```

To set for current session only

```
C:\> set AWS_USE_FIPS_ENDPOINT=true
```

PowerShell

```
PS C:\> $Env:AWS_USE_FIPS_ENDPOINT="true"
```

- use_fips_endpoint file setting.

```
use_fips_endpoint = true
```

Some Amazon services offer endpoints that support Federal Information Processing Standard (FIPS) 140-2 in some Amazon Web Services Regions. When the Amazon service supports FIPS, this setting specifies what FIPS endpoint the Amazon CLI should use . Unlike standard Amazon endpoints, FIPS endpoints use a TLS software library that complies with FIPS 140-2. These endpoints might be required by enterprises that interact with the United States government.

If this setting is enabled, but a FIPS endpoint does not exist for the service in your Amazon Web Services Region, the Amazon command may fail. In this case, manually specify the endpoint to use in the command using the --endpoint-url option or use service-specific endpoints.

For more information on specifying FIPS endpoints by Amazon Web Services Region, see FIPS Endpoints by Service.

Set to use dual-stack endpoints for all Amazon Web Services services

To route requests for all services to use dual-stack endpoints when available, use one of the following settings:

- AWS_USE_DUALSTACK_ENDPOINT environment variable.

  Linux or macOS

```
$ export AWS_USE_DUALSTACK_ENDPOINT=true
```

Windows Command Prompt

To set for all sessions

```
C:\> setx AWS_USE_DUALSTACK_ENDPOINT true
```

To set for current session only

```
C:\> set AWS_USE_DUALSTACK_ENDPOINT=true
```

PowerShell

```
PS C:\> $Env:AWS_USE_DUALSTACK_ENDPOINT="true"
```

- `use_dualstack_endpoint` file setting.

```
use_dualstack_endpoint = true
```

Enables the use of dual-stack endpoints to send Amazon requests. To learn more about dual-stack endpoints, which support both IPv4 and IPv6 traffic, see Using Amazon S3 dual-stack endpoints in the *Amazon Simple Storage Service User Guide*. Dual-stack endpoints are available for some services in some regions. If a dual-stack endpoint does not exist for the service or Amazon Web Services Region, the request fails. This is disabled by default.

Set service-specific endpoints

Service-specific endpoint configuration provides the option to use a persistent endpoint of your choosing for Amazon CLI requests. These settings provide flexibility to support local endpoints, VPC endpoints, and third-party local Amazon development environments. Different endpoints can be used for testing and production environments. You can specify an endpoint URL for individual Amazon Web Services services.

Service-specific endpoints can be specified in the following ways:

- The command line option `--endpoint-url` for a single command.
- Environment variables:

- AWS_IGNORE_CONFIGURED_ENDPOINT_URLS - Ignore all configured endpoint URLs, unless specified on the command line.
- AWS_ENDPOINT_URL_<SERVICE> - Specifies a custom endpoint that is used for a specific service, where <SERVICE> is replace with the Amazon Web Services service identifier. For all service-specific variables, see the section called "List of service-specific identifiers".

- config file:
  - ignore_configure_endpoint_urls - Ignore all configured endpoint URLs, unless specified using environment variables or on the command line.
  - The services section of the config file combined with the endpoint_url file setting.

Service-specific endpoints topics:

- Service-specific endpoints: Environment variables
- Service-specific endpoints: Shared config file
- Service-specific endpoints: List of service-specific identifiers

Service-specific endpoints: Environment variables

Environment variables override settings in your config file, but do not override options specified on the command line. Use environment variables if you want all profiles to use the same endpoints on your device.

The following are service-specific environment variables:

- AWS_IGNORE_CONFIGURED_ENDPOINT_URLS - Ignore all configured endpoint URLs, unless specified on the command line.

  Linux or macOS

  ```
  $ export AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
  ```

  Windows Command Prompt

  To set for all sessions

  ```
  C:\> setx AWS_IGNORE_CONFIGURED_ENDPOINT_URLS true
  ```

  To set for current session only

```
C:\> set AWS_IGNORE_CONFIGURED_ENDPOINT_URLS=true
```

PowerShell

```
PS C:\> $Env:AWS_IGNORE_CONFIGURED_ENDPOINT_URLS="true"
```

- AWS_ENDPOINT_URL_<SERVICE> - Specifies a custom endpoint that is used for a specific service, where <SERVICE> is replaced with the Amazon Web Services service identifier. For all service-specific variables, see the section called "List of service-specific identifiers".

  The following environment variable examples sets an endpoint for Amazon Elastic Beanstalk:

  Linux or macOS

  ```
  $ export AWS_ENDPOINT_URL_ELASTIC_BEANSTALK=http://localhost:4567
  ```

  Windows Command Prompt

  To set for all sessions

  ```
  C:\> setx AWS_ENDPOINT_URL_ELASTIC_BEANSTALK http://localhost:4567
  ```

  To set for current session only

  ```
  C:\> set AWS_ENDPOINT_URL_ELASTIC_BEANSTALK=http://localhost:4567
  ```

  PowerShell

  ```
  PS C:\> $Env:AWS_ENDPOINT_URL_ELASTIC_BEANSTALK="http://localhost:4567"
  ```

For more information on setting environment variables, see the section called "Environment Variables".

Service-specific endpoints: Shared `config` file

In the shared `config` file, `endpoint_url` is used in multiple sections. To set a service-specific endpoint, use the `endpoint_url` setting nested under a service identifier key within a `services`

section. For details on defining a `services` section in your shared `config` file, see the section called "`services`".

The following example uses a `services` section to configure a service-specific endpoint URL for Amazon S3 and a custom global endpoint used for all other services:

```
[profile dev1]
endpoint_url = http://localhost:1234
services = s3-specific

[services testing-s3]
s3 =
  endpoint_url = http://localhost:4567
```

A single profile can configure endpoints for multiple services. The following example sets the service-specific endpoint URLs for Amazon S3 and Amazon Elastic Beanstalk in the same profile.

For a list of all service identifier keys to use in the `services` section, see List of service-specific identifiers.

```
[profile dev1]
services = testing-s3-and-eb

[services testing-s3-and-eb]
s3 =
  endpoint_url = http://localhost:4567
elastic_beanstalk =
  endpoint_url = http://localhost:8000
```

The service configuration section can be used in multiple profiles. The following example has two profiles use the same `services` definition:

```
[profile dev1]
output = json
services = testing-s3

[profile dev2]
output = text
services = testing-s3

[services testing-s3]
s3 =
```

```
endpoint_url = https://localhost:4567
```

Service-specific endpoints: List of service-specific identifiers

The Amazon Web Services service identifier is based on the API model's `serviceId` by replacing all spaces with underscores and lowercasing all letters.

The following table lists all service-specific identifiers, `config` file keys, and environment variables.

serviceId	**Se id r ke fo sh A c fil**	**AWS_ENDPOINT_URL_<SERVICE> environment variable**
AccessAnalyzer	a l	AWS_ENDPOINT_URL_ACCESSANALYZER

Account-based endpoints

Account-based endpoints can be specified in the following ways:

- Environment variables
  - AWS_ACCOUNT_ID - Specifies the Amazon account-based endpoint ID to use for calls to supported Amazon Web Services services.

Linux or macOS

```
$ export AWS_ACCOUNT_ID=<account-id>
```

Windows Command Prompt

To set for all sessions

```
C:\> setx AWS_ACCOUNT_ID <account-id>
```

To set for current session only

```
C:\> set AWS_ACCOUNT_ID=<account-id>
```

PowerShell

```
PS C:\> $Env:AWS_ACCOUNT_ID="<account-id>"
```

- AWS_ACCOUNT_ID_ENDPOINT_MODE - Specifies whether to use Amazon account-based endpoint IDs for calls to supported Amazon Web Services services. Can be set to `preferred`, `disabled`, or `required`. Default value is `preferred`.

  Linux or macOS

  ```
  $ export AWS_ACCOUNT_ID_ENDPOINT_MODE=preferred
  ```

  Windows Command Prompt

  To set for all sessions

  ```
  C:\> setx AWS_ACCOUNT_ID_ENDPOINT_MODE preferred
  ```

  To set for current session only

  ```
  C:\> set AWS_ACCOUNT_ID_ENDPOINT_MODE=preferred
  ```

PowerShell

```
PS C:\> $Env:AWS_ACCOUNT_ID_ENDPOINT_MODE="preferred"
```

- The `config` file:
  - `aws_account_id` - Specifies the Amazon account-based endpoint ID to use for calls to supported Amazon Web Services services.

    ```
    aws_account_id = <account-id>
    ```

  - `account_id_endpoint_mode` - Specifies whether to use Amazon account-based endpoint IDs for calls to supported Amazon Web Services services. Can be set to `preferred`, `disabled`, or `required`. Default value is preferred.

    ```
    account_id_endpoint_mode = preferred
    ```

Account-based endpoints help ensure high performance and scalability by using your Amazon account ID to streamline the routing of Amazon Web Services service requests for services that support this feature. When you use a credential provider and a service that supports account-based endpoints, the Amazon CLI automatically constructs and uses an account-based endpoint instead of a regional endpoint.

Account-based endpoints use the following format, where `<account-id>` is replaced with your Amazon account ID and `<region>` is replaced with your Amazon Web Services Region:

```
https://<account-id>.myservice.<region>.amazonaws.com
```

By default in the Amazon CLI, the account-based endpoint mode is set to `preferred`.

Endpoint configuration and settings precedence

Endpoint configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. The Amazon CLI endpoint configuration settings take precedence in the following order:

1. The `--endpoint-url` command line option.

2. If enabled, the AWS_IGNORE_CONFIGURED_ENDPOINT_URLS global endpoint environment variable or profile setting ignore_configure_endpoint_urls to ignore custom endpoints.
3. The value provided by a service-specific environment variable AWS_ENDPOINT_URL_<SERVICE>, such as AWS_ENDPOINT_URL_DYNAMODB.
4. The values provided by the AWS_USE_DUALSTACK_ENDPOINT, AWS_USE_FIPS_ENDPOINT, and AWS_ENDPOINT_URL environment variables.
5. The AWS_ACCOUNT_ID_ENDPOINT_MODE environment variable is set to preferred or required using the Account ID in the AWS_ACCOUNT_ID environment variable or aws_account_id setting.
6. The service-specific endpoint value provided by the endpoint_url setting within a services section of the shared config file.
7. The value provided by the endpoint_url setting within a profile of the shared config file.
8. use_dualstack_endpoint, use_fips_endpoint, and endpoint_url settings.
9. The account_id_endpoint_mode setting is set to preferred or required using the Account ID in the AWS_ACCOUNT_ID environment variable or aws_account_id setting.
10. Any default endpoint URL for the respective Amazon Web Services service is used last. For a list of the standard service endpoints available in each Region, see Amazon Regions and Endpoints in the *Amazon Web Services General Reference*.

Authentication and access credentials for the Amazon CLI

You must establish how the Amazon CLI authenticates with Amazon when you develop with Amazon services. To configure credentials for programmatic access for the Amazon CLI, choose one of the following options. The options are in order of recommendation.

Authentication type	Purpose	Instructions
IAM user short-term credentials	Use IAM user short-term credentials, which are more secure than long-term credentials. If your credentials are compromised, there is a limited time they can be used before they expire.	the section called “Short-term credentials”
IAM on an Amazon EC2 instance.	Use Amazon EC2 instance metadata to query for temporary credentials using the role assigned to the Amazon EC2 instance.	the section called “Amazon EC2 metadata”
Assume roles for permissions	Pair another credential method and assume a role for temporary access to Amazon Web Services services your user might not have access to.	the section called “IAM roles”
IAM user long-term credentials	**(Not recommended)** Use long-term credentials, which have no expiration.	the section called “IAM users”
External storage of IAM	**(Not recommended)** Pair another credential method but store credential values in a location outside of the Amazon CLI. This method is	the section called “External credentials”

Authentication type	Purpose	Instructions
	only as secure as the external location the credentials are stored.	

Configuration and credential precedence

Credentials and configuration settings are located in multiple places, such as the system or user environment variables, local Amazon configuration files, or explicitly declared on the command line as a parameter. Certain locations take precedence over others. The Amazon CLI credentials and configuration settings take precedence in the following order:

1. **Command line options** – Overrides settings in any other location, such as the `--region`, `--output`, and `--profile` parameters.
2. **Environment variables** – You can store values in your system's environment variables.
3. **Assume role** – Assume the permissions of an IAM role through configuration or the `assume-role` command.
4. **Assume role with web identity** – Assume the permissions of an IAM role using web identity through configuration or the `assume-role-with-web-identity` command.
5. **Credentials file** – The `credentials` and `config` file are updated when you run the command `aws configure`. The `credentials` file is located at `~/.aws/credentials` on Linux or macOS, or at `C:\Users\`*`USERNAME`*`\.aws\credentials` on Windows.
6. **Custom process** – Get your credentials from an external source.
7. **Configuration file** – The `credentials` and `config` file are updated when you run the command `aws configure`. The `config` file is located at `~/.aws/config` on Linux or macOS, or at `C:\Users\`*`USERNAME`*`\.aws\config` on Windows.
8. **Container credentials** – You can associate an IAM role with each of your Amazon Elastic Container Service (Amazon ECS) task definitions. Temporary credentials for that role are then available to that task's containers. For more information, see IAM Roles for Tasks in the *Amazon Elastic Container Service Developer Guide*.
9. **Amazon EC2 instance profile credentials** – You can associate an IAM role with each of your Amazon Elastic Compute Cloud (Amazon EC2) instances. Temporary credentials for that role are then available to code running in the instance. The credentials are delivered through the

Amazon EC2 metadata service. For more information, see IAM Roles for Amazon EC2 in the *Amazon EC2 User Guide* and Using Instance Profiles in the *IAM User Guide*.

Authenticating with short-term credentials for the Amazon CLI

We recommend configuring your SDK or tool to use IAM Identity Center authentication with extended session duration options. However, you can copy and use temporary credentials that are available in the Amazon access portal. New credentials will need to be copied when these expire. You can use the temporary credentials in a profile or use them as values for system properties and environment variables.

1. Sign in to the Amazon access portal.
2. Follow these instructions to copy IAM role credentials from the Amazon access portal.
    1. For step 2 in the linked instructions, choose the Amazon account and IAM role name that grants access for your development needs. This role typically has a name like **PowerUserAccess** or **Developer**.
    2. For step 4, select the **Add a profile to your Amazon credentials file** option and copy the contents.
3. Create or open the shared `credentials` file. This file is `~/.aws/credentials` on Linux and macOS systems, and `%USERPROFILE%\.aws\credentials` on Windows. For more information, see the section called “Configuration settings”.
4. Add the following text to the shared `credentials` file. Replace the sample values with the credentials you copied.

```
[default]
aws_access_key_id = AKIAIOSFODNN7EXAMPLE
```

```
aws_secret_access_key = wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
aws_session_token =
 IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONGSTRINGEXAMPLE
```

5. Add your preferred default region and format to the shared `config` file.

```
[default]
region=us-west-2
output=json

[profile user1]
region=us-east-1
output=text
```

When the SDK creates a service client, it will access these temporary credentials and use them for each request. The settings for the IAM role chosen in step 2a determine how long the temporary credentials are valid. The maximum duration is twelve hours.

Repeat these steps each time your credentials expire.

Using an IAM role in the Amazon CLI

An Amazon Identity and Access Management (IAM) role is an authorization tool that lets a user gain additional (or different) permissions, or get permissions to perform actions in a different Amazon account.

Topics

- Prerequisites
- Overview of using IAM roles
- Configuring and using a role
- Using multi-factor authentication
- Cross-account roles and external ID
- Specifying a role session name for easier auditing
- Assume role with web identity
- Clearing cached credentials

Prerequisites

To run the `iam` commands, you need to install and configure the Amazon CLI. This includes setting up a configured profile, as assuming a role is paired with another credential method. For more information, see *Install the Amazon CLI*.

Overview of using IAM roles

You can configure the Amazon Command Line Interface (Amazon CLI) to use an IAM role by defining a profile for the role in the `~/.aws/config` file.

The following example shows a role profile named `marketingadmin`. If you run commands with `--profile marketingadmin` (or specify it with the AWS_PROFILE environment variable), the Amazon CLI uses the credentials defined in a separate profile `user1` to assume the role with the Amazon Resource Name (ARN) `arn:aws-cn:iam::123456789012:role/marketingadminrole`. You can run any operations that are allowed by the permissions assigned to that role.

```
[profile marketingadmin]
role_arn = arn:aws-cn:iam::123456789012:role/marketingadminrole
source_profile = user1
```

You can then specify a `source_profile` that points to a separate named profile that contains user credentials with permission to use the role. In the previous example, the `marketingadmin` profile uses the credentials in the `user1` profile. When you specify that an Amazon CLI command is to use the profile `marketingadmin`, the Amazon CLI automatically looks up the credentials for the linked `user1` profile and uses them to request temporary credentials for the specified IAM role. The CLI uses the sts:AssumeRole operation in the background to accomplish this. Those temporary credentials are then used to run the requested Amazon CLI command. The specified role must have attached IAM permission policies that allow the requested Amazon CLI command to run.

To run a Amazon CLI command from within an Amazon Elastic Compute Cloud (Amazon EC2) instance or an Amazon Elastic Container Service (Amazon ECS) container, you can use an IAM role attached to the instance profile or the container. If you specify no profile or set no environment variables, that role is used directly. This enables you to avoid storing long-lived access keys on your instances. You can also use those instance or container roles only to get credentials for another role. To do this, you use `credential_source` (instead of `source_profile`) to specify how to find the credentials. The `credential_source` attribute supports the following values:

- `Environment` – Retrieves the source credentials from environment variables.
- `Ec2InstanceMetadata` – Uses the IAM role attached to the Amazon EC2 instance profile.
- `EcsContainer` – Uses the IAM role attached to the Amazon ECS container.

The following example shows the same `marketingadminrole` role used by referencing an Amazon EC2 instance profile.

```
[profile marketingadmin]
role_arn = arn:aws-cn:iam::123456789012:role/marketingadminrole
credential_source = Ec2InstanceMetadata
```

When you invoke a role, you have additional options that you can require, such as the use of multi-factor authentication and an External ID (used by third-party companies to access their clients' resources). You can also specify unique role session names that can be more easily audited in Amazon CloudTrail logs.

Configuring and using a role

When you run commands using a profile that specifies an IAM role, the Amazon CLI uses the source profile's credentials to call Amazon Security Token Service (Amazon STS) and request temporary credentials for the specified role. The user in the source profile must have permission to call `sts:assume-role` for the role in the specified profile. The role must have a trust relationship that allows the user in the source profile to use the role. The process of retrieving and then using temporary credentials for a role is often referred to as *assuming the role*.

You can create a role in IAM with the permissions that you want users to assume by following the procedure under Creating a Role to Delegate Permissions to an IAM user in the *Amazon Identity and Access Management User Guide*. If the role and the source profile's user are in the same account, you can enter your own account ID when configuring the role's trust relationship.

After creating the role, modify the trust relationship to allow the user to assume it.

The following example shows a trust policy that you could attach to a role. This policy allows the role to be assumed by any user in the account 123456789012, ***if*** the administrator of that account explicitly grants the `sts:AssumeRole` permission to the user.

```
{
  "Version": "2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws-cn:iam::123456789012:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The trust policy doesn't actually grant permissions. The administrator of the account must delegate the permission to assume the role to individual users by attaching a policy with the appropriate permissions. The following example shows a policy that you can attach to a user that allows the user to assume only the `marketingadminrole` role. For more information about granting a user access to assume a role, see Granting a User Permission to Switch Roles in the *IAM User Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws-cn:iam::123456789012:role/marketingadminrole"
    }
  ]
}
```

The user doesn't need to have additional permissions to run the Amazon CLI commands using the role profile. Instead, the permissions to run the command come from those attached to the *role*. You attach permission policies to the role to specify which actions can be performed against which Amazon resources. For more information about attaching permissions to a role (which works identically to a user), see Changing Permissions for an IAM user in the *IAM User Guide*.

Now that you have the role profile, role permissions, role trust relationship, and user permissions correctly configured, you can use the role at the command line by invoking the `--profile` option. For example, the following calls the Amazon S3 `ls` command using the permissions attached to the `marketingadmin` role as defined by the example at the beginning of this topic.

```
$ aws s3 ls --profile marketingadmin
```

To use the role for several calls, you can set the `AWS_PROFILE` environment variable for the current session from the command line. While that environment variable is defined, you don't have to specify the `--profile` option on each command.

Linux or macOS

```
$ export AWS_PROFILE=marketingadmin
```

Windows

```
C:\> setx AWS_PROFILE marketingadmin
```

For more information about configuring users and roles, see IAM Identities (users, user groups, and roles) and IAM roles in the *IAM User Guide*.

Using multi-factor authentication

For additional security, you can require that users provide a one-time key generated from a multi-factor authentication (MFA) device, a U2F device, or mobile app when they attempt to make a call using the role profile.

First, you can choose to modify the trust relationship on the IAM role to require MFA. This prevents anyone from using the role without first authenticating by using MFA. For an example, see the `Condition` line in the following example. This policy allows the user named `anika` to assume the role the policy is attached to, but only if they authenticate by using MFA.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": { "AWS": "arn:aws-cn:iam::123456789012:user/anika" },
      "Action": "sts:AssumeRole",
      "Condition": { "Bool": { "aws:multifactorAuthPresent": true } }
    }
  ]
}
```

Next, add a line to the role profile that specifies the ARN of the user's MFA device. The following sample `config` file entries show two role profiles that both use the access keys for the user `anika`

to request temporary credentials for the role `cli-role`. The user `anika` has permissions to assume the role, granted by the role's trust policy.

```
[profile role-without-mfa]
region = us-west-2
role_arn= arn:aws:iam::128716708097:role/cli-role
source_profile=cli-user

[profile role-with-mfa]
region = us-west-2
role_arn= arn:aws:iam::128716708097:role/cli-role
source_profile = cli-user
mfa_serial = arn:aws:iam::128716708097:mfa/cli-user

[profile cli-user]
region = us-west-2
output = json
```

The `mfa_serial` setting can take an ARN, as shown, or the serial number of a hardware MFA token.

The first profile, `role-without-mfa`, doesn't require MFA. However, because the previous example trust policy attached to the role requires MFA, any attempt to run a command with this profile fails.

```
$ aws iam list-users --profile role-without-mfa

An error occurred (AccessDenied) when calling the AssumeRole operation: Access denied
```

The second profile entry, `role-with-mfa`, identifies an MFA device to use. When the user attempts to run a Amazon CLI command with this profile, the Amazon CLI prompts the user to enter the one-time password (OTP) that the MFA device provides. If the MFA authentication succeeds, the command performs the requested operation. The OTP is not displayed on the screen.

```
$ aws iam list-users --profile role-with-mfa
Enter MFA code for arn:aws:iam::123456789012:mfa/cli-user:
{
    "Users": [
        {
            ...
```

Cross-account roles and external ID

You can enable users to use roles that belong to different accounts by configuring the role as a cross-account role. During role creation, set the role type to **Another Amazon account**, as described in Creating a Role to Delegate Permissions to an IAM user. Optionally, select **Require MFA**. **Require MFA** configures the appropriate condition in the trust relationship, as described in Using multi-factor authentication.

If you use an external ID to provide additional control over who can use a role across accounts, you must also add the `external_id` parameter to the role profile. You typically use this only when the other account is controlled by someone outside your company or organization.

```
[profile crossaccountrole]
role_arn = arn:aws-cn:iam::234567890123:role/SomeRole
source_profile = default
mfa_serial = arn:aws-cn:iam::123456789012:mfa/saanvi
external_id = 123456
```

Specifying a role session name for easier auditing

When many individuals share a role, auditing becomes more of a challenge. You want to associate each operation invoked with the individual who invoked the action. However, when the individual uses a role, the assumption of the role by the individual is a separate action from the invoking of an operation, and you must manually correlate the two.

You can simplify this by specifying unique role session names when users assume a role. You do this by adding a `role_session_name` parameter to each named profile in the `config` file that specifies a role. The `role_session_name` value is passed to the `AssumeRole` operation and becomes part of the ARN for the role session. It is also included in the Amazon CloudTrail logs for all logged operations.

For example, you could create a role-based profile as follows.

```
[profile namedsessionrole]
role_arn = arn:aws-cn:iam::234567890123:role/SomeRole
source_profile = default
role_session_name = Session_Maria_Garcia
```

This results in the role session having the following ARN.

```
arn:aws-cn:iam::234567890123:assumed-role/SomeRole/Session_Maria_Garcia
```

Also, all Amazon CloudTrail logs include the role session name in the information captured for each operation.

Assume role with web identity

You can configure a profile to indicate that the Amazon CLI should assume a role using web identity federation and Open ID Connect (OIDC). When you specify this in a profile, the Amazon CLI automatically makes the corresponding Amazon STS `AssumeRoleWithWebIdentity` call for you.

> **Note**
>
> When you specify a profile that uses an IAM role, the Amazon CLI makes the appropriate calls to retrieve temporary credentials. These credentials are stored in `~/.aws/cli/cache`. Subsequent Amazon CLI commands that specify the same profile use the cached temporary credentials until they expire. At that point, the Amazon CLI automatically refreshes the credentials.

To retrieve and use temporary credentials using web identity federation, you can specify the following configuration values in a shared profile.

role_arn

Specifies the ARN of the role to assume.

web_identity_token_file

Specifies the path to a file which contains an OAuth 2.0 access token or OpenID Connect ID token that is provided by the identity provider. The Amazon CLI loads this file and passes its content as the `WebIdentityToken` argument of the `AssumeRoleWithWebIdentity` operation.

role_session_name

Specifies an optional name applied to this assume-role session.

The following is an example of the minimal amount of configuration needed to configure an assume role with web identity profile.

```
# In ~/.aws/config

[profile web-identity]
role_arn=arn:aws:iam:123456789012:role/RoleNameToAssume
web_identity_token_file=/path/to/a/token
```

You can also provide this configuration by using environment variables.

AWS_ROLE_ARN

The ARN of the role to assume.

AWS_WEB_IDENTITY_TOKEN_FILE

The path to the web identity token file.

AWS_ROLE_SESSION_NAME

The name applied to this assume-role session.

> **Note**
>
> These environment variables currently apply only to the assume role with web identity provider. They don't apply to the general assume role provider configuration.

Clearing cached credentials

When you use a role, the Amazon CLI caches the temporary credentials locally until they expire. The next time you try to use them, the Amazon CLI attempts to renew them on your behalf.

If your role's temporary credentials are revoked, they are not renewed automatically, and attempts to use them fail. However, you can delete the cache to force the Amazon CLI to retrieve new credentials.

Linux or macOS

```
$ rm -r ~/.aws/cli/cache
```

Windows

```
C:\> del /s /q %UserProfile%\.aws\cli\cache
```

Authenticating using IAM user credentials for the Amazon CLI

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as Amazon IAM Identity Center.

This section explains how to configure basic settings with an IAM user. These include your security credentials using the `config` and `credentials` files.

Topics

- Step 1: Create your IAM user
- Step 2: Get your access keys
- Configure the Amazon CLI
  - Using aws configure

Step 1: Create your IAM user

Create your IAM user by following the Creating IAM users (console) procedure in the *IAM User Guide*.

- For **Permission options**, choose **Attach policies directly** for how you want to assign permissions to this user.
- Most "Getting Started" SDK tutorials use the Amazon S3 service as an example. To provide your application with full access to Amazon S3, select the `AmazonS3FullAccess` policy to attach to this user.

Step 2: Get your access keys

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

2. In the navigation pane of the IAM console, select **Users** and then select the **`User name`** of the user that you created previously.
3. On the user's page, select the **Security credentials** page. Then, under **Access keys**, select **Create access key**.
4. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.
5. For **Create access key Step 2**, enter an optional tag and select **Next**.
6. For **Create access key Step 3**, select **Download .csv file** to save a `.csv` file with your IAM user's access key and secret access key. You need this information for later.
7. Select Done.

Configure the Amazon CLI

For general use, the Amazon CLI needs the following pieces of information:

- Access key ID
- Secret access key
- Amazon Region
- Output format

The Amazon CLI stores this information in a *profile* (a collection of settings) named `default` in the `credentials` file. By default, the information in this profile is used when you run an Amazon CLI command that doesn't explicitly specify a profile to use. For more information on the `credentials` file, see Configuration and credential file settings in the Amazon CLI.

To configure the Amazon CLI, use one of the following procedures:

Topics

- Using aws configure

Using `aws configure`

For general use, the `aws configure` command is the fastest way to set up your Amazon CLI installation. This configure wizard prompts you for each piece of information you need to get started. Unless otherwise specified by using the `--profile` option, the Amazon CLI stores this information in the `default` profile.

The following example configures a `default` profile using sample values. Replace them with your own values as described in the following sections.

```
$ aws configure
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

The following example configures a profile named `userprod` using sample values. Replace them with your own values as described in the following sections.

```
$ aws configure --profile userprod
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-west-2
Default output format [None]: json
```

Using Amazon EC2 instance metadata as credentials in the Amazon CLI

When you run the Amazon CLI from within an Amazon Elastic Compute Cloud (Amazon EC2) instance, you can simplify providing credentials to your commands. Each Amazon EC2 instance contains metadata that the Amazon CLI can directly query for temporary credentials. When an IAM role is attached to the instance, the Amazon CLI automatically and securely retrieves the credentials from the instance metadata.

To disable this service, use the AWS_EC2_METADATA_DISABLED environment variable.

Topics

- Prerequisites
- Configuring a profile for Amazon EC2 metadata

Prerequisites

To use Amazon EC2 credentials with the Amazon CLI, you need to complete the following:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- You understand configuration files and named profiles. For more information, see Configuration and credential file settings in the Amazon CLI.
- You've created an Amazon Identity and Access Management (IAM) role that has access to the resources needed, and attached that role to the Amazon EC2 instance when you launch it. For more information, see IAM policies for Amazon EC2 in the *Amazon EC2 User Guide* and Granting Applications That Run on Amazon EC2 Instances Access to Amazon Resources in the *IAM User Guide*.

Configuring a profile for Amazon EC2 metadata

To specify that you want to use the credentials available in the hosting Amazon EC2 instance profile, use the following syntax in the named profile in your configuration file. See the following steps for more instructions.

```
[profile profilename]
role_arn = arn:aws-cn:iam::123456789012:role/rolename
credential_source = Ec2InstanceMetadata
region = region
```

1. Create a profile in your configuration file.

   ```
   [profile profilename]
   ```

2. Add your IAM arn role that has access to the resources needed.

   ```
   role_arn = arn:aws-cn:iam::123456789012:role/rolename
   ```

3. Specify `Ec2InstanceMetadata` as your credential source.

   ```
   credential_source = Ec2InstanceMetadata
   ```

4. Set your Region.

   ```
   region = region
   ```

Example

The following example assumes the *marketingadminrole* role and uses the *us-west-2* Region in an Amazon EC2 instance profile named *marketingadmin*.

```
[profile marketingadmin]
role_arn = arn:aws-cn:iam::123456789012:role/marketingadminrole
credential_source = Ec2InstanceMetadata
region = us-west-2
```

Sourcing credentials with an external process in the Amazon CLI

> **Warning**
>
> This topic discusses sourcing credentials from an external process. This could be a security risk if the command to generate the credentials becomes accessible by non-approved processes or users. We recommend that you use the supported, secure alternatives provided by the Amazon CLI and Amazon to reduce the risk of compromising your credentials. Ensure that you secure the `config` file and any supporting files and tools to prevent disclosure.
>
> Ensure that your custom credential tool does not write any secret information to `StdErr` because the SDKs and Amazon CLI can capture and log such information, potentially exposing it to unauthorized users.

If you have a method to generate or look up credentials that isn't directly supported by the Amazon CLI, you can configure the Amazon CLI to use it by configuring the `credential_process` setting in the `config` file.

For example, you might include an entry similar to the following in the `config` file.

```
[profile developer]
credential_process = /opt/bin/awscreds-custom --username helen
```

Syntax

To create this string in a way that is compatible with any operating system, follow these rules:

- If the path or file name contains a space, surround the complete path and file name with double-quotation marks (" "). The path and file name can consist of only the characters: A-Z a-z 0-9 - _ . space
- If a parameter name or a parameter value contains a space, surround that element with double-quotation marks (" "). Surround only the name or value, not the pair.
- Do not include any environment variables in the strings. For example, you can't include `$HOME` or `%USERPROFILE%`.
- Do not specify the home folder as ~. You must specify the full path.

Example for Windows

```
credential_process = "C:\Path\To\credentials.cmd" parameterWithoutSpaces "parameter
 with spaces"
```

Example for Linux or macOS

```
credential_process = "/Users/Dave/path/to/credentials.sh" parameterWithoutSpaces
 "parameter with spaces"
```

Expected output from the Credentials program

The Amazon CLI runs the command as specified in the profile and then reads data from `STDOUT`. The command you specify must generate JSON output on `STDOUT` that matches the following syntax.

```
{
  "Version": 1,
  "AccessKeyId": "an Amazon access key",
  "SecretAccessKey": "your Amazon secret access key",
  "SessionToken": "the Amazon session token for temporary credentials",
  "Expiration": "ISO8601 timestamp when the credentials expire"
}
```

> **Note**
>
> As of this writing, the `Version` key must be set to 1. This might increment over time as the structure evolves.

The `Expiration` key is an ISO8601 formatted timestamp. If the `Expiration` key is not present in the tool's output, the CLI assumes that the credentials are long-term credentials that do not refresh. Otherwise the credentials are considered temporary credentials and are refreshed automatically by rerunning the `credential_process` command before they expire.

> **Note**
>
> The Amazon CLI does ***not*** cache external process credentials the way it does assume-role credentials. If caching is required, you must implement it in the external process.

The external process can return a non-zero return code to indicate that an error occurred while retrieving the credentials.

Using the Amazon CLI

This section provides a comprehensive overview of the general use, common features, and options available in the Amazon Command Line Interface (Amazon CLI), going beyond the details covered in the Configuration the section called “Endpoints” section.

This guide delves into the fundamental aspects of writing Amazon CLI commands, including their basic structure, formatting, and filtering capabilities. By understanding these core elements, you'll be able to construct commands that precisely target the resources and actions you require, without the need to navigate complex web-based consoles.

Additionally, this highlights the help content and documentation available for the Amazon CLI. From the built-in command line help to the comprehensive Amazon CLI reference guide, you'll have access to information to assist you in exploring the features and capabilities of the Amazon CLI.

For Amazon Web Services service specific examples and use cases, see *Code examples* or the Amazon CLI reference guide. These provide command specific information and demonstrate examples on how to leverage the Amazon CLI for various Amazon Web Services services.

> **Note**
>
> By default, the Amazon CLI sends requests to Amazon Web Services services by using HTTPS on TCP port 443. To ensure successful use of the Amazon CLI, you must be able to make outbound connections on this port.

Topics in this guide

- Accessing help and resources for the Amazon CLI
- Command structure in the Amazon CLI
- Specifying parameter values in the Amazon CLI
- Controlling command output in the Amazon CLI
- Command line return codes in the Amazon CLI
- Creating and using aliases in the Amazon CLI

Accessing help and resources for the Amazon CLI

This topic describes how to access help content for the Amazon Command Line Interface (Amazon CLI).

Topics

- The built-in Amazon CLI help command
- Amazon CLI reference guide
- API documentation
- Troubleshooting errors
- Additional help

The built-in Amazon CLI help command

You can get help with any command when using the Amazon Command Line Interface (Amazon CLI). To do so, simply type `help` at the end of a command name.

For example, the following command displays help for the general Amazon CLI options and the available top-level commands.

```
$ aws help
```

The following command displays the available Amazon Elastic Compute Cloud (Amazon EC2) specific commands.

```
$ aws ec2 help
```

The following example displays detailed help for the Amazon EC2 `DescribeInstances` operation. The help includes descriptions of its input parameters, available filters, and what is included as output. It also includes examples showing how to type common variations of the command.

```
$ aws ec2 describe-instances help
```

The help for each command is divided into six sections:

Name

The name of the command.

```
NAME
       describe-instances -
```

Description

A description of the API operation that the command invokes.

```
DESCRIPTION
       Describes one or more of your instances.

       If you specify one or more instance IDs, Amazon EC2 returns information
       for those instances. If you do not specify  instance  IDs,  Amazon  EC2
       returns  information  for  all  relevant  instances.  If you specify an
       instance ID that is not valid, an error is returned. If you specify  an
       instance  that  you  do  not  own,  it  is not included in the returned
       results.
...
```

Synopsis

The basic syntax for using the command and its options. If an option is shown in square brackets, it's optional, has a default value, or has an alternative option that you can use.

```
SYNOPSIS
            describe-instances
          [--dry-run | --no-dry-run]
          [--instance-ids <value>]
          [--filters <value>]
          [--cli-input-json <value>]
          [--starting-token <value>]
          [--page-size <value>]
          [--max-items <value>]
          [--generate-cli-skeleton]
```

For example, `describe-instances` has a default behavior that describes ***all*** instances in the current account and Amazon Region. You can optionally specify a list of `instance-ids` to describe one or more instances; `dry-run` is an optional Boolean flag that doesn't take a value. To use a Boolean flag, specify either shown value, in this case `--dry-run` or `--no-dry-`

`run`. Likewise, `--generate-cli-skeleton` doesn't take a value. If there are conditions on an option's use, they are described in the `OPTIONS` section, or shown in the examples.

Options

A description of each of the options shown in the synopsis.

```
OPTIONS
       --dry-run | --no-dry-run (boolean)
          Checks whether you have the required  permissions  for  the  action,
          without actually making the request, and provides an error response.
          If you have the required permissions, the error response is  DryRun-
          Operation . Otherwise, it is UnauthorizedOperation .

       --instance-ids (list)
          One or more instance IDs.

          Default: Describes all your instances.
...
```

Examples

Examples showing the usage of the command and its options. If no example is available for a command or use case that you need, request one using the feedback link on this page, or in the Amazon CLI command reference on the help page for the command.

```
    EXAMPLES
    To describe an Amazon EC2 instance

    Command:

    aws ec2 describe-instances --instance-ids i-5203422c

    To describe all instances with the instance type m1.small

    Command:

    aws ec2 describe-instances --filters "Name=instance-type,Values=m1.small"

    To describe all instances with an Owner tag

    Command:
```

```
    aws ec2 describe-instances --filters "Name=tag-key,Values=Owner"
...
```

Output

Descriptions of each of the fields and data types included in the response from Amazon.

For `describe-instances`, the output is a list of reservation objects, each of which contains several fields and objects that contain information about the instances associated with it. This information comes from the API documentation for the reservation data type used by Amazon EC2.

```
OUTPUT
       Reservations -> (list)
          One or more reservations.

          (structure)
              Describes a reservation.

              ReservationId -> (string)
                 The ID of the reservation.

              OwnerId -> (string)
                 The ID of the Amazon account that owns the reservation.

              RequesterId -> (string)
                 The ID of the requester that launched the instances  on  your
                 behalf (for example, Amazon Management Console or Auto Scaling).

              Groups -> (list)
                 One or more security groups.

                 (structure)
                     Describes a security group.

                     GroupName -> (string)
                        The name of the security group.

                     GroupId -> (string)
                        The ID of the security group.

              Instances -> (list)
                 One or more instances.
```

```
                (structure)
                    Describes an instance.

                    InstanceId -> (string)
                       The ID of the instance.

                    ImageId -> (string)
                       The ID of the AMI used to launch the instance.

                    State -> (structure)
                       The current state of the instance.

                       Code -> (integer)
                           The  low  byte represents the state. The high byte
                           is an opaque internal value and should be ignored.
...
```

When the Amazon CLI renders the output into JSON, it becomes an array of reservation objects, similar to the following example.

```
{
    "Reservations": [
        {
            "OwnerId": "012345678901",
            "ReservationId": "r-4c58f8a0",
            "Groups": [],
            "RequesterId": "012345678901",
            "Instances": [
                {
                    "Monitoring": {
                        "State": "disabled"
                    },
                    "PublicDnsName": "ec2-52-74-16-12.us-
west-2.compute.amazonaws.com",
                    "State": {
                        "Code": 16,
                        "Name": "running"
                    },
...
```

Each reservation object contains fields describing the reservation and an array of instance objects, each with its own fields (for example, `PublicDnsName`) and objects (for example, `State`) that describe it.

Windows users

You can *pipe* (|) the output of the help command to the `more` command to view the help file one page at a time. Press the space bar or **PgDn** to view more of the document, and **q** to quit.

```
C:\> aws ec2 describe-instances help | more
```

Amazon CLI reference guide

The help files contain links that cannot be viewed or navigated to from the command line. You can view and interact with these links by using the online Amazon CLI version 1 reference guide. The reference also contains the help content for all Amazon CLI commands. The descriptions are presented for easy navigation and viewing on mobile, tablet, or desktop screens.

API documentation

All commands in the Amazon CLI correspond to requests made to an Amazon service's public API. Each service with a public API has an API reference that can be found on the service's home page on the Amazon Documentation website. The content for an API reference varies based on how the API is constructed and which protocol is used. Typically, an API reference contains detailed information about the operations supported by the API, the data sent to and from the service, and any error conditions that the service can report.

API Documentation Sections

- **Actions** – Detailed information on each operation and its parameters (including constraints on length or content, and default values). It lists the errors that can occur for this operation. Each operation corresponds to a subcommand in the Amazon CLI.
- **Data Types** – Detailed information about structures that a command might require as a parameter, or return in response to a request.
- **Common Parameters** – Detailed information about the parameters that are shared by all of action for the service.

- **Common Errors** – Detailed information about errors that can be returned by any of the service's operations.

The name and availability of each section can vary, depending on the service.

> **Service-specific CLIs**
>
> Some services have a separate CLI that dates from before a single Amazon CLI was created to work with all services. These service-specific CLIs have separate documentation that is linked from the service's documentation page. Documentation for service-specific CLIs do not apply to the Amazon CLI.

Troubleshooting errors

For help diagnosing and fixing Amazon CLI errors, see *Troubleshoot errors*.

Additional help

For additional help with your Amazon CLI issues, visit the Amazon CLI community on *GitHub*.

Command structure in the Amazon CLI

This topic covers how Amazon Command Line Interface (Amazon CLI) command is structured, and how to use wait commands.

Topics

- Command structure
- Wait commands

Command structure

The Amazon CLI uses a multipart structure on the command line that must be specified in this order:

1. The base call to the `aws` program.

2. The top-level *command*, which typically corresponds to an Amazon service supported by the Amazon CLI.
3. The *subcommand* that specifies which operation to perform.
4. General Amazon CLI options or parameters required by the operation. You can specify these in any order as long as they follow the first three parts. If an exclusive parameter is specified multiple times, only the *last value* applies.

```
$ aws <command> <subcommand> [options and parameters]
```

Parameters can take various types of input values, such as numbers, strings, lists, maps, and JSON structures. What is supported is dependent upon the command and subcommand you specify.

Examples

Amazon S3

The following example lists all of your Amazon S3 buckets.

```
$ aws s3 ls
2018-12-11 17:08:50 amzn-s3-demo-bucket1
2018-12-14 14:55:44 amzn-s3-demo-bucket2
```

For more information on the Amazon S3 commands, see `aws s3` in the *Amazon CLI Command Reference*.

Amazon CloudFormation

The following `create-change-set`command example changes the cloudformation stack name to *`my-change-set`*.

```
$ aws cloudformation create-change-set --stack-name my-stack --change-set-name my-
change-set
```

For more information on the Amazon CloudFormation commands, see `aws cloudformation` in the *Amazon CLI Command Reference*.

Wait commands

Some Amazon services have `wait` commands available. Any command that uses `aws wait` usually waits until a command is complete before it moves on to the next step. This is especially useful for multipart commands or scripting, as you can use a wait command to prevent moving to subsequent steps if the wait command fails.

The Amazon CLI uses a multipart structure on the command line for the `wait` command that must be specified in this order:

1. The base call to the `aws` program.
2. The top-level *command*, which typically corresponds to an Amazon service supported by the Amazon CLI.
3. The `wait` command.
4. The *subcommand* that specifies which operation to perform.
5. General CLI options or parameters required by the operation. You can specify these in any order as long as they follow the first three parts. If an exclusive parameter is specified multiple times, only the *last value* applies.

```
$ aws <command> wait <subcommand> [options and parameters]
```

Parameters can take various types of input values, such as numbers, strings, lists, maps, and JSON structures. What is supported is dependent upon the command and subcommand you specify.

> **Note**
>
> Not every AWS service supports `wait` commands. See the Amazon CLI reference guide to see if your service supports `wait` commands.

Examples

Amazon CloudFormation

The following `wait change-set-create-complete` command examples pauses and resumes only after it can confirm that the *`my-change-set`* change set in the *`my-stack`* stack is ready to run.

```
$ aws cloudformation wait change-set-create-complete --stack-name my-stack --change-set-name my-change-set
```

For more information on the Amazon CloudFormation `wait` commands, see `wait` in the *Amazon CLI Command Reference*.

Amazon CodeDeploy

The following `wait deployment-successful` command examples pauses until the *d-A1B2C3111* deployment completes successfully.

```
$ aws deploy wait deployment-successful --deployment-id d-A1B2C3111
```

For more information on the Amazon CodeDeploy `wait` commands, see `wait` in the *Amazon CLI Command Reference*.

Specifying parameter values in the Amazon CLI

Many parameters used in the Amazon Command Line Interface (Amazon CLI) are simple string or numeric values, such as the key-pair name `my-key-pair` in the following `aws ec2 create-key-pair` command example.

```
$ aws ec2 create-key-pair --key-name my-key-pair
```

Formatting for command can vary between terminals. For example, most terminals are case sensitive but Powershell is case insensitive. This means the two following command examples would yield different results for case sensitive terminals as they view `MyFile*.txt` and `myfile*.txt` as **different** parameters.

However, PowerShell would process these requests as the same as it sees `MyFile*.txt` and `myfile*.txt` as the **same** parameters. The following command example demonstrates these paramaters using the `aws s3 cp` command:

```
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --include "MyFile*.txt"
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --include "myfile*.txt"
```

For more information on PowerShell's case insensitivy, see about_Case-Sensitivity in the *PowerShell documentation*.

Sometimes you need to use quotation marks or literals around strings that include special or space characters. The rules around this formatting can also vary between terminals. For more information about using quotation marks around complex parameters, see Using quotation marks and literals with strings in the Amazon CLI.

These topics cover the most common terminal formatting rules. If you are having issues with your terminal recognizing your parameter values, be sure to review the topics in this section and also to check your terminal's documentation for their specific syntax rules.

Parameter topics

- Common parameter types in the Amazon CLI
- Using quotation marks and literals with strings in the Amazon CLI
- Loading a parameter from a file in the Amazon CLI
- Amazon CLI skeletons and input files in the Amazon CLI
- Using shorthand syntax in the Amazon CLI

Common parameter types in the Amazon CLI

This section describes some of the common parameter types and the typical required format.

If you are having trouble formatting a parameter for a specific command, check the help by entering **`help`** after the command name. The help for each subcommand includes an option's name and description. The option's parameter type is listed in parentheses. For more information on viewing help, see the section called “Get Help”.

Parameter types include:

- String
- Timestamp
- List
- Boolean
- Integer
- Binary / blob (binary large object) and streaming blob
- Map
- Document

String

String parameters can contain alphanumeric characters, symbols, and white spaces from the ASCII character set. Strings that contain white spaces must be surrounded by quotation marks. We recommend that you don't use symbols or white spaces other than the standard space character and to observe your terminal's quoting rules to prevent unexpected results.

Some string parameters can accept binary data from a file. See Binary files for an example.

Timestamp

Timestamps are formatted according to the ISO 8601 standard. These are often referred to as "`DateTime`" or "`Date`" parameters.

```
$ aws ec2 describe-spot-price-history --start-time 2014-10-13T19:00:00Z
```

Acceptable formats include:

- *YYYY*-*MM*-*DD*T*hh*:*mm*:*ss.sssTZD (UTC)*, for example, 2014-10-01T20:30:00.000Z
- *YYYY*-*MM*-*DD*T*hh*:*mm*:*ss.sssTZD (with offset)*, for example, 2014-10-01T12:30:00.000-08:00
- *YYYY*-*MM*-*DD*, for example, 2014-10-01
- Unix time in seconds, for example, 1412195400. This is sometimes referred to as Unix Epoch time and represents the number of seconds since midnight, January 1, 1970 UTC.

You can set the timestamp format by using the `cli_timestamp_format` file setting.

List

One or more strings separated by spaces. If any of the string items contain a space, you must put quotation marks around that item. Observe your terminal's quoting rules to prevent unexpected results.

```
$ aws ec2 describe-spot-price-history --instance-types m1.xlarge m1.medium
```

Boolean

Binary flag that turns an option on or off. For example, `ec2 describe-spot-price-history` has a Boolean `--dry-run` parameter that, when specified, validates the query with the service without actually running the query.

```
$ aws ec2 describe-spot-price-history --dry-run
```

The output indicates whether the command was well formed. This command also includes a `--no-dry-run` version of the parameter that you can use to explicitly indicate that the command should be run normally. Including it isn't necessary because this is the default behavior.

Integer

An unsigned, whole number.

```
$ aws ec2 describe-spot-price-history --max-items 5
```

Binary / blob (binary large object) and streaming blob

In the Amazon CLI, you can pass a binary value as a string directly on the command line. There are two types of blobs:

- Blob
- Streaming blob

Blob

To pass a value to a parameter with type `blob`, you must specify a path to a local file that contains the binary data using the `fileb://` prefix. Files referenced using the `fileb://` prefix are always treated as raw unencoded binary. The specified path is interpreted as being relative to the current working directory. For example, the `--plaintext` parameter for `aws kms encrypt` is a blob.

```
$ aws kms encrypt \
    --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
    --plaintext fileb://ExamplePlaintextFile \
    --output text \
    --query CiphertextBlob | base64 \
    --decode > ExampleEncryptedFile
```

Streaming blob

Streaming blobs such as `aws cloudsearchdomain upload-documents` do not use prefixes. Instead, streaming blob parameters are formatted using the direct file path. The following example uses the direct file path `document-batch.json` for the `aws cloudsearchdomain upload-documents` command:

```
$ aws cloudsearchdomain upload-documents \
    --endpoint-url https://doc-my-domain.us-west-1.cloudsearch.amazonaws.com \
    --content-type application/json \
    --documents document-batch.json
```

Map

A set of key-value pairs specified in JSON or by using the CLI's shorthand syntax. The following JSON example reads an item from an Amazon DynamoDB table named *my-table* with a map parameter, `--key`. The parameter specifies the primary key named *id* with a number value of *1* in a nested JSON structure.

For more advanced JSON usage in a command line, consider using a command line JSON processor, like `jq`, to create JSON strings. For more information on `jq`, see the jq repository on *GitHub*.

```
$ aws dynamodb get-item --table-name my-table --key '{"id": {"N":"1"}}'

{
    "Item": {
        "name": {
            "S": "John"
        },
        "id": {
            "N": "1"
        }
    }
}
```

Document

> **Note**
>
> Shorthand syntax is not compatible with document types.

Document types are used to send data without needing to embed JSON inside strings. The document type enables services to provide arbitrary schemas for you to use more flexible data types.

This allows for sending JSON data without needing to escape values. For example, instead of using the following escaped JSON input:

```
{"document": "{\"key\":true}"}
```

You can use the following document type:

```
{"document": {"key": true}}
```

Valid values for document types

Due to the flexible nature of document types, there are multiple valid value types. Valid values include the following:

String

```
--option '"value"'
```

Number

```
--option 123
--option 123.456
```

Boolean

```
--option true
```

Null

```
--option null
```

Array

```
--option '["value1", "value2", "value3"]'
```

```
--option '["value", 1, true, null, ["key1", 2.34], {"key2": "value2"}]'
```

Object

```
--option '{"key": "value"}'
--option '{"key1": "value1", "key2": 123, "key3": true, "key4": null, "key5":
 ["value3", "value4"], "key6": {"value5": "value6"}'
```

Using quotation marks and literals with strings in the Amazon CLI

There are primarily two ways single and double quotes are used in the Amazon CLI.

- Using quotation marks around strings that contain white spaces
- Using quotation marks inside strings

Using quotation marks around strings that contain white spaces

Parameter names and their values are separated by spaces on the command line. If a string value contains an embedded space, then you must surround the entire string with quotation marks to prevent the Amazon CLI from misinterpreting the space as a divider between the value and the next parameter name. Which type of quotation mark you use depends on the operating system you are running the Amazon CLI on.

Linux and macOS

Use single quotation marks `' '`

```
$ aws ec2 create-key-pair --key-name 'my key pair'
```

For more information on using quotes, see the user documentation for your preferred shell.

PowerShell

Single quotations (recommended)

Single quotation marks `' '` are called `verbatim` strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through.

```
PS C:\> aws ec2 create-key-pair --key-name 'my key pair'
```

Double quotations

Double quotation marks " " are called `expandable` string. Variables can be passed in expandable strings.

```
PS C:\> aws ec2 create-key-pair --key-name "my key pair"
```

For more information on using quotes, see About Quoting Rules in the *Microsoft PowerShell Docs*.

Windows command prompt

Use double quotation marks " " .

```
C:\> aws ec2 create-key-pair --key-name "my key pair"
```

Optionally, you can separate the parameter name from the value with an equals sign = instead of a space. This is typically necessary only if the value of the parameter starts with a hyphen.

```
$ aws ec2 delete-key-pair --key-name=-mykey
```

Using quotation marks inside strings

Strings might contain quotation marks, and your shell might require escaping quotations for them to work properly. One of the common parameter value types is a JSON string. This is complex since it includes spaces and double quotation marks " " around each element name and value in the JSON structure. The way you enter JSON-formatted parameters on the command line differs depending on your operating system.

For more advanced JSON usage in the command line, consider using a command line JSON processor, like `jq`, to create JSON strings. For more information on `jq`, see the jq repository on *GitHub*.

Linux and macOS

For Linux and macOS to interpret strings literally use single quotation marks ' ' to enclose the JSON data structure, as in the following example. You do not need to escape double quotation marks embedded in the JSON string, as they are being treated literally. Since the JSON is

enclosed in single quotation marks, any single quotation marks in the string will need to be escaped, this is usually accomplished using a backslash before the single quote `\'`.

```
$ aws ec2 run-instances \
    --image-id ami-12345678 \
    --block-device-mappings '[{"DeviceName":"/dev/sdb","Ebs":
{"VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"standard"}}]'
```

For more information on using quotes, see the user documentation for your preferred shell.

PowerShell

Use single quotation marks `' '` or double quotation marks `" "`.

Single quotations (recommended)

Single quotation marks `' '` are called `verbatim` strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through.

Since JSON data structures include double quotes, we suggest **single** quotation marks `' '` to enclose it. If you use **single** quotation marks, you do not need to escape **double** quotation marks embedded in the JSON string. However, you need to escape each **single** quotation mark with a backtick ` within the JSON structure.

```
PS C:\> aws ec2 run-instances `
    --image-id ami-12345678 `
    --block-device-mappings '[{"DeviceName":"/dev/sdb","Ebs":
{"VolumeSize":20,"DeleteOnTermination":false,"VolumeType":"standard"}}]'
```

Double quotations

Double quotation marks `" "` are called `expandable` strings. Variables can be passed in expandable strings.

If you use **double** quotation marks, you do not need to escape **single** quotation marks embedded in the JSON string. However, you need to escape each **double** quotation mark with a backtick ` within the JSON structure, as with the following example.

```
PS C:\> aws ec2 run-instances `
    --image-id ami-12345678 `
```

```
    --block-device-mappings "[{`"DeviceName`":`"/dev/sdb`",`"Ebs`":
{`"VolumeSize`":20,`"DeleteOnTermination`":false,`"VolumeType`":`"standard`"}}]"
```

For more information on using quotes, see About Quoting Rules in the *Microsoft PowerShell Docs*.

⚠ Warning

Before PowerShell sends a command to the Amazon CLI, it determines if your command is interpreted using typical PowerShell or `CommandLineToArgvW` quoting rules. When PowerShell processes using `CommandLineToArgvW`, you must escape characters with a backslash \.

For more information on `CommandLineToArgvW` in PowerShell, see What's up with the strange treatment of quotation marks and backslashes by CommandLineToArgvW in the *Microsoft DevBlogs*, Everyone quotes command line arguments the wrong way in the *Microsoft Docs Blog*, and CommandLineToArgvW function in the *Microsoft Docs*.

Single quotations

Single quotation marks `' '` are called `verbatim` strings. The string is passed to the command exactly as you type it, which means PowerShell variables will not pass through. Escape characters with a backslash \.

```
PS C:\> aws ec2 run-instances `
    --image-id ami-12345678 `
    --block-device-mappings '[{\"DeviceName\":\"/dev/sdb\",\"Ebs\":
{\"VolumeSize\":20,\"DeleteOnTermination\":false,\"VolumeType\":\"standard\"}}]'
```

Double quotations

Double quotation marks `" "` are called `expandable` strings. Variables can be passed in `expandable` strings. For double quoted strings you have to escape twice using `` ` \ `` for each quote instead of only using a backtick. The backtick escapes the backslash, and then the backslash is used as an escape character for the `CommandLineToArgvW` process.

```
PS C:\> aws ec2 run-instances `
    --image-id ami-12345678 `
    --block-device-mappings "[{`\"DeviceName`\":`\"/dev/sdb`\",`\"Ebs`\":
{`\"VolumeSize`\":20,`\"DeleteOnTermination`\":false,`\"VolumeType`\":`
\"standard`\"}}]"
```

Blobs (recommended)
To bypass PowerShell quoting rules for JSON data input, use Blobs to pass your JSON data directly to the Amazon CLI. For more information on Blobs, see Blob.

Windows command prompt

The Windows command prompt requires double quotation marks " " to enclose the JSON data structure. Also, to prevent the command processor from misinterpreting the double quotation marks embedded in the JSON, you must also escape (precede with a backslash \ character) each double quotation mark " within the JSON data structure itself, as in the following example.

```
C:\> aws ec2 run-instances ^
    --image-id ami-12345678 ^
    --block-device-mappings "[{\"DeviceName\":\"/dev/sdb\",\"Ebs\":
{\"VolumeSize\":20,\"DeleteOnTermination\":false,\"VolumeType\":\"standard\"}}]"
```

Only the outermost double quotation marks are not escaped.

Loading a parameter from a file in the Amazon CLI

Some parameters expect file names as arguments, from which the Amazon CLI loads the data. Other parameters enable you to specify the parameter value as either text typed on the command line or read from a file. Whether a file is required or optional, you must encode the file correctly so that the Amazon CLI can understand it. The file's encoding must match the reading system's default locale. You can determine this by using the Python `locale.getpreferredencoding()` method.

This method is for loading a file for a single parameter. For information on loading multiple parameters with a single file, see the section called “Generate a CLI Skeleton Template”.

Note

By default, Windows PowerShell outputs text as UTF-16, which conflicts with the UTF-8 encoding used by JSON files and many Linux systems. We recommend that you use `-Encoding ascii` with your PowerShell `Out-File` commands to ensure the Amazon CLI can read the resulting file.

- Binary files
- Remote files
- Loading a file as a shorthand syntax value

How to load a parameter from a file

Sometimes it's convenient to load a parameter value from a file instead of trying to type it all as a command line parameter value, such as when the parameter is a complex JSON string. To specify a file that contains the value, specify a file URL in the following format.

```
file://complete/path/to/file
```

- The first two slash '/' characters are part of the specification. If the required path begins with a '/', the result is three slash characters: `file:///folder/file`.
- The URL provides the path to the file that contains the actual parameter content.
- When using files with spaces or special characters, follow the quoting and escaping rules for your terminal.

> **Note**
>
> This behavior is disabled automatically for parameters that already expect a URL, such as parameter that identifies a Amazon CloudFormation template URL. You can also disable this behavior by disabling the `cli_follow_urlparam` setting in your Amazon CLI configuration file.

The file paths in the following examples are interpreted to be relative to the current working directory.

Linux or macOS

```
// Read from a file in the current directory
$ aws ec2 describe-instances --filters file://filter.json
```

```
// Read from a file in /tmp
$ aws ec2 describe-instances --filters file:///tmp/filter.json

// Read from a file with a filename with whitespaces
$ aws ec2 describe-instances --filters 'file://filter content.json'
```

Windows command prompt

```
// Read from a file in C:\temp
C:\> aws ec2 describe-instances --filters file://C:\temp\filter.json

// Read from a file with a filename with whitespaces
C:\> aws ec2 describe-instances --filters "file://C:\temp\filter content.json"
```

The `file://` prefix option supports Unix-style expansions, including "~/", "./", and "../". On Windows, the "~/" expression expands to your user directory, stored in the `%USERPROFILE%` environment variable. For example, on Windows 10 you would typically have a user directory under `C:\Users\`*`UserName`*`\`.

You must still escape JSON documents that are embedded as the value of another JSON document.

```
$ aws sqs create-queue --queue-name my-queue --attributes file://attributes.json
```

attributes.json

```
{
  "RedrivePolicy": "{\"deadLetterTargetArn\":\"arn:aws-cn:sqs:us-
west-2:0123456789012:deadletter\", \"maxReceiveCount\":\"5\"}"
}
```

Binary files

For commands that take binary data as a parameter, specify that the data is binary content by using the `fileb://` prefix. Commands that accept binary data include:

- **`aws ec2 run-instances:`** `--user-data` parameter.
- **`aws s3api put-object:`** `--sse-customer-key` parameter.
- **`aws kms decrypt:`** `--ciphertext-blob` parameter.

The following example generates a binary 256-bit AES key using a Linux command line tool, and then provides it to Amazon S3 to encrypt an uploaded file server-side.

```
$ dd if=/dev/urandom bs=1 count=32 > sse.key
32+0 records in
32+0 records out
32 bytes (32 B) copied, 0.000164441 s, 195 kB/s
$ aws s3api put-object \
    --bucket amzn-s3-demo-bucket \
    --key test.txt \
    --body test.txt \
    --sse-customer-key fileb://sse.key \
    --sse-customer-algorithm AES256
{
    "SSECustomerKeyMD5": "iVg8oWa8sy714+FjtesrJg==",
    "SSECustomerAlgorithm": "AES256",
    "ETag": "\"a6118e84b76cf98bf04bbe14b6045c6c\""
}
```

Remote files

The Amazon CLI also supports loading parameters from a file hosted on the internet with an `http://` or `https://` URL. The following example references a file stored in an Amazon S3 bucket. This allows you to access parameter files from any computer, but it does require that the container is publicly accessible.

```
$ aws ec2 run-instances \
    --image-id ami-12345678 \
    --block-device-mappings http://amzn-s3-demo-bucket.s3.amazonaws.com/filename.json
```

The preceding example assumes that the file `filename.json` contains the following JSON data.

```
[
  {
    "DeviceName": "/dev/sdb",
    "Ebs": {
      "VolumeSize": 20,
      "DeleteOnTermination": false,
      "VolumeType": "standard"
    }
  }
```

```
]
```

For another example referencing a file containing JSON-formatted parameters, see Attaching an IAM managed policy to a user.

Loading a file as a shorthand syntax value

When using shorthand syntax where a value is large or complex, it is often easier to load in a file as a value. To load a file as a shorthand syntax value, the formatting will change slightly. Instead of `key=value` you'll use the `@=` operator instead of the `=` operator. The `@=` signifies to the Amazon CLI that the value should be read as a file path and not a string. The following example shows a key-value pair loading a file for its value.

Linux or macOS

```
--option key@=file://template.txt
```

Windows

```
--option "key1@=file://template.txt"
```

The following example demonstrates loading a certificate file for the `aws rolesanywhere create-trust-anchor` command.

```
$ aws rolesanywhere create-trust-anchor --name TrustAnchor \
    --source sourceData={x509CertificateData@=file://root-
ca.crt},sourceType="CERTIFICATE_BUNDLE"  \
    --enabled
```

For more information on shorthand syntax, see the section called “Shorthand Syntax”.

Amazon CLI skeletons and input files in the Amazon CLI

Most of the Amazon CLI commands accept importing parameter inputs from a file. These templates can be generated using the `generate-cli-skeleton` option and then be imported using the `--cli-input-json` parameters.

Topics

- About Amazon CLI skeletons and input files

- Generate and import a command skeleton
- Combining input files and command line parameters

About Amazon CLI skeletons and input files

Most of the Amazon Command Line Interface (Amazon CLI) commands support the ability to accept parameter inputs from a file using the `--cli-input-json` parameters.

Those same commands use the `--generate-cli-skeleton` parameter to generate a file in JSON format with all of the parameters that you can edit and fill in. Then you can run the command with the `--cli-input-json` parameter and point to the filled-in file.

> **Important**
>
> Custom Amazon CLI commands, such as the `aws s3` commands don't support either the `--generate-cli-skeleton` or `--cli-input-json` parameters described in this topic. To check if a specific command supports these parameters, run the `help` command for the command you want to use or refer to the Amazon CLI version 1 reference guide.

The `--generate-cli-skeleton` generates and displays a parameter template that you can customize and use as input on a command. The generated template includes all of the parameters that the command supports.

The `--generate-cli-skeleton` parameter accepts one of the following values:

- `input` – The generated template includes all input parameters formatted as JSON. This is the default value.
- `output` – The generated template includes all output parameters formatted as JSON.

Because the Amazon CLI is essentially a "wrapper" around the service's API, the skeleton file expects you to reference all parameters by their underlying API parameter names. This is likely different from the Amazon CLI parameter name. For example, an Amazon CLI parameter named `user-name` might map to the Amazon service's API parameter named `UserName` (notice the altered capitalization and missing dash). We recommend that you use the `--generate-cli-skeleton` option to generate the template with the "correct" parameter names to avoid errors. You can reference the API Reference Guide for the service to see the expected parameter names.

You can delete any parameters from the template that are not required and for which you don't want to supply a value.

For example, if you run the following command, it generates the parameter template for the Amazon Elastic Compute Cloud (Amazon EC2) command **run-instances**.

JSON

The following example shows how to generate a template formatted in JSON by using the default value (`input`) for the `--generate-cli-skeleton` parameter.

```
$ aws ec2 run-instances --generate-cli-skeleton
```

```
{
    "DryRun": true,
    "ImageId": "",
    "MinCount": 0,
    "MaxCount": 0,
    "KeyName": "",
    "SecurityGroups": [
        ""
    ],
    "SecurityGroupIds": [
        ""
    ],
    "UserData": "",
    "InstanceType": "",
    "Placement": {
        "AvailabilityZone": "",
        "GroupName": "",
        "Tenancy": ""
    },
    "KernelId": "",
    "RamdiskId": "",
    "BlockDeviceMappings": [
        {
            "VirtualName": "",
            "DeviceName": "",
            "Ebs": {
                "SnapshotId": "",
                "VolumeSize": 0,
                "DeleteOnTermination": true,
                "VolumeType": "",
```

```
                "Iops": 0,
                "Encrypted": true
            },
            "NoDevice": ""
        }
    ],
    "Monitoring": {
        "Enabled": true
    },
    "SubnetId": "",
    "DisableApiTermination": true,
    "InstanceInitiatedShutdownBehavior": "",
    "PrivateIpAddress": "",
    "ClientToken": "",
    "AdditionalInfo": "",
    "NetworkInterfaces": [
        {
            "NetworkInterfaceId": "",
            "DeviceIndex": 0,
            "SubnetId": "",
            "Description": "",
            "PrivateIpAddress": "",
            "Groups": [
                ""
            ],
            "DeleteOnTermination": true,
            "PrivateIpAddresses": [
                {
                    "PrivateIpAddress": "",
                    "Primary": true
                }
            ],
            "SecondaryPrivateIpAddressCount": 0,
            "AssociatePublicIpAddress": true
        }
    ],
    "IamInstanceProfile": {
        "Arn": "",
        "Name": ""
    },
    "EbsOptimized": true
}
```

Generate and import a command skeleton

To generate and use a parameter skeleton file

1. Run the command with the `--generate-cli-skeleton` parameter to produce JSON and direct the output to a file to save it.

   JSON

   ```
   $ aws ec2 run-instances --generate-cli-skeleton input > ec2runinst.json
   ```

2. Open the parameter skeleton file in your text editor and remove any of the parameters that you don't need. For example, you might strip the template down to the following. Confirm the file is still valid JSON after you remove the elements you don't need.

   JSON

   ```
   {
       "DryRun": true,
       "ImageId": "",
       "KeyName": "",
       "SecurityGroups": [
           ""
       ],
       "InstanceType": "",
       "Monitoring": {
           "Enabled": true
       }
   }
   ```

   In this example, we leave the `DryRun` parameter set to `true` to use the Amazon EC2 dry run feature. This feature lets you safely test the command without actually creating or modifying any resources.

3. Fill in the remaining values with values appropriate for your scenario. In this example, we provide the instance type, key name, security group, and identifier of the Amazon Machine Image (AMI) to use. This example assumes the default Amazon Web Services Region. The AMI `ami-dfc39aef` is a 64-bit Amazon Linux image hosted in the `us-west-2` Region. If you use a different Region, you must find the correct AMI ID to use.

JSON

```
{
    "DryRun": true,
    "ImageId": "ami-dfc39aef",
    "KeyName": "mykey",
    "SecurityGroups": [
        "my-sg"
    ],
    "InstanceType": "t2.micro",
    "Monitoring": {
        "Enabled": true
    }
}
```

4. Run the command with the completed parameters by passing the completed template file to the `--cli-input-json` parameter by using the `file://` prefix. The Amazon CLI interprets the path to be relative to your current working directory. The following example the Amazon CLI looks for the file in the current working directory.

   JSON

   ```
   $ aws ec2 run-instances --cli-input-json file://ec2runinst.json
   ```

   ```
   A client error (DryRunOperation) occurred when calling the RunInstances
    operation: Request would have succeeded, but DryRun flag is set.
   ```

   The dry run error indicates that the JSON is formed correctly and that the parameter values are valid. If other issues are reported in the output, fix them and repeat the previous step until the "`Request would have succeeded`" message is displayed.

5. Now you can set the `DryRun` parameter to `false` to disable dry run.

   JSON

   ```
   {
       "DryRun": false,
       "ImageId": "ami-dfc39aef",
       "KeyName": "mykey",
       "SecurityGroups": [
   ```

```
        "my-sg"
    ],
    "InstanceType": "t2.micro",
    "Monitoring": {
        "Enabled": true
    }
}
```

6. Run the command, and `run-instances` actually launches an Amazon EC2 instance and displays the details generated by the successful launch. The format of the output is controlled by the `--output` parameter, separately from the format of your input parameter template.

   JSON

```
$ aws ec2 run-instances --cli-input-json file://ec2runinst.json --output json
```

```
{
    "OwnerId": "123456789012",
    "ReservationId": "r-d94a2b1",
    "Groups": [],
    "Instances": [
...
```

Combining input files and command line parameters

An input file can be used for all parameters, or can be combined with parameters specified in the Amazon CLI. You can use this feature for settings you frequently reuse in an input file, while keeping your individual settings in the command itself.

The following `aws ec2 run-instances` examples combine the use of an input file and parameters. We provide the instance type, key name, security group, identifier of the Amazon Machine Image (AMI) to use and assume the default Amazon Web Services Region. The AMI `ami-dfc39aef` is a 64-bit Amazon Linux image hosted in the `us-west-2` Region. If you use a different Region, you must find the correct AMI ID to use.

JSON

Contents of the JSON file:

```
{
```

```
    "ImageId": "ami-dfc39aef",
    "KeyName": "mykey",
    "SecurityGroups": [
        "my-sg"
    ],
    "InstanceType": "t2.micro",
    "Monitoring": {
        "Enabled": true
    }
}
```

The following example uses the input file in combination with the `--dry-run` parameter to perform a dry-run of the command to confirm whether you have the required permissions and have filled out the file with valid values.

JSON

```
$ aws ec2 run-instances --cli-input-json file://ec2runinst.json --dry-run
```

```
A client error (DryRunOperation) occurred when calling the RunInstances operation:
 Request would have succeeded, but DryRun flag is set.
```

The following example then uses the same input file, but with the `--no-dry-run` parameter to perform the command in full.

JSON

```
$ aws ec2 run-instances --cli-input-json file://ec2runinst.json --no-dry-run --
output json
```

```
{
    "OwnerId": "123456789012",
    "ReservationId": "r-d94a2b1",
    "Groups": [],
    "Instances": [
...
```

Using shorthand syntax in the Amazon CLI

The Amazon Command Line Interface (Amazon CLI) can accept many of its option parameters in JSON format. However, it can be tedious to enter large JSON lists or structures on the command line. To make this easier, the Amazon CLI also supports a shorthand syntax that enables a simpler representation of your option parameters than using the full JSON format.

Topics

- Structure parameters with key-value pairs
- Loading a file as a shorthand syntax value
- Using shorthand syntax with the Amazon CLI

Structure parameters with key-value pairs

The shorthand syntax in the Amazon CLI makes it easier for users to input parameters that are flat (non-nested structures). The format is a comma-separated list of key-value pairs. Be sure to use the quoting and escaping rules appropriate for your terminal as shorthand syntax are strings.

Linux or macOS

```
--option key1=value1,key2=value2,key3=value3
```

Is equivalent to the following example, formatted in JSON.

```
--option '{"key1":"value1","key2":"value2","key3":"value3"}'
```

Windows

```
--option "key1=value1,key2=value2,key3=value3"
```

Is equivalent to the following example, formatted in JSON.

```
--option '{"key1":"value1","key2":"value2","key3":"value3"}'
```

There must be no white space between each comma-separated key-value pair. Here is an example of the Amazon DynamoDB `update-table` command with the `--provisioned-throughput` option specified in shorthand.

```
$ aws dynamodb update-table \
    --provisioned-throughput ReadCapacityUnits=15,WriteCapacityUnits=10 \
    --table-name MyDDBTable
```

This is equivalent to the following example formatted in JSON.

```
$ aws dynamodb update-table \
    --provisioned-throughput '{"ReadCapacityUnits":15,"WriteCapacityUnits":10}' \
    --table-name MyDDBTable
```

Loading a file as a shorthand syntax value

When a value is large or complex, it is often easier to load in as a value. To load a file as a shorthand syntax value, the formatting will change slightly. Instead of `key=value` you'll use the `@=` operator instead of the `=` operator. The `@=` signifies to the Amazon CLI that the value should be read as a file path and not a string. When loading files in shorthand syntax, the usual Amazon CLI file formatting rules apply. The following example shows a key-value pair loading a file for its value.

Linux or macOS

```
--option key@=file://template.txt
```

Windows

```
--option "key1@=file://template.txt"
```

The following example demonstrates loading a certificate file for the `aws rolesanywhere create-trust-anchor` command.

```
$ aws rolesanywhere create-trust-anchor --name TrustAnchor \
    --source sourceData={x509CertificateData@=file://root-
ca.crt},sourceType="CERTIFICATE_BUNDLE"  \
    --enabled
```

Using shorthand syntax with the Amazon CLI

You can specify Input parameters in a list form in two ways: JSON or shorthand. The Amazon CLI shorthand syntax is designed to make it easier to pass in lists with number, string, or non-nested structures.

The basic format is shown here, where values in the list are separated by a single space.

```
--option value1 value2 value3
```

This is equivalent to the following example, formatted in JSON.

```
--option '[value1,value2,value3]'
```

As previously mentioned, you can specify a list of numbers, a list of strings, or a list of non-nested structures in shorthand. The following is an example of the `stop-instances` command for Amazon Elastic Compute Cloud (Amazon EC2), where the input parameter (list of strings) for the `--instance-ids` option is specified in shorthand.

```
$ aws ec2 stop-instances \
    --instance-ids i-1486157a i-1286157c i-ec3a7e87
```

This is equivalent to the following example formatted in JSON.

```
$ aws ec2 stop-instances \
    --instance-ids '["i-1486157a","i-1286157c","i-ec3a7e87"]'
```

The following example shows the Amazon EC2 `create-tags` command, which takes a list of non-nested structures for the `--tags` option. The `--resources` option specifies the ID of the instance to tag.

```
$ aws ec2 create-tags \
    --resources i-1286157c \
    --tags Key=My1stTag,Value=Value1 Key=My2ndTag,Value=Value2
 Key=My3rdTag,Value=Value3
```

This is equivalent to the following example, formatted in JSON. The JSON parameter is written over multiple lines for readability.

```
$ aws ec2 create-tags \
```

```
    --resources i-1286157c \
    --tags '[
        {"Key": "My1stTag", "Value": "Value1"},
        {"Key": "My2ndTag", "Value": "Value2"},
        {"Key": "My3rdTag", "Value": "Value3"}
    ]'
```

Controlling command output in the Amazon CLI

This section describes the different ways to control the output from the Amazon Command Line Interface (Amazon CLI). Customizing the Amazon CLI output in your terminal can improve readability, streamline scripting automation and provide easier navigation through larger data sets.

The Amazon CLI supports multiple output formats, including `json`, `text`, and `table`. Some services have server-side pagination for their data.

Lastly, the Amazon CLI has both server-side and client-side filtering that you can use individually or together to filter your Amazon CLI output.

Topics

- Sensitive output
- Server-side vs client-side output options
- Setting the output format in the Amazon CLI
- Using the pagination options in the Amazon CLI
- Filtering output in the Amazon CLI

Sensitive output

Some operations of the Amazon CLI might return information that could be considered sensitive, including information from environment variables. The exposure of this information might represent a security risk in certain scenarios; for example, the information could be included in continuous integration and continuous deployment (CI/CD) logs. It is therefore important that you review when you are including such output as part of your logs, and suppress the output when not needed.

For additional information about protecting sensitive data, see the section called “Data Protection”.

Consider the following best practices:

- Consider programmatically retrieving your secrets from a secrets store, such as Amazon Secrets Manager.
- Review the contents of your build logs to ensure they do not contain sensitive information. Consider approaches such as piping to `/dev/null` or capturing the output as a bash or PowerShell variable to suppress command outputs.

  The following is a bash example for redirecting output, but not errors, to `/dev/null`:

  ```
  $ aws s3 ls > /dev/null
  ```

  For specifics on suppressing output for your terminal, see the user documentation of the terminal you use.
- Consider the access of your logs and scope the access appropriately for your use case.

Server-side vs client-side output options

The Amazon CLI has both server-side and client-side filtering that you can use individually or together to filter your Amazon CLI output. Server-side filtering is processed first and returns your output for client-side filtering. Server-side filtering is supported by the service API. Client-side filtering is supported by the Amazon CLI client using the `--query` parameter.

Server-side output options are features directly supported by the Amazon Web Services service API. Any data that is filtered or paged out is not sent to the client, which can speed up HTTP response times and improve bandwidth for larger data sets.

Client-side output options are features created by the Amazon CLI. All data is sent to the client, then the Amazon CLI filters or pages the content displayed. Client-side operations do not save on speed or bandwidth for larger datasets.

When server-side and client-side options are used together, server-side operations are completed first and then sent to the client for client-side operations. This uses the potential speed and bandwidth savings of server-side options, while using additional Amazon CLI features to get your desired output.

Setting the output format in the Amazon CLI

This topic describes the different output formats for the Amazon Command Line Interface (Amazon CLI). The Amazon CLI supports the following output formats:

- **`json`** – The output is formatted as a JSON string.
- **`text`** – The output is formatted as multiple lines of tab-separated string values. This can be useful to pass the output to a text processor, like `grep`, `sed`, or `awk`.
- **`table`** – The output is formatted as a table using the characters +|- to form the cell borders. It typically presents the information in a "human-friendly" format that is much easier to read than the others, but not as programmatically useful.

How to select the output format

As explained in the configuration topic, you can specify the output format in three ways:

- **Using the `output` option in a named profile in the `config` file** – The following example sets the default output format to `text`.

```
[default]
output=text
```

- **Using the `AWS_DEFAULT_OUTPUT` environment variable** – The following output sets the format to `table` for the commands in this command line session until the variable is changed or the session ends. Using this environment variable overrides any value set in the `config` file.

```
$ export AWS_DEFAULT_OUTPUT="table"
```

- **Using the `--output` option on the command line** – The following example sets the output of only this one command to `json`. Using this option on the command overrides any currently set environment variable or the value in the `config` file.

```
$ aws swf list-domains --registration-status REGISTERED --output json
```

Important

The output type you specify changes how the `--query` option operates:

- If you specify `--output text`, the output is paginated *before* the `--query` filter is applied, and the Amazon CLI runs the query once on *each page* of the output. Due to this, the query includes the first matching element on each page which can result in

unexpected extra output. To additionally filter the output, you can use other command line tools such as `head` or `tail`.

- If you specify `--output json`, the output is completely processed as a single, native structure before the `--query` filter is applied. The Amazon CLI runs the query only once against the entire structure, producing a filtered result that is then output.

JSON output format

JSON is the default output format of the Amazon CLI. Most programming languages can easily decode JSON strings using built-in functions or with publicly available libraries. You can combine JSON output with the --query option in powerful ways to filter and format the Amazon CLI JSON-formatted output.

For more advanced filtering that you might not be able to do with `--query`, you can consider `jq`, a command line JSON processor. You can download it and find the official tutorial at http://stedolan.github.io/jq/.

The following is an example of JSON output.

```
$ aws iam list-users --output json
```

```
{
    "Users": [
        {
            "Path": "/",
            "UserName": "Admin",
            "UserId": "AIDA1111111111EXAMPLE",
            "Arn": "arn:aws:iam::123456789012:user/Admin",
            "CreateDate": "2014-10-16T16:03:09+00:00",
            "PasswordLastUsed": "2016-06-03T18:37:29+00:00"
        },
        {
            "Path": "/backup/",
            "UserName": "backup-user",
            "UserId": "AIDA2222222222EXAMPLE",
            "Arn": "arn:aws:iam::123456789012:user/backup/backup-user",
            "CreateDate": "2019-09-17T19:30:40+00:00"
        },
        {
```

```
            "Path": "/",
            "UserName": "cli-user",
            "UserId": "AIDA3333333333EXAMPLE",
            "Arn": "arn:aws:iam::123456789012:user/cli-user",
            "CreateDate": "2019-09-17T19:11:39+00:00"
        }
    ]
}
```

Text output format

The `text` format organizes the Amazon CLI output into tab-delimited lines. It works well with traditional Unix text tools such as `grep`, `sed`, and `awk`, and the text processing performed by PowerShell.

The `text` output format follows the basic structure shown below. The columns are sorted alphabetically by the corresponding key names of the underlying JSON object.

```
IDENTIFIER  sorted-column1 sorted-column2
IDENTIFIER2 sorted-column1 sorted-column2
```

The following is an example of `text` output. Each field is tab separated from the others, with an extra tab where there is an empty field.

```
$ aws iam list-users --output text
```

```
USERS   arn:aws:iam::123456789012:user/Admin                2014-10-16T16:03:09+00:00
 2016-06-03T18:37:29+00:00   /          AIDA1111111111EXAMPLE   Admin
USERS   arn:aws:iam::123456789012:user/backup/backup-user   2019-09-17T19:30:40+00:00
                            /backup/   AIDA2222222222EXAMPLE   backup-user
USERS   arn:aws:iam::123456789012:user/cli-user             2019-09-17T19:11:39+00:00
                            /          AIDA3333333333EXAMPLE   cli-user
```

The fourth column is the `PasswordLastUsed` field, and is empty for the last two entries because those users never sign in to the Amazon Web Services Management Console.

> **Important**
>
> *We strongly recommend that if you specify `text` output, you also always use the `--query` option to ensure consistent behavior.*

This is because the text format alphabetically orders output columns by the key name of the underlying JSON object returned by the Amazon service, and similar resources might not have the same key names. For example, the JSON representation of a Linux-based Amazon EC2 instance might have elements that are not present in the JSON representation of a Windows-based instance, or vice versa. Also, resources might have key-value elements added or removed in future updates, altering the column ordering. This is where `--query` augments the functionality of the `text` output to provide you with complete control over the output format.

In the following example, the command specifies which elements to display and *defines the ordering* of the columns with the list notation `[key1, key2, ...]`. This gives you full confidence that the correct key values are always displayed in the expected column. Finally, notice how the Amazon CLI outputs None as the value for keys that don't exist.

```
$ aws iam list-users --output text --query 'Users[*].
[UserName,Arn,CreateDate,PasswordLastUsed,UserId]'
```

```
Admin         arn:aws:iam::123456789012:user/Admin
 2014-10-16T16:03:09+00:00   2016-06-03T18:37:29+00:00   AIDA1111111111EXAMPLE
backup-user   arn:aws:iam::123456789012:user/backup-user
 2019-09-17T19:30:40+00:00   None                        AIDA2222222222EXAMPLE
cli-user      arn:aws:iam::123456789012:user/cli-backup
 2019-09-17T19:11:39+00:00   None                        AIDA3333333333EXAMPLE
```

The following example shows how you can use `grep` and `awk` with the `text` output from the `aws ec2 describe-instances` command. The first command displays the Availability Zone, current state, and the instance ID of each instance in `text` output. The second command processes that output to display only the instance IDs of all running instances in the `us-west-2a` Availability Zone.

```
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*].
[Placement.AvailabilityZone, State.Name, InstanceId]' --output text
```

```
us-west-2a      running i-4b41a37c
us-west-2a      stopped i-a071c394
us-west-2b      stopped i-97a217a0
us-west-2a      running i-3045b007
```

```
us-west-2a      running i-6fc67758
```

```
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*].
[Placement.AvailabilityZone, State.Name, InstanceId]' --output text | grep us-west-2a |
 grep running | awk '{print $3}'
```

```
i-4b41a37c
i-3045b007
i-6fc67758
```

The following example goes a step further and shows not only how to filter the output, but how to use that output to automate changing instance types for each stopped instance.

```
$ aws ec2 describe-instances --query 'Reservations[*].Instances[*].[State.Name,
 InstanceId]' --output text |
> grep stopped |
> awk '{print $2}' |
> while read line;
> do aws ec2 modify-instance-attribute --instance-id $line --instance-type '{"Value":
 "m1.medium"}';
> done
```

The `text` output can also be useful in PowerShell. Because the columns in `text` output are tab delimited, you can easily split the output into an array by using PowerShell's `` `t `` delimiter. The following command displays the value of the third column (`InstanceId`) if the first column (`AvailabilityZone`) matches the string `us-west-2a`.

```
PS C:\>aws ec2 describe-instances --query 'Reservations[*].Instances[*].
[Placement.AvailabilityZone, State.Name, InstanceId]' --output text |
%{if ($_.split("`t")[0] -match "us-west-2a") { $_.split("`t")[2]; } }
```

```
-4b41a37c
i-a071c394
i-3045b007
i-6fc67758
```

Notice that although the previous example does show how to use the `--query` parameter to parse the underlying JSON objects and pull out the desired column, PowerShell has its own ability to

handle JSON, if cross-platform compatibility isn't a concern. Instead of handling the output as text, as most command shells require, PowerShell lets you use the `ConvertFrom-JSON` cmdlet to produce a hierarchically structured object. You can then directly access the member you want from that object.

```
(aws ec2 describe-instances --output json | ConvertFrom-
Json).Reservations.Instances.InstanceId
```

Tip

If you output text, and filter the output to a single field using the `--query` parameter, the output is a single line of tab-separated values. To get each value onto a separate line, you can put the output field in brackets, as shown in the following examples.
Tab separated, single-line output:

```
$ aws iam list-groups-for-user --user-name susan  --output text --query
 "Groups[].GroupName"
```

```
HRDepartment    Developers      SpreadsheetUsers  LocalAdmins
```

Each value on its own line by putting `[GroupName]` in brackets:

```
$ aws iam list-groups-for-user --user-name susan  --output text --query
 "Groups[].[GroupName]"
```

```
HRDepartment
Developers
SpreadsheetUsers
LocalAdmins
```

Table output format

The `table` format produces human-readable representations of complex Amazon CLI output in a tabular form.

```
$ aws iam list-users --output table
```

```
-------------------------------------------------------------------------------------------
|
 ListUsers                                                                                |
+-----------------------------------------------------------------------------------------
+
||
 Users                                                                                  ||
|+-----------------------------------------------------+--------------------------
+--------------------------+----------+----------------------+-------------+|
||                         Arn                          |       CreateDate          |
 PasswordLastUsed       |   Path   |        UserId         |   UserName  ||
|+-----------------------------------------------------+--------------------------
+--------------------------+----------+----------------------+-------------+|
||  arn:aws:iam::123456789012:user/Admin              | 2014-10-16T16:03:09+00:00 |
 2016-06-03T18:37:29+00:00 | /        | AIDA1111111111EXAMPLE | Admin       ||
||  arn:aws:iam::123456789012:user/backup/backup-user | 2019-09-17T19:30:40+00:00 |
                        | /backup/ | AIDA2222222222EXAMPLE | backup-user ||
||  arn:aws:iam::123456789012:user/cli-user           | 2019-09-17T19:11:39+00:00 |
                        | /        | AIDA3333333333EXAMPLE | cli-user    ||
+-------------------------------------------------------------------------------------------
+
```

You can combine the `--query` option with the `table` format to display a set of elements preselected from the raw output. Notice the output differences between dictionary and list notations: in the first example, column names are ordered alphabetically, and in the second example, unnamed columns are ordered as defined by the user. For more information about the `--query` option, see Filtering output in the Amazon CLI.

```
$ aws ec2 describe-volumes --query 'Volumes[*].
{ID:VolumeId,InstanceId:Attachments[0].InstanceId,AZ:AvailabilityZone,Size:Size}' --
output table
```

```
-----------------------------------------------------
|                  DescribeVolumes                  |
+------------+---------------+-------------+-------+
|     AZ     |      ID       | InstanceId  | Size  |
+------------+---------------+-------------+-------+
|  us-west-2a|  vol-e11a5288 |  i-a071c394 |  30   |
|  us-west-2a|  vol-2e410a47 |  i-4b41a37c |  8    |
+------------+---------------+-------------+-------+
```

```
$ aws ec2 describe-volumes --query 'Volumes[*].
[VolumeId,Attachments[0].InstanceId,AvailabilityZone,Size]' --output table
```

```
-------------------------------------------------

|  vol-e11a5288|  i-a071c394  |  us-west-2a  |  30 |
|  vol-2e410a47|  i-4b41a37c  |  us-west-2a  |  8  |
+--------------+-------------+--------------+-----+
```

Using the pagination options in the Amazon CLI

This topic describes the different ways to paginate output from the Amazon Command Line Interface (Amazon CLI).

Server-side pagination

For most commands that return a large list of items, the Amazon CLI has multiple server-side options to control the number of items included in the output when the Amazon CLI calls a service's API to populate the list. Server-side pagination in the Amazon CLI is enabled by the Amazon service API, therefore these options only work if the service API enables them.

The options for most Amazon CLI commands include the following:

- How to use the --no-paginate parameter
- How to use the --page-size parameter
- How to use the --max-items parameter
- How to use the --starting-token parameter

By default, the Amazon CLI uses a page size determined by the individual service and retrieves all available items. For example, Amazon S3 has a default page size of 1000. If you run `aws s3api list-objects` on an Amazon S3 bucket that contains 3,500 objects, the Amazon CLI automatically makes four calls to Amazon S3, handling the service-specific pagination logic for you in the background and returning all 3,500 objects in the final output.

For information about whether a specific command has server-side pagination, see the Amazon CLI reference guide.

How to use the --no-paginate parameter

The `--no-paginate` option disables following pagination tokens on the client side. When using a command, by default the Amazon CLI automatically makes multiple calls to return all possible results to create pagination. One call for each page. Disabling pagination has the Amazon CLI only call once for the first page of command results.

For example, if you run `aws s3api list-objects` on an Amazon S3 bucket that contains 3,500 objects, the Amazon CLI only makes the first call to Amazon S3, returning only the first 1,000 objects in the final output.

```
$ aws s3api list-objects \
    --bucket amzn-s3-demo-bucket \
    --no-paginate
{
    "Contents": [
...
```

How to use the --page-size parameter

If you see issues when running list commands on a large number of resources, the default page size might be too high. This can cause calls to Amazon services to exceed the maximum allowed time and generate a "timed out" error. You can use the `--page-size` option to specify that the Amazon CLI request a smaller number of items from each call to the Amazon service. The Amazon CLI still retrieves the full list, but performs a larger number of service API calls in the background and retrieves a smaller number of items with each call. This gives the individual calls a better chance of succeeding without a timeout. Changing the page size doesn't affect the output; it affects only the number of API calls that need to be made to generate the output.

```
$ aws s3api list-objects \
    --bucket amzn-s3-demo-bucket \
    --page-size 100
{
    "Contents": [
...
```

How to use the --max-items parameter

To include fewer items at a time in the Amazon CLI output, use the `--max-items` option. The Amazon CLI still handles pagination with the service as described previously, but prints out only the number of items at a time that you specify.

```
$ aws s3api list-objects \
    --bucket amzn-s3-demo-bucket \
    --max-items 100
{
    "NextToken": "eyJNYXJrZXIiOiBudWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQiOiAxfQ==",
    "Contents": [
...
```

How to use the --starting-token parameter

If the number of items output (`--max-items`) is fewer than the total number of items returned by the underlying API calls, the output includes a `NextToken` that you can pass to a subsequent command to retrieve the next set of items. The following example shows how to use the `NextToken` value returned by the previous example, and enables you to retrieve the second 100 items.

> **Note**
>
> The parameter `--starting-token` cannot be null or empty. If the previous command does not return a `NextToken` value, there are no more items to return and you do not need to call the command again.

```
$ aws s3api list-objects \
    --bucket amzn-s3-demo-bucket \
    --max-items 100 \
    --starting-token eyJNYXJrZXIiOiBudWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQiOiAxfQ==
{
    "Contents": [
...
```

The specified Amazon service might not return items in the same order each time you call. If you specify different values for `--page-size` and `--max-items`, you can get unexpected results with missing or duplicated items. To prevent this, use the same number for `--page-size` and `--max-`

`items` to sync the Amazon CLI pagination with the pagination of the underlying service. You can also retrieve the whole list and perform any necessary paging operations locally.

Filtering output in the Amazon CLI

The Amazon Command Line Interface (Amazon CLI) has both server-side and client-side filtering that you can use individually or together to filter your Amazon CLI output. Server-side filtering is processed first and returns your output for client-side filtering.

- Server-side filtering is supported by the API, and you usually implement it with a `--filter` parameter. The service only returns matching results which can speed up HTTP response times for large data sets.
- Client-side filtering is supported by the Amazon CLI client using the `--query` parameter. This parameter has capabilities the server-side filtering might not have.

Topics

- Server-side filtering
- Client-side filtering
- Combining server-side and client-side filtering
- Additional resources

Server-side filtering

Server-side filtering in the Amazon CLI is provided by the Amazon service API. The Amazon service only returns the records in the HTTP response that match your filter, which can speed up HTTP response times for large data sets. Since server-side filtering is defined by the service API, the parameter names and functions vary between services. Some common parameter names used for filtering are:

- `--filter` such as ses and ce.
- `--filters` such as ec2, autoscaling, and rds.
- Names starting with the word `filter`, for example `--filter-expression` for the `aws dynamodb scan` command.

For information about whether a specific command has server-side filtering and the filtering rules, see the Amazon CLI reference guide.

Client-side filtering

The Amazon CLI provides built-in JSON-based client-side filtering capabilities with the `--query` parameter. The `--query` parameter is a powerful tool you can use to customize the content and style of your output. The `--query` parameter takes the HTTP response that comes back from the server and filters the results before displaying them. Since the entire HTTP response is sent to the client before filtering, client-side filtering can be slower than server-side filtering for large data-sets.

Querying uses JMESPath syntax to create expressions for filtering your output. To learn JMESPath syntax, see Tutorial on the *JMESPath website*.

> **Important**
>
> The output type you specify changes how the `--query` option operates:
>
> - If you specify `--output text`, the output is paginated *before* the `--query` filter is applied, and the Amazon CLI runs the query once on *each page* of the output. Due to this, the query includes the first matching element on each page which can result in unexpected extra output. To additionally filter the output, you can use other command line tools such as `head` or `tail`.
> - If you specify `--output json`, the output is completely processed as a single, native structure before the `--query` filter is applied. The Amazon CLI runs the query only once against the entire structure, producing a filtered result that is then output.

Client-side filtering topics

- Before you start
- Identifiers
- Selecting from a list
- Filtering nested data
- Flattening results
- Filtering for specific values
- Piping expressions
- Filtering for multiple identifier values
- Adding labels to identifier values

- Functions
- Advanced --query examples

Before you start

> **Note**
>
> These filter expression examples are written for basic linux-like shells. When using these examples, be sure to use the correct quoting rules for your terminal shell. The way your terminal interprets your inputs can vastly change what is sent to the Amazon CLI. How your terminal reads single quotes', double quotes ", or backticks ` can change how content is read.
> For more information, see the section called “Quotes with Strings”.

The following JSON output shows an example of what the `--query` parameter can produce. The output describes three Amazon EBS volumes attached to separate Amazon EC2 instances.

Example output

```
$ aws ec2 describe-volumes
{
  "Volumes": [
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2013-09-17T00:55:03.000Z",
          "InstanceId": "i-a071c394",
          "VolumeId": "vol-e11a5288",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-e11a5288",
      "State": "in-use",
      "SnapshotId": "snap-f23ec1c8",
      "CreateTime": "2013-09-17T00:55:03.000Z",
      "Size": 30
```

```
    },
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2013-09-18T20:26:16.000Z",
          "InstanceId": "i-4b41a37c",
          "VolumeId": "vol-2e410a47",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-2e410a47",
      "State": "in-use",
      "SnapshotId": "snap-708e8348",
      "CreateTime": "2013-09-18T20:26:15.000Z",
      "Size": 8
    },
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2020-11-20T19:54:06.000Z",
          "InstanceId": "i-1jd73kv8",
          "VolumeId": "vol-a1b3c7nd",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-a1b3c7nd",
      "State": "in-use",
      "SnapshotId": "snap-234087fb",
      "CreateTime": "2020-11-20T19:54:05.000Z",
      "Size": 15
    }
  ]
}
```

Identifiers

Identifier are the labels for output values. When creating filters, you use identifiers to narrow down your query results. In the following output example, all identifiers such as `Volumes`, `AvailabilityZone`, and `AttachTime` are highlighted.

```
$ aws ec2 describe-volumes
{
  "Volumes": [
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2013-09-17T00:55:03.000Z",
          "InstanceId": "i-a071c394",
          "VolumeId": "vol-e11a5288",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-e11a5288",
      "State": "in-use",
      "SnapshotId": "snap-f23ec1c8",
      "CreateTime": "2013-09-17T00:55:03.000Z",
      "Size": 30
    },
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2013-09-18T20:26:16.000Z",
          "InstanceId": "i-4b41a37c",
          "VolumeId": "vol-2e410a47",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-2e410a47",
      "State": "in-use",
```

```
      "SnapshotId": "snap-708e8348",
      "CreateTime": "2013-09-18T20:26:15.000Z",
      "Size": 8
    },
    {
      "AvailabilityZone": "us-west-2a",
      "Attachments": [
        {
          "AttachTime": "2020-11-20T19:54:06.000Z",
          "InstanceId": "i-1jd73kv8",
          "VolumeId": "vol-a1b3c7nd",
          "State": "attached",
          "DeleteOnTermination": true,
          "Device": "/dev/sda1"
        }
      ],
      "VolumeType": "standard",
      "VolumeId": "vol-a1b3c7nd",
      "State": "in-use",
      "SnapshotId": "snap-234087fb",
      "CreateTime": "2020-11-20T19:54:05.000Z",
      "Size": 15
    }
  ]
}
```

For more information, see Identifiers on the *JMESPath website*.

Selecting from a list

A list or array is an identifier that is followed by a square bracket "[" such as `Volumes` and `Attachments` in the the section called “Before you start”.

Syntax

```
<listName>[ ]
```

To filter through all output from an array, you can use the wildcard notation. Wildcard expressions are expressions used to return elements using the * notation.

The following example queries all `Volumes` content.

```
$ aws ec2 describe-volumes \
```

```
    --query 'Volumes[*]'
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-234087fb",
    "CreateTime": "2020-11-20T19:54:05.000Z",
    "Size": 15
  }
]
```

To view a specific volume in the array by index, you call the array index. For example, the first item in the `Volumes` array has an index of 0, resulting in the `Volumes[0]` query. For more information about array indexes, see index expressions on the *JMESPath website*.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[0]'
{
  "AvailabilityZone": "us-west-2a",
  "Attachments": [
    {
      "AttachTime": "2013-09-17T00:55:03.000Z",
      "InstanceId": "i-a071c394",
      "VolumeId": "vol-e11a5288",
      "State": "attached",
      "DeleteOnTermination": true,
      "Device": "/dev/sda1"
    }
  ],
  "VolumeType": "standard",
  "VolumeId": "vol-e11a5288",
  "State": "in-use",
  "SnapshotId": "snap-f23ec1c8",
  "CreateTime": "2013-09-17T00:55:03.000Z",
  "Size": 30
}
```

To view a specific range of volumes by index, use `slice` with the following syntax, where **start** is the starting array index, **stop** is the index where the filter stops processing, and **step** is the skip interval.

Syntax

```
<arrayName>[<start>:<stop>:<step>]
```

If any of these are omitted from the slice expression, they use the following default values:

- Start – The first index in the list, 0.
- Stop – The last index in the list.
- Step – No step skipping, where the value is 1.

To return only the first two volumes, you use a start value of 0, a stop value of 2, and a step value of 1 as shown in the following example.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[0:2:1]'
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-18T20:26:16.000Z",
        "InstanceId": "i-4b41a37c",
        "VolumeId": "vol-2e410a47",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-2e410a47",
    "State": "in-use",
    "SnapshotId": "snap-708e8348",
    "CreateTime": "2013-09-18T20:26:15.000Z",
    "Size": 8
```

```
  }
]
```

Since this example contains default values, you can shorten the slice from `Volumes[0:2:1]` to `Volumes[:2]`.

The following example omits default values and returns every two volumes in the entire array.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[::2]'
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
```

```
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-234087fb",
    "CreateTime": "2020-11-20T19:54:05.000Z",
    "Size": 15
  }
]
```

Steps can also use negative numbers to filter in the reverse order of an array as shown in the following example.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[::-2]'
[
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2020-11-20T19:54:06.000Z",
        "InstanceId": "i-1jd73kv8",
        "VolumeId": "vol-a1b3c7nd",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-a1b3c7nd",
    "State": "in-use",
    "SnapshotId": "snap-234087fb",
    "CreateTime": "2020-11-20T19:54:05.000Z",
    "Size": 15
  },
  {
    "AvailabilityZone": "us-west-2a",
    "Attachments": [
      {
        "AttachTime": "2013-09-17T00:55:03.000Z",
        "InstanceId": "i-a071c394",
        "VolumeId": "vol-e11a5288",
        "State": "attached",
        "DeleteOnTermination": true,
        "Device": "/dev/sda1"
```

```
      }
    ],
    "VolumeType": "standard",
    "VolumeId": "vol-e11a5288",
    "State": "in-use",
    "SnapshotId": "snap-f23ec1c8",
    "CreateTime": "2013-09-17T00:55:03.000Z",
    "Size": 30
  }
]
```

For more information, see Slices on the *JMESPath website*.

Filtering nested data

To narrow the filtering of the `Volumes[*]` for nested values, you use subexpressions by appending a period and your filter criteria.

Syntax

```
<expression>.<expression>
```

The following example shows all `Attachments` information for all volumes.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments'
[
  [
    {
      "AttachTime": "2013-09-17T00:55:03.000Z",
      "InstanceId": "i-a071c394",
      "VolumeId": "vol-e11a5288",
      "State": "attached",
      "DeleteOnTermination": true,
      "Device": "/dev/sda1"
    }
  ],
  [
    {
      "AttachTime": "2013-09-18T20:26:16.000Z",
      "InstanceId": "i-4b41a37c",
      "VolumeId": "vol-2e410a47",
      "State": "attached",
```

```
      "DeleteOnTermination": true,
      "Device": "/dev/sda1"
    }
  ],
  [
    {
      "AttachTime": "2020-11-20T19:54:06.000Z",
      "InstanceId": "i-1jd73kv8",
      "VolumeId": "vol-a1b3c7nd",
      "State": "attached",
      "DeleteOnTermination": true,
      "Device": "/dev/sda1"
    }
  ]
]
```

To filter further into the nested values, append the expression for each nested indentifier. The following example lists the `State` for all `Volumes`.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments[*].State'
[
  [
    "attached"
  ],
  [
    "attached"
  ],
  [
    "attached"
  ]
]
```

Flattening results

For more information, see SubExpressions on the *JMESPath website*.

You can flatten the results for `Volumes[*].Attachments[*].State` by removing the wildcard notation resulting in the `Volumes[*].Attachments[].State` query. Flattening often is useful to improve the readablity of results.

```
$ aws ec2 describe-volumes \
```

```
    --query 'Volumes[*].Attachments[].State'
[
  "attached",
  "attached",
  "attached"
]
```

For more information, see Flatten on the *JMESPath website*.

Filtering for specific values

To filter for specific values in a list, you use a filter expression as shown in the following syntax.

Syntax

```
? <expression> <comparator> <expression>]
```

Expression comparators include ==, !=, <, <=, >, and >= . The following example filters for the `VolumeIds` for all `Volumes` in an `AttachedState`.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments[?State==`attached`].VolumeId'
[
  [
    "vol-e11a5288"
  ],
  [
    "vol-2e410a47"
  ],
  [
    "vol-a1b3c7nd"
  ]
]
```

This can then be flattened resulting in the following example.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments[?State==`attached`].VolumeId[]'
[
  "vol-e11a5288",
  "vol-2e410a47",
  "vol-a1b3c7nd"
```

```
]
```

The following example filters for the `VolumeIds` of all `Volumes` that have a size less than 20.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[?Size < `20`].VolumeId'
[
  "vol-2e410a47",
  "vol-a1b3c7nd"
]
```

For more information, see Filter Expressions on the *JMESPath website*.

Piping expressions

You can pipe results of a filter to a new list, and then filter the result with another expression using the following syntax:

Syntax

```
<expression> | <expression>]
```

The following example takes the filter results of the `Volumes[*].Attachments[].InstanceId` expression and outputs the first result in the array.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments[].InstanceId | [0]'
"i-a071c394"
```

This example does this by first creating the array from the following expression.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Attachments[].InstanceId'
"i-a071c394",
  "i-4b41a37c",
  "i-1jd73kv8"
```

And then returns the first element in that array.

```
"i-a071c394"
```

For more information, see Pipe Expressions on the *JMESPath website*.

Filtering for multiple identifier values

To filter for multiple identifiers, you use a multiselect list by using the following syntax:

Syntax

```
<listName>[].[<expression>, <expression>]
```

In the following example, `VolumeId` and `VolumeType` are filtered in the `Volumes` list resulting in the following expression.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[].[VolumeId, VolumeType]'
[
  [
    "vol-e11a5288",
    "standard"
  ],
  [
    "vol-2e410a47",
    "standard"
  ],
  [
    "vol-a1b3c7nd",
    "standard"
  ]
]
```

To add nested data to the list, you add another multiselect list. The following example expands on the previous example by also filtering for `InstanceId` and `State` in the nested `Attachments` list. This results in the following expression.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[].[VolumeId, VolumeType, Attachments[].[InstanceId, State]]'
[
  [
    "vol-e11a5288",
    "standard",
    [
      [
```

```
        "i-a071c394",
        "attached"
      ]
    ]
  ],
  [
    "vol-2e410a47",
    "standard",
    [
      [
        "i-4b41a37c",
        "attached"
      ]
    ]
  ],
  [
    "vol-a1b3c7nd",
    "standard",
    [
      [
        "i-1jd73kv8",
        "attached"
      ]
    ]
  ]
]
```

To be more readable, flatten out the expression as shown in the following example.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[].[VolumeId, VolumeType, Attachments[].[InstanceId, State][]][]'
[
  "vol-e11a5288",
  "standard",
  [
    "i-a071c394",
    "attached"
  ],
  "vol-2e410a47",
  "standard",
  [
    "i-4b41a37c",
    "attached"
```

```
  ],
  "vol-a1b3c7nd",
  "standard",
  [
    "i-1jd73kv8",
    "attached"
  ]
]
```

For more information, see Multiselect list on the *JMESPath website*.

Adding labels to identifier values

To make this output easier to read, use a multiselect hash with the following syntax.

Syntax

```
<listName>[].{<label>: <expression>, <label>: <expression>}
```

Your identifier label does not need to be the same as the name of the identifier. The following example uses the label `VolumeType` for the `VolumeType` values.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[].{VolumeType: VolumeType}'
[
  {
    "VolumeType": "standard",
  },
  {
    "VolumeType": "standard",
  },
  {
    "VolumeType": "standard",
  }
]
```

For simplicity, the following example keeps the identifier names for each label and displays the `VolumeId`, `VolumeType`, `InstanceId`, and `State` for all volumes:

```
$ aws ec2 describe-volumes \
    --query 'Volumes[].{VolumeId: VolumeId, VolumeType: VolumeType, InstanceId:
 Attachments[0].InstanceId, State: Attachments[0].State}'
```

```
[
  {
    "VolumeId": "vol-e11a5288",
    "VolumeType": "standard",
    "InstanceId": "i-a071c394",
    "State": "attached"
  },
  {
    "VolumeId": "vol-2e410a47",
    "VolumeType": "standard",
    "InstanceId": "i-4b41a37c",
    "State": "attached"
  },
  {
    "VolumeId": "vol-a1b3c7nd",
    "VolumeType": "standard",
    "InstanceId": "i-1jd73kv8",
    "State": "attached"
  }
]
```

For more information, see Multiselect hash on the *JMESPath website*.

Functions

The JMESPath syntax contains many functions that you can use for your queries. For information on JMESPath functions, see Built-in Functions on the *JMESPath website*.

To demonstrate how you can incorporate a function into your queries, the following example uses the `sort_by` function. The `sort_by` function sorts an array using an expression as the sort key using the following syntax:

Syntax

```
sort_by(<listName>, <sort expression>)[].<expression>
```

The following example uses the previous multiselect hash example and sorts the output by `VolumeId`.

```
$ aws ec2 describe-volumes \
    --query 'sort_by(Volumes, &VolumeId)[].{VolumeId: VolumeId, VolumeType: VolumeType,
 InstanceId: Attachments[0].InstanceId, State: Attachments[0].State}'
```

```
[
  {
    "VolumeId": "vol-2e410a47",
    "VolumeType": "standard",
    "InstanceId": "i-4b41a37c",
    "State": "attached"
  },
  {
    "VolumeId": "vol-a1b3c7nd",
    "VolumeType": "standard",
    "InstanceId": "i-1jd73kv8",
    "State": "attached"
  },
  {
    "VolumeId": "vol-e11a5288",
    "VolumeType": "standard",
    "InstanceId": "i-a071c394",
    "State": "attached"
  }
]
```

For more information, see sort_by on the *JMESPath website*.

Advanced `--query` examples

To extract information from a specific item

The following example uses the `--query` parameter to find a specific item in a list and then extracts information from that item. The example lists all of the `AvailabilityZones` associated with the specified service endpoint. It extracts the item from the `ServiceDetails` list that has the specified `ServiceName`, then outputs the `AvailabilityZones` field from that selected item.

```
$ aws --region us-east-1 ec2 describe-vpc-endpoint-services \
    --query 'ServiceDetails[?ServiceName==`com.amazonaws.us-
east-1.ecs`].AvailabilityZones'
[
    [
        "us-east-1a",
        "us-east-1b",
        "us-east-1c",
        "us-east-1d",
        "us-east-1e",
        "us-east-1f"
```

```
    ]
]
```

To show snapshots after the specified creation date

The following example shows how to list all of your snapshots that were created after a specified date, including only a few of the available fields in the output.

```
$ aws ec2 describe-snapshots --owner self \
    --output json \
    --query 'Snapshots[?StartTime>=`2018-02-07`].
{Id:SnapshotId,VId:VolumeId,Size:VolumeSize}'
[
    {
        "id": "snap-0effb42b7a1b2c3d4",
        "vid": "vol-0be9bb0bf12345678",
        "Size": 8
    }
]
```

To show the most recent AMIs

The following example lists the five most recent Amazon Machine Images (AMIs) that you created, sorted from most recent to oldest.

```
$ aws ec2 describe-images \
    --owners self \
    --query 'reverse(sort_by(Images,&CreationDate))[:5].{id:ImageId,date:CreationDate}'
[
    {
        "id": "ami-0a1b2c3d4e5f60001",
        "date": "2018-11-28T17:16:38.000Z"
    },
    {
        "id": "ami-0a1b2c3d4e5f60002",
        "date": "2018-09-15T13:51:22.000Z"
    },
    {
        "id": "ami-0a1b2c3d4e5f60003",
        "date": "2018-08-19T10:22:45.000Z"
    },
    {
        "id": "ami-0a1b2c3d4e5f60004",
```

```
        "date": "2018-05-03T12:04:02.000Z"
    },
    {
        "id": "ami-0a1b2c3d4e5f60005",
        "date": "2017-12-13T17:16:38.000Z"
    }
]
```

To show unhealthy Auto Scaling instances

The following example shows only the `InstanceId` for any unhealthy instances in the specified Auto Scaling group.

```
$ aws autoscaling describe-auto-scaling-groups \
    --auto-scaling-group-name My-AutoScaling-Group-Name \
    --output text \
    --query 'AutoScalingGroups[*].Instances[?HealthStatus==`Unhealthy`].InstanceId'
```

To include volumes with the specified tag

The following example describes all instances with a `test` tag. As long as there is another tag beside `test` attached to the volume, the volume is still returned in the results.

The below expression to return all tags with the `test` tag in an array. Any tags that are not the `test` tag contain a `null` value.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Tags[?Value == `test`]'
```

To exclude volumes with the specified tag

The following example describes all instances without a `test` tag. Using a simple `?Value != `test`` expression does not work for excluding a volume as volumes can have multiple tags. As long as there is another tag beside `test` attached to the volume, the volume is still returned in the results.

To exclude all volumes with the `test` tag, start with the below expression to return all tags with the `test` tag in an array. Any tags that are not the `test` tag contain a `null` value.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[*].Tags[?Value == `test`]'
```

Then filter out all the positive `test` results using the `not_null` function.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[?!not_null(Tags[?Value == `test`].Value)]'
```

Pipe the results to flatten out the results resulting in the following query.

```
$ aws ec2 describe-volumes \
    --query 'Volumes[?!not_null(Tags[?Value == `test`].Value)] | []'
```

Combining server-side and client-side filtering

You can use server-side and client-side filtering together. Server-side filtering is completed first, which sends the data to the client that the `--query` parameter then filters. If you're using large data sets, using server-side filtering first can lower the amount of data sent to the client for each Amazon CLI call, while still keeping the powerful customization that client-side filtering provides.

The following example lists Amazon EC2 volumes using both server-side and client-side filtering. The service filters a list of all attached volumes in the `us-west-2a` Availability Zone. The `--query` parameter further limits the output to only those volumes with a `Size` value that is larger than 50, and shows only the specified fields with user-defined names.

```
$ aws ec2 describe-volumes \
    --filters "Name=availability-zone,Values=us-west-2a" "Name=status,Values=attached"
 \
    --query 'Volumes[?Size > `50`].{Id:VolumeId,Size:Size,Type:VolumeType}'
[
    {
        "Id": "vol-0be9bb0bf12345678",
        "Size": 80,
        "VolumeType": "gp2"
    }
]
```

The following example retrieves a list of images that meet several criteria. It then uses the `--query` parameter to sort the output by `CreationDate`, selecting only the most recent. Finally, it displays the `ImageId` of that one image.

```
$ aws ec2 describe-images \
    --owners amazon \
```

```
    --filters "Name=name,Values=amzn*gp2" "Name=virtualization-type,Values=hvm"
 "Name=root-device-type,Values=ebs" \
    --query "sort_by(Images, &CreationDate)[-1].ImageId" \
    --output text
ami-00ced3122871a4921
```

The following example displays the number of available volumes that are more than 1000 IOPS by using `length` to count how many are in a list.

```
$ aws ec2 describe-volumes \
    --filters "Name=status,Values=available" \
    --query 'length(Volumes[?Iops > `1000`])'
3
```

Additional resources

JMESPath Terminal

JMESPath Terminal is an interactive terminal command to experiment with JMESPath expressions that are used for client-side filtering. Using the `jpterm` command, the terminal shows immediate query results as you're typing. You can directly pipe Amazon CLI output to the terminal, enabling advanced querying experimentation.

The following example pipes `aws ec2 describe-volumes` output directly to JMESPath Terminal.

```
$ aws ec2 describe-volumes | jpterm
```

For more information on JMESPath Terminal and installation instructions, see JMESPath Terminal on *GitHub*.

jq utility

The `jq` utility provides you a way to transform your output on the client-side to an output format you desire. For more information on `jq` and installation instructions, see jq on *GitHub*.

Command line return codes in the Amazon CLI

The return code is usually a hidden code sent after running a Amazon Command Line Interface (Amazon CLI) command which describes the status of the command. You can use the `echo`

command to display the code sent from the last Amazon CLI command and use these codes to determine if a command was successful or if it failed, and why a command might have an error. In addition to the return codes, you can view more details about a failure by running your commands with the `--debug` switch. This switch produces a detailed report of the steps the Amazon CLI uses to process the command, and what the result of each step was.

To determine the return code of an Amazon CLI command, run one of the following commands immediately after running the CLI command.

Linux and macOS

```
$ echo $?
0
```

Windows PowerShell

```
PS> echo $lastexitcode
0
```

Windows Command Prompt

```
C:\> echo %errorlevel%
0
```

The following are the return code values that can be returned at the end of running an Amazon Command Line Interface (Amazon CLI) command.

Code	Meaning
0	The service responded with an HTTP response status code of 200 indicating that there were no errors generated by the Amazon CLI and Amazon service the request was sent to.
1	One or more Amazon S3 transfer operations failed. *Limited to S3 commands.*
2	The meaning of this return code depends on the command:

Code	Meaning
	• *Applicable to all Amazon CLI commands* – the command entered couldn't be parsed. Parsing failures can be caused by, but aren't limited to, missing required subcommands or arguments, or using unknown commands or arguments. • *Limited to S3 commands* – One or more files marked for transfer were skipped during the transfer process. However, all other files marked for transfer were successfully transferred. Files that are skipped during the transfer process include: files that don't exist; files that are character special devices, block special device, FIFO queues, or sockets; and files that the user doesn't have read permissions to.
130	The command was interrupted by a SIGINT. This is the signal sent by you to cancel a command with `Ctrl+C`.
255	The command failed. There were errors generated by the Amazon CLI or by the Amazon service to which the request was sent.

Creating and using aliases in the Amazon CLI

Aliases are shortcuts you can create in the Amazon Command Line Interface (Amazon CLI) to shorten commands or scripts that you frequently use. You create aliases in the `alias` file located in your configuration folder.

Topics

- Prerequisites
- Step 1: Creating the alias file
- Step 2: Creating an alias
- Step 3: Calling an alias
- Alias repository examples
- Resources

Prerequisites

To use alias commands, you need to complete the following:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- Use a minimum Amazon CLI version of 1.11.24 or 2.0.0.
- (Optional) To use Amazon CLI alias bash scripts, you must use a bash-compatible terminal.

Step 1: Creating the alias file

To create the `alias` file, you can use your file navigation and a text editor, or use your preferred terminal by using the step-by-step procedure. To quickly create your alias file, use the following command block.

Linux and macOS

```
$ mkdir -p ~/.aws/cli
$ echo '[toplevel]' > ~/.aws/cli/alias
```

Windows

```
C:\> md %USERPROFILE%\.aws\cli
C:\> echo [toplevel] > %USERPROFILE%/.aws/cli/alias
```

To create the alias file

1. Create a folder named `cli` in your Amazon CLI configuration folder. By default the configuration folder is `~/.aws/` on Linux or macOS and `%USERPROFILE%\.aws\` on Windows. You can create this through your file navigation or by using the following command.

   Linux and macOS

   ```
   $ mkdir -p ~/.aws/cli
   ```

   Windows

   ```
   C:\> md %USERPROFILE%\.aws\cli
   ```

The resulting `cli` folder default path is `~/.aws/cli/` on Linux or macOS and `%USERPROFILE%\.aws\cli` on Windows.

2. In the `cli` folder, create a text file named `alias` with no extension and add `[toplevel]` to the first line. You can create this file through your preferred text editor or use the following command.

   Linux and macOS

   ```
   $ echo '[toplevel]' > ~/.aws/cli/alias
   ```

   Windows

   ```
   C:\> echo [toplevel] > %USERPROFILE%/.aws/cli/alias
   ```

Step 2: Creating an alias

You can create an alias using basic commands or bash scripting.

Creating a basic command alias

You can create your alias by adding a command using the following syntax in the `alias` file you created in the previous step.

Syntax

```
aliasname = command [--options]
```

The *`aliasname`* is what you call your alias. The *`command`* is the command you want to call, which can include other aliases. You can include options or parameters in your alias, or add them when calling your alias.

The following example creates an alias named `aws whoami` using the `aws sts get-caller-identity` command. Since this alias calls an existing Amazon CLI command, you can write the command without the `aws` prefix.

```
whoami = sts get-caller-identity
```

The following example takes the previous `whoami` example and adds the `Account` filter and text `output` options.

```
whoami2 = sts get-caller-identity --query Account --output text
```

Creating a sub-command alias

> **Note**
>
> The sub-command alias feature requires a minimum Amazon CLI version of 1.11.24 or 2.0.0

You can create an alias for sub-commands by adding a command using the following syntax in the `alias` file you created in the previous step.

Syntax

```
[command commandGroup]
aliasname = command [--options]
```

The *commandGroup* is the command namespace, e.g. The command `aws ec2 describe-regions` is under the `ec2` command group. The *aliasname* is what you call your alias. The *command* is the command you want to call, which can include other aliases. You can include options or parameters in your alias, or add them when calling your alias.

The following example creates an alias named `aws ec2 regions` using the `aws ec2 describe-regions` command. Since this alias calls an existing Amazon CLI command under the `ec2` command namespace, you can write the command without the `aws ec2` prefix.

```
[command ec2]
regions = describe-regions --query Regions[].RegionName
```

To create aliases from commands outside of the command namespace, prefix the full command with an exclamation mark. The following example creates an alias named `aws ec2 instance-profiles` using the `aws iam list-instance-profiles` command.

```
[command ec2]
instance-profiles = !aws iam list-instance-profiles
```

> **Note**
>
> Aliases only use existing command namespaces and you cannot create new ones. e.g. You can't create an alias with the `[command johnsmith]` section as the `johnsmith` command namespace does not already exist.

Creating a bash scripting alias

> **Warning**
>
> To use Amazon CLI alias bash scripts, you must use a bash-compatible terminal

You can create an alias using bash scripts for more advanced processes using the following syntax.

Syntax

```
aliasname =
    !f() {
        script content
}; f
```

The *aliasname* is what you call your alias and *script content* is the script you want to run when you call the alias.

The following example uses `opendns` to output your current IP address. Since you can use aliases in other aliases, the following `myip` alias is useful to allow or revoke access for your IP address from within other aliases.

```
myip =
  !f() {
    dig +short myip.opendns.com @resolver1.opendns.com
  }; f
```

The following script example calls the previous `aws myip` alias to authorize your IP address for an Amazon EC2 security group ingress.

```
authorize-my-ip =
  !f() {
```

```
    ip=$(aws myip)
    aws ec2 authorize-security-group-ingress --group-id ${1} --cidr $ip/32 --protocol
 tcp --port 22
  }; f
```

When you call aliases that use bash scripting, the variables are always passed in the order that you entered them. In bash scripting, the variable names are not taken into consideration, only the order they appear. In the following `textalert` alias example, the variable for the `--message` option is first and `--phone-number` option is second.

```
textalert =
  !f() {
    aws sns publish --message "${1}" --phone-number ${2}
  }; f
```

Step 3: Calling an alias

To run the alias you created in your `alias` file use the following syntax. You can add additional options when you call your alias.

Syntax

```
$ aws aliasname
```

The following example uses the `aws whoami` command alias.

```
$ aws
 whoami
{
    "UserId": "A12BCD34E5FGHI6JKLM",
    "Account": "1234567890987",
    "Arn": "arn:aws:iam::1234567890987:user/userName"
}
```

The following example uses the `aws whoami` alias with additional options to only return the `Account` number in `text` output.

```
$ aws whoami --query Account --output
 text
1234567890987
```

The following example uses the `aws ec2 regions` sub-command alias.

```
$ aws ec2
 regions
[
    "ap-south-1",
    "eu-north-1",
    "eu-west-3",
    "eu-west-2",
...
```

Calling an alias using bash scripting variables

When you call aliases that use bash scripting, variables are passed in the order they are entered. In bash scripting, the name of the variables are not taken into consideration, only the order they appear. For example, in the following `textalert` alias, the variable for the option `--message` is first and `--phone-number` is second.

```
textalert =
  !f() {
    aws sns publish --message "${1}" --phone-number ${2}
  }; f
```

When you call the `textalert` alias, you need to pass variables in the same order as they are run in the alias. In the following example we use the variables `$message` and `$phone`. The `$message` variable is passed as `${1}` for the `--message` option and the `$phone` variable is passed as `${2}` for the `--phone-number` option. This results in successfully calling the `textalert` alias to send a message.

```
$ aws textalert $message
 $phone
{
    "MessageId": "1ab2cd3e4-fg56-7h89-i01j-2klmn34567"
}
```

In the following example, the order is switched when calling the alias to `$phone` and `$message`. The `$phone` variable is passed as `${1}` for the `--message` option and the `$message` variable is passed as `${2}` for the `--phone-number` option. Since the variables are out of order, the alias passes the variables incorrectly. This causes an error because the contents of `$message` do not match the phone number formatting requirements for the `--phone-number` option.

```
$ aws textalert $phone
 $message
usage: aws [options] <command> <subcommand> [<subcommand> ...] [parameters]
To see help text, you can run:

  aws help
  aws <command> help
  aws <command> <subcommand> help

Unknown options: text
```

Alias repository examples

The Amazon CLI alias repository on *GitHub* contains Amazon CLI alias examples created by the Amazon CLI developer team and community. You can use the entire `alias` file example or take individual aliases for your own use.

> **Warning**
>
> Running the commands in this section deletes your existing `alias` file. To avoid overwriting your existing alias file, change your download location.

To use aliases from the repository

1. Install Git. For installation instructions, see Getting Started - Installing Git in the *Git Documentation*.
2. Install the `jp` command. The `jp` command is used in the `tostring` alias. For installation instructions, see the JMESPath (jp) README.md on *GitHub*.
3. Install the `jq` command. The `jq` command is used in the `tostring-with-jq` alias. For installation instructions, see the JSON processor (jq) on *GitHub*.
4. Download the `alias` file by doing one of the following:

   - Run the following commands that downloads from the repository and copies the `alias` file to your configuration folder.

     Linux and macOS

     ```
     $ git clone https://github.com/awslabs/awscli-aliases.git
     ```

```
$ mkdir -p ~/.aws/cli
$ cp awscli-aliases/alias ~/.aws/cli/alias
```

Windows

```
C:\> git clone https://github.com/awslabs/awscli-aliases.git
C:\> md %USERPROFILE%\.aws\cli
C:\> copy awscli-aliases\alias %USERPROFILE%\.aws\cli
```

- Download directly from the repository and save to the `cli` folder in your Amazon CLI configuration folder. By default the configuration folder is `~/.aws/` on Linux or macOS and `%USERPROFILE%\.aws\` on Windows.

5. To verify the aliases are working, run the following alias.

```
$ aws whoami
```

This displays the same response as the `aws sts get-caller-identity` command:

```
{
    "Account": "012345678901",
    "UserId": "AIUAINBADX2VEG2TC6HD6",
    "Arn": "arn:aws:iam::012345678901:user/myuser"
}
```

Resources

- The Amazon CLI alias repository on *GitHub* contains Amazon CLI alias examples created by the Amazon CLI developer team and the contribution of the Amazon CLI community.
- The alias feature announcement from Amazon re:Invent 2016: The Effective Amazon CLI User on *YouTube*.
- `aws sts get-caller-identity`
- `aws ec2 describe-instances`
- `aws sns publish`

Code examples for the Amazon CLI

This chapter provides a collection of examples that show you how to use the Amazon Command Line Interface (Amazon CLI) with Amazon Web Services services.

The Amazon CLI has the following types of examples in this guide:

- **Guided command examples** - Guided command examples for the Amazon CLI User Guide on how to use the Amazon CLI with some Amazon Web Services services. These are often more detailed examples than the examples from the Amazon CLI reference guide.
- **Amazon CLI command examples** - Open source command examples that are also available in the Amazon CLI reference guide. Command examples are hosted in the Amazon CLI repository on *GitHub*.
- **Amazon CLI using Bash scripting code examples** - Open source bash scripting examples. Bash scripting examples are hosted in the Amazon Code Examples Repository on *GitHub*.

Example feedback

Can't find what you need? Request a command example by using the **Provide feedback** link at the bottom of this page or on the relevant command page in the Amazon CLI reference guide.
Want to contribute? Contribute Amazon CLI command examples in the Amazon Code Examples Repository on *GitHub*. For more information on contributing, see Amazon CLI code example contribution quick steps on *GitHub pages*.

Guided command examples for the Amazon CLI

The Amazon Command Line Interface (Amazon CLI) is an open source tool that enables you to interact with a wide range of Amazon Web Services services using commands in your command-line shell. This section provides guided examples that show how to leverage the Amazon CLI to access some of the Amazon Web Services services. This includes some of the custom Amazon CLI commands, such as the high-level `aws s3` commands. These command examples demonstrate common actions used for some Amazon Web Services services and provide additional resources for more information.

Whether you are an experienced Amazon user or new to the Amazon CLI, these guided examples serve as a resource for streamlining your Amazon operations.

For a complete reference of all the available commands for each Amazon Web Services service, see the Amazon CLI reference guide. Additionally, you can utilize the built-in command line help to explore the array of Amazon Web Services services, commands, options, and features in the Amazon CLI.

For more command examples that are not available in this section, see the Amazon CLI command examples section. These are open source command examples that are also available in the Amazon CLI reference guide. Command examples are hosted in the Amazon CLI repository on *GitHub*.

For open source bash scripting examples, see the section called "Bash script examples". Bash scripting examples are hosted in the Amazon Code Examples Repository on *GitHub*.

Using Amazon DynamoDB in the Amazon CLI

An introduction to Amazon DynamoDB
What is Amazon DynamoDB?

The Amazon Command Line Interface (Amazon CLI) provides support for all of the Amazon database services, including Amazon DynamoDB. You can use the Amazon CLI for impromptu operations, such as creating a table. You can also use it to embed DynamoDB operations within utility scripts.

For more information about using the Amazon CLI with DynamoDB, see `dynamodb` in the *Amazon CLI Command Reference*.

To list the Amazon CLI commands for DynamoDB, use the following command.

```
$ aws dynamodb help
```

Topics

- Prerequisites
- Creating and using DynamoDB tables
- Using DynamoDB Local
- Resources

Prerequisites

To run the dynamodb commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.

Creating and using DynamoDB tables

The command line format consists of an DynamoDB command name, followed by the parameters for that command. The Amazon CLI supports the CLI shorthand syntax for the parameter values, and full JSON.

The following example creates a table named `MusicCollection`.

```
$ aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S
 AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH
 AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=1,WriteCapacityUnits=1
```

You can add new lines to the table with commands similar to those shown in the following example. These examples use a combination of shorthand syntax and JSON.

```
$ aws dynamodb put-item \
```

```
    --table-name MusicCollection \
    --item '{
        "Artist": {"S": "No One You Know"},
        "SongTitle": {"S": "Call Me Today"} ,
        "AlbumTitle": {"S": "Somewhat Famous"}
      }' \
    --return-consumed-capacity TOTAL
{
    "ConsumedCapacity": {
        "CapacityUnits": 1.0,
        "TableName": "MusicCollection"
    }
}
```

```
$ aws dynamodb put-item \
    --table-name MusicCollection \
    --item '{
        "Artist": {"S": "Acme Band"},
        "SongTitle": {"S": "Happy Day"} ,
        "AlbumTitle": {"S": "Songs About Life"}
      }' \
    --return-consumed-capacity TOTAL
{
    "ConsumedCapacity": {
        "CapacityUnits": 1.0,
        "TableName": "MusicCollection"
    }
}
```

It can be difficult to compose valid JSON in a single-line command. To make this easier, the Amazon CLI can read JSON files. For example, consider the following JSON snippet, which is stored in a file named `expression-attributes.json`.

```
{
  ":v1": {"S": "No One You Know"},
  ":v2": {"S": "Call Me Today"}
}
```

You can use that file to issue a `query` request using the Amazon CLI. In the following example, the content of the `expression-attributes.json` file is used as the value for the `--expression-attribute-values` parameter.

```
$ aws dynamodb query --table-name MusicCollection \
    --key-condition-expression "Artist = :v1 AND SongTitle = :v2" \
    --expression-attribute-values file://expression-attributes.json
{
    "Count": 1,
    "Items": [
        {
            "AlbumTitle": {
                "S": "Somewhat Famous"
            },
            "SongTitle": {
                "S": "Call Me Today"
            },
            "Artist": {
                "S": "No One You Know"
            }
        }
    ],
    "ScannedCount": 1,
    "ConsumedCapacity": null
}
```

Using DynamoDB Local

In addition to DynamoDB, you can use the Amazon CLI with DynamoDB Local. DynamoDB Local is a small client-side database and server that mimics the DynamoDB service. DynamoDB Local enables you to write applications that use the DynamoDB API, without manipulating any tables or data in the DynamoDB web service. Instead, all of the API actions are rerouted to a local database. This lets you save on provisioned throughput, data storage, and data transfer fees.

For more information about DynamoDB Local and how to use it with the Amazon CLI, see the following sections of the Amazon DynamoDB Developer Guide:

- DynamoDB Local
- Using the Amazon CLI with DynamoDB Local

Using Amazon EC2 in the Amazon CLI

An introduction to Amazon Elastic Compute Cloud
Introduction to Amazon EC2 - Elastic Cloud Server and Hosting with Amazon

Amazon Elastic Compute Cloud (Amazon EC2) provides highly scalable and flexible virtual computing environments. Amazon EC2 allows you to provision and manage virtual servers, known as Amazon EC2 instances, to meet a wide range of computing needs.

Amazon EC2 instances are virtual machines that can be customized with various configurations of CPU, memory, storage, and networking capabilities. You can choose from a diverse selection of instance types, ranging from lightweight, cost-effective options to powerful, high-performance instances, depending on your application requirements. This flexibility enables you to match your computing needs to optimize performance and cost-efficiency.

Additionally, Amazon EC2 offers a suite of features that empowers you to manage your compute resources effectively. These include the ability to quickly launch new instances, create custom machine images (AMIs) for rapid deployment, and scaling computing capacity up or down as needed.

You can access the features of Amazon EC2 using the Amazon Command Line Interface (Amazon CLI). To list the Amazon CLI commands for Amazon EC2, use the following command.

```
aws ec2 help
```

Before you run any commands, set your default credentials. For more information, see Configuring settings for the Amazon CLI.

This topic shows short-form examples of Amazon CLI commands that perform common tasks for Amazon EC2.

For long-form examples of Amazon CLI commands, see Amazon CLI code examples repository on *GitHub*.

Topics

- Creating, displaying, and deleting Amazon EC2 key pairs in the Amazon CLI
- Creating, configuring, and deleteing Amazon EC2 security groups in the Amazon CLI
- Launching, listing, and deleting Amazon EC2 instances in the Amazon CLI
- Change an Amazon EC2 instance type with a bash script in the Amazon CLI

Creating, displaying, and deleting Amazon EC2 key pairs in the Amazon CLI

You can use the Amazon Command Line Interface (Amazon CLI) to create, display, and delete your key pairs for Amazon Elastic Compute Cloud (Amazon EC2). You use key pairs to connect to an Amazon EC2 instance.

You must provide the key pair to Amazon EC2 when you create the instance, and then use that key pair to authenticate when you connect to the instance.

> **Note**
>
> For additional command examples, see the Amazon CLI reference guide.

Topics

- Prerequisites
- Create a key pair
- Display your key pair
- Delete your key pair
- References

Prerequisites

To run the `ec2` commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the *Amazon EC2 User Guide*.

Create a key pair

To create a key pair, use the `aws ec2 create-key-pair` command with the `--query` option, and the `--output text` option to pipe your private key directly into a file.

```
$ aws ec2 create-key-pair --key-name MyKeyPair --query 'KeyMaterial' --output text
 > MyKeyPair.pem
```

For PowerShell, the `> file` redirection defaults to UTF-8 encoding, which cannot be used with some SSH clients. So, you must convert the output by piping it to the `out-file` command and explicitly set the encoding to `ascii`.

```
PS C:\>aws ec2 create-key-pair --key-name MyKeyPair --query 'KeyMaterial' --output text
 | out-file -encoding ascii -filepath MyKeyPair.pem
```

The resulting `MyKeyPair.pem` file looks similar to the following.

```
-----BEGIN RSA PRIVATE KEY-----
EXAMPLEKEYKCAQEAy7WZhaDsrA1W3mRlQtvhwyORRX8gnxgDAfRt/gx42kWXsT4rXE/b5CpSgie/

VRkAKKKYeGjkpUfVTrW0YFjXkfcrR/V+QFL5OndHAKJXjW7a4ejJLncTzmZSpYzwApc=
-----END RSA PRIVATE KEY-----
```

Your private key isn't stored in Amazon and can be retrieved ***only*** when it's created. You can't recover it later. Instead, if you lose the private key, you must create a new key pair.

If you're connecting to your instance from a Linux computer, we recommend that you use the following command to set the permissions of your private key file so that only you can read it.

```
$ chmod 400 MyKeyPair.pem
```

Display your key pair

A "fingerprint" is generated from your key pair, and you can use it to verify that the private key that you have on your local machine matches the public key that's stored in Amazon.

The fingerprint is an SHA1 hash taken from a DER-encoded copy of the private key. This value is captured when the key pair is created, and is stored in Amazon with the public key. You can view the fingerprint in the Amazon EC2 console or by running the Amazon CLI command `aws ec2 describe-key-pairs`.

The following example displays the fingerprint for `MyKeyPair`.

```
$ aws ec2 describe-key-pairs --key-name MyKeyPair
{
    "KeyPairs": [
        {
            "KeyName": "MyKeyPair",
            "KeyFingerprint":
 "1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f"
        }
    ]
}
```

For more information about keys and fingerprints, see Amazon EC2 Key Pairs in the *Amazon EC2 User Guide*.

Delete your key pair

To delete a key pair, run the `aws ec2 delete-key-pair` command, substituting *MyKeyPair* with the name of the pair to delete.

```
$ aws ec2 delete-key-pair --key-name MyKeyPair
```

Creating, configuring, and deleteing Amazon EC2 security groups in the Amazon CLI

You can create a security group for your Amazon Elastic Compute Cloud (Amazon EC2) instances that essentially operates as a firewall, with rules that determine what network traffic can enter and leave.

Use the Amazon Command Line Interface (Amazon CLI) to create a security group, add rules to existing security groups, and delete security groups.

> **Note**
>
> For additional command examples, see the Amazon CLI reference guide.

Topics

- Prerequisites
- Create a security group
- Add rules to your security group
- Delete your security group
- References

Prerequisites

To run the ec2 commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the *Amazon EC2 User Guide*.

Create a security group

You can create security groups associated with virtual private clouds (VPCs) .

The following `aws ec2 create-security-group` example shows how to create a security group for a specified VPC.

```
$ aws ec2 create-security-group --group-name my-sg --description "My security group" --
vpc-id vpc-1a2b3c4d
{
    "GroupId": "sg-903004f8"
}
```

To view the initial information for a security group, run the `aws ec2 describe-security-groups` command. You can reference an EC2-VPC security group only by its `vpc-id`, not its name.

```
$ aws ec2 describe-security-groups --group-ids sg-903004f8
{
    "SecurityGroups": [
        {
            "IpPermissionsEgress": [
                {
                    "IpProtocol": "-1",
```

```
                    "IpRanges": [
                        {
                            "CidrIp": "0.0.0.0/0"
                        }
                    ],
                    "UserIdGroupPairs": []
                }
            ],
            "Description": "My security group"
            "IpPermissions": [],
            "GroupName": "my-sg",
            "VpcId": "vpc-1a2b3c4d",
            "OwnerId": "123456789012",
            "GroupId": "sg-903004f8"
        }
    ]
}
```

Add rules to your security group

When you run an Amazon EC2 instance, you must enable rules in the security group to allow incoming network traffic for your means of connecting to the image.

For example, if you're launching a Windows instance, you typically add a rule to allow inbound traffic on TCP port 3389 to support Remote Desktop Protocol (RDP). If you're launching a Linux instance, you typically add a rule to allow inbound traffic on TCP port 22 to support SSH connections.

Use the `aws ec2 authorize-security-group-ingress` command to add a rule to your security group. A required parameter of this command is the public IP address of your computer, or the network (in the form of an address range) that your computer is attached to, in CIDR notation.

The following example shows how to add a rule for RDP (TCP port 3389) to an EC2-VPC security group with the ID `sg-903004f8` using your IP address.

To start, find your IP address.

```
$ curl https://checkip.amazonaws.com
x.x.x.x
```

You can then add the IP address to your security group by running the `aws ec2 authorize-security-group-ingress` command.

```
$ aws ec2 authorize-security-group-ingress --group-id sg-903004f8 --protocol tcp --port
 3389 --cidr x.x.x.x/x
```

The following command adds another rule to enable SSH to instances in the same security group.

```
$ aws ec2 authorize-security-group-ingress --group-id sg-903004f8 --protocol tcp --port
 22 --cidr x.x.x.x/x
```

To view the changes to the security group, run the aws ec2 describe-security-groups command.

```
$ aws ec2 describe-security-groups --group-ids sg-903004f8
{
    "SecurityGroups": [
        {
            "IpPermissionsEgress": [
                {
                    "IpProtocol": "-1",
                    "IpRanges": [
                        {
                            "CidrIp": "0.0.0.0/0"
                        }
                    ],
                    "UserIdGroupPairs": []
                }
            ],
            "Description": "My security group"
            "IpPermissions": [
                {
                    "ToPort": 22,
                    "IpProtocol": "tcp",
                    "IpRanges": [
                        {
                            "CidrIp": "x.x.x.x/x"
                        }
                    ]
                    "UserIdGroupPairs": [],
                    "FromPort": 22
                }
            ],
            "GroupName": "my-sg",
            "OwnerId": "123456789012",
```

```
            "GroupId": "sg-903004f8"
        }
    ]
}
```

Delete your security group

To delete a security group, run the `aws ec2 delete-security-group` command.

> **Note**
>
> You can't delete a security group if it's currently attached to an environment.

The following command example deletes an EC2-VPC security group.

```
$ aws ec2 delete-security-group --group-id sg-903004f8
```

References

Launching, listing, and deleting Amazon EC2 instances in the Amazon CLI

You can use the Amazon Command Line Interface (Amazon CLI) to launch, list, and delete Amazon Elastic Compute Cloud (Amazon EC2) instances. If you launch an instance that isn't within the

Amazon Free Tier, you are billed after you launch the instance and charged for the time that the instance is running, even if it remains idle.

> **Note**
>
> For additional command examples, see the Amazon CLI reference guide.

Topics

- Prerequisites
- Launch your instance
- Add a block device to your instance
- Add a tag to your instance
- Connect to your instance
- List your instances
- Delete your instance
- References

Prerequisites

To run the `ec2` commands in this topic, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- Set your IAM permissions to allow for Amazon EC2 access. For more information about IAM permissions for Amazon EC2, see IAM policies for Amazon EC2 in the *Amazon EC2 User Guide*.
- Create a key pair and a security group.
- Select an Amazon Machine Image (AMI) and note the AMI ID. For more information, see Finding a Suitable AMI in the *Amazon EC2 User Guide*.

Launch your instance

To launch an Amazon EC2 instance using the AMI you selected, use the `aws ec2 run-instances` command. You can launch the instance into a virtual private cloud (VPC).

Initially, your instance appears in the `pending` state, but changes to the `running` state after a few minutes.

The following example shows how to launch a `t2.micro` instance in the specified subnet of a VPC. Replace the *`italicized`* parameter values with your own.

```
$ aws ec2 run-instances --image-id ami-xxxxxxxx --count 1 --instance-type t2.micro --
key-name MyKeyPair --security-group-ids sg-903004f8 --subnet-id subnet-6e7f829e
{
    "OwnerId": "123456789012",
    "ReservationId": "r-5875ca20",
    "Groups": [
        {
            "GroupName": "my-sg",
            "GroupId": "sg-903004f8"
        }
    ],
    "Instances": [
        {
            "Monitoring": {
                "State": "disabled"
            },
            "PublicDnsName": null,
            "Platform": "windows",
            "State": {
                "Code": 0,
                "Name": "pending"
            },

}
```

Add a block device to your instance

Each instance that you launch has an associated root device volume. You can use block device mapping to specify additional Amazon Elastic Block Store (Amazon EBS) volumes or instance store volumes to attach to an instance when it's launched.

To add a block device to your instance, specify the `--block-device-mappings` option when you use `run-instances`.

The following example parameter provisions a standard Amazon EBS volume that is 20 GB in size, and maps it to your instance using the identifier `/dev/sdf`.

```
--block-device-mappings "[{\"DeviceName\":\"/dev/sdf\",\"Ebs\":{\"VolumeSize\":20,
\"DeleteOnTermination\":false}}]"
```

The following example adds an Amazon EBS volume, mapped to `/dev/sdf`, based on an existing snapshot. A snapshot represents an image that is loaded onto the volume for you. When you specify a snapshot, you don't have to specify a volume size; it will be large enough to hold your image. However, if you do specify a size, it must be greater than or equal to the size of the snapshot.

```
--block-device-mappings "[{\"DeviceName\":\"/dev/sdf\",\"Ebs\":{\"SnapshotId\":\"snap-
a1b2c3d4\"}}]"
```

The following example adds two volumes to your instance. The number of volumes available to your instance depends on its instance type.

```
--block-device-mappings "[{\"DeviceName\":\"/dev/sdf\",\"VirtualName\":\"ephemeral0\"},
{\"DeviceName\":\"/dev/sdg\",\"VirtualName\":\"ephemeral1\"}]"
```

The following example creates the mapping (`/dev/sdj`), but doesn't provision a volume for the instance.

```
--block-device-mappings "[{\"DeviceName\":\"/dev/sdj\",\"NoDevice\":\"\"}]"
```

For more information, see Block Device Mapping in the *Amazon EC2 User Guide*.

Add a tag to your instance

A tag is a label that you assign to an Amazon resource. It enables you to add metadata to your resources that you can use for a variety of purposes. For more information, see Tagging Your Resources in the *Amazon EC2 User Guide*.

The following example shows how to add a tag with the key name "Name" and the value "MyInstance" to the specified instance, by using the `aws ec2 create-tags` command.

```
$ aws ec2 create-tags --resources i-5203422c --tags Key=Name,Value=MyInstance
```

Connect to your instance

When your instance is running, you can connect to it and use it just as you'd use a computer sitting in front of you. For more information, see Connect to Your Amazon EC2 Instance in the *Amazon EC2 User Guide*.

List your instances

You can use the Amazon CLI to list your instances and view information about them. You can list all your instances, or filter the results based on the instances that you're interested in.

The following examples show how to use the `aws ec2 describe-instances` command.

The following command lists all your instances.

```
$ aws ec2 describe-instances
```

The following command filters the list to only your `t2.micro` instances and outputs only the `InstanceId` values for each match.

```
$ aws ec2 describe-instances --filters "Name=instance-type,Values=t2.micro" --query
 "Reservations[].Instances[].InstanceId"
[
    "i-05e998023d9c69f9a"
]
```

The following command lists any of your instances that have the tag `Name=MyInstance`.

```
$ aws ec2 describe-instances --filters "Name=tag:Name,Values=MyInstance"
```

The following command lists your instances that were launched using any of the following AMIs: `ami-x0123456`, `ami-y0123456`, and `ami-z0123456`.

```
$ aws ec2 describe-instances --filters "Name=image-id,Values=ami-x0123456,ami-
y0123456,ami-z0123456"
```

Delete your instance

Terminating an instance deletes it. You can't reconnect to an instance after you've terminated it.

As soon as the state of the instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance. If you want to reconnect to an instance later, use stop-instances instead of `terminate-instances`. For more information, see Terminate Your Instance in the *Amazon EC2 User Guide*.

To delete an instance, you use the command `aws ec2 terminate-instances` to delete it.

```
$ aws ec2 terminate-instances --instance-ids i-5203422c
{
    "TerminatingInstances": [
        {
            "InstanceId": "i-5203422c",
            "CurrentState": {
                "Code": 32,
                "Name": "shutting-down"
            },
            "PreviousState": {
                "Code": 16,
                "Name": "running"
            }
        }
    ]
}
```

Change an Amazon EC2 instance type with a bash script in the Amazon CLI

This bash scripting example for Amazon EC2 changes the instance type for an Amazon EC2 instance using the Amazon Command Line Interface (Amazon CLI). It stops the instance if it's running, changes the instance type, and then, if requested, restarts the instance. Shell scripts are programs designed to run in a command line interface.

> **Note**
>
> For additional command examples, see the Amazon CLI reference guide.

Topics

- Before you start
- About this example
- Parameters
- Files
- References

Before you start

Before you can run any of the below examples, the following things need to be completed.

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- The profile that you use must have permissions that allow the Amazon operations performed by the examples.
- A running Amazon EC2 instance in the account for which you have permission to stop and modify. If you run the test script, it launches an instance for you, tests changing the type, and then terminates the instance.
- As an Amazon best practice, grant this code least privilege, or only the permissions required to perform a task. For more information, see Grant Least Privilege in the *Amazon Identity and Access Management (IAM) User Guide*.
- This code has not been tested in all Amazon Regions. Some Amazon services are available only in specific Regions. For more information, see Service Endpoints and Quotas in the *Amazon General Reference Guide*.

- Running this code can result in charges to your Amazon account. It is your responsibility to ensure that any resources created by this script are removed when you are done with them.

About this example

This example is written as a function in the shell script file `change_ec2_instance_type.sh` that you can `source` from another script or from the command line. Each script file contains comments describing each of the functions. Once the function is in memory, you can invoke it from the command line. For example, the following commands change the type of the specified instance to `t2.nano`:

```
$ source ./change_ec2_instance_type.sh
$ ./change_ec2_instance_type -i *instance-id* -t new-type
```

For the full example and downloadable script files, see Change Amazon EC2 Instance Type in the *Amazon Code Examples Repository* on *GitHub*.

Parameters

-i - *(string)* Specifies the instance ID to modify.

-t - *(string)* Specifies the Amazon EC2 instance type to switch to.

-r - *(switch)* By default, this is unset. If `-r` is set, restarts the instance after the type switch.

-f - *(switch)* By default, the script prompts the user to confirm shutting down the instance before making the switch. If `-f` is set, the function doesn't prompt the user before shutting down the instance to make the type switch

-v - *(switch)* By default, the script operates silently and displays output only in the event of an error. If `-v` is set, the function displays status throughout its operation.

Files

`change_ec2_instance_type.sh`

The main script file contains the `change_ec2_instance_type()` function that performs the following tasks:

- Verifies that the specified Amazon EC2 instance exists.
- Unless `-f` is selected, warns the user before stopping the instance.

- Changes the instance type
- If you set `-r`, restarts the instance and confirms that the instance is running

View the code for `change_ec2_instance_type.sh` on *GitHub*.

`test_change_ec2_instance_type.sh`

The file `test_change_ec2_instance_type.sh` script tests the various code paths for the `change_ec2_instance_type` function. If all steps in the test script work correctly, the test script removes all resources that it created.

You can run the test script with the following parameters:

- **-v** - *(switch)* The each test shows a pass/failure status as they run. By default, the tests runs silently and the output includes only the final overall pass/failure status.
- **-i** - *(switch)* The script pauses after each test to enable you to browse the intermediate results of each step. Enables you to examine the current status of the instance using the Amazon EC2 console. The script proceeds to the next step after you press *ENTER* at the prompt.

View the code for `test_change_ec2_instance_type.sh` on *GitHub*.

`awsdocs_general.sh`

The script file `awsdocs_general.sh` holds general purpose functions used across advanced examples for the Amazon CLI.

View the code for `awsdocs_general.sh` on *GitHub*.

Using Amazon S3 Glacier in the Amazon CLI

An introduction to Amazon S3 Glacier
Introduction to Amazon S3 Glacier

This topic shows examples of Amazon CLI commands that perform common tasks for S3 Glacier. The examples demonstrate how to use the Amazon CLI to upload a large file to S3 Glacier by splitting it into smaller parts and uploading them from the command line.

You can access Amazon S3 Glacier features using the Amazon Command Line Interface (Amazon CLI). To list the Amazon CLI commands for S3 Glacier, use the following command.

```
aws glacier help
```

> **Note**
>
> For command reference and additional examples, see `aws glacier` in the *Amazon CLI Command Reference*.

Topics

- Prerequisites
- Create an Amazon S3 Glacier vault
- Prepare a file for uploading
- Initiate a multipart upload and upload files
- Complete the upload

- Resources

Prerequisites

To run the `glacier` commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- This tutorial uses several command line tools that typically come preinstalled on Unix-like operating systems, including Linux and macOS. Windows users can use the same tools by installing Cygwin and running the commands from the Cygwin terminal. We note Windows native commands and utilities that perform the same functions where available.

Create an Amazon S3 Glacier vault

Create a vault with the `create-vault` command.

```
$ aws glacier create-vault --account-id - --vault-name myvault
{
    "location": "/123456789012/vaults/myvault"
}
```

> **Note**
>
> All S3 Glacier commands require an account ID parameter. Use the hyphen character (`--account-id -`) to use the current account.

Prepare a file for uploading

Create a file for the test upload. The following commands create a file named *`largefile`* that contains exactly 3 MiB of random data.

Linux or macOS

```
$ dd if=/dev/urandom of=largefile bs=3145728 count=1
1+0 records in
1+0 records out
```

```
3145728 bytes (3.1 MB) copied, 0.205813 s, 15.3 MB/s
```

dd is a utility that copies a number of bytes from an input file to an output file. The previous example uses the system device file `/dev/urandom` as a source of random data. `fsutil` performs a similar function in Windows.

Windows

```
C:\> fsutil file createnew largefile 3145728
File C:\temp\largefile is created
```

Next, split the file into 1 MiB (1,048,576 byte) chunks using a file splitter.

```
$ split -b 1048576 --verbose largefile chunk
creating file `chunkaa'
creating file `chunkab'
creating file `chunkac'
```

Initiate a multipart upload and upload files

Create a multipart upload in Amazon S3 Glacier by using the initiate-multipart-upload command.

```
$ aws glacier initiate-multipart-upload --account-id - --archive-description "multipart
 upload test" --part-size 1048576 --vault-name myvault
{
    "uploadId": "19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-
OssZtLqyFu7sY1_lR7vgFuJV6NtcV5zpsJ",
    "location": "/123456789012/vaults/myvault/multipart-
uploads/19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-
OssZtLqyFu7sY1_lR7vgFuJV6NtcV5zpsJ"
}
```

S3 Glacier requires the size of each part in bytes (1 MiB in this example), your vault name, and an account ID to configure the multipart upload. The Amazon CLI outputs an upload ID when the operation is complete. Save the upload ID to a shell variable for later use.

Linux or macOS

```
$ UPLOADID="19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-
OssZtLqyFu7sY1_lR7vgFuJV6NtcV5zpsJ"
```

Windows

```
C:\> set UPLOADID="19gaRezEXAMPLES6Ry5YYdqthHOC_kGRCT03L9yetr220UmPtBYKk-
OssZtLqyFu7sY1_lR7vgFuJV6NtcV5zpsJ"
```

Next, use the upload-multipart-part command to upload each of the three parts.

```
$ aws glacier upload-multipart-part --upload-id $UPLOADID --body chunkaa --range 'bytes
 0-1048575/*' --account-id - --vault-name myvault
{
    "checksum": "e1f2a7cd6e047fa606fe2f0280350f69b9f8cfa602097a9a026360a7edc1f553"
}
$ aws glacier upload-multipart-part --upload-id $UPLOADID --body chunkab --range 'bytes
 1048576-2097151/*' --account-id - --vault-name myvault
{
    "checksum": "e1f2a7cd6e047fa606fe2f0280350f69b9f8cfa602097a9a026360a7edc1f553"
}
$ aws glacier upload-multipart-part --upload-id $UPLOADID --body chunkac --range 'bytes
 2097152-3145727/*' --account-id - --vault-name myvault
{
    "checksum": "e1f2a7cd6e047fa606fe2f0280350f69b9f8cfa602097a9a026360a7edc1f553"
}
```

> **Note**
>
> The previous example uses the dollar sign ($) to reference the contents of the UPLOADID shell variable on Linux. On the Windows command line, use a percent sign (%) on either side of the variable name (for example, %UPLOADID%).

You must specify the byte range of each part when you upload it so that S3 Glacier can reassemble it in the correct order. Each piece is 1,048,576 bytes, so the first piece occupies bytes 0-1048575, the second 1048576-2097151, and the third 2097152-3145727.

Complete the upload

Amazon S3 Glacier requires a tree hash of the original file to confirm that all of the uploaded pieces reached Amazon intact.

To calculate a tree hash, you must split the file into 1 MiB parts and calculate a binary SHA-256 hash of each piece. Then you split the list of hashes into pairs, combine the two binary hashes in

each pair, and take hashes of the results. Repeat this process until there is only one hash left. If there is an odd number of hashes at any level, promote it to the next level without modifying it.

The key to calculating a tree hash correctly when using command line utilities is to store each hash in binary format and convert to hexadecimal only at the last step. Combining or hashing the hexadecimal version of any hash in the tree will cause an incorrect result.

> **Note**
>
> Windows users can use the `type` command in place of `cat`. OpenSSL is available for Windows at OpenSSL.org.

To calculate a tree hash

1. If you haven't already, split the original file into 1 MiB parts.

```
$ split --bytes=1048576 --verbose largefile chunk
creating file `chunkaa'
creating file `chunkab'
creating file `chunkac'
```

2. Calculate and store the binary SHA-256 hash of each chunk.

```
$ openssl dgst -sha256 -binary chunkaa > hash1
$ openssl dgst -sha256 -binary chunkab > hash2
$ openssl dgst -sha256 -binary chunkac > hash3
```

3. Combine the first two hashes and take the binary hash of the result.

```
$ cat hash1 hash2 > hash12
$ openssl dgst -sha256 -binary hash12 > hash12hash
```

4. Combine the parent hash of chunks `aa` and `ab` with the hash of chunk `ac` and hash the result, this time outputting hexadecimal. Store the result in a shell variable.

```
$ cat hash12hash hash3 > hash123
$ openssl dgst -sha256 hash123
SHA256(hash123)= 9628195fcdbcbbe76cdde932d4646fa7de5f219fb39823836d81f0cc0e18aa67
$ TREEHASH=9628195fcdbcbbe76cdde932d4646fa7de5f219fb39823836d81f0cc0e18aa67
```

Finally, complete the upload with the `complete-multipart-upload` command. This command takes the original file's size in bytes, the final tree hash value in hexadecimal, and your account ID and vault name.

```
$ aws glacier complete-multipart-upload --checksum $TREEHASH --archive-size 3145728 --
upload-id $UPLOADID --account-id - --vault-name myvault
{
    "archiveId": "d3AbWhE0YE1m6f_fI1jPG82F8xzbMEEZmrAlLGAAONJAzo5QdP-
N83MKqd96Unspoa5H5lItWX-sK8-QS0ZhwsyGiu9-R-
kwWUyS1dSBlmgPPWkEbeFfqDSav053rU7FvVLHfRc6hg",
    "checksum": "9628195fcdbcbbe76cdde932d4646fa7de5f219fb39823836d81f0cc0e18aa67",
    "location": "/123456789012/vaults/myvault/archives/
d3AbWhE0YE1m6f_fI1jPG82F8xzbMEEZmrAlLGAAONJAzo5QdP-N83MKqd96Unspoa5H5lItWX-sK8-
QS0ZhwsyGiu9-R-kwWUyS1dSBlmgPPWkEbeFfqDSav053rU7FvVLHfRc6hg"
}
```

You can also check the status of the vault using the `describe-vault` command.

```
$ aws glacier describe-vault --account-id - --vault-name myvault
{
    "SizeInBytes": 3178496,
    "VaultARN": "arn:aws-cn:glacier:us-west-2:123456789012:vaults/myvault",
    "LastInventoryDate": "2018-12-07T00:26:19.028Z",
    "NumberOfArchives": 1,
    "CreationDate": "2018-12-06T21:23:45.708Z",
    "VaultName": "myvault"
}
```

> **Note**
>
> Vault status is updated about once per day. See Working with Vaults for more information.

Now it's safe to remove the chunk and hash files that you created.

```
$ rm chunk* hash*
```

For more information on multipart uploads, see Uploading Large Archives in Parts and Computing Checksums in the *Amazon S3 Glacier Developer Guide*.

Using IAM in the Amazon CLI

An introduction to Amazon Identity and Access Management
Introduction to Amazon Identity and Access Management

You can access the features of Amazon Identity and Access Management (IAM) using the Amazon Command Line Interface (Amazon CLI). To list the Amazon CLI commands for IAM, use the following command.

```
aws iam help
```

This topic shows examples of Amazon CLI commands that perform common tasks for IAM.

Before you run any commands, set your default credentials. For more information, see Configuring settings for the Amazon CLI.

For more information on the IAM service, see the Amazon Identity and Access Management User Guide.

Topics

- Creating IAM users and groups
- Attaching an IAM managed policy to a user
- Setting an initial password for an IAM user
- Creating an access key for an IAM user

Creating IAM users and groups

To create a group and add a new user to it

1. Use the `create-group` command to create the group.

```
$ aws iam create-group --group-name MyIamGroup
{
    "Group": {
        "GroupName": "MyIamGroup",
        "CreateDate": "2018-12-14T03:03:52.834Z",
        "GroupId": "AGPAJNUJ2W4IJVEXAMPLE",
        "Arn": "arn:aws-cn:iam::123456789012:group/MyIamGroup",
        "Path": "/"
    }
}
```

2. Use the `create-user` command to create the user.

```
$ aws iam create-user --user-name MyUser
{
    "User": {
        "UserName": "MyUser",
        "Path": "/",
        "CreateDate": "2018-12-14T03:13:02.581Z",
        "UserId": "AIDAJY2PE5XUZ4EXAMPLE",
        "Arn": "arn:aws-cn:iam::123456789012:user/MyUser"
    }
}
```

3. Use the `add-user-to-group` command to add the user to the group.

```
$ aws iam add-user-to-group --user-name MyUser --group-name MyIamGroup
```

4. To verify that the `MyIamGroup` group contains the `MyUser`, use the `get-group` command.

```
$ aws iam get-group --group-name MyIamGroup
{
    "Group": {
        "GroupName": "MyIamGroup",
        "CreateDate": "2018-12-14T03:03:52Z",
        "GroupId": "AGPAJNUJ2W4IJVEXAMPLE",
        "Arn": "arn:aws-cn:iam::123456789012:group/MyIamGroup",
        "Path": "/"
    },
    "Users": [
        {
            "UserName": "MyUser",
            "Path": "/",
            "CreateDate": "2018-12-14T03:13:02Z",
            "UserId": "AIDAJY2PE5XUZ4EXAMPLE",
            "Arn": "arn:aws-cn:iam::123456789012:user/MyUser"
        }
    ],
    "IsTruncated": "false"
}
```

Attaching an IAM managed policy to a user

The policy in this example provides the user with "Power User Access".

To attach an IAM managed policy to a user

1. Determine the Amazon Resource Name (ARN) of the policy to attach. The following command uses `list-policies` to find the ARN of the policy with the name `PowerUserAccess`. It then stores that ARN in an environment variable.

```
$ export POLICYARN=$(aws iam list-policies --query 'Policies[?
PolicyName==`PowerUserAccess`].{ARN:Arn}' --output text)       ~
$ echo $POLICYARN
arn:aws-cn:iam::aws:policy/PowerUserAccess
```

2. To attach the policy, use the `attach-user-policyattach-user-policy` command, and reference the environment variable that holds the policy ARN.

```
$ aws iam attach-user-policy --user-name MyUser --policy-arn $POLICYARN
```

3. Verify that the policy is attached to the user by running the `list-attached-user-policies` command.

```
$ aws iam list-attached-user-policies --user-name MyUser
{
    "AttachedPolicies": [
        {
            "PolicyName": "PowerUserAccess",
            "PolicyArn": "arn:aws-cn:iam::aws:policy/PowerUserAccess"
        }
    ]
}
```

For more information, see Access Management Resources. This topic provides links to an overview of permissions and policies, and links to examples of policies for accessing Amazon S3, Amazon EC2, and other services.

Setting an initial password for an IAM user

The following command uses `create-login-profile` to set an initial password on the specified user. When the user signs in for the first time, the user is required to change the password to something that only the user knows.

```
$ aws iam create-login-profile --user-name MyUser --password My!User1Login8P@ssword --
password-reset-required
{
    "LoginProfile": {
        "UserName": "MyUser",
        "CreateDate": "2018-12-14T17:27:18Z",
        "PasswordResetRequired": true
    }
}
```

You can use the `update-login-profile` command to *change* the password for a user.

```
$ aws iam update-login-profile --user-name MyUser --password My!User1ADifferentP@ssword
```

Creating an access key for an IAM user

You can use the create-access-key command to create an access key for a user. An access key is a set of security credentials that consists of an access key ID and a secret key.

A user can create only two access keys at one time. If you try to create a third set, the command returns a LimitExceeded error.

```
$ aws iam create-access-key --user-name MyUser
{
    "AccessKey": {
        "UserName": "MyUser",
        "AccessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "Status": "Active",
        "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
        "CreateDate": "2018-12-14T17:34:16Z"
    }
}
```

Use the delete-access-key command to delete an access key for a user. Specify which access key to delete by using the access key ID.

```
$ aws iam delete-access-key --user-name MyUser --access-key-id AKIAIOSFODNN7EXAMPLE
```

Using Amazon S3 in the Amazon CLI

An introduction to Amazon Simple Storage Service (Amazon S3)

Introduction to Amazon Simple Storage Service (Amazon S3 - Cloud Storage on Amazon

You can access the features of Amazon Simple Storage Service (Amazon S3) using the Amazon Command Line Interface (Amazon CLI). Amazon S3 is a highly scalable and durable object storage service. Amazon S3 is designed to provide virtually unlimited storage capacity, making it an ideal solution for a wide range of data storage and management needs.

Amazon S3 allows you to store and retrieve any amount of data, from small files to large datasets, in the form of objects. Each object is stored in a container called a bucket, which can be accessed and managed through the Amazon Web Services Management Console or programatically through the Amazon SDKs, tools, and Amazon CLI.

Including basic storage, Amazon S3 also offers a range of features including lifecycle management, versioning, scalability, and security. These integrate with other Amazon Web Services services enabling you to build cloud-based solutions that scale to your needs.

The Amazon CLI provides two tiers of commands for accessing Amazon S3:

- **s3** – Custom high-level commands made specifically for the Amazon CLI that simplify performing common tasks, such as creating, manipulating, deleting, and syncing objects and buckets.
- **s3api** – Exposes direct access to all Amazon S3 API operations which enables you to carry out advanced operations.

Topics in this guide:

- Using high-level (s3) commands in the Amazon CLI
- Using API-Level (s3api) commands in the Amazon CLI
- Scripting example for the Amazon S3 bucket lifecycle in the Amazon CLI

Using high-level (s3) commands in the Amazon CLI

This topic describes some of the commands you can use to manage Amazon S3 buckets and objects using the `aws s3` commands in the Amazon CLI. For commands not covered in this topic and additional command examples, see the `aws s3` commands in the *Amazon CLI Reference*.

The high-level `aws s3` commands simplify managing Amazon S3 objects. These commands enable you to manage the contents of Amazon S3 within itself and with local directories.

Topics

- Prerequisites
- Before you start
- Create a bucket
- List buckets and objects
- Delete buckets
- Delete objects
- Move objects
- Copy objects
- Sync objects

- Frequently used options for s3 commands
- Resources

Prerequisites

To run the `s3` commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- The profile that you use must have permissions that allow the Amazon operations performed by the examples.
- Understand these Amazon S3 terms:
  - **Bucket** – A top-level Amazon S3 folder.
  - **Prefix** – An Amazon S3 folder in a bucket.
  - **Object** – Any item that's hosted in an Amazon S3 bucket.

Before you start

This section describes a few things to note before you use `aws s3` commands.

Large object uploads

When you use `aws s3` commands to upload large objects to an Amazon S3 bucket, the Amazon CLI automatically performs a multipart upload. You can't resume a failed upload when using these `aws s3` commands.

If the multipart upload fails due to a timeout, or if you manually canceled in the Amazon CLI, the Amazon CLI stops the upload and cleans up any files that were created. This process can take several minutes.

If the multipart upload or cleanup process is canceled by a kill command or system failure, the created files remain in the Amazon S3 bucket. To clean up the multipart upload, use the s3api abort-multipart-upload command.

File properties and tags in multipart copies

When you use the Amazon CLI version 1 version of commands in the `aws s3` namespace to copy a file from one Amazon S3 bucket location to another Amazon S3 bucket location, and

that operation uses multipart copy, no file properties from the source object are copied to the destination object.

Create a bucket

Use the `s3 mb` command to make a bucket. Bucket names must be ***globally*** unique (unique across all of Amazon S3) and should be DNS compliant.

Bucket names can contain lowercase letters, numbers, hyphens, and periods. Bucket names can start and end only with a letter or number, and cannot contain a period next to a hyphen or another period.

Syntax

```
$ aws s3 mb <target> [--options]
```

s3 mb examples

The following example creates the `s3://amzn-s3-demo-bucket` bucket.

```
$ aws s3 mb s3://amzn-s3-demo-bucket
```

List buckets and objects

To list your buckets, folders, or objects, use the `s3 ls` command. Using the command without a target or options lists all buckets.

Syntax

```
$ aws s3 ls <target> [--options]
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of available options, see `s3 ls` in the *Amazon CLI Command Reference*.

s3 ls examples

The following example lists all of your Amazon S3 buckets.

```
$ aws s3 ls
2018-12-11 17:08:50 amzn-s3-demo-bucket1
2018-12-14 14:55:44 amzn-s3-demo-bucket2
```

The following command lists all objects and prefixes in a bucket. In this example output, the prefix `example/` has one file named `MyFile1.txt`.

```
$ aws s3 ls s3://amzn-s3-demo-bucket
                           PRE example/
2018-12-04 19:05:48          3 MyFile1.txt
```

You can filter the output to a specific prefix by including it in the command. The following command lists the objects in *bucket-name/example/* (that is, objects in *bucket-name* filtered by the prefix *example/*).

```
$ aws s3 ls s3://amzn-s3-demo-bucket/example/
2018-12-06 18:59:32          3 MyFile1.txt
```

To display only the buckets and objects in a specific region, use the `--region` options

```
$ aws s3 ls --region us-east-2
2018-12-06 18:59:32          3 MyFile1.txt
```

If you have a large list of buckets and objects, you can paginated the results using the `--max-items` or `--page-size` options. The `--max-items` option limits how many total buckets and objects are returned in a call and the `--page-size` option limits how many of those are listed on a page.

```
$ aws s3 ls --max-items 100 --page-size 10
```

For more information on pagination, see the section called "--page-size" and the section called "--max-items".

Delete buckets

To delete a bucket, use the `s3 rb` command.

Syntax

```
$ aws s3 rb <target> [--options]
```

s3 rb examples

The following example removes the `s3://amzn-s3-demo-bucket` bucket.

```
$ aws s3 rb s3://amzn-s3-demo-bucket
```

By default, the bucket must be empty for the operation to succeed. To remove a bucket that's not empty, you need to include the `--force` option. If you're using a versioned bucket that contains previously deleted—but retained—objects, this command does *not* allow you to remove the bucket. You must first remove all of the content.

The following example deletes all objects and prefixes in the bucket, and then deletes the bucket.

```
$ aws s3 rb s3://amzn-s3-demo-bucket --force
```

Delete objects

To delete objects in a bucket or your local directory, use the `s3 rm` command.

Syntax

```
$ aws s3 rm  <target> [--options]
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of options, see `s3 rm` in the *Amazon CLI Command Reference*.

s3 rm examples

The following example deletes `filename.txt` from `s3://amzn-s3-demo-bucket/example`.

```
$ aws s3 rm s3://amzn-s3-demo-bucket/example/filename.txt
```

The following example deletes all objects from `s3://amzn-s3-demo-bucket/example` using the `--recursive` option.

```
$ aws s3 rm s3://amzn-s3-demo-bucket/example --recursive
```

Move objects

Use the `s3 mv` command to move objects from a bucket or a local directory. The `s3 mv` command copies the source object or file to the specified destination and then deletes the source object or file.

Syntax

```
$ aws s3 mv <source> <target> [--options]
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of available options, see `s3 mv` in the *Amazon CLI Command Reference*.

> **Warning**
>
> If you are using any type of access point ARNs or access point aliases in your Amazon S3 source or destination URIs, you must take extra care that your source and destination Amazon S3 URIs resolve to different underlying buckets. If the source and destination buckets are the same, the source file or object can be moved onto itself, which can result in accidental deletion of your source file or object. To verify that the source and destination buckets are not the same, use the `--validate-same-s3-paths` parameter, or set the environment variable `AWS_CLI_S3_MV_VALIDATE_SAME_S3_PATHS` to `true`.

s3 mv examples

The following example moves all objects from `s3://amzn-s3-demo-bucket/example` to `s3://amzn-s3-demo-bucket/`.

```
$ aws s3 mv s3://amzn-s3-demo-bucket/example s3://amzn-s3-demo-bucket/
```

The following example moves a local file from your current working directory to the Amazon S3 bucket with the `s3 mv` command.

```
$ aws s3 mv filename.txt s3://amzn-s3-demo-bucket
```

The following example moves a file from your Amazon S3 bucket to your current working directory, where `./` specifies your current working directory.

```
$ aws s3 mv s3://amzn-s3-demo-bucket/filename.txt ./
```

Copy objects

Use the `s3 cp` command to copy objects from a bucket or a local directory.

Syntax

```
$ aws s3 cp <source> <target> [--options]
```

You can use the dash parameter for file streaming to standard input (`stdin`) or standard output (`stdout`).

> **Warning**
>
> If you're using PowerShell, the shell might alter the encoding of a CRLF or add a CRLF to piped input or output, or redirected output.

The `s3 cp` command uses the following syntax to upload a file stream from `stdin` to a specified bucket.

Syntax

```
$ aws s3 cp - <target> [--options]
```

The `s3 cp` command uses the following syntax to download an Amazon S3 file stream for `stdout`.

Syntax

```
$ aws s3 cp <target> [--options] -
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For the complete list of options, see `s3 cp` in the *Amazon CLI Command Reference*.

`s3 cp` examples

The following example copies all objects from `s3://amzn-s3-demo-bucket/example` to `s3://amzn-s3-demo-bucket/`.

```
$ aws s3 cp s3://amzn-s3-demo-bucket/example s3://amzn-s3-demo-bucket/
```

The following example copies a local file from your current working directory to the Amazon S3 bucket with the `s3 cp` command.

```
$ aws s3 cp filename.txt s3://amzn-s3-demo-bucket
```

The following example copies a file from your Amazon S3 bucket to your current working directory, where `./` specifies your current working directory.

```
$ aws s3 cp s3://amzn-s3-demo-bucket/filename.txt ./
```

The following example uses echo to stream the text "hello world" to the `s3://bucket-name/filename.txt` file.

```
$ echo "hello world" | aws s3 cp - s3://amzn-s3-demo-bucket/filename.txt
```

The following example streams the `s3://amzn-s3-demo-bucket/filename.txt` file to `stdout` and prints the contents to the console.

```
$ aws s3 cp s3://amzn-s3-demo-bucket/filename.txt -
hello world
```

The following example streams the contents of `s3://bucket-name/pre` to `stdout`, uses the `bzip2` command to compress the files, and uploads the new compressed file named `key.bz2` to `s3://bucket-name`.

```
$ aws s3 cp s3://amzn-s3-demo-bucket/pre - | bzip2 --best | aws s3 cp - s3://amzn-s3-demo-bucket/key.bz2
```

Sync objects

The `s3 sync` command synchronizes the contents of a bucket and a directory, or the contents of two buckets. Typically, `s3 sync` copies missing or outdated files or objects between the source and target. However, you can also supply the `--delete` option to remove files or objects from the target that are not present in the source.

Syntax

```
$ aws s3 sync <source> <target> [--options]
```

For a few common options to use with this command, and examples, see Frequently used options for s3 commands. For a complete list of options, see `s3 sync` in the *Amazon CLI Command Reference*.

s3 sync examples

The following example synchronizes the contents of an Amazon S3 prefix named *path* in the bucket named *amzn-s3-demo-bucket* with the current working directory.

`s3 sync` updates any files that have a size or modified time that are different from files with the same name at the destination. The output displays specific operations performed during the sync. Notice that the operation recursively synchronizes the subdirectory `MySubdirectory` and its contents with `s3://amzn-s3-demo-bucket/path/MySubdirectory`.

```
$ aws s3 sync . s3://amzn-s3-demo-bucket/path
upload: MySubdirectory\MyFile3.txt to s3://amzn-s3-demo-bucket/path/MySubdirectory/
MyFile3.txt
upload: MyFile2.txt to s3://amzn-s3-demo-bucket/path/MyFile2.txt
upload: MyFile1.txt to s3://amzn-s3-demo-bucket/path/MyFile1.txt
```

The following example, which extends the previous one, shows how to use the `--delete` option.

```
// Delete local file
$ rm ./MyFile1.txt

// Attempt sync without --delete option - nothing happens
$ aws s3 sync . s3://amzn-s3-demo-bucket/path

// Sync with deletion - object is deleted from bucket
$ aws s3 sync . s3://amzn-s3-demo-bucket/path --delete
delete: s3://amzn-s3-demo-bucket/path/MyFile1.txt

// Delete object from bucket
$ aws s3 rm s3://amzn-s3-demo-bucket/path/MySubdirectory/MyFile3.txt
delete: s3://amzn-s3-demo-bucket/path/MySubdirectory/MyFile3.txt

// Sync with deletion - local file is deleted
$ aws s3 sync s3://amzn-s3-demo-bucket/path . --delete
delete: MySubdirectory\MyFile3.txt

// Sync with Infrequent Access storage class
$ aws s3 sync . s3://amzn-s3-demo-bucket/path --storage-class STANDARD_IA
```

When using the `--delete` option, the `--exclude` and `--include` options can filter files or objects to delete during an `s3 sync` operation. In this case, the parameter string must specify

files to exclude from, or include for, deletion in the context of the target directory or bucket. The following shows an example.

```
Assume local directory and s3://amzn-s3-demo-bucket/path currently in sync and each
 contains 3 files:
MyFile1.txt
MyFile2.rtf
MyFile88.txt
'''

// Sync with delete, excluding files that match a pattern. MyFile88.txt is deleted,
 while remote MyFile1.txt is not.
$ aws s3 sync . s3://amzn-s3-demo-bucket/path --delete --exclude "path/MyFile?.txt"
delete: s3://amzn-s3-demo-bucket/path/MyFile88.txt
'''

// Sync with delete, excluding MyFile2.rtf - local file is NOT deleted
$ aws s3 sync s3://amzn-s3-demo-bucket/path . --delete --exclude "./MyFile2.rtf"
download: s3://amzn-s3-demo-bucket/path/MyFile1.txt to MyFile1.txt
'''

// Sync with delete, local copy of MyFile2.rtf is deleted
$ aws s3 sync s3://amzn-s3-demo-bucket/path . --delete
delete: MyFile2.rtf
```

Frequently used options for s3 commands

The following options are frequently used for the commands described in this topic. For a complete list of options you can use on a command, see the specific command in the Amazon CLI reference guide.

acl

`s3 sync` and `s3 cp` can use the `--acl` option. This enables you to set the access permissions for files copied to Amazon S3. The `--acl` option accepts `private`, `public-read`, and `public-read-write` values. For more information, see Canned ACL in the *Amazon S3 User Guide*.

```
$ aws s3 sync . s3://amzn-s3-demo-bucket/path --acl public-read
```

exclude

When you use the `s3 cp`, `s3 mv`, `s3 sync`, or `s3 rm` command, you can filter the results by using the `--exclude` or `--include` option. The `--exclude` option sets rules to only exclude objects from the command, and the options apply in the order specified. This is shown in the following example.

```
Local directory contains 3 files:
MyFile1.txt
MyFile2.rtf
MyFile88.txt

// Exclude all .txt files, resulting in only MyFile2.rtf being copied
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --exclude "*.txt"

// Exclude all .txt files but include all files with the "MyFile*.txt" format,
 resulting in, MyFile1.txt, MyFile2.rtf, MyFile88.txt being copied
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --exclude "*.txt" --include
 "MyFile*.txt"

// Exclude all .txt files, but include all files with the "MyFile*.txt" format,
 but exclude all files with the "MyFile?.txt" format resulting in, MyFile2.rtf and
 MyFile88.txt being copied
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --exclude "*.txt" --include
 "MyFile*.txt" --exclude "MyFile?.txt"
```

include

When you use the `s3 cp`, `s3 mv`, `s3 sync`, or `s3 rm` command, you can filter the results using the `--exclude` or `--include` option. The `--include` option sets rules to only include objects specified for the command, and the options apply in the order specified. This is shown in the following example.

```
Local directory contains 3 files:
MyFile1.txt
MyFile2.rtf
MyFile88.txt

// Include all .txt files, resulting in MyFile1.txt and MyFile88.txt being copied
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --include "*.txt"
```

```
// Include all .txt files but exclude all files with the "MyFile*.txt" format,
 resulting in no files being copied
$ aws s3 cp . s3://amzn-s3-demo-bucket/path --include "*.txt" --exclude
 "MyFile*.txt"

// Include all .txt files, but exclude all files with the "MyFile*.txt" format, but
 include all files with the "MyFile?.txt" format resulting in MyFile1.txt being
 copied

$ aws s3 cp . s3://amzn-s3-demo-bucket/path --include "*.txt" --exclude
 "MyFile*.txt" --include "MyFile?.txt"
```

grant

The `s3 cp`, `s3 mv`, and `s3 sync` commands include a `--grants` option that you can use to grant permissions on the object to specified users or groups. Set the `--grants` option to a list of permissions using the following syntax. Replace `Permission`, `Grantee_Type`, and `Grantee_ID` with your own values.

Syntax

```
--grants Permission=Grantee_Type=Grantee_ID
         [Permission=Grantee_Type=Grantee_ID ...]
```

Each value contains the following elements:

- *`Permission`* – Specifies the granted permissions. Can be set to `read`, `readacl`, `writeacl`, or `full`.
- *`Grantee_Type`* – Specifies how to identify the grantee. Can be set to `uri`, `emailaddress`, or `id`.
- *`Grantee_ID`* – Specifies the grantee based on *`Grantee_Type`*.
  - `uri` – The group's URI. For more information, see Who is a grantee?
  - `emailaddress` – The account's email address.
  - `id` – The account's canonical ID.

For more information about Amazon S3 access control, see Access control.

The following example copies an object into a bucket. It grants `read` permissions on the object to everyone, and `full` permissions (`read`, `readacl`, and `writeacl`) to the account associated with `user@example.com`.

```
$ aws s3 cp file.txt s3://amzn-s3-demo-bucket/ --grants read=uri=http://
acs.amazonaws.com.cn/groups/global/AllUsers full=emailaddress=user@example.com
```

You can also specify a nondefault storage class (`REDUCED_REDUNDANCY` or `STANDARD_IA`) for objects that you upload to Amazon S3. To do this, use the `--storage-class` option.

```
$ aws s3 cp file.txt s3://amzn-s3-demo-bucket/ --storage-class REDUCED_REDUNDANCY
```

recursive

When you use this option, the command is performed on all files or objects under the specified directory or prefix. The following example deletes `s3://amzn-s3-demo-bucket/path` and all of its contents.

```
$ aws s3 rm s3://amzn-s3-demo-bucket/path --recursive
```

- Abort multipart uploads to an S3 bucket using the Amazon SDK for .NET (low-level) in the *Amazon S3 User Guide*

Using API-Level (s3api) commands in the Amazon CLI

The API-level commands (contained in the `s3api` command set) provide direct access to the Amazon Simple Storage Service (Amazon S3) APIs, and enable some operations that are not exposed in the high-level `s3` commands. These commands are the equivalent of the other Amazon services that provide API-level access to the services' functionality. For more information on the `s3` commands, see Using high-level (s3) commands in the Amazon CLI

This topic provides examples that demonstrate how to use the lower-level commands that map to the Amazon S3 APIs. In addition, you can find examples for each S3 API command in the `s3api` section of the Amazon CLI reference guide.

Topics

- Prerequisites
- Apply a custom ACL
- Configure a logging policy
- Resources

Prerequisites

To run the `s3api` commands, you need to:

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- The profile that you use must have permissions that allow the Amazon operations performed by the examples.
- Understand these Amazon S3 terms:
  - **Bucket** – A top-level Amazon S3 folder.
  - **Prefix** – An Amazon S3 folder in a bucket.
  - **Object** – Any item that's hosted in an Amazon S3 bucket.

Apply a custom ACL

With high-level commands, you can use the `--acl` option to apply predefined access control lists (ACLs) to Amazon S3 objects. But you can't use that command to set bucket-wide ACLs. However, you can do this by using the `put-bucket-acl` API-level command.

The following example shows how to grant full control to two Amazon users (*user1@example.com* and *user2@example.com*) and read permission to everyone. The identifier for "everyone" comes from a special URI that you pass as a parameter.

```
$ aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --grant-full-control
 'emailaddress="user1@example.com",emailaddress="user2@example.com"' --grant-read
 'uri="http://acs.amazonaws.com.cn/groups/global/AllUsers"'
```

For details about how to construct the ACLs, see PUT Bucket acl in the *Amazon Simple Storage Service API Reference*. The `s3api` ACL commands in the CLI, such as `put-bucket-acl`, use the same shorthand argument notation.

Configure a logging policy

The API command `put-bucket-logging` configures a bucket logging policy.

In the following example, the Amazon user *user@example.com* is granted full control over the log files, and all users have read access to them. Notice that the `put-bucket-acl` command is also required to grant the Amazon S3 log delivery system (specified by a URI) the permissions needed to read and write the logs to the bucket.

```
$ aws s3api put-bucket-acl --bucket amzn-s3-demo-bucket --grant-read-acp
 'URI="http://acs.amazonaws.com.cn/groups/s3/LogDelivery"' --grant-write 'URI="http://
acs.amazonaws.com.cn/groups/s3/LogDelivery"'
$ aws s3api put-bucket-logging --bucket amzn-s3-demo-bucket --bucket-logging-status
 file://logging.json
```

The `logging.json` file in the previous command has the following content.

```
{
  "LoggingEnabled": {
    "TargetBucket": "amzn-s3-demo-bucket",
    "TargetPrefix": "amzn-s3-demo-bucketLogs/",
    "TargetGrants": [
```

```
      {
        "Grantee": {
          "Type": "AmazonCustomerByEmail",
          "EmailAddress": "user@example.com"
        },
        "Permission": "FULL_CONTROL"
      },
      {
        "Grantee": {
          "Type": "Group",
          "URI": "http://acs.amazonaws.com.cn/groups/global/AllUsers"
        },
        "Permission": "READ"
      }
    ]
  }
}
```

Scripting example for the Amazon S3 bucket lifecycle in the Amazon CLI

This topic uses a bash scripting example for Amazon S3 bucket lifecycle operations using the Amazon Command Line Interface (Amazon CLI). This scripting example uses the `aws s3api` set of commands. Shell scripts are programs designed to run in a command line interface.

Topics

- About this example
- Files
- References

Before you start

Before you can run any of the below examples, the following things need to be completed.

- Install and configure the Amazon CLI. For more information, see *Install the Amazon CLI* and Authentication and access credentials for the Amazon CLI.
- The profile that you use must have permissions that allow the Amazon operations performed by the examples.

- As an Amazon best practice, grant this code least privilege, or only the permissions required to perform a task. For more information, see Grant Least Privilege in the *IAM User Guide*.
- This code has not been tested in all Amazon Regions. Some Amazon services are available only in specific Regions. For more information, see Service Endpoints and Quotas in the *Amazon General Reference Guide*.
- Running this code can result in charges to your Amazon account. It is your responsibility to ensure that any resources created by this script are removed when you are done with them.

The Amazon S3 service uses the following terms:

- Bucket — A top level Amazon S3 folder.
- Prefix — An Amazon S3 folder in a bucket.
- Object — Any item hosted in an Amazon S3 bucket.

About this example

This example demonstrates how to interact with some of the basic Amazon S3 operations using a set of functions in shell script files. The functions are located in the shell script file named `bucket-operations.sh`. You can call these functions in another file. Each script file contains comments describing each of the functions.

To see the intermediate results of each step, run the script with a `-i` parameter. You can view the current status of the bucket or its contents using the Amazon S3 console. The script only proceeds to the next step when you press **enter** at the prompt.

For the full example and downloadable script files, see Amazon S3 Bucket Lifecycle Operations in the *Amazon Code Examples Repository* on *GitHub*.

Files

The example contains the following files:

bucket-operations.sh

This main script file can be sourced from another file. It includes functions that perform the following tasks:

- Creating a bucket and verifying that it exists
- Copying a file from the local computer to a bucket
- Copying a file from one bucket location to a different bucket location
- Listing the contents of a bucket
- Deleting a file from a bucket
- Deleting a bucket

View the code for `bucket-operations.sh` on *GitHub*.

test-bucket-operations.sh

The shell script file `test-bucket-operations.sh` demonstrates how to call the functions by sourcing the `bucket-operations.sh` file and calling each of the functions. After calling functions, the test script removes all resources that it created.

View the code for `test-bucket-operations.sh` on *GitHub*.

awsdocs-general.sh

The script file `awsdocs-general.sh` holds general purpose functions used across advanced code examples for the Amazon CLI.

View the code for `awsdocs-general.sh` on *GitHub*.

Accessing Amazon SNS in the Amazon CLI

You can access the features of Amazon Simple Notification Service (Amazon SNS) using the Amazon Command Line Interface (Amazon CLI). To list the Amazon CLI commands for Amazon SNS, use the following command.

```
aws sns help
```

Before you run any commands, set your default credentials. For more information, see Configuring settings for the Amazon CLI.

This topic shows examples of Amazon CLI commands that perform common tasks for Amazon SNS.

Topics

- Create a topic

- Subscribe to a topic
- Publish to a topic
- Unsubscribe from a topic
- Delete a topic

Create a topic

To create a topic, use the `sns create-topic` command and specify the name to assign to the topic.

```
$ aws sns create-topic --name my-topic
{
    "TopicArn": "arn:aws-cn:sns:us-west-2:123456789012:my-topic"
}
```

Make a note of the response's `TopicArn`, which you use later to publish a message.

Subscribe to a topic

To subscribe to a topic, use the `sns subscribe` command.

The following example specifies the `email` protocol and an email address for the `notification-endpoint`.

```
$ aws sns subscribe --topic-arn arn:aws-cn:sns:us-west-2:123456789012:my-topic --
protocol email --notification-endpoint saanvi@example.com
{
    "SubscriptionArn": "pending confirmation"
}
```

Amazon immediately sends a confirmation message by email to the address you specified in the `subscribe` command. The email message has the following text.

```
You have chosen to subscribe to the topic:
arn:aws-cn:sns:us-west-2:123456789012:my-topic
To confirm this subscription, click or visit the following link (If this was in error
 no action is necessary):
Confirm subscription
```

After the recipient clicks the **Confirm subscription** link, the recipient's browser displays a notification message with information similar to the following.

```
Subscription confirmed!

You have subscribed saanvi@example.com to the topic:my-topic.

Your subscription's id is:
arn:aws-cn:sns:us-west-2:123456789012:my-topic:1328f057-de93-4c15-512e-8bb22EXAMPLE

If it was not your intention to subscribe, click here to unsubscribe.
```

Publish to a topic

To send a message to all subscribers of a topic, use the `sns publish` command.

The following example sends the message "Hello World!" to all subscribers of the specified topic.

```
$ aws sns publish --topic-arn arn:aws-cn:sns:us-west-2:123456789012:my-topic --
message "Hello World!"
{
    "MessageId": "4e41661d-5eec-5ddf-8dab-2c867EXAMPLE"
}
```

In this example, Amazon sends an email message with the text "Hello World!" to `saanvi@example.com`.

Unsubscribe from a topic

To unsubscribe from a topic and stop receiving messages published to that topic, use the `sns unsubscribe` command and specify the ARN of the topic you want to unsubscribe from.

```
$ aws sns unsubscribe --subscription-arn arn:aws-cn:sns:us-west-2:123456789012:my-
topic:1328f057-de93-4c15-512e-8bb22EXAMPLE
```

To verify that you successfully unsubscribed, use the `sns list-subscriptions` command to confirm that the ARN no longer appears in the list.

```
$ aws sns list-subscriptions
```

Delete a topic

To delete a topic, run the `sns delete-topic` command.

```
$ aws sns delete-topic --topic-arn arn:aws-cn:sns:us-west-2:123456789012:my-topic
```

To verify that Amazon successfully deleted the topic, use the `sns list-topics` command to confirm that the topic no longer appears in the list.

```
$ aws sns list-topics
```

Amazon CLI command examples

The code examples in this topic show you how to use the Amazon Command Line Interface with Amazon.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

Some services contain additional example categories that show how to leverage libraries or functions specific to the service.

ACM examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with ACM.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`add-tags-to-certificate`

The following code example shows how to use `add-tags-to-certificate`.

Amazon CLI

To add tags to an existing ACM Certificate

The following `add-tags-to-certificate` command adds two tags to the specified certificate. Use a space to separate multiple tags:

```
aws acm add-tags-to-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
tags Key=Admin,Value=Alice Key=Purpose,Value=Website
```

- For API details, see AddTagsToCertificate in *Amazon CLI Command Reference*.

`delete-certificate`

The following code example shows how to use `delete-certificate`.

Amazon CLI

To delete an ACM certificate from your account

The following `delete-certificate` command deletes the certificate with the specified ARN:

```
aws acm delete-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

- For API details, see DeleteCertificate in *Amazon CLI Command Reference*.

`describe-certificate`

The following code example shows how to use `describe-certificate`.

Amazon CLI

To retrieve the fields contained in an ACM certificate

The following `describe-certificate` command retrieves all of the fields for the certificate with the specified ARN:

```
aws acm describe-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

Output similar to the following is displayed:

```
{
  "Certificate": {
    "CertificateArn":
 "arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012",
    "CreatedAt": 1446835267.0,
    "DomainName": "www.example.com",
    "DomainValidationOptions": [

      "www.example.net"
    ]
  }
}
```

- For API details, see DescribeCertificate in *Amazon CLI Command Reference*.

`export-certificate`

The following code example shows how to use `export-certificate`.

Amazon CLI

To export a private certificate issued by a private CA.

The following `export-certificate` command exports a private certificate, certificate chain, and private key to your display:

```
aws acm export-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
passphrase file://path-to-passphrase-file
```

To export the certificate, chain, and private key to a local file, use the following command:

```
aws acm export-certificate --certificate-
arn arn:aws:acm:region:sccount:certificate/12345678-1234-1234-1234-123456789012 --
passphrase file://path-to-passphrase-file > c:\temp\export.txt
```

- For API details, see ExportCertificate in *Amazon CLI Command Reference*.

`get-certificate`

The following code example shows how to use `get-certificate`.

Amazon CLI

To retrieve an ACM certificate

The following `get-certificate` command retrieves the certificate for the specified ARN and the certificate chain:

```
aws acm get-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

Output similar to the following is displayed:

```

-----END CERTIFICATE-----"
}
```

- For API details, see GetCertificate in *Amazon CLI Command Reference*.

`import-certificate`

The following code example shows how to use `import-certificate`.

Amazon CLI

To import a certificate into ACM.

The following `import-certificate` command imports a certificate into ACM. Replace the file names with your own:

```
aws acm import-certificate --certificate file://Certificate.pem --certificate-
chain file://CertificateChain.pem --private-key file://PrivateKey.pem
```

- For API details, see ImportCertificate in *Amazon CLI Command Reference*.

`list-certificates`

The following code example shows how to use `list-certificates`.

Amazon CLI

To list the ACM certificates for an Amazon account

The following `list-certificates` command lists the ARNs of the certificates in your account:

```
aws acm list-certificates
```

The preceding command produces output similar to the following:

```
{
    "CertificateSummaryList": [
        {
            "CertificateArn":
 "arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012",
            "DomainName": "www.example.com"
        },
        {
            "CertificateArn": "arn:aws:acm:region:account:certificate/aaaaaaaa-bbbb-
cccc-dddd-eeeeeeeeeeee",
            "DomainName": "www.example.net"
        }
    ]
}
```

You can decide how many certificates you want to display each time you call `list-certificates`. For example, if you have four certificates and you want to display no more than two at a time, set the `max-items` argument to 2 as in the following example:

```
aws acm list-certificates --max-items 2
```

Two certificate ARNs and a `NextToken` value will be displayed:

```
"CertificateSummaryList": [
  {
    "CertificateArn": "arn:aws:acm:region:account: \
            certificate/12345678-1234-1234-1234-123456789012",
    "DomainName": "www.example.com"
  },
  {
    "CertificateArn": "arn:aws:acm:region:account: \
             certificate/aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
    "DomainName": "www.example.net"
  }
  ],
    "NextToken": "9f4d9f69-275a-41fe-b58e-2b837bd9ba48"
```

To display the next two certificates in your account, set this `NextToken` value in your next call:

```
aws acm list-certificates --max-items 2 --next-token 9f4d9f69-275a-41fe-
b58e-2b837bd9ba48
```

You can filter your output by using the `certificate-statuses` argument. The following command displays certificates that have a PENDING_VALIDATION status:

```
aws acm list-certificates --certificate-statuses PENDING_VALIDATION
```

You can also filter your output by using the `includes` argument. The following command displays certificates filtered on the following properties. The certificates to be displayed:

```
- Specify that the RSA algorithm and a 2048 bit key are used to generate key pairs.
- Contain a Key Usage extension that specifies that the certificates can be used to
 create digital signatures.
- Contain an Extended Key Usage extension that specifies that the certificates can
 be used for code signing.

aws acm list-certificates --max-items 10 --includes
 extendedKeyUsage=CODE_SIGNING,keyUsage=DIGITAL_SIGNATURE,keyTypes=RSA_2048
```

- For API details, see ListCertificates in *Amazon CLI Command Reference*.

`list-tags-for-certificate`

The following code example shows how to use `list-tags-for-certificate`.

Amazon CLI

To list the tags applied to an ACM Certificate

The following `list-tags-for-certificate` command lists the tags applied to a certificate in your account:

```
aws acm list-tags-for-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012
```

The preceding command produces output similar to the following:

```
{
```

```
  "Tags": [
      {
          "Value": "Website",
          "Key": "Purpose"
      },
      {
          "Value": "Alice",
          "Key": "Admin"
      }
  ]
}
```

- For API details, see ListTagsForCertificate in *Amazon CLI Command Reference*.

`remove-tags-from-certificate`

The following code example shows how to use `remove-tags-from-certificate`.

Amazon CLI

To remove a tag from an ACM Certificate

The following `remove-tags-from-certificate` command removes two tags from the specified certificate. Use a space to separate multiple tags:

```
aws acm remove-tags-from-certificate --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
tags Key=Admin,Value=Alice Key=Purpose,Value=Website
```

- For API details, see RemoveTagsFromCertificate in *Amazon CLI Command Reference*.

`request-certificate`

The following code example shows how to use `request-certificate`.

Amazon CLI

To request a new ACM certificate

The following `request-certificate` command requests a new certificate for the www.example.com domain using DNS validation:

```
aws acm request-certificate --domain-name www.example.com --validation-method DNS
```

You can enter an idempotency token to distinguish between calls to `request-certificate`:

```
aws acm request-certificate --domain-name www.example.com --validation-method DNS --
idempotency-token 91adc45q
```

You can enter one or more subject alternative names to request a certificate that will protect more than one apex domain:

```
aws acm request-certificate --domain-name example.com --validation-method DNS --
idempotency-token 91adc45q --subject-alternative-names www.example.net
```

You can enter an alternative name that can also be used to reach your website:

```
aws acm request-certificate --domain-name example.com --validation-method DNS --
idempotency-token 91adc45q --subject-alternative-names www.example.com
```

You can use an asterisk (*) as a wildcard to create a certificate for several subdomains in the same domain:

```
aws acm request-certificate --domain-name example.com --validation-method DNS --
idempotency-token 91adc45q --subject-alternative-names *.example.com
```

You can also enter multiple alternative names:

```
aws acm request-certificate --domain-name example.com --validation-method DNS --
subject-alternative-names b.example.com c.example.com d.example.com
```

If you are using email for validation, you can enter domain validation options to specify the domain to which the validation email will be sent:

```
aws acm request-certificate --domain-name example.com --validation-
method EMAIL --subject-alternative-names www.example.com --domain-validation-
options DomainName=example.com,ValidationDomain=example.com
```

The following command opts out of certificate transparency logging when you request a new certificate:

```
aws acm request-certificate --domain-name www.example.com --validation-method DNS --
options CertificateTransparencyLoggingPreference=DISABLED --idempotency-token 184627
```

- For API details, see RequestCertificate in *Amazon CLI Command Reference*.

`resend-validation-email`

The following code example shows how to use `resend-validation-email`.

Amazon CLI

To resend validation email for your ACM certificate request

The following `resend-validation-email` command tells the Amazon certificate authority to send validation email to the appropriate addresses:

```
aws acm resend-validation-email --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
domain www.example.com --validation-domain example.com
```

- For API details, see ResendValidationEmail in *Amazon CLI Command Reference*.

`update-certificate-options`

The following code example shows how to use `update-certificate-options`.

Amazon CLI

To update the certificate options

The following `update-certificate-options` command opts out of certificate transparency logging:

```
aws acm update-certificate-options --certificate-
arn arn:aws:acm:region:account:certificate/12345678-1234-1234-1234-123456789012 --
options CertificateTransparencyLoggingPreference=DISABLED
```

- For API details, see UpdateCertificateOptions in *Amazon CLI Command Reference*.

API Gateway examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with API Gateway.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-api-key`

The following code example shows how to use `create-api-key`.

Amazon CLI

To create an API key that is enabled for an existing API and Stage

Command:

```
aws apigateway create-api-key --name 'Dev API Key' --description 'Used for
 development' --enabled --stage-keys restApiId='a1b2c3d4e5',stageName='dev'
```

- For API details, see CreateApiKey in *Amazon CLI Command Reference*.

`create-authorizer`

The following code example shows how to use `create-authorizer`.

Amazon CLI

Example 1: To create a token-based API Gateway Custom Authorizer for the API

The following `create-authorizer` example creates a token-based authorizer.

```
aws apigateway create-authorizer \
    --rest-api-id 1234123412 \
    --name 'First_Token_Custom_Authorizer' \
    --type TOKEN \
    --authorizer-uri 'arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:customAuthFunction/invocations' \
    --identity-source 'method.request.header.Authorization' \
    --authorizer-result-ttl-in-seconds 300
```

Output:

```
{
    "authType": "custom",
    "name": "First_Token_Custom_Authorizer",
    "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:customAuthFunction/invocations",
    "authorizerResultTtlInSeconds": 300,
    "identitySource": "method.request.header.Authorization",
    "type": "TOKEN",
    "id": "z40xj0"
}
```

Example 2: To create a Cognito User Pools based API Gateway Custom Authorizer for the API

The following `create-authorizer` example creates a Cognito User Pools based API Gateway Custom Authorizer.

```
aws apigateway create-authorizer \
    --rest-api-id 1234123412 \
    --name 'First_Cognito_Custom_Authorizer' \
    --type COGNITO_USER_POOLS \
    --provider-arns 'arn:aws:cognito-idp:us-east-1:123412341234:userpool/us-
east-1_aWcZeQbuD' \
    --identity-source 'method.request.header.Authorization'
```

Output:

```
{
    "authType": "cognito_user_pools",
    "identitySource": "method.request.header.Authorization",
    "name": "First_Cognito_Custom_Authorizer",
```

```
    "providerARNs": [
        "arn:aws:cognito-idp:us-east-1:342398297714:userpool/us-east-1_qWbZzQhzE"
    ],
    "type": "COGNITO_USER_POOLS",
    "id": "5yid1t"
}
```

Example 3: To create a request-based API Gateway Custom Authorizer for the API

The following `create-authorizer` example creates a request-based authorizer.

```
aws apigateway create-authorizer \
    --rest-api-id 1234123412 \
    --name 'First_Request_Custom_Authorizer' \
    --type REQUEST \
    --authorizer-uri 'arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:customAuthFunction/invocations' \
    --identity-source 'method.request.header.Authorization,context.accountId' \
    --authorizer-result-ttl-in-seconds 300
```

Output:

```
{
    "id": "z40xj0",
    "name": "First_Request_Custom_Authorizer",
    "type": "REQUEST",
    "authType": "custom",
    "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:customAuthFunction/invocations",
    "identitySource": "method.request.header.Authorization,context.accountId",
    "authorizerResultTtlInSeconds": 300
}
```

- For API details, see CreateAuthorizer in *Amazon CLI Command Reference*.

`create-base-path-mapping`

The following code example shows how to use `create-base-path-mapping`.

Amazon CLI

To create the base path mapping for a custom domain name

Command:

```
aws apigateway create-base-path-mapping --domain-name subdomain.domain.tld --rest-
api-id 1234123412 --stage prod --base-path v1
```

- For API details, see CreateBasePathMapping in *Amazon CLI Command Reference*.

`create-deployment`

The following code example shows how to use `create-deployment`.

Amazon CLI

To deploy the configured resources for an API to a new Stage

Command:

```
aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --stage-
description 'Development Stage' --description 'First deployment to the dev stage'
```

To deploy the configured resources for an API to an existing stage

Command:

```
aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --
description 'Second deployment to the dev stage'
```

To deploy the configured resources for an API to an existing stage with Stage Variables

aws apigateway create-deployment --rest-api-id 1234123412 --stage-name dev --description 'Third deployment to the dev stage' --variables key='value',otherKey='otherValue'

- For API details, see CreateDeployment in *Amazon CLI Command Reference*.

`create-domain-name-access-association`

The following code example shows how to use `create-domain-name-access-association`.

Amazon CLI

To create a domain name access association

The following `create-domain-name-access-association` example creates a domain name access association between a private custom domain name and VPC endpoint.

```
aws apigateway create-domain-name-access-association \
    --domain-name-arn arn:aws:apigateway:us-west-2:111122223333:/domainnames/
my.private.domain.tld+abcd1234 \
    --access-association-source vpce-abcd1234efg \
    --access-association-source-type VPCE
```

Output:

```
{
    "domainNameAccessAssociationArn": "arn:aws:apigateway:us-west-2:012345678910:/
domainnameaccessassociations/domainname/my.private.domain.tld/vpcesource/vpce-
abcd1234efg
    "accessAssociationSource": "vpce-abcd1234efg",
    "accessAssociationSourceType": "VPCE",
    "domainNameArn" : "arn:aws:apigateway:us-west-2:111122223333:/domainnames/
private.example.com+abcd1234"
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateDomainNameAccessAssociation in *Amazon CLI Command Reference*.

`create-domain-name`

The following code example shows how to use `create-domain-name`.

Amazon CLI

Example 1: To create a public custom domain name

The following `create-domain-name` example creates a public custom domain name.

```
aws apigateway create-domain-name \
    --domain-name 'my.domain.tld' \
    --certificate-name 'my.domain.tld cert'\
    --certificate-arn 'arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-
a305-495d-aefb-27e5e101ff3'
```

Output:

```
{
    "domainName": "my.domain.tld",
    "certificateName": "my.domain.tld cert",
    "certificateArn": "arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-
a305-495d-aefb-27e5e101ff3",
    "certificateUploadDate": "2024-10-08T11:29:49-07:00",
    "distributionDomainName": "abcd1234.cloudfront.net",
    "distributionHostedZoneId": "Z2FDTNDATAQYW2",
    "endpointConfiguration": {
        "types": [
            "EDGE"
        ]
    },
    "domainNameStatus": "AVAILABLE",
    "securityPolicy": "TLS_1_2"
}
```

For more information, see Custom domain name for public REST APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

Example 2: To create a private custom domain name

The following `create-domain-name` example creates a private custom domain name.

```
aws apigateway create-domain-name \
    --domain-name 'my.private.domain.tld' \
    --certificate-name 'my.domain.tld cert' \
    --certificate-arn 'arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-
a305-495d-aefb-27e5e101ff3' \
    --endpoint-configuration '{"types": ["PRIVATE"]}' \
    --security-policy 'TLS_1_2' \
    --policy file://policy.json
```

Contents of `policy.json`:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Principal": "*",
            "Action": "execute-api:Invoke",
            "Resource": [
                "execute-api:/*"
            ]
        },
        {
            "Effect": "Deny",
            "Principal": "*",
            "Action": "execute-api:Invoke",
            "Resource": [
                "execute-api:/*"
            ],
            "Condition" : {
                "StringNotEquals": {
                    "aws:SourceVpce": "vpce-abcd1234efg"
                }
            }
        }
    ]
}
```

Output:

```
{
    "domainName": "my.private.domain.tld",
    "domainNameId": "abcd1234",
    "domainNameArn": "arn:aws:apigateway:us-east-1:012345678910:/domainnames/
my.private.domain.tld+abcd1234",
    "certificateArn": "arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-
a305-495d-aefb-27e5e101ff3",
    "certificateUploadDate": "2024-09-10T10:31:20-07:00",
    "endpointConfiguration": {
        "types": [
            "PRIVATE"
        ]
    },
    "domainNameStatus": "AVAILABLE",
    "securityPolicy": "TLS_1_2",
    "policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"execute-api:Invoke\",\"Resource\":
\"arn:aws:execute-api:us-east-1:012345678910:/domainnames/my.private.domain.tld
+abcd1234\"},{\"Effect\":\"Deny\",\"Principal\":\"*\",\"Action\":\"execute-
```

```
api:Invoke\",\"Resource\":\"arn:aws:execute-api:us-east-1:012345678910:/domainnames/
my.private.domain.tld+abcd1234\",\"Condition\":{\"StringNotEquals\":{\"aws:SourceVpc
\":\"vpc-1a2b3c4d\"}}}]}"
}
```

For more information, see Custom domain name for public REST APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateDomainName in *Amazon CLI Command Reference*.

`create-model`

The following code example shows how to use `create-model`.

Amazon CLI

To create a model for an API

Command:

```
aws apigateway create-model --rest-api-id 1234123412 --name 'firstModel' --
description 'The First Model' --content-type 'application/json'  --schema
 '{ "$schema": "http://json-schema.org/draft-04/schema#", "title": "firstModel",
 "type": "object", "properties": { "firstProperty" : { "type": "object",
 "properties": { "key": { "type": "string" } } } } }'
```

Output:

```
{
    "contentType": "application/json",
    "description": "The First Model",
    "name": "firstModel",
    "id": "2rzg0l",
    "schema": "{ \"$schema\": \"http://json-schema.org/draft-04/schema#\", \"title
\": \"firstModel\", \"type\": \"object\", \"properties\": { \"firstProperty
\" : { \"type\": \"object\", \"properties\": { \"key\": { \"type\": \"string
\" } } } } }"
}
```

- For API details, see CreateModel in *Amazon CLI Command Reference*.

`create-resource`

The following code example shows how to use `create-resource`.

Amazon CLI

To create a resource in an API

Command:

```
aws apigateway create-resource --rest-api-id 1234123412 --parent-id a1b2c3 --path-
part 'new-resource'
```

- For API details, see CreateResource in *Amazon CLI Command Reference*.

`create-rest-api`

The following code example shows how to use `create-rest-api`.

Amazon CLI

To create an API

Command:

```
aws apigateway create-rest-api --name 'My First API' --description 'This is my first
 API'
```

To create a duplicate API from an existing API

Command:

```
aws apigateway create-rest-api --name 'Copy of My First API' --description 'This is
 a copy of my first API' --clone-from 1234123412
```

- For API details, see CreateRestApi in *Amazon CLI Command Reference*.

`create-stage`

The following code example shows how to use `create-stage`.

Amazon CLI

To create a stage in an API which will contain an existing deployment

Command:

```
aws apigateway create-stage --rest-api-id 1234123412 --stage-name 'dev' --
description 'Development stage' --deployment-id a1b2c3
```

To create a stage in an API which will contain an existing deployment and custom Stage Variables

Command:

```
aws apigateway create-stage --rest-api-id 1234123412 --stage-name 'dev'
 --description 'Development stage' --deployment-id a1b2c3 --variables
 key='value',otherKey='otherValue'
```

- For API details, see CreateStage in *Amazon CLI Command Reference*.

`create-usage-plan-key`

The following code example shows how to use `create-usage-plan-key`.

Amazon CLI

Associate an existing API key with a Usage Plan

Command:

```
aws apigateway create-usage-plan-key --usage-plan-id a1b2c3 --key-type "API_KEY" --
key-id 4vq3yryqm5
```

- For API details, see CreateUsagePlanKey in *Amazon CLI Command Reference*.

`create-usage-plan`

The following code example shows how to use `create-usage-plan`.

Amazon CLI

To create a usage plan with throttle and quota limits that resets at the beginning of the month

Command:

```
aws apigateway create-usage-plan --name "New Usage Plan" --description "A new usage
 plan" --throttle burstLimit=10,rateLimit=5 --quota limit=500,offset=0,period=MONTH
```

- For API details, see CreateUsagePlan in *Amazon CLI Command Reference*.

`delete-api-key`

The following code example shows how to use `delete-api-key`.

Amazon CLI

To delete an API key

Command:

```
aws apigateway delete-api-key --api-key 8bklk8bl1k3sB38D9B3l0enyWT8c09B30lkq0blk
```

- For API details, see DeleteApiKey in *Amazon CLI Command Reference*.

`delete-authorizer`

The following code example shows how to use `delete-authorizer`.

Amazon CLI

To delete a Custom Authorizer in an API

Command:

```
aws apigateway delete-authorizer --rest-api-id 1234123412 --authorizer-id 7gkfbo
```

- For API details, see DeleteAuthorizer in *Amazon CLI Command Reference*.

`delete-base-path-mapping`

The following code example shows how to use `delete-base-path-mapping`.

Amazon CLI

To delete a base path mapping for a custom domain name

Command:

```
aws apigateway delete-base-path-mapping --domain-name 'api.domain.tld' --base-path
 'dev'
```

- For API details, see DeleteBasePathMapping in *Amazon CLI Command Reference*.

`delete-client-certificate`

The following code example shows how to use `delete-client-certificate`.

Amazon CLI

To delete a client certificate

Command:

```
aws apigateway delete-client-certificate --client-certificate-id a1b2c3
```

- For API details, see DeleteClientCertificate in *Amazon CLI Command Reference*.

`delete-deployment`

The following code example shows how to use `delete-deployment`.

Amazon CLI

To delete a deployment in an API

Command:

```
aws apigateway delete-deployment --rest-api-id 1234123412 --deployment-id a1b2c3
```

- For API details, see DeleteDeployment in *Amazon CLI Command Reference*.

`delete-domain-name-access-association`

The following code example shows how to use `delete-domain-name-access-association`.

Amazon CLI

To delete a domain name access association

The following `delete-domain-name-access-association` example deletes a domain name access association between a private custom domain name and VPC endpoint.

```
aws apigateway delete-domain-name-access-association \
    --domain-name-access-association-arn arn:aws:apigateway:us-west-2:012345678910:/domainnameaccessassociations/domainname/my.private.domain.tld/vpcesource/vpce-abcd1234efg
```

This command produces no output.

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteDomainNameAccessAssociation in *Amazon CLI Command Reference*.

`delete-domain-name`

The following code example shows how to use `delete-domain-name`.

Amazon CLI

To delete a custom domain name

Command:

```
aws apigateway delete-domain-name --domain-name 'api.domain.tld'
```

- For API details, see DeleteDomainName in *Amazon CLI Command Reference*.

`delete-integration-response`

The following code example shows how to use `delete-integration-response`.

Amazon CLI

To delete an integration response for a given resource, method, and status code in an API

Command:

```
aws apigateway delete-integration-response --rest-api-id 1234123412 --resource-
id a1b2c3 --http-method GET --status-code 200
```

- For API details, see DeleteIntegrationResponse in *Amazon CLI Command Reference*.

`delete-integration`

The following code example shows how to use `delete-integration`.

Amazon CLI

To delete an integration for a given resource and method in an API

Command:

```
aws apigateway delete-integration --rest-api-id 1234123412 --resource-id a1b2c3 --
http-method GET
```

- For API details, see DeleteIntegration in *Amazon CLI Command Reference*.

`delete-method-response`

The following code example shows how to use `delete-method-response`.

Amazon CLI

To delete a method response for the given resource, method, and status code in an API

Command:

```
aws apigateway delete-method-response --rest-api-id 1234123412 --resource-id a1b2c3
 --http-method GET --status-code 200
```

- For API details, see DeleteMethodResponse in *Amazon CLI Command Reference*.

`delete-method`

The following code example shows how to use `delete-method`.

Amazon CLI

To delete a method for the given resource in an API

Command:

```
aws apigateway delete-method --rest-api-id 1234123412 --resource-id a1b2c3 --http-method GET
```

- For API details, see DeleteMethod in *Amazon CLI Command Reference*.

`delete-model`

The following code example shows how to use `delete-model`.

Amazon CLI

To delete a model in the given API

Command:

```
aws apigateway delete-model --rest-api-id 1234123412 --model-name 'customModel'
```

- For API details, see DeleteModel in *Amazon CLI Command Reference*.

`delete-resource`

The following code example shows how to use `delete-resource`.

Amazon CLI

To delete a resource in an API

Command:

```
aws apigateway delete-resource --rest-api-id 1234123412 --resource-id a1b2c3
```

- For API details, see DeleteResource in *Amazon CLI Command Reference*.

`delete-rest-api`

The following code example shows how to use `delete-rest-api`.

Amazon CLI

To delete an API

Command:

```
aws apigateway delete-rest-api --rest-api-id 1234123412
```

- For API details, see DeleteRestApi in *Amazon CLI Command Reference*.

`delete-stage`

The following code example shows how to use `delete-stage`.

Amazon CLI

To delete a stage in an API

Command:

```
aws apigateway delete-stage --rest-api-id 1234123412 --stage-name 'dev'
```

- For API details, see DeleteStage in *Amazon CLI Command Reference*.

`delete-usage-plan-key`

The following code example shows how to use `delete-usage-plan-key`.

Amazon CLI

To remove an API key from a Usage Plan

Command:

```
aws apigateway delete-usage-plan-key --usage-plan-id a1b2c3 --key-
id 1NbjQzMReAkeEQPNAW8r3dXsU2rDD7fc7f2Sipnu
```

- For API details, see DeleteUsagePlanKey in *Amazon CLI Command Reference*.

`delete-usage-plan`

The following code example shows how to use `delete-usage-plan`.

Amazon CLI

To delete a Usage Plan

Command:

```
aws apigateway delete-usage-plan --usage-plan-id a1b2c3
```

- For API details, see DeleteUsagePlan in *Amazon CLI Command Reference*.

`flush-stage-authorizers-cache`

The following code example shows how to use `flush-stage-authorizers-cache`.

Amazon CLI

To flush all authorizer cache entries on a stage

Command:

```
aws apigateway flush-stage-authorizers-cache --rest-api-id 1234123412 --stage-
name dev
```

- For API details, see FlushStageAuthorizersCache in *Amazon CLI Command Reference*.

`flush-stage-cache`

The following code example shows how to use `flush-stage-cache`.

Amazon CLI

To flush the cache for an API's stage

The following `flush-stage-cache` example flushes the cache of a stage.

```
aws apigateway flush-stage-cache \
    --rest-api-id 1234123412 \
    --stage-name dev
```

This command produces no output.

For more information, see Flush the API stage cache in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see FlushStageCache in *Amazon CLI Command Reference*.

`generate-client-certificate`

The following code example shows how to use `generate-client-certificate`.

Amazon CLI

To create a Client-Side SSL Certificate

Command:

```
aws apigateway generate-client-certificate --description 'My First Client
 Certificate'
```

- For API details, see GenerateClientCertificate in *Amazon CLI Command Reference*.

`get-account`

The following code example shows how to use `get-account`.

Amazon CLI

To get API Gateway account settings

Command:

```
aws apigateway get-account
```

Output:

```
{
    "cloudwatchRoleArn": "arn:aws:iam::123412341234:role/
APIGatewayToCloudWatchLogsRole",
    "throttleSettings": {
        "rateLimit": 500.0,
        "burstLimit": 1000
    }
}
```

- For API details, see GetAccount in *Amazon CLI Command Reference*.

`get-api-key`

The following code example shows how to use `get-api-key`.

Amazon CLI

To get the information about a specific API key

Command:

```
aws apigateway get-api-key --api-key 8bklk8bl1k3sB38D9B3l0enyWT8c09B30lkq0blk
```

Output:

```
{
    "description": "My first key",
    "enabled": true,
    "stageKeys": [
        "a1b2c3d4e5/dev",
        "e5d4c3b2a1/dev"
    ],
    "lastUpdatedDate": 1456184515,
    "createdDate": 1456184452,
    "id": "8bklk8bl1k3sB38D9B3l0enyWT8c09B30lkq0blk",
    "name": "My key"
}
```

- For API details, see GetApiKey in *Amazon CLI Command Reference*.

`get-api-keys`

The following code example shows how to use `get-api-keys`.

Amazon CLI

To get the list of API keys

Command:

```
aws apigateway get-api-keys
```

Output:

```
{
    "items": [
        {
            "description": "My first key",
            "enabled": true,
            "stageKeys": [
                "a1b2c3d4e5/dev",
                "e5d4c3b2a1/dev"
            ],
            "lastUpdatedDate": 1456184515,
            "createdDate": 1456184452,
            "id": "8bklk8bl1k3sB38D9B3l0enyWT8c09B30lkq0blk",
            "name": "My key"
        }
    ]
}
```

- For API details, see GetApiKeys in *Amazon CLI Command Reference*.

`get-authorizer`

The following code example shows how to use `get-authorizer`.

Amazon CLI

To get the API Gateway per-API Authorizer settings

Command:

```
aws apigateway get-authorizer --rest-api-id 1234123412 --authorizer-id gfi4n3
```

Output:

```
{
    "authorizerResultTtlInSeconds": 300,
    "name": "MyAuthorizer",
    "type": "TOKEN",
    "identitySource": "method.request.header.Authorization",
    "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:authorizer_function/invocations",
    "id": "gfi4n3"
}
```

- For API details, see GetAuthorizer in *Amazon CLI Command Reference*.

`get-authorizers`

The following code example shows how to use `get-authorizers`.

Amazon CLI

To get the list of authorizers for a REST API

Command:

```
aws apigateway get-authorizers --rest-api-id 1234123412
```

Output:

```
{
    "items": [
        {
            "name": "MyAuthorizer",
            "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/
functions/arn:aws:lambda:us-west-2:123412341234:function:My_Authorizer_Function/
invocations",
            "authorizerResultTtlInSeconds": 300,
            "identitySource": "method.request.header.Authorization",
            "type": "TOKEN",
            "id": "gfi4n3"
```

```
        }
    ]
}
```

- For API details, see GetAuthorizers in *Amazon CLI Command Reference*.

`get-base-path-mapping`

The following code example shows how to use `get-base-path-mapping`.

Amazon CLI

To get the base path mapping for a custom domain name

Command:

```
aws apigateway get-base-path-mapping --domain-name subdomain.domain.tld --base-
path v1
```

Output:

```
{
    "basePath": "v1",
    "restApiId": "1234w4321e",
    "stage": "api"
}
```

- For API details, see GetBasePathMapping in *Amazon CLI Command Reference*.

`get-base-path-mappings`

The following code example shows how to use `get-base-path-mappings`.

Amazon CLI

To get the base path mappings for a custom domain name

Command:

```
aws apigateway get-base-path-mappings --domain-name subdomain.domain.tld
```

Output:

```
{
    "items": [
        {
            "basePath": "(none)",
            "restApiId": "1234w4321e",
            "stage": "dev"
        },
        {
            "basePath": "v1",
            "restApiId": "1234w4321e",
            "stage": "api"
        }
    ]
}
```

- For API details, see GetBasePathMappings in *Amazon CLI Command Reference*.

`get-client-certificate`

The following code example shows how to use `get-client-certificate`.

Amazon CLI

To get a client certificate

Command:

```
aws apigateway get-client-certificate --client-certificate-id a1b2c3
```

- For API details, see GetClientCertificate in *Amazon CLI Command Reference*.

`get-client-certificates`

The following code example shows how to use `get-client-certificates`.

Amazon CLI

To get a list of client certificates

Command:

```
aws apigateway get-client-certificates
```

Output:

```
{
    "items": [
        {
            "pemEncodedCertificate": "-----BEGIN CERTIFICATE----- <certificate
 content> -----END CERTIFICATE-----",
            "clientCertificateId": "a1b2c3",
            "expirationDate": 1483556561,
            "description": "My Client Certificate",
            "createdDate": 1452020561
        }
    ]
}
```

- For API details, see GetClientCertificates in *Amazon CLI Command Reference*.

`get-deployment`

The following code example shows how to use `get-deployment`.

Amazon CLI

To get information about a deployment

Command:

```
aws apigateway get-deployment --rest-api-id 1234123412 --deployment-id ztt4m2
```

Output:

```
{
    "description": "myDeployment",
    "id": "ztt4m2",
    "createdDate": 1455218022
}
```

- For API details, see GetDeployment in *Amazon CLI Command Reference*.

`get-deployments`

The following code example shows how to use `get-deployments`.

Amazon CLI

To get a list of deployments for a REST API

Command:

```
aws apigateway get-deployments --rest-api-id 1234123412
```

Output:

```
{
    "items": [
        {
            "createdDate": 1453797217,
            "id": "0a2b4c",
            "description": "Deployed my API for the first time"
        }
    ]
}
```

- For API details, see GetDeployments in *Amazon CLI Command Reference*.

`get-domain-name-access-associations`

The following code example shows how to use `get-domain-name-access-associations`.

Amazon CLI

Example 1: To list all domain name access associations

The following `get-domain-name-access-associations` example lists all domain name access associations.

```
aws apigateway get-domain-name-access-associations
```

Output:

```
{
```

```
    "items": [
        {
        "domainNameAccessAssociationArn": "arn:aws:apigateway:us-
west-2:012345678910:/domainnameaccessassociations/domainname/my.private.domain.tld/
vpcesource/vpce-abcd1234efg
        "accessAssociationSource": "vpce-abcd1234efg",
        "accessAssociationSourceType": "VPCE",
        "domainNameArn" : "arn:aws:apigateway:us-west-2:111122223333:/domainnames/
private.example.com+abcd1234"
        }
    ]
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

Example 2: To list all domain name access associations owned by this Amazon account

The following `get-domain-name-access-associations` example lists all the domain name access associations owned by the current Amazon account.

```
aws apigateway get-domain-name-access-associations \
    --resource-owner SELF
```

Output:

```
{
    "items": [
        {
        "domainNameAccessAssociationArn": "arn:aws:apigateway:us-
west-2:012345678910:/domainnameaccessassociations/domainname/my.private.domain.tld/
vpcesource/vpce-abcd1234efg
        "accessAssociationSource": "vpce-abcd1234efg",
        "accessAssociationSourceType": "VPCE",
        "domainNameArn" : "arn:aws:apigateway:us-west-2:111122223333:/domainnames/
private.example.com+abcd1234"
        }
    ]
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDomainNameAccessAssociations in *Amazon CLI Command Reference*.

`get-domain-name`

The following code example shows how to use `get-domain-name`.

Amazon CLI

Example 1: To get information about a public custom domain name

The following `get-domain-name` example gets information about a public custom domain name.

```
aws apigateway get-domain-name \
    --domain-name api.domain.tld
```

Output:

```
{
    "domainName": "api.domain.tld",
    "distributionDomainName": "d1a2f3a4c5o6d.cloudfront.net",
    "certificateName": "uploadedCertificate",
    "certificateUploadDate": 1462565487
}
```

For more information, see Custom domain name for public REST APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

Example 2: To get information about a private custom domain name

The following `get-domain-name` example gets information about a private custom domain name.

```
aws apigateway get-domain-name \
    --domain-name api.private.domain.tld \
    --domain-name-id abcd1234
```

Output:

```
{
    "domainName": "my.private.domain.tld",
```

```
    "domainNameId": "abcd1234",
    "domainNameArn": "arn:aws:apigateway:us-east-1:012345678910:/domainnames/
my.private.domain.tld+abcd1234",
    "certificateArn": "arn:aws:acm:us-east-1:012345678910:certificate/fb1b9770-
a305-495d-aefb-27e5e101ff3",
    "certificateUploadDate": "2024-09-10T10:31:20-07:00",
    "endpointConfiguration": {
        "types": [
            "PRIVATE"
        ]
    },
    "domainNameStatus": "AVAILABLE",
    "securityPolicy": "TLS_1_2",
    "policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":\"*\",\"Action\":\"execute-api:Invoke\",\"Resource\":
\"arn:aws:execute-api:us-east-1:012345678910:/domainnames/my.private.domain.tld
+abcd1234\"},{\"Effect\":\"Deny\",\"Principal\":\"*\",\"Action\":\"execute-
api:Invoke\",\"Resource\":\"arn:aws:execute-api:us-east-1:012345678910:/domainnames/
my.private.domain.tld+abcd1234\",\"Condition\":{\"StringNotEquals\":{\"aws:SourceVpc
\":\"vpc-1a2b3c4d\"}}}]}"
}
```

For more information, see Custom domain name for public REST APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDomainName in *Amazon CLI Command Reference*.

`get-domain-names`

The following code example shows how to use `get-domain-names`.

Amazon CLI

Example 1: To get a list of custom domain names

The following `get-domain-names` command gets a list of domain names.

```
aws apigateway get-domain-names
```

Output:

```
{
```

```
    "items": [
        {
            "distributionDomainName": "d9511k3l09bkd.cloudfront.net",
            "certificateUploadDate": 1452812505,
            "certificateName": "my_custom_domain-certificate",
            "domainName": "subdomain.domain.tld"
        }
    ]
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

Example 2: To get a list of custom domain names owned by this Amazon account

The following `get-domain-names` command gets a list of domain names owned by this Amazon account.

```
aws apigateway get-domain-names \
    --resource-owner SELF
```

Output:

```
{
    "items": [
        {
            "domainName": "my.domain.tld",
            "domainNameArn": "arn:aws:apigateway:us-east-1::/domainnames/
my.private.domain.tld",
            "certificateUploadDate": "2024-08-15T17:02:55-07:00",
            "regionalDomainName": "d-abcd1234.execute-api.us-east-1.amazonaws.com",
            "regionalHostedZoneId": "Z1UJRXOUMOOFQ8",
            "regionalCertificateArn": "arn:aws:acm:us-
east-1:012345678910:certificate/fb1b9770-a305-495d-aefb-27e5e101ff3",
            "endpointConfiguration": {
                "types": [
                    "REGIONAL"
                ]
            },
            "domainNameStatus": "AVAILABLE",
            "securityPolicy": "TLS_1_2"
        },
```

```
        {
            "domainName": "my.private.domain.tld",
            "domainNameId": "abcd1234",
            "domainNameArn": "arn:aws:apigateway:us-east-1:012345678910:/
domainnames/my.private.domain.tld+abcd1234",
            "certificateArn": "arn:aws:acm:us-east-1:012345678910:certificate/
fb1b9770-a305-495d-aefb-27e5e101ff3",
            "certificateUploadDate": "2024-11-26T11:44:40-08:00",
            "endpointConfiguration": {
                "types": [
                    "PRIVATE"
                ]
            },
            "domainNameStatus": "AVAILABLE",
            "securityPolicy": "TLS_1_2"
        }
    ]
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

Example 3: To get a list of custom domain names owned by other Amazon accounts that you can create a domain name access association with.

The following `get-domain-names` command gets a list of domain names owned by other Amazon accounts that you have access to create a domain name access association with.

```
aws apigateway get-domain-names \
    --resource-owner OTHER_ACCOUNTS
```

Output:

```
{
    "items": [
        {
            "domainName": "my.private.domain.tld",
            "domainNameId": "abcd1234",
            "domainNameArn": "arn:aws:apigateway:us-east-1:012345678910:/
domainnames/my.private.domain.tld+abcd1234"
        }
    ]
```

```
}
```

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDomainNames in *Amazon CLI Command Reference*.

`get-export`

The following code example shows how to use `get-export`.

Amazon CLI

To get the JSON Swagger template for a stage

Command:

```
aws apigateway get-export --rest-api-id a1b2c3d4e5 --stage-name dev --export-
type swagger /path/to/filename.json
```

To get the JSON Swagger template + API Gateway Extentions for a stage

Command:

```
aws apigateway get-export --parameters extensions='integrations' --rest-api-
id a1b2c3d4e5 --stage-name dev --export-type swagger /path/to/filename.json
```

To get the JSON Swagger template + Postman Extensions for a stage

Command:

```
aws apigateway get-export --parameters extensions='postman' --rest-api-id a1b2c3d4e5
 --stage-name dev --export-type swagger /path/to/filename.json
```

- For API details, see GetExport in *Amazon CLI Command Reference*.

`get-integration-response`

The following code example shows how to use `get-integration-response`.

Amazon CLI

To get the integration response configuration for a HTTP method defined under a REST API's resource

Command:

```
aws apigateway get-integration-response --rest-api-id 1234123412 --resource-
id y9h6rt --http-method GET --status-code 200
```

Output:

```
{
    "statusCode": "200",
    "responseTemplates": {
        "application/json": null
    }
}
```

- For API details, see GetIntegrationResponse in *Amazon CLI Command Reference*.

`get-integration`

The following code example shows how to use `get-integration`.

Amazon CLI

To get the integration configuration for a HTTP method defined under a REST API's resource

Command:

```
aws apigateway get-integration --rest-api-id 1234123412 --resource-id y9h6rt --http-
method GET
```

Output:

```
{
    "httpMethod": "POST",
    "integrationResponses": {
        "200": {
            "responseTemplates": {
                "application/json": null
```

```
            },
            "statusCode": "200"
        }
    },
    "cacheKeyParameters": [],
    "type": "AWS",
    "uri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:My_Function/invocations",
    "cacheNamespace": "y9h6rt"
}
```

- For API details, see GetIntegration in *Amazon CLI Command Reference*.

`get-method-response`

The following code example shows how to use `get-method-response`.

Amazon CLI

To get the method response resource configuration for a HTTP method defined under a REST API's resource

Command:

```
aws apigateway get-method-response --rest-api-id 1234123412 --resource-id y9h6rt --
http-method GET --status-code 200
```

Output:

```
{
    "responseModels": {
        "application/json": "Empty"
    },
    "statusCode": "200"
}
```

- For API details, see GetMethodResponse in *Amazon CLI Command Reference*.

`get-method`

The following code example shows how to use `get-method`.

Amazon CLI

To get the method resource configuration for a HTTP method defined under a REST API's resource

Command:

```
aws apigateway get-method --rest-api-id 1234123412 --resource-id y9h6rt --http-
method GET
```

Output:

```
{
    "apiKeyRequired": false,
    "httpMethod": "GET",
    "methodIntegration": {
        "integrationResponses": {
            "200": {
                "responseTemplates": {
                    "application/json": null
                },
                "statusCode": "200"
            }
        },
        "cacheKeyParameters": [],
        "uri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:My_Function/invocations",
        "httpMethod": "POST",
        "cacheNamespace": "y9h6rt",
        "type": "AWS"
    },
    "requestParameters": {},
    "methodResponses": {
        "200": {
            "responseModels": {
                "application/json": "Empty"
            },
            "statusCode": "200"
        }
    },
    "authorizationType": "NONE"
}
```

- For API details, see GetMethod in *Amazon CLI Command Reference*.

`get-model-template`

The following code example shows how to use `get-model-template`.

Amazon CLI

To get the mapping template for a model defined under a REST API

Command:

```
aws apigateway get-model-template --rest-api-id 1234123412 --model-name Empty
```

Output:

```
{
    "value": "#set($inputRoot = $input.path('$'))\n{ }"
}
```

- For API details, see GetModelTemplate in *Amazon CLI Command Reference*.

`get-model`

The following code example shows how to use `get-model`.

Amazon CLI

To get the configuration for a model defined under a REST API

Command:

```
aws apigateway get-model --rest-api-id 1234123412 --model-name Empty
```

Output:

```
{
    "contentType": "application/json",
    "description": "This is a default empty schema model",
```

```
    "name": "Empty",
    "id": "etd5w5",
    "schema": "{\n  \"$schema\": \"http://json-schema.org/draft-04/schema#\",\n
 \"title\" : \"Empty Schema\",\n  \"type\" : \"object\"\n}"
}
```

- For API details, see GetModel in *Amazon CLI Command Reference*.

`get-models`

The following code example shows how to use `get-models`.

Amazon CLI

To get a list of models for a REST API

Command:

```
aws apigateway get-models --rest-api-id 1234123412
```

Output:

```
{
    "items": [
        {
            "description": "This is a default error schema model",
            "schema": "{\n  \"$schema\" : \"http://json-schema.org/draft-04/schema#
\",\n  \"title\" : \"Error Schema\",\n  \"type\" : \"object\",\n  \"properties\" :
 {\n    \"message\" : { \"type\" : \"string\" }\n  }\n}",
            "contentType": "application/json",
            "id": "7tpbze",
            "name": "Error"
        },
        {
            "description": "This is a default empty schema model",
            "schema": "{\n  \"$schema\": \"http://json-schema.org/draft-04/schema#
\",\n  \"title\" : \"Empty Schema\",\n  \"type\" : \"object\"\n}",
            "contentType": "application/json",
            "id": "etd5w5",
            "name": "Empty"
        }
    ]
```

```
}
```

- For API details, see GetModels in *Amazon CLI Command Reference*.

`get-resource`

The following code example shows how to use `get-resource`.

Amazon CLI

To get information about a resource

Command:

```
aws apigateway get-resource --rest-api-id 1234123412 --resource-id zwo0y3
```

Output:

```
{
    "path": "/path",
    "pathPart": "path",
    "id": "zwo0y3",
    "parentId": "uyokt6ij2g"
}
```

- For API details, see GetResource in *Amazon CLI Command Reference*.

`get-resources`

The following code example shows how to use `get-resources`.

Amazon CLI

To get a list of resources for a REST API

Command:

```
aws apigateway get-resources --rest-api-id 1234123412
```

Output:

```
{
    "items": [
        {
            "path": "/resource/subresource",
            "resourceMethods": {
                "POST": {}
            },
            "id": "024ace",
            "pathPart": "subresource",
            "parentId": "ai5b02"
        }
    ]
}
```

- For API details, see GetResources in *Amazon CLI Command Reference*.

`get-rest-api`

The following code example shows how to use `get-rest-api`.

Amazon CLI

To get information about an API

Command:

```
aws apigateway get-rest-api --rest-api-id 1234123412
```

Output:

```
{
    "name": "myAPI",
    "id": "o1y243m4f5",
    "createdDate": 1453416433
}
```

- For API details, see GetRestApi in *Amazon CLI Command Reference*.

`get-rest-apis`

The following code example shows how to use `get-rest-apis`.

Amazon CLI

To get a list of REST APIs

Command:

```
aws apigateway get-rest-apis
```

Output:

```
{
    "items": [
        {
            "createdDate": 1438884790,
            "id": "12s44z21rb",
            "name": "My First API"
        }
    ]
}
```

- For API details, see GetRestApis in *Amazon CLI Command Reference*.

`get-sdk`

The following code example shows how to use `get-sdk`.

Amazon CLI

To get the Android SDK for a REST API stage

Command:

```
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-type android
 --parameters
 groupId='com.mycompany',invokerPackage='com.mycompany.clientsdk',artifactId='Mycompany-
client',artifactVersion='1.0.0' /path/to/android_sdk.zip
```

Output:

```
{
```

```
    "contentType": "application/octet-stream",
    "contentDisposition": "attachment; filename=\"android_2016-02-22_23-52Z.zip\""
}
```

To get the IOS SDK for a REST API stage

Command:

```
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-
type objectivec --parameters classPrefix='myprefix' /path/to/iOS_sdk.zip
```

Output:

```
{
    "contentType": "application/octet-stream",
    "contentDisposition": "attachment; filename=\"objectivec_2016-02-22_23-52Z.zip
\""
}
```

To get the Javascript SDK for a REST API stage

Command:

```
aws apigateway get-sdk --rest-api-id 1234123412 --stage-name dev --sdk-
type javascript /path/to/javascript_sdk.zip
```

Output:

```
{
    "contentType": "application/octet-stream",
    "contentDisposition": "attachment; filename=\"javascript_2016-02-22_23-52Z.zip
\""
}
```

- For API details, see GetSdk in *Amazon CLI Command Reference*.

`get-stage`

The following code example shows how to use `get-stage`.

Amazon CLI

To get information about an API's stage

Command:

```
aws apigateway get-stage --rest-api-id 1234123412 --stage-name dev
```

Output:

```
{
    "stageName": "dev",
    "cacheClusterSize": "0.5",
    "cacheClusterEnabled": false,
    "cacheClusterStatus": "NOT_AVAILABLE",
    "deploymentId": "rbh1fj",
    "lastUpdatedDate": 1466802961,
    "createdDate": 1460682074,
    "methodSettings": {
        "*/*": {
            "cacheTtlInSeconds": 300,
            "loggingLevel": "INFO",
            "dataTraceEnabled": false,
            "metricsEnabled": true,
            "unauthorizedCacheControlHeaderStrategy":
 "SUCCEED_WITH_RESPONSE_HEADER",
            "throttlingRateLimit": 500.0,
            "cacheDataEncrypted": false,
            "cachingEnabled": false,
            "throttlingBurstLimit": 1000,
            "requireAuthorizationForCacheControl": true
        },
        "~1resource/GET": {
            "cacheTtlInSeconds": 300,
            "loggingLevel": "INFO",
            "dataTraceEnabled": false,
            "metricsEnabled": true,
            "unauthorizedCacheControlHeaderStrategy":
 "SUCCEED_WITH_RESPONSE_HEADER",
            "throttlingRateLimit": 500.0,
            "cacheDataEncrypted": false,
            "cachingEnabled": false,
            "throttlingBurstLimit": 1000,
```

```
            "requireAuthorizationForCacheControl": true
        }
    }
}
```

- For API details, see GetStage in *Amazon CLI Command Reference*.

`get-stages`

The following code example shows how to use `get-stages`.

Amazon CLI

To get the list of stages for a REST API

Command:

```
aws apigateway get-stages --rest-api-id 1234123412
```

Output:

```
{
    "item": [
        {
            "stageName": "dev",
            "cacheClusterSize": "0.5",
            "cacheClusterEnabled": true,
            "cacheClusterStatus": "AVAILABLE",
            "deploymentId": "123h64",
            "lastUpdatedDate": 1456185138,
            "createdDate": 1453589092,
            "methodSettings": {
                "~1resource~1subresource/POST": {
                    "cacheTtlInSeconds": 300,
                    "loggingLevel": "INFO",
                    "dataTraceEnabled": true,
                    "metricsEnabled": true,
                    "throttlingRateLimit": 500.0,
                    "cacheDataEncrypted": false,
                    "cachingEnabled": false,
                    "throttlingBurstLimit": 1000
                }
```

```
            }
        }
    ]
}
```

- For API details, see GetStages in *Amazon CLI Command Reference*.

`get-usage-plan-key`

The following code example shows how to use `get-usage-plan-key`.

Amazon CLI

To get the details of an API key associated with a Usage Plan

Command:

```
aws apigateway get-usage-plan-key --usage-plan-id a1b2c3 --key-
id 1NbjQzMReAkeEQPNAW8r3dXsU2rDD7fc7f2Sipnu
```

- For API details, see GetUsagePlanKey in *Amazon CLI Command Reference*.

`get-usage-plan-keys`

The following code example shows how to use `get-usage-plan-keys`.

Amazon CLI

To get the list of API keys associated with a Usage Plan

Command:

```
aws apigateway get-usage-plan-keys --usage-plan-id a1b2c3
```

- For API details, see GetUsagePlanKeys in *Amazon CLI Command Reference*.

`get-usage-plan`

The following code example shows how to use `get-usage-plan`.

Amazon CLI

To get the details of a Usage Plan

Command:

```
aws apigateway get-usage-plan --usage-plan-id a1b2c3
```

- For API details, see GetUsagePlan in *Amazon CLI Command Reference*.

`get-usage-plans`

The following code example shows how to use `get-usage-plans`.

Amazon CLI

To get the details of all Usage Plans

Command:

```
aws apigateway get-usage-plans
```

- For API details, see GetUsagePlans in *Amazon CLI Command Reference*.

`get-usage`

The following code example shows how to use `get-usage`.

Amazon CLI

To get the usage details for a Usage Plan

Command:

```
aws apigateway get-usage --usage-plan-id a1b2c3 --start-date "2016-08-16" --end-
date "2016-08-17"
```

- For API details, see GetUsage in *Amazon CLI Command Reference*.

`import-rest-api`

The following code example shows how to use `import-rest-api`.

Amazon CLI

To import a Swagger template and create an API

Command:

```
aws apigateway import-rest-api --body 'file:///path/to/API_Swagger_template.json'
```

- For API details, see ImportRestApi in *Amazon CLI Command Reference*.

`put-integration-response`

The following code example shows how to use `put-integration-response`.

Amazon CLI

To create an integration response as the default response with a mapping template defined

Command:

```
aws apigateway put-integration-response --rest-api-id 1234123412 --resource-
id a1b2c3 --http-method GET --status-code 200 --selection-pattern "" --response-
templates '{"application/json": "{\"json\": \"template\"}"}'
```

To create an integration response with a regex of 400 and a statically defined header value

Command:

```
aws apigateway put-integration-response --rest-api-id 1234123412 --resource-
id a1b2c3 --http-method GET --status-code 400 --selection-pattern 400 --response-
parameters '{"method.response.header.custom-header": "'"'"'custom-value'"'"'"}'
```

- For API details, see PutIntegrationResponse in *Amazon CLI Command Reference*.

`put-integration`

The following code example shows how to use `put-integration`.

Amazon CLI

To create a MOCK integration request

Command:

```
aws apigateway put-integration --rest-api-id 1234123412 --resource-id a1b2c3 --http-
method GET --type MOCK --request-templates '{ "application/json": "{\"statusCode\":
 200}" }'
```

To create a HTTP integration request

Command:

```
aws apigateway put-integration --rest-api-id 1234123412 --resource-id a1b2c3 --http-
method GET --type HTTP --integration-http-method GET --uri 'https://domain.tld/path'
```

To create an Amazon integration request with a Lambda Function endpoint

Command:

```
aws apigateway put-integration --rest-api-id 1234123412 --resource-
id a1b2c3 --http-method GET --type AWS --integration-http-method POST --uri
 'arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/arn:aws:lambda:us-
west-2:123412341234:function:function_name/invocations'
```

- For API details, see PutIntegration in *Amazon CLI Command Reference*.

`put-method-response`

The following code example shows how to use `put-method-response`.

Amazon CLI

To create a method response under the specified status code with a custom method response header

Command:

```
aws apigateway put-method-response --rest-api-id 1234123412 --
resource-id a1b2c3 --http-method GET --status-code 400 --response-
parameters "method.response.header.custom-header=false"
```

- For API details, see PutMethodResponse in *Amazon CLI Command Reference*.

put-method

The following code example shows how to use put-method.

Amazon CLI

To create a method for a resource in an API with no authorization, no API key, and a custom method request header

Command:

```
aws apigateway put-method --rest-api-id 1234123412 --resource-id a1b2c3 --
http-method PUT --authorization-type "NONE" --no-api-key-required --request-
parameters "method.request.header.custom-header=false"
```

- For API details, see PutMethod in *Amazon CLI Command Reference*.

put-rest-api

The following code example shows how to use put-rest-api.

Amazon CLI

To overwrite an existing API using a Swagger template

Command:

```
aws apigateway put-rest-api --rest-api-id 1234123412 --mode overwrite --body
 'fileb:///path/to/API_Swagger_template.json'
```

To merge a Swagger template into an existing API

Command:

```
aws apigateway put-rest-api --rest-api-id 1234123412 --mode merge --body 'fileb:///
path/to/API_Swagger_template.json'
```

- For API details, see PutRestApi in *Amazon CLI Command Reference*.

reject-domain-name-access-association

The following code example shows how to use reject-domain-name-access-association.

Amazon CLI

To reject a domain name access association

The following `reject-domain-name-access-association` example rejects a domain name access association between a private custom domain name and VPC endpoint.

```
aws apigateway reject-domain-name-access-association \
    --domain-name-access-association-arn arn:aws:apigateway:us-west-2:012345678910:/domainnameaccessassociations/domainname/my.private.domain.tld/vpcesource/vpce-abcd1234efg \
    --domain-name-arn arn:aws:apigateway:us-east-1:012345678910:/domainnames/my.private.domain.tld+abcd1234
```

This command produces no output.

For more information, see Custom domain names for private APIs in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see RejectDomainNameAccessAssociation in *Amazon CLI Command Reference*.

`test-invoke-authorizer`

The following code example shows how to use `test-invoke-authorizer`.

Amazon CLI

To test invoke a request to a Custom Authorizer including the required header and value

Command:

```
aws apigateway test-invoke-authorizer --rest-api-id 1234123412 --authorizer-id 5yid1t --headers Authorization='Value'
```

- For API details, see TestInvokeAuthorizer in *Amazon CLI Command Reference*.

`test-invoke-method`

The following code example shows how to use `test-invoke-method`.

Amazon CLI

To test invoke the root resource in an API by making a GET request

Command:

```
aws apigateway test-invoke-method --rest-api-id 1234123412 --resource-id avl5sg8fw8
 --http-method GET --path-with-query-string '/'
```

To test invoke a sub-resource in an API by making a GET request with a path parameter value specified

Command:

```
aws apigateway test-invoke-method --rest-api-id 1234123412 --resource-id 3gapai --
http-method GET --path-with-query-string '/pets/1'
```

- For API details, see TestInvokeMethod in *Amazon CLI Command Reference*.

`update-account`

The following code example shows how to use `update-account`.

Amazon CLI

To change the IAM Role ARN for logging to CloudWatch Logs

Command:

```
aws apigateway update-account --patch-operations op='replace',path='/
cloudwatchRoleArn',value='arn:aws:iam::123412341234:role/APIGatewayToCloudWatchLogs'
```

Output:

```
{
    "cloudwatchRoleArn": "arn:aws:iam::123412341234:role/
APIGatewayToCloudWatchLogs",
    "throttleSettings": {
        "rateLimit": 1000.0,
        "burstLimit": 2000
    }
}
```

- For API details, see UpdateAccount in *Amazon CLI Command Reference*.

update-api-key

The following code example shows how to use `update-api-key`.

Amazon CLI

To change the name for an API Key

Command:

```
aws apigateway update-api-key --api-key sNvjQDMReA1eEQPNAW8r37XsU2rDD7fc7m2SiMnu --
patch-operations op='replace',path='/name',value='newName'
```

Output:

```
{
    "description": "currentDescription",
    "enabled": true,
    "stageKeys": [
        "41t2j324r5/dev"
    ],
    "lastUpdatedDate": 1470086052,
    "createdDate": 1445460347,
    "id": "sNvjQDMReA1vEQPNzW8r3dXsU2rrD7fcjm2SiMnu",
    "name": "newName"
}
```

To disable the API Key

Command:

```
aws apigateway update-api-key --api-key sNvjQDMReA1eEQPNAW8r37XsU2rDD7fc7m2SiMnu --
patch-operations op='replace',path='/enabled',value='false'
```

Output:

```
{
    "description": "currentDescription",
    "enabled": false,
    "stageKeys": [
        "41t2j324r5/dev"
```

```
    ],
    "lastUpdatedDate": 1470086052,
    "createdDate": 1445460347,
    "id": "sNvjQDMReA1vEQPNzW8r3dXsU2rrD7fcjm2SiMnu",
    "name": "newName"
}
```

- For API details, see UpdateApiKey in *Amazon CLI Command Reference*.

`update-authorizer`

The following code example shows how to use `update-authorizer`.

Amazon CLI

To change the name of the Custom Authorizer

Command:

```
aws apigateway update-authorizer --rest-api-id 1234123412 --authorizer-id gfi4n3 --
patch-operations op='replace',path='/name',value='testAuthorizer'
```

Output:

```
{
    "authType": "custom",
    "name": "testAuthorizer",
    "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:customAuthorizer/invocations",
    "authorizerResultTtlInSeconds": 300,
    "identitySource": "method.request.header.Authorization",
    "type": "TOKEN",
    "id": "gfi4n3"
}
```

To change the Lambda Function that is invoked by the Custom Authorizer

Command:

```
aws apigateway update-authorizer --rest-api-id 1234123412 --authorizer-id gfi4n3 --
patch-operations op='replace',path='/authorizerUri',value='arn:aws:apigateway:us-
```

```
west-2:lambda:path/2015-03-31/functions/arn:aws:lambda:us-
west-2:123412341234:function:newAuthorizer/invocations'
```

Output:

```
{
    "authType": "custom",
    "name": "testAuthorizer",
    "authorizerUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123412341234:function:newAuthorizer/invocations",
    "authorizerResultTtlInSeconds": 300,
    "identitySource": "method.request.header.Authorization",
    "type": "TOKEN",
    "id": "gfi4n3"
}
```

- For API details, see UpdateAuthorizer in *Amazon CLI Command Reference*.

`update-base-path-mapping`

The following code example shows how to use `update-base-path-mapping`.

Amazon CLI

To change the base path for a custom domain name

Command:

```
aws apigateway update-base-path-mapping --domain-name api.domain.tld --base-
path prod --patch-operations op='replace',path='/basePath',value='v1'
```

Output:

```
{
    "basePath": "v1",
    "restApiId": "1234123412",
    "stage": "api"
}
```

- For API details, see UpdateBasePathMapping in *Amazon CLI Command Reference*.

`update-client-certificate`

The following code example shows how to use `update-client-certificate`.

Amazon CLI

To update the description of a client certificate

Command:

```
aws apigateway update-client-certificate --client-certificate-id a1b2c3 --patch-operations op='replace',path='/description',value='My new description'
```

- For API details, see UpdateClientCertificate in *Amazon CLI Command Reference*.

`update-deployment`

The following code example shows how to use `update-deployment`.

Amazon CLI

To change the description of a deployment

Command:

```
aws apigateway update-deployment --rest-api-id 1234123412 --deployment-id ztt4m2 --patch-operations op='replace',path='/description',value='newDescription'
```

Output:

```
{
    "description": "newDescription",
    "id": "ztt4m2",
    "createdDate": 1455218022
}
```

- For API details, see UpdateDeployment in *Amazon CLI Command Reference*.

`update-domain-name`

The following code example shows how to use `update-domain-name`.

Amazon CLI

To change the certificate name for a custom domain name

The following `update-domain-name` example changes the certificate name for a custom domain.

```
aws apigateway update-domain-name \
    --domain-name api.domain.tld \
    --patch-operations op='replace',path='/certificateArn',value='arn:aws:acm:us-
west-2:111122223333:certificate/CERTEXAMPLE123EXAMPLE'
```

Output:

```
{
    "domainName": "api.domain.tld",
    "distributionDomainName": "d123456789012.cloudfront.net",
    "certificateArn": "arn:aws:acm:us-west-2:111122223333:certificate/
CERTEXAMPLE123EXAMPLE",
    "certificateUploadDate": 1462565487
}
```

For more information, see Set up Custom Domain Name for an API in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateDomainName in *Amazon CLI Command Reference*.

`update-integration-response`

The following code example shows how to use `update-integration-response`.

Amazon CLI

To change an integration response header to have a static mapping of '*'

Command:

```
aws apigateway update-integration-response --rest-api-id 1234123412 --
resource-id 3gapai --http-method GET --status-code 200 --patch-operations
 op='replace',path='/responseParameters/method.response.header.Access-Control-Allow-
Origin',value='"'"'*'"'"'
```

Output:

```
{
    "statusCode": "200",
    "responseParameters": {
        "method.response.header.Access-Control-Allow-Origin": "'*'"
    }
}
```

To remove an integration response header

Command:

```
aws apigateway update-integration-response --rest-api-id 1234123412 --resource-
id 3gapai --http-method GET --status-code 200 --patch-operations op='remove',path='/
responseParameters/method.response.header.Access-Control-Allow-Origin'
```

- For API details, see UpdateIntegrationResponse in *Amazon CLI Command Reference*.

`update-integration`

The following code example shows how to use `update-integration`.

Amazon CLI

To add the 'Content-Type: application/json' Mapping Template configured with Input Passthrough

Command:

```
aws apigateway update-integration \
    --rest-api-id a1b2c3d4e5 \
    --resource-id a1b2c3 \
    --http-method POST \
    --patch-operations "op='add',path='/requestTemplates/application~1json'"
```

To update (replace) the 'Content-Type: application/json' Mapping Template configured with a custom template

Command:

```
aws apigateway update-integration \
    --rest-api-id a1b2c3d4e5 \
    --resource-id a1b2c3 \
    --http-method POST \
    --patch-operations "op='replace',path='/requestTemplates/
application~1json',value='{"example": "json"}'"
```

To update (replace) a custom template associated with 'Content-Type: application/json' with Input Passthrough

Command:

```
aws apigateway update-integration \
    --rest-api-id a1b2c3d4e5 \
    --resource-id a1b2c3 \
    --http-method POST \
    --patch-operations "op='replace',path='requestTemplates/application~1json'"
```

To remove the 'Content-Type: application/json' Mapping Template

Command:

```
aws apigateway update-integration \
    --rest-api-id a1b2c3d4e5 \
    --resource-id a1b2c3 \
    --http-method POST \
    --patch-operations "op='remove',path='/requestTemplates/application~1json'"
```

- For API details, see UpdateIntegration in *Amazon CLI Command Reference*.

`update-method-response`

The following code example shows how to use `update-method-response`.

Amazon CLI

To create a new method response header for the 200 response in a method and define it as not required (default)

Command:

```
aws apigateway update-method-response --rest-api-id 1234123412 --resource-
id a1b2c3 --http-method GET --status-code 200 --patch-operations op="add",path="/
responseParameters/method.response.header.custom-header",value="false"
```

To delete a response model for the 200 response in a method

Command:

```
aws apigateway update-method-response --rest-api-id 1234123412 --resource-id a1b2c3
 --http-method GET --status-code 200 --patch-operations op="remove",path="/
responseModels/application~1json"
```

- For API details, see UpdateMethodResponse in *Amazon CLI Command Reference*.

update-method

The following code example shows how to use update-method.

Amazon CLI

Example 1: To modify a method to require an API key

The following update-method example modifies the method to require an API key.

```
aws apigateway update-method \
    --rest-api-id 1234123412 \
    --resource-id a1b2c3 \
    --http-method GET \
    --patch-operations op="replace",path="/apiKeyRequired",value="true"
```

Output:

```
{
    "httpMethod": "GET",
    "authorizationType": "NONE",
    "apiKeyRequired": true,
    "methodResponses": {
        "200": {
            "statusCode": "200",
            "responseModels": {}
```

```
        }
    },
    "methodIntegration": {
        "type": "AWS",
        "httpMethod": "POST",
        "uri": "arn:aws:apigateway:us-east-1:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-east-1:123456789111:function:hello-world/invocations",
        "passthroughBehavior": "WHEN_NO_MATCH",
        "contentHandling": "CONVERT_TO_TEXT",
        "timeoutInMillis": 29000,
        "cacheNamespace": "h7i8j9",
        "cacheKeyParameters": [],
        "integrationResponses": {
            "200": {
                "statusCode": "200",
                "responseTemplates": {}
            }
        }
    }
}
```

Example 2: To modify a method to require IAM authorization

The following `update-method` example modifies the method to require IAM authorization.

```
aws apigateway update-method \
    --rest-api-id 1234123412 \
    --resource-id a1b2c3 \
    --http-method GET \
    --patch-operations op="replace",path="/authorizationType",value="AWS_IAM"
```

Output:

```
 {
    "httpMethod": "GET",
    "authorizationType": "AWS_IAM",
    "apiKeyRequired": false,
    "methodResponses": {
        "200": {
            "statusCode": "200",
            "responseModels": {}
        }
    },
```

```
    "methodIntegration": {
        "type": "AWS",
        "httpMethod": "POST",
        "uri": "arn:aws:apigateway:us-east-1:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-east-1:123456789111:function:hello-world/invocations",
        "passthroughBehavior": "WHEN_NO_MATCH",
        "contentHandling": "CONVERT_TO_TEXT",
        "timeoutInMillis": 29000,
        "cacheNamespace": "h7i8j9",
        "cacheKeyParameters": [],
        "integrationResponses": {
            "200": {
                "statusCode": "200",
                "responseTemplates": {}
            }
        }
    }
}
```

Example 3: To modify a method to require Lambda authorization

The following `update-method` example modifies the method to required Lambda authorization.

```
aws apigateway update-method --rest-api-id 1234123412 \
    --resource-id a1b2c3 \
    --http-method GET \
    --patch-operations op="replace",path="/authorizationType",value="CUSTOM"
 op="replace",path="/authorizerId",value="e4f5g6"
```

Output:

```
 {
    "httpMethod": "GET",
    "authorizationType": "CUSTOM",
    "authorizerId" : "e4f5g6",
    "apiKeyRequired": false,
    "methodResponses": {
        "200": {
            "statusCode": "200",
            "responseModels": {}
        }
```

```
    },
    "methodIntegration": {
        "type": "AWS",
        "httpMethod": "POST",
        "uri": "arn:aws:apigateway:us-east-1:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-east-1:123456789111:function:hello-world/invocations",
        "passthroughBehavior": "WHEN_NO_MATCH",
        "contentHandling": "CONVERT_TO_TEXT",
        "timeoutInMillis": 29000,
        "cacheNamespace": "h7i8j9",
        "cacheKeyParameters": [],
        "integrationResponses": {
            "200": {
                "statusCode": "200",
                "responseTemplates": {}
            }
        }
    }
}
```

For more information, see Create, configure, and test usage plans using the API Gateway CLI and REST API and Controlling and managing access to a REST API in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateMethod in *Amazon CLI Command Reference*.

`update-model`

The following code example shows how to use `update-model`.

Amazon CLI

To change the description of a model in an API

Command:

```
aws apigateway update-model --rest-api-id 1234123412 --model-name 'Empty' --patch-
operations op=replace,path=/description,value='New Description'
```

To change the schema of a model in an API

Command:

```
aws apigateway update-model --rest-api-id 1234123412 --model-name 'Empty' --patch-
operations op=replace,path=/schema,value='"{ \"$schema\": \"http://json-schema.org/
draft-04/schema#\", \"title\" : \"Empty Schema\", \"type\" : \"object\" }"'
```

- For API details, see UpdateModel in *Amazon CLI Command Reference*.

`update-resource`

The following code example shows how to use `update-resource`.

Amazon CLI

To move a resource and place it under a different parent resource in an API

Command:

```
aws apigateway update-resource --rest-api-id 1234123412 --resource-id 1a2b3c --
patch-operations op=replace,path=/parentId,value='3c2b1a'
```

Output:

```
{
    "path": "/resource",
    "pathPart": "resource",
    "id": "1a2b3c",
    "parentId": "3c2b1a"
}
```

To rename a resource (pathPart) in an API

Command:

```
aws apigateway update-resource --rest-api-id 1234123412 --resource-id 1a2b3c --
patch-operations op=replace,path=/pathPart,value=newresourcename
```

Output:

```
{
    "path": "/newresourcename",
    "pathPart": "newresourcename",
```

```
    "id": "1a2b3c",
    "parentId": "3c2b1a"
}
```

- For API details, see UpdateResource in *Amazon CLI Command Reference*.

update-rest-api

The following code example shows how to use `update-rest-api`.

Amazon CLI

To change the name of an API

Command:

```
aws apigateway update-rest-api --rest-api-id 1234123412 --patch-operations
 op=replace,path=/name,value='New Name'
```

To change the description of an API

Command:

```
aws apigateway update-rest-api --rest-api-id 1234123412 --patch-operations
 op=replace,path=/description,value='New Description'
```

- For API details, see UpdateRestApi in *Amazon CLI Command Reference*.

update-stage

The following code example shows how to use `update-stage`.

Amazon CLI

Example 1: To override the stage settings for a resource and method

The following `update-stage` example overrides the stage settings and turns off full request/response logging for a specific resource and method.

```
aws apigateway update-stage \
```

```
    --rest-api-id 1234123412 \
    --stage-name 'dev' \
    --patch-operations op=replace,path=/~1resourceName/GET/logging/
dataTrace,value=false
```

Output:

```
{
    "deploymentId": "5ubd17",
    "stageName": "dev",
    "cacheClusterEnabled": false,
    "cacheClusterStatus": "NOT_AVAILABLE",
    "methodSettings": {
        "~1resourceName/GET": {
            "metricsEnabled": false,
            "dataTraceEnabled": false,
            "throttlingBurstLimit": 5000,
            "throttlingRateLimit": 10000.0,
            "cachingEnabled": false,
            "cacheTtlInSeconds": 300,
            "cacheDataEncrypted": false,
            "requireAuthorizationForCacheControl": true,
            "unauthorizedCacheControlHeaderStrategy": "SUCCEED_WITH_RESPONSE_HEADER"
        }
    },
    "tracingEnabled": false,
    "createdDate": "2022-07-18T10:11:18-07:00",
    "lastUpdatedDate": "2022-07-18T10:19:04-07:00"
}
```

For more information, see Setting up a stage for a REST API in the *Amazon API Gateway Developer Guide*.

Example 2: To update the stage settings for all resources and methods of an API stage

The following `update-stage` example turns on full request/response logging for all resources and methods of an API stage.

```
aws apigateway update-stage \
    --rest-api-id 1234123412 \
    --stage-name 'dev' \
    --patch-operations 'op=replace,path=/*/*/logging/dataTrace,value=true'
```

Output:

```
{
    "deploymentId": "5ubd17",
    "stageName": "dev",
    "cacheClusterEnabled": false,
    "cacheClusterStatus": "NOT_AVAILABLE",
    "methodSettings": {
        "*/*": {
            "metricsEnabled": false,
            "dataTraceEnabled": true,
            "throttlingBurstLimit": 5000,
            "throttlingRateLimit": 10000.0,
            "cachingEnabled": false,
            "cacheTtlInSeconds": 300,
            "cacheDataEncrypted": false,
            "requireAuthorizationForCacheControl": true,
            "unauthorizedCacheControlHeaderStrategy": "SUCCEED_WITH_RESPONSE_HEADER"
        }
    },
    "tracingEnabled": false,
    "createdDate": "2022-07-18T10:11:18-07:00",
    "lastUpdatedDate": "2022-07-18T10:31:04-07:00"
}
```

For more information, see Setting up a stage for a REST API in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateStage in *Amazon CLI Command Reference*.

`update-usage-plan`

The following code example shows how to use `update-usage-plan`.

Amazon CLI

To change the period defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
 op="replace",path="/quota/period",value="MONTH"
```

To change the quota limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
 op="replace",path="/quota/limit",value="500"
```

To change the throttle rate limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
 op="replace",path="/throttle/rateLimit",value="10"
```

To change the throttle burst limit defined in a Usage Plan

Command:

```
aws apigateway update-usage-plan --usage-plan-id a1b2c3 --patch-operations
 op="replace",path="/throttle/burstLimit",value="20"
```

- For API details, see UpdateUsagePlan in *Amazon CLI Command Reference*.

`update-usage`

The following code example shows how to use `update-usage`.

Amazon CLI

To temporarily modify the quota on an API key for the current period defined in the Usage Plan

Command:

```
aws apigateway update-usage --usage-plan-id a1b2c3 --key-
id 1NbjQzMReAkeEQPNAW8r3dXsU2rDD7fc7f2Sipnu --patch-operations op="replace",path="/
remaining",value="50"
```

- For API details, see UpdateUsage in *Amazon CLI Command Reference*.

API Gateway HTTP and WebSocket API examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with API Gateway HTTP and WebSocket API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-api-mapping`

The following code example shows how to use `create-api-mapping`.

Amazon CLI

To create an API mapping for an API

The following `create-api-mapping` example maps the `test` stage of an API to the `/myApi` path of the `regional.example.com` custom domain name.

```
aws apigatewayv2 create-api-mapping \
    --domain-name regional.example.com \
    --api-mapping-key myApi \
    --api-id a1b2c3d4 \
    --stage test
```

Output:

```
{
    "ApiId": "a1b2c3d4",
    "ApiMappingId": "0qzs2sy7bh",
    "ApiMappingKey": "myApi"
```

```
    "Stage": "test"
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateApiMapping in *Amazon CLI Command Reference*.

`create-api`

The following code example shows how to use `create-api`.

Amazon CLI

To create an HTTP API

The following `create-api` example creates an HTTP API by using quick create. You can use quick create to create an API with an Amazon Lambda or HTTP integration, a default catch-all route, and a default stage that is configured to automatically deploy changes. The following command uses quick create to create an HTTP API that integrates with a Lambda function.

```
aws apigatewayv2 create-api \
    --name my-http-api \
    --protocol-type HTTP \
    --target arn:aws:lambda:us-west-2:123456789012:function:my-lambda-function
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CreatedDate": "2020-04-08T19:05:45+00:00",
    "Name": "my-http-api",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path"
}
```

For more information, see Developing an HTTP API in API Gateway in the *Amazon API Gateway Developer Guide*.

To create a WebSocket API

The following `create-api` example creates a WebSocket API with the specified name.

```
aws apigatewayv2 create-api \
    --name "myWebSocketApi" \
    --protocol-type WEBSOCKET \
    --route-selection-expression '$request.body.action'
```

Output:

```
{
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "Name": "myWebSocketApi",
    "CreatedDate": "2018-11-15T06:23:51Z",
    "ProtocolType": "WEBSOCKET",
    "RouteSelectionExpression": "'$request.body.action'",
    "ApiId": "aabbccddee"
}
```

For more information, see Create a WebSocket API in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateApi in *Amazon CLI Command Reference*.

`create-authorizer`

The following code example shows how to use `create-authorizer`.

Amazon CLI

To create a JWT authorizer for an HTTP API

The following `create-authorizer` example creates a JWT authorizer that uses Amazon Cognito as an identity provider.

```
aws apigatewayv2 create-authorizer \
    --name my-jwt-authorizer \
    --api-id a1b2c3d4 \
    --authorizer-type JWT \
    --identity-source '$request.header.Authorization' \
```

```
    --jwt-configuration Audience=123456abc,Issuer=https://cognito-idp.us-
west-2.amazonaws.com/us-west-2_abc123
```

Output:

```
{
    "AuthorizerId": "a1b2c3",
    "AuthorizerType": "JWT",
    "IdentitySource": [
        "$request.header.Authorization"
    ],
    "JwtConfiguration": {
        "Audience": [
            "123456abc"
        ],
        "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-west-2_abc123"
    },
    "Name": "my-jwt-authorizer"
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateAuthorizer in *Amazon CLI Command Reference*.

`create-deployment`

The following code example shows how to use `create-deployment`.

Amazon CLI

To create a deployment for an API

The following `create-deployment` example creates a deployment for an API and associates that deployment with the `dev` stage of the API.

```
aws apigatewayv2 create-deployment \
    --api-id a1b2c3d4 \
    --stage-name dev
```

Output:

```
{
    "AutoDeployed": false,
    "CreatedDate": "2020-04-06T23:38:08Z",
    "DeploymentId": "53lz9l",
    "DeploymentStatus": "DEPLOYED"
}
```

For more information, see API deployment in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateDeployment in *Amazon CLI Command Reference*.

`create-domain-name`

The following code example shows how to use `create-domain-name`.

Amazon CLI

To create a custom domain name

The following `create-domain-name` example creates a regional custom domain name for an API.

```
aws apigatewayv2 create-domain-name \
    --domain-name regional.example.com \
    --domain-name-configurations CertificateArn=arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678
```

Output:

```
{
    "ApiMappingSelectionExpression": "$request.basepath",
    "DomainName": "regional.example.com",
    "DomainNameConfigurations": [
        {
            "ApiGatewayDomainName": "d-id.execute-api.us-west-2.amazonaws.com",
            "CertificateArn": "arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678",
            "EndpointType": "REGIONAL",
            "HostedZoneId": "123456789111",
            "SecurityPolicy": "TLS_1_2",
            "DomainNameStatus": "AVAILABLE"
        }
```

```
    ]
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateDomainName in *Amazon CLI Command Reference*.

`create-integration`

The following code example shows how to use `create-integration`.

Amazon CLI

To create a WebSocket API integration

The following `create-integration` example creates a mock integration for a WebSocket API.

```
aws apigatewayv2 create-integration \
    --api-id aabbccddee \
    --passthrough-behavior WHEN_NO_MATCH \
    --timeout-in-millis 29000 \
    --connection-type INTERNET \
    --integration-type MOCK
```

Output:

```
{
    "ConnectionType": "INTERNET",
    "IntegrationId": "0abcdef",
    "IntegrationResponseSelectionExpression": "${integration.response.statuscode}",
    "IntegrationType": "MOCK",
    "PassthroughBehavior": "WHEN_NO_MATCH",
    "PayloadFormatVersion": "1.0",
    "TimeoutInMillis": 29000
}
```

For more information, see Set up a WebSocket API integration request in API Gateway in the *Amazon API Gateway Developer Guide*.

To create an HTTP API integration

The following `create-integration` example creates an Amazon Lambda integration for an HTTP API.

```
aws apigatewayv2 create-integration \
    --api-id a1b2c3d4 \
    --integration-type AWS_PROXY \
    --integration-uri arn:aws:lambda:us-west-2:123456789012:function:my-function \
    --payload-format-version 2.0
```

Output:

```
{
    "ConnectionType": "INTERNET",
    "IntegrationId": "0abcdef",
    "IntegrationMethod": "POST",
    "IntegrationType": "AWS_PROXY",
    "IntegrationUri": "arn:aws:lambda:us-west-2:123456789012:function:my-function",
    "PayloadFormatVersion": "2.0",
    "TimeoutInMillis": 30000
}
```

For more information, see Configuring integrations for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateIntegration in *Amazon CLI Command Reference*.

`create-route`

The following code example shows how to use `create-route`.

Amazon CLI

To create a $default route for a WebSocket or HTTP API

The following `create-route` example creates a `$default` route for a WebSocket or HTTP API.

```
aws apigatewayv2 create-route \
    --api-id aabbccddee \
    --route-key '$default'
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteKey": "$default",
    "RouteId": "1122334"
}
```

For more information, see Working with routes for WebSocket APIs in the *Amazon API Gateway Developer Guide*

To create a route for an HTTP API

The following `create-route` example creates a route named `signup` that accepts POST requests.

```
aws apigatewayv2 create-route \
    --api-id aabbccddee \
    --route-key 'POST /signup'
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteKey": "POST /signup",
    "RouteId": "1122334"
}
```

For more information, see Working with routes for HTTP APIs in the *Amazon API Gateway Developer Guide*

- For API details, see CreateRoute in *Amazon CLI Command Reference*.

`create-routing-rule`

The following code example shows how to use `create-routing-rule`.

Amazon CLI

To create a routing rule

The following `create-routing-rule` example creates a routing rule with a priority of `50`.

```
aws apigatewayv2 create-routing-rule \
    --domain-name 'regional.example.com' \
    --priority 50 \
    --conditions '[ \
        { \
            "MatchBasePaths": { \
                "AnyOf": [ \
                    "PetStoreShopper" \
                ] \
            } \
        } \
    ]' \
    --actions '[ \
        { \
            "InvokeApi": { \
                "ApiId": "abcd1234", \
                "Stage": "prod" \
            } \
        } \
    ]'
```

Output:

```
{
    "Actions": [
        {
            "InvokeApi": {
                "ApiId": "abcd1234",
                "Stage": "prod",
                "StripBasePath": false
            }
        }
    ],
    "Conditions": [
        {
            "MatchBasePaths": {
                "AnyOf": [
                    "PetStoreShopper"
                ]
            }
        }
```

```
    ],
    "Priority": 50,
    "RoutingRuleArn": "arn:aws:apigateway:us-east-2:123456789012:/domainnames/
regional.example.com/routingrules/aaa111",
    "RoutingRuleId": "aaa111"
}
```

For more information, see Routing rules to connect API stages to a custom domain name for REST APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateRoutingRule in *Amazon CLI Command Reference*.

`create-stage`

The following code example shows how to use `create-stage`.

Amazon CLI

To create a stage

The following `create-stage` example creates a stage named dev for an API.

```
aws apigatewayv2 create-stage \
    --api-id a1b2c3d4 \
    --stage-name dev
```

Output:

```
{
    "CreatedDate": "2020-04-06T23:23:46Z",
    "DefaultRouteSettings": {
        "DetailedMetricsEnabled": false
    },
    "LastUpdatedDate": "2020-04-06T23:23:46Z",
    "RouteSettings": {},
    "StageName": "dev",
    "StageVariables": {},
    "Tags": {}
}
```

For more information, see Working with stages for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateStage in *Amazon CLI Command Reference*.

`create-vpc-link`

The following code example shows how to use `create-vpc-link`.

Amazon CLI

To create a VPC link for an HTTP API

The following `create-vpc-link` example creates a VPC link for HTTP APIs.

```
aws apigatewayv2 create-vpc-link \
    --name MyVpcLink \
    --subnet-ids subnet-aaaa subnet-bbbb \
    --security-group-ids sg1234 sg5678
```

Output:

```
{
    "CreatedDate": "2020-04-07T00:11:46Z",
    "Name": "MyVpcLink",
    "SecurityGroupIds": [
        "sg1234",
        "sg5678"
    ],
    "SubnetIds": [
        "subnet-aaaa",
        "subnet-bbbb"
    ],
    "Tags": {},
    "VpcLinkId": "abcd123",
    "VpcLinkStatus": "PENDING",
    "VpcLinkStatusMessage": "VPC link is provisioning ENIs",
    "VpcLinkVersion": "V2"
}
```

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see CreateVpcLink in *Amazon CLI Command Reference*.

`delete-access-log-settings`

The following code example shows how to use `delete-access-log-settings`.

Amazon CLI

To disable access logging for an API

The following `delete-access-log-settings` example deletes the access log settings for the `$default` stage of an API. To disable access logging for a stage, delete its access log settings.

```
aws apigatewayv2 delete-access-log-settings \
    --api-id a1b2c3d4 \
    --stage-name '$default'
```

This command produces no output.

For more information, see Configuring logging for an HTTP API in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteAccessLogSettings in *Amazon CLI Command Reference*.

`delete-api-mapping`

The following code example shows how to use `delete-api-mapping`.

Amazon CLI

To delete an API mapping

The following `delete-api-mapping` example deletes an API mapping for the `api.example.com` custom domain name.

```
aws apigatewayv2 delete-api-mapping \
    --api-mapping-id a1b2c3 \
    --domain-name api.example.com
```

This command produces no output.

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteApiMapping in *Amazon CLI Command Reference*.

`delete-api`

The following code example shows how to use `delete-api`.

Amazon CLI

To delete an API

The following `delete-api` example deletes an API.

```
aws apigatewayv2 delete-api \
    --api-id a1b2c3d4
```

This command produces no output.

For more information, see Working with HTTP APIs and Working with WebSocket APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteApi in *Amazon CLI Command Reference*.

`delete-authorizer`

The following code example shows how to use `delete-authorizer`.

Amazon CLI

To delete an authorizer

The following `delete-authorizer` example deletes an authorizer.

```
aws apigatewayv2 delete-authorizer \
    --api-id a1b2c3d4 \
    --authorizer-id a1b2c3
```

This command produces no output.

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteAuthorizer in *Amazon CLI Command Reference*.

`delete-cors-configuration`

The following code example shows how to use `delete-cors-configuration`.

Amazon CLI

To delete the CORS configuration for an HTTP API

The following `delete-cors-configuration` example disables CORS for an HTTP API by deleting its CORS configuration.

```
aws apigatewayv2 delete-cors-configuration \
    --api-id a1b2c3d4
```

This command produces no output.

For more information, see Configuring CORS for an HTTP API in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteCorsConfiguration in *Amazon CLI Command Reference*.

`delete-deployment`

The following code example shows how to use `delete-deployment`.

Amazon CLI

To delete a deployment

The following `delete-deployment` example deletes a deployment of an API.

```
aws apigatewayv2 delete-deployment \
    --api-id a1b2c3d4 \
    --deployment-id a1b2c3
```

This command produces no output.

For more information, see API deployment in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteDeployment in *Amazon CLI Command Reference*.

`delete-domain-name`

The following code example shows how to use `delete-domain-name`.

Amazon CLI

To delete a custom domain name

The following `delete-domain-name` example deletes a custom domain name.

```
aws apigatewayv2 delete-domain-name \
    --domain-name api.example.com
```

This command produces no output.

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteDomainName in *Amazon CLI Command Reference*.

`delete-integration`

The following code example shows how to use `delete-integration`.

Amazon CLI

To delete an integration

The following `delete-integration` example deletes an API integration.

```
aws apigatewayv2 delete-integration \
    --api-id a1b2c3d4 \
    --integration-id a1b2c3
```

This command produces no output.

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteIntegration in *Amazon CLI Command Reference*.

`delete-route-settings`

The following code example shows how to use `delete-route-settings`.

Amazon CLI

To delete route settings

The following `delete-route-settings` example deletes the route settings for the specified route.

```
aws apigatewayv2 delete-route-settings \
    --api-id a1b2c3d4 \
    --stage-name dev \
    --route-key 'GET /pets'
```

This command produces no output.

For more information, see Working with routes for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteRouteSettings in *Amazon CLI Command Reference*.

`delete-route`

The following code example shows how to use `delete-route`.

Amazon CLI

To delete a route

The following `delete-route` example deletes an API route.

```
aws apigatewayv2 delete-route \
    --api-id a1b2c3d4 \
    --route-id a1b2c3
```

This command produces no output.

For more information, see Working with routes for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteRoute in *Amazon CLI Command Reference*.

`delete-routing-rule`

The following code example shows how to use `delete-routing-rule`.

Amazon CLI

To delete a routing rule

The following `delete-routing-rule` example deletes a routing rule for a custom domain name.

```
aws apigatewayv2 delete-routing-rule \
    --domain-name 'regional.example.com' \
    --routing-rule-id aaa111
```

This command produces no output.

For more information, see Routing rules to connect API stages to a custom domain name for REST APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteRoutingRule in *Amazon CLI Command Reference*.

`delete-stage`

The following code example shows how to use `delete-stage`.

Amazon CLI

To delete a stage

The following `delete-stage` example deletes the `test` stage of an API.

```
aws apigatewayv2 delete-stage \
    --api-id a1b2c3d4 \
    --stage-name test
```

This command produces no output.

For more information, see Working with stages for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteStage in *Amazon CLI Command Reference*.

`delete-vpc-link`

The following code example shows how to use `delete-vpc-link`.

Amazon CLI

To delete a VPC link for an HTTP API

The following `delete-vpc-link` example deletes a VPC link.

```
aws apigatewayv2 delete-vpc-link \
    --vpc-link-id abcd123
```

This command produces no output.

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteVpcLink in *Amazon CLI Command Reference*.

`export-api`

The following code example shows how to use `export-api`.

Amazon CLI

To export an OpenAPI definition of an HTTP API

The following `export-api` example exports an OpenAPI 3.0 definition of an API stage named `prod` to a YAML file named `stage-definition.yaml`. The exported definition file includes API Gateway extensions by default.

```
aws apigatewayv2 export-api \
```

```
    --api-id a1b2c3d4 \
    --output-type YAML \
    --specification OAS30 \
    --stage-name prod \
    stage-definition.yaml
```

This command produces no output.

For more information, see Exporting an HTTP API from API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see ExportApi in *Amazon CLI Command Reference*.

`get-api-mapping`

The following code example shows how to use `get-api-mapping`.

Amazon CLI

To get information about an API mapping for a custom domain name

The following `get-api-mapping` example displays infomation about an API mapping for the `api.example.com` custom domain name.

```
aws apigatewayv2 get-api-mapping \
    --api-mapping-id a1b2c3 \
    --domain-name api.example.com
```

Output:

```
{
    "ApiId": "a1b2c3d4",
    "ApiMappingId": "a1b2c3d5",
    "ApiMappingKey": "myTestApi"
    "Stage": "test"
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetApiMapping in *Amazon CLI Command Reference*.

`get-api-mappings`

The following code example shows how to use `get-api-mappings`.

Amazon CLI

To get API mappings for a custom domain name

The following `get-api-mappings` example displays a list of all of the API mappings for the `api.example.com` custom domain name.

```
aws apigatewayv2 get-api-mappings \
    --domain-name api.example.com
```

Output:

```
{
    "Items": [
        {
            "ApiId": "a1b2c3d4",
            "ApiMappingId": "a1b2c3d5",
            "ApiMappingKey": "myTestApi"
            "Stage": "test"
        },
        {
            "ApiId": "a5b6c7d8",
            "ApiMappingId": "a1b2c3d6",
            "ApiMappingKey": "myDevApi"
            "Stage": "dev"
        },
    ]
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetApiMappings in *Amazon CLI Command Reference*.

`get-api`

The following code example shows how to use `get-api`.

Amazon CLI

To retrieve information about an API

The following `get-api` example displays information about an API.

```
aws apigatewayv2 get-api \
    --api-id a1b2c3d4
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CreatedDate": "2020-03-28T00:32:37Z",
    "Name": "my-api",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path",
    "Tags": {
        "department": "finance"
    }
}
```

- For API details, see GetApi in *Amazon CLI Command Reference*.

`get-apis`

The following code example shows how to use `get-apis`.

Amazon CLI

To retrieve a list of APIs

The following `get-apis` example lists all of the APIs for the current user.

```
aws apigatewayv2 get-apis
```

Output:

```
{
```

```
    "Items": [
        {
            "ApiEndpoint": "wss://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
            "ApiId": "a1b2c3d4",
            "ApiKeySelectionExpression": "$request.header.x-api-key",
            "CreatedDate": "2020-04-07T20:21:59Z",
            "Name": "my-websocket-api",
            "ProtocolType": "WEBSOCKET",
            "RouteSelectionExpression": "$request.body.message",
            "Tags": {}
        },
        {
            "ApiEndpoint": "https://a1b2c3d5.execute-api.us-west-2.amazonaws.com",
            "ApiId": "a1b2c3d5",
            "ApiKeySelectionExpression": "$request.header.x-api-key",
            "CreatedDate": "2020-04-07T20:23:50Z",
            "Name": "my-http-api",
            "ProtocolType": "HTTP",
            "RouteSelectionExpression": "$request.method $request.path",
            "Tags": {}
        }
    ]
}
```

For more information, see Working with HTTP APIs and Working with WebSocket APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetApis in *Amazon CLI Command Reference*.

`get-authorizer`

The following code example shows how to use `get-authorizer`.

Amazon CLI

To retrieve information about an authorizer

The following `get-authorizer` example displays information about an authorizer.

```
aws apigatewayv2 get-authorizer \
    --api-id a1b2c3d4 \
    --authorizer-id a1b2c3
```

Output:

```
{
    "AuthorizerId": "a1b2c3",
    "AuthorizerType": "JWT",
    "IdentitySource": [
        "$request.header.Authorization"
    ],
    "JwtConfiguration": {
        "Audience": [
            "123456abc"
        ],
        "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-west-2_abc123"
    },
    "Name": "my-jwt-authorizer"
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see GetAuthorizer in *Amazon CLI Command Reference*.

`get-authorizers`

The following code example shows how to use `get-authorizers`.

Amazon CLI

To retrieve a list of authorizers for an API

The following `get-authorizers` example displays a list of all of the authorizers for an API.

```
aws apigatewayv2 get-authorizers \
    --api-id a1b2c3d4
```

Output:

```
{
    "Items": [
        {
            "AuthorizerId": "a1b2c3",
```

```
            "AuthorizerType": "JWT",
            "IdentitySource": [
                "$request.header.Authorization"
            ],
            "JwtConfiguration": {
                "Audience": [
                    "123456abc"
                ],
                "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-
west-2_abc123"
            },
            "Name": "my-jwt-authorizer"
        },
        {
            "AuthorizerId": "a1b2c4",
            "AuthorizerType": "JWT",
            "IdentitySource": [
                "$request.header.Authorization"
            ],
            "JwtConfiguration": {
                "Audience": [
                    "6789abcde"
                ],
                "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-
west-2_abc234"
            },
            "Name": "new-jwt-authorizer"
        }
    ]
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see GetAuthorizers in *Amazon CLI Command Reference*.

`get-deployment`

The following code example shows how to use `get-deployment`.

Amazon CLI

To retrieve information about a deployment

The following `get-deployment` example displays information about a deployment.

```
aws apigatewayv2 get-deployment \
    --api-id a1b2c3d4 \
    --deployment-id abcdef
```

Output:

```
{
    "AutoDeployed": true,
    "CreatedDate": "2020-04-07T23:58:40Z",
    "DeploymentId": "abcdef",
    "DeploymentStatus": "DEPLOYED",
    "Description": "Automatic deployment triggered by changes to the Api
 configuration"
}
```

For more information, see API deployment in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDeployment in *Amazon CLI Command Reference*.

`get-deployments`

The following code example shows how to use `get-deployments`.

Amazon CLI

To retrieve a list of deployments

The following `get-deployments` example displays a list of all of an API's deployments.

```
aws apigatewayv2 get-deployments \
    --api-id a1b2c3d4
```

Output:

```
{
    "Items": [
        {
            "AutoDeployed": true,
```

```
            "CreatedDate": "2020-04-07T23:58:40Z",
            "DeploymentId": "abcdef",
            "DeploymentStatus": "DEPLOYED",
            "Description": "Automatic deployment triggered by changes to the Api
 configuration"
        },
        {
            "AutoDeployed": true,
            "CreatedDate": "2020-04-06T00:33:00Z",
            "DeploymentId": "bcdefg",
            "DeploymentStatus": "DEPLOYED",
            "Description": "Automatic deployment triggered by changes to the Api
 configuration"
        }
    ]
}
```

For more information, see API deployment in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDeployments in *Amazon CLI Command Reference*.

`get-domain-name`

The following code example shows how to use `get-domain-name`.

Amazon CLI

To retrieve information about a custom domain name

The following `get-domain-name` example displays information about a custom domain name.

```
aws apigatewayv2 get-domain-name \
    --domain-name api.example.com
```

Output:

```
{
    "ApiMappingSelectionExpression": "$request.basepath",
    "DomainName": "api.example.com",
    "DomainNameConfigurations": [
        {
            "ApiGatewayDomainName": "d-1234.execute-api.us-west-2.amazonaws.com",
```

```
            "CertificateArn": "arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678",
            "EndpointType": "REGIONAL",
            "HostedZoneId": "123456789111",
            "SecurityPolicy": "TLS_1_2",
            "DomainNameStatus": "AVAILABLE"
        }
    ],
    "Tags": {}
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDomainName in *Amazon CLI Command Reference*.

`get-domain-names`

The following code example shows how to use `get-domain-names`.

Amazon CLI

To retrieve a list of custom domain names

The following `get-domain-names` example displays a list of all of the custom domain names for the current user.

```
aws apigatewayv2 get-domain-names
```

Output:

```
{
    "Items": [
        {
            "ApiMappingSelectionExpression": "$request.basepath",
            "DomainName": "api.example.com",
            "DomainNameConfigurations": [
                {
                    "ApiGatewayDomainName": "d-1234.execute-api.us-
west-2.amazonaws.com",
                    "CertificateArn": "arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678",
```

```
                    "EndpointType": "REGIONAL",
                    "HostedZoneId": "123456789111",
                    "SecurityPolicy": "TLS_1_2",
                    "DomainNameStatus": "AVAILABLE"
                }
            ]
        },
        {
            "ApiMappingSelectionExpression": "$request.basepath",
            "DomainName": "newApi.example.com",
            "DomainNameConfigurations": [
                {
                    "ApiGatewayDomainName": "d-5678.execute-api.us-
west-2.amazonaws.com",
                    "CertificateArn": "arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678",
                    "EndpointType": "REGIONAL",
                    "HostedZoneId": "123456789222",
                    "SecurityPolicy": "TLS_1_2",
                    "DomainNameStatus": "AVAILABLE"
                }
            ]
        }
    ]
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see GetDomainNames in *Amazon CLI Command Reference*.

`get-integration`

The following code example shows how to use `get-integration`.

Amazon CLI

To retrieve information about an integration

The following `get-integration` example displays information about an integration.

```
aws apigatewayv2 get-integration \
    --api-id a1b2c3d4 \
```

```
    --integration-id a1b2c3
```

Output:

```
{
    "ApiGatewayManaged": true,
    "ConnectionType": "INTERNET",
    "IntegrationId": "a1b2c3",
    "IntegrationMethod": "POST",
    "IntegrationType": "AWS_PROXY",
    "IntegrationUri": "arn:aws:lambda:us-west-2:12356789012:function:hello12",
    "PayloadFormatVersion": "2.0",
    "TimeoutInMillis": 30000
}
```

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the *Amazon API Gateway Developer Guide*.

- For API details, see GetIntegration in *Amazon CLI Command Reference*.

`get-integrations`

The following code example shows how to use `get-integrations`.

Amazon CLI

To retrieve a list of integrations

The following `get-integrations` example displays a list of all of an API's integrations.

```
aws apigatewayv2 get-integrations \
    --api-id a1b2c3d4
```

Output:

```
{
    "Items": [
        {
            "ApiGatewayManaged": true,
            "ConnectionType": "INTERNET",
            "IntegrationId": "a1b2c3",
```

```
            "IntegrationMethod": "POST",
            "IntegrationType": "AWS_PROXY",
            "IntegrationUri": "arn:aws:lambda:us-west-2:123456789012:function:my-
function",
            "PayloadFormatVersion": "2.0",
            "TimeoutInMillis": 30000
        },
        {
            "ConnectionType": "INTERNET",
            "IntegrationId": "a1b2c4",
            "IntegrationMethod": "ANY",
            "IntegrationType": "HTTP_PROXY",
            "IntegrationUri": "https://www.example.com",
            "PayloadFormatVersion": "1.0",
            "TimeoutInMillis": 30000
        }
    ]
}
```

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the *Amazon API Gateway Developer Guide*.

- For API details, see GetIntegrations in *Amazon CLI Command Reference*.

`get-route`

The following code example shows how to use `get-route`.

Amazon CLI

To retrieve information about a route

The following `get-route` example displays information about a route.

```
aws apigatewayv2 get-route \
    --api-id a1b2c3d4 \
    --route-id 72jz1wk
```

Output:

```
{
    "ApiKeyRequired": false,
```

```
    "AuthorizationType": "NONE",
    "RouteId": "72jz1wk",
    "RouteKey": "ANY /pets",
    "Target": "integrations/a1b2c3"
}
```

For more information, see Working with routes for HTTP APIs in the *Amazon API Gateway Developer Guide*

- For API details, see GetRoute in *Amazon CLI Command Reference*.

`get-routes`

The following code example shows how to use `get-routes`.

Amazon CLI

To retrieve a list of routes

The following `get-routes` example displays a list of all of an API's routes.

```
aws apigatewayv2 get-routes \
    --api-id a1b2c3d4
```

Output:

```
{
    "Items": [
        {
            "ApiKeyRequired": false,
            "AuthorizationType": "NONE",
            "RouteId": "72jz1wk",
            "RouteKey": "ANY /admin",
            "Target": "integrations/a1b2c3"
        },
        {
            "ApiGatewayManaged": true,
            "ApiKeyRequired": false,
            "AuthorizationType": "NONE",
            "RouteId": "go65gqi",
            "RouteKey": "$default",
            "Target": "integrations/a1b2c4"
```

```
        }
    ]
}
```

For more information, see Working with routes for HTTP APIs in the *Amazon API Gateway Developer Guide*

- For API details, see GetRoutes in *Amazon CLI Command Reference*.

`get-routing-rule`

The following code example shows how to use `get-routing-rule`.

Amazon CLI

To get a routing rule

The following `get-routing-rule` example gets a routing rule for a domain name.

```
aws apigatewayv2 get-routing-rule \
    --domain-name 'regional.example.com' \
    --routing-rule-id aaa111
```

Output:

```
{
    "Actions": [
        {
            "InvokeApi": {
                "ApiId": "abcd1234",
                "Stage": "prod",
                "StripBasePath": false
            }
        }
    ],
    "Conditions": [
        {
            "MatchBasePaths": {
                "AnyOf": [
                    "PetStoreShopper"
                ]
            }
```

```
        }
    ],
    "Priority": 50,
    "RoutingRuleArn": "arn:aws:apigateway:us-east-2:123456789012:/domainnames/
regional.example.com/routingrules/aaa111",
    "RoutingRuleId": "aaa111"
}
```

For more information, see Routing rules to connect API stages to a custom domain name for REST APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetRoutingRule in *Amazon CLI Command Reference*.

`get-stage`

The following code example shows how to use `get-stage`.

Amazon CLI

To retrieve information about a stage

The following `get-stage` example displays information about the `prod` stage of an API.

```
aws apigatewayv2 get-stage \
    --api-id a1b2c3d4 \
    --stage-name prod
```

Output:

```
{
    "CreatedDate": "2020-04-08T00:36:05Z",
    "DefaultRouteSettings": {
        "DetailedMetricsEnabled": false
    },
    "DeploymentId": "x1zwyv",
    "LastUpdatedDate": "2020-04-08T00:36:13Z",
    "RouteSettings": {},
    "StageName": "prod",
    "StageVariables": {
        "function": "my-prod-function"
    },
    "Tags": {}
```

```
}
```

For more information, see Working with stages for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetStage in *Amazon CLI Command Reference*.

`get-stages`

The following code example shows how to use `get-stages`.

Amazon CLI

To retrieve a list of stages

The following `get-stages` example lists all of an API's stages.

```
aws apigatewayv2 get-stages \
    --api-id a1b2c3d4
```

Output:

```
{
    "Items": [
        {
            "ApiGatewayManaged": true,
            "AutoDeploy": true,
            "CreatedDate": "2020-04-08T00:08:44Z",
            "DefaultRouteSettings": {
                "DetailedMetricsEnabled": false
            },
            "DeploymentId": "dty748",
            "LastDeploymentStatusMessage": "Successfully deployed stage with
 deployment ID 'dty748'",
            "LastUpdatedDate": "2020-04-08T00:09:49Z",
            "RouteSettings": {},
            "StageName": "$default",
            "StageVariables": {},
            "Tags": {}
        },
        {
            "AutoDeploy": true,
```

```
            "CreatedDate": "2020-04-08T00:35:06Z",
            "DefaultRouteSettings": {
                "DetailedMetricsEnabled": false
            },
            "LastUpdatedDate": "2020-04-08T00:35:48Z",
            "RouteSettings": {},
            "StageName": "dev",
            "StageVariables": {
                "function": "my-dev-function"
            },
            "Tags": {}
        },
        {
            "CreatedDate": "2020-04-08T00:36:05Z",
            "DefaultRouteSettings": {
                "DetailedMetricsEnabled": false
            },
            "DeploymentId": "x1zwyv",
            "LastUpdatedDate": "2020-04-08T00:36:13Z",
            "RouteSettings": {},
            "StageName": "prod",
            "StageVariables": {
                "function": "my-prod-function"
            },
            "Tags": {}
        }
    ]
}
```

For more information, see Working with stages for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetStages in *Amazon CLI Command Reference*.

`get-tags`

The following code example shows how to use `get-tags`.

Amazon CLI

To retrieve a list of tags for a resource

The following `get-tags` example lists all of an API's tags.

```
aws apigatewayv2 get-tags \
    --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4
```

Output:

```
{
    "Tags": {
        "owner": "dev-team",
        "environment": "prod"
    }
}
```

For more information, see Tagging your API Gateway resources in the *Amazon API Gateway Developer Guide*.

- For API details, see GetTags in *Amazon CLI Command Reference*.

`get-vpc-link`

The following code example shows how to use `get-vpc-link`.

Amazon CLI

To retrieve information about a VPC link

The following `get-vpc-link` example displays information about a VPC link.

```
aws apigatewayv2 get-vpc-link \
    --vpc-link-id abcd123
```

Output:

```
{
    "CreatedDate": "2020-04-07T00:27:47Z",
    "Name": "MyVpcLink",
    "SecurityGroupIds": [
        "sg1234",
        "sg5678"
    ],
    "SubnetIds": [
        "subnet-aaaa",
```

```
        "subnet-bbbb"
    ],
    "Tags": {},
    "VpcLinkId": "abcd123",
    "VpcLinkStatus": "AVAILABLE",
    "VpcLinkStatusMessage": "VPC link is ready to route traffic",
    "VpcLinkVersion": "V2"
}
```

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetVpcLink in *Amazon CLI Command Reference*.

`get-vpc-links`

The following code example shows how to use `get-vpc-links`.

Amazon CLI

To retrieve a list of VPC links

The following `get-vpc-links` example displays a list of all of the VPC links for the current user.

```
aws apigatewayv2 get-vpc-links
```

Output:

```
{
    "Items": [
        {
            "CreatedDate": "2020-04-07T00:27:47Z",
            "Name": "MyVpcLink",
            "SecurityGroupIds": [
                "sg1234",
                "sg5678"
            ],
            "SubnetIds": [
                "subnet-aaaa",
                "subnet-bbbb"
            ],
```

```
            "Tags": {},
            "VpcLinkId": "abcd123",
            "VpcLinkStatus": "AVAILABLE",
            "VpcLinkStatusMessage": "VPC link is ready to route traffic",
            "VpcLinkVersion": "V2"
        }
        {
            "CreatedDate": "2020-04-07T00:27:47Z",
            "Name": "MyOtherVpcLink",
            "SecurityGroupIds": [
                "sg1234",
                "sg5678"
            ],
            "SubnetIds": [
                "subnet-aaaa",
                "subnet-bbbb"
            ],
            "Tags": {},
            "VpcLinkId": "abcd456",
            "VpcLinkStatus": "AVAILABLE",
            "VpcLinkStatusMessage": "VPC link is ready to route traffic",
            "VpcLinkVersion": "V2"
        }
    ]
}
```

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see GetVpcLinks in *Amazon CLI Command Reference*.

`import-api`

The following code example shows how to use `import-api`.

Amazon CLI

To import an HTTP API

The following `import-api` example creates an HTTP API from an OpenAPI 3.0 definition file named `api-definition.yaml`.

```
aws apigatewayv2 import-api \
```

```
    --body file://api-definition.yaml
```

Contents of `api-definition.yaml`:

```
openapi: 3.0.1
info:
    title: My Lambda API
    version: v1.0
paths:
    /hello:
        x-amazon-apigateway-any-method:
            x-amazon-apigateway-integration:
                payloadFormatVersion: 2.0
                type: aws_proxy
                httpMethod: POST
                uri: arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123456789012:function:hello/invocations
                connectionType: INTERNET
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CreatedDate": "2020-04-08T17:19:38+00:00",
    "Name": "My Lambda API",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path",
    "Tags": {},
    "Version": "v1.0"
}
```

For more information, see Working with OpenAPI definitions for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see ImportApi in *Amazon CLI Command Reference*.

`list-routing-rules`

The following code example shows how to use `list-routing-rules`.

Amazon CLI

To list routing rules

The following `list-routing-rules` example lists the routing rules for a domain name.

```
aws apigatewayv2 list-routing-rules \
    --domain-name 'regional.example.com'
```

Output:

```
{
    "RoutingRules": [
        {
            "Actions": [
                {
                    "InvokeApi": {
                        "ApiId": "abcd1234",
                        "Stage": "prod",
                        "StripBasePath": false
                    }
                }
            ],
            "Conditions": [
                {
                    "MatchBasePaths": {
                        "AnyOf": [
                            "PetStoreShopper"
                        ]
                    }
                }
            ],
            "Priority": 150,
            "RoutingRuleArn": "arn:aws:apigateway:us-east-1:123456789012:/
domainnames/regional.example.com/routingrules/aaa111",
            "RoutingRuleId": "aaa111"
        }
    ]
}
```

For more information, see Routing rules to connect API stages to a custom domain name for REST APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see ListRoutingRules in *Amazon CLI Command Reference*.

`put-routing-rule`

The following code example shows how to use `put-routing-rule`.

Amazon CLI

To update a routing rule

The following `put-routing-rule` example updates the priority of a routing rule.

```
aws apigatewayv2 put-routing-rule \
    --domain-name 'regional.example.com' \
    --priority 150 \
    --conditions '[ \
        { \
            "MatchBasePaths": { \
                "AnyOf": [ \
                    "PetStoreShopper" \
                ] \
            } \
        } \
    ]' \
    --actions '[ \
        { \
            "InvokeApi": { \
                "ApiId": "abcd1234", \
                "Stage": "prod" \
            } \
        } \
    ]'
```

Output:

```
{
    "Actions": [
        {
            "InvokeApi": {
                "ApiId": "abcd1234",
                "Stage": "prod",
                "StripBasePath": false
```

```
            }
        }
    ],
    "Conditions": [
        {
            "MatchBasePaths": {
                "AnyOf": [
                    "PetStoreShopper"
                ]
            }
        }
    ],
    "Priority": 150,
    "RoutingRuleArn": "arn:aws:apigateway:us-east-2:123456789012:/domainnames/
regional.example.com/routingrules/aaa111",
    "RoutingRuleId": "aaa111"
}
```

For more information, see Routing rules to connect API stages to a custom domain name for REST APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see PutRoutingRule in *Amazon CLI Command Reference*.

`reimport-api`

The following code example shows how to use `reimport-api`.

Amazon CLI

To reimport an HTTP API

The following `reimport-api` example updates an existing HTTP API to use the OpenAPI 3.0 definition specified in `api-definition.yaml`.

```
aws apigatewayv2 reimport-api \
    --body file://api-definition.yaml \
    --api-id a1b2c3d4
```

Contents of `api-definition.yaml`:

```
openapi: 3.0.1
info:
```

```
    title: My Lambda API
    version: v1.0
paths:
    /hello:
        x-amazon-apigateway-any-method:
            x-amazon-apigateway-integration:
                payloadFormatVersion: 2.0
                type: aws_proxy
                httpMethod: POST
                uri: arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:12356789012:function:hello/invocations
                connectionType: INTERNET
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CreatedDate": "2020-04-08T17:19:38+00:00",
    "Name": "My Lambda API",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path",
    "Tags": {},
    "Version": "v1.0"
}
```

For more information, see Working with OpenAPI definitions for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see ReimportApi in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resource

The following `tag-resource` example adds a tag with the key name `Department` and a value of `Accounting` to the specified API.

```
aws apigatewayv2 tag-resource \
    --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4 \
    --tags Department=Accounting
```

This command produces no output.

For more information, see Tagging your API Gateway resources in the *Amazon API Gateway Developer Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from a resource

The following `untag-resource` example removes tags with the key names `Project` and `Owner` from the specified API.

```
aws apigatewayv2 untag-resource \
    --resource-arn arn:aws:apigateway:us-west-2::/apis/a1b2c3d4 \
    --tag-keys Project Owner
```

This command produces no output.

For more information, see Tagging your API Gateway resources in the *Amazon API Gateway Developer Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-api-mapping`

The following code example shows how to use `update-api-mapping`.

Amazon CLI

To update an API mapping

The following `update-api-mapping` example changes an API mapping for a custom domain name. As a result, the base URL using the custom domain name for the specified API and stage becomes `https://api.example.com/dev`.

```
aws apigatewayv2 update-api-mapping \
    --api-id a1b2c3d4 \
    --stage dev \
    --domain-name api.example.com \
    --api-mapping-id 0qzs2sy7bh \
    --api-mapping-key dev
```

Output:

```
{
    "ApiId": "a1b2c3d4",
    "ApiMappingId": "0qzs2sy7bh",
    "ApiMappingKey": "dev"
    "Stage": "dev"
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateApiMapping in *Amazon CLI Command Reference*.

`update-api`

The following code example shows how to use `update-api`.

Amazon CLI

To enable CORS for an HTTP API

The following `update-api` example updates the specified API's CORS configuration to allow requests from `https://www.example.com`.

```
aws apigatewayv2 update-api \
    --api-id a1b2c3d4 \
    --cors-configuration AllowOrigins=https://www.example.com
```

Output:

```
{
    "ApiEndpoint": "https://a1b2c3d4.execute-api.us-west-2.amazonaws.com",
    "ApiId": "a1b2c3d4",
    "ApiKeySelectionExpression": "$request.header.x-api-key",
    "CorsConfiguration": {
        "AllowCredentials": false,
        "AllowHeaders": [
            "header1",
            "header2"
        ],
        "AllowMethods": [
            "GET",
            "OPTIONS"
        ],
        "AllowOrigins": [
            "https://www.example.com"
        ]
    },
    "CreatedDate": "2020-04-08T18:39:37+00:00",
    "Name": "my-http-api",
    "ProtocolType": "HTTP",
    "RouteSelectionExpression": "$request.method $request.path",
    "Tags": {},
    "Version": "v1.0"
}
```

For more information, see Configuring CORS for an HTTP API in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateApi in *Amazon CLI Command Reference*.

`update-authorizer`

The following code example shows how to use `update-authorizer`.

Amazon CLI

To update an authorizer

The following `update-authorizer` example changes a JWT authorizer's identity source to a header named `Authorization`.

```
aws apigatewayv2 update-authorizer \
```

```
    --api-id a1b2c3d4 \
    --authorizer-id a1b2c3 \
    --identity-source '$request.header.Authorization'
```

Output:

```
{
    "AuthorizerId": "a1b2c3",
    "AuthorizerType": "JWT",
    "IdentitySource": [
        "$request.header.Authorization"
    ],
    "JwtConfiguration": {
        "Audience": [
            "123456abc"
        ],
        "Issuer": "https://cognito-idp.us-west-2.amazonaws.com/us-west-2_abc123"
    },
    "Name": "my-jwt-authorizer"
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateAuthorizer in *Amazon CLI Command Reference*.

`update-deployment`

The following code example shows how to use `update-deployment`.

Amazon CLI

To change a deployment's description

The following `update-deployment` example updates a deployment's description.

```
aws apigatewayv2 update-deployment \
    --api-id a1b2c3d4 \
    --deployment-id abcdef \
    --description 'Manual deployment to fix integration test failures.'
```

Output:

```
{
    "AutoDeployed": false,
    "CreatedDate": "2020-02-05T16:21:48+00:00",
    "DeploymentId": "abcdef",
    "DeploymentStatus": "DEPLOYED",
    "Description": "Manual deployment to fix integration test failures."
}
```

For more information, see Developing an HTTP API in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateDeployment in *Amazon CLI Command Reference*.

`update-domain-name`

The following code example shows how to use `update-domain-name`.

Amazon CLI

To update a custom domain name

The following `update-domain-name` example specifies a new ACM certificate for the `api.example.com` custom domain name.

```
aws apigatewayv2 update-domain-name \
    --domain-name api.example.com \
    --domain-name-configurations CertificateArn=arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678
```

Output:

```
{
    "ApiMappingSelectionExpression": "$request.basepath",
    "DomainName": "regional.example.com",
    "DomainNameConfigurations": [
        {
            "ApiGatewayDomainName": "d-id.execute-api.us-west-2.amazonaws.com",
            "CertificateArn": "arn:aws:acm:us-
west-2:123456789012:certificate/123456789012-1234-1234-1234-12345678",
            "EndpointType": "REGIONAL",
            "HostedZoneId": "123456789111",
```

```
            "SecurityPolicy": "TLS_1_2",
            "DomainNameStatus": "AVAILABLE"
        }
    ]
}
```

For more information, see Setting up a regional custom domain name in API Gateway in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateDomainName in *Amazon CLI Command Reference*.

`update-integration`

The following code example shows how to use `update-integration`.

Amazon CLI

To update a Lambda integration

The following `update-integration` example updates an existing Amazon Lambda integration to use the specified Lambda function.

```
aws apigatewayv2 update-integration \
    --api-id a1b2c3d4 \
    --integration-id a1b2c3 \
    --integration-uri arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/functions/
arn:aws:lambda:us-west-2:123456789012:function:my-new-function/invocations
```

Output:

```
{
    "ConnectionType": "INTERNET",
    "IntegrationId": "a1b2c3",
    "IntegrationMethod": "POST",
    "IntegrationType": "AWS_PROXY",
    "IntegrationUri": "arn:aws:apigateway:us-west-2:lambda:path/2015-03-31/
functions/arn:aws:lambda:us-west-2:123456789012:function:my-new-function/
invocations",
    "PayloadFormatVersion": "2.0",
    "TimeoutInMillis": 5000
}
```

For more information, see Configuring integrations for HTTP APIs and Setting up WebSocket API integrations in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateIntegration in *Amazon CLI Command Reference*.

`update-route`

The following code example shows how to use `update-route`.

Amazon CLI

Example 1: To update the integration of a route

The following `update-route` example updates the integration of a specified route.

```
aws apigatewayv2 update-route \
    --api-id a1b2c3d4 \
    --route-id a1b2c3 \
    --target integrations/a1b2c6
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationType": "NONE",
    "RouteId": "a1b2c3",
    "RouteKey": "ANY /pets",
    "Target": "integrations/a1b2c6"
}
```

Example 2: To add an authorizer to a route

The following `update-route` example updates the specified route to use a JWT authorizer.

```
aws apigatewayv2 update-route \
    --api-id a1b2c3d4  \
    --route-id a1b2c3  \
    --authorization-type JWT \
    --authorizer-id a1b2c5 \
    --authorization-scopes user.id user.email
```

Output:

```
{
    "ApiKeyRequired": false,
    "AuthorizationScopes": [
        "user.id",
        "user.email"
    ],
    "AuthorizationType": "JWT",
    "AuthorizerId": "a1b2c5",
    "OperationName": "GET HTTP",
    "RequestParameters": {},
    "RouteId": "a1b2c3",
    "RouteKey": "GET /pets",
    "Target": "integrations/a1b2c6"
}
```

For more information, see Controlling access to HTTP APIs with JWT authorizers in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateRoute in *Amazon CLI Command Reference*.

`update-stage`

The following code example shows how to use `update-stage`.

Amazon CLI

To configure custom throttling

The following `update-stage` example configures custom throttling for the specified stage and route of an API.

```
aws apigatewayv2 update-stage \
    --api-id a1b2c3d4 \
    --stage-name dev \
    --route-settings '{"GET /pets":
{"ThrottlingBurstLimit":100,"ThrottlingRateLimit":2000}}'
```

Output:

```
{
```

```
    "CreatedDate": "2020-04-05T16:21:16+00:00",
    "DefaultRouteSettings": {
        "DetailedMetricsEnabled": false
    },
    "DeploymentId": "shktxb",
    "LastUpdatedDate": "2020-04-08T22:23:17+00:00",
    "RouteSettings": {
        "GET /pets": {
            "ThrottlingBurstLimit": 100,
            "ThrottlingRateLimit": 2000.0
        }
    },
    "StageName": "dev",
    "StageVariables": {},
    "Tags": {}
}
```

For more information, see Protecting your HTTP API in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateStage in *Amazon CLI Command Reference*.

`update-vpc-link`

The following code example shows how to use `update-vpc-link`.

Amazon CLI

To update a VPC link

The following `update-vpc-link` example updates the name of a VPC link. After you've created a VPC link, you can't change its security groups or subnets.

```
aws apigatewayv2 update-vpc-link \
    --vpc-link-id abcd123 \
    --name MyUpdatedVpcLink
```

Output:

```
{
    "CreatedDate": "2020-04-07T00:27:47Z",
```

```
    "Name": "MyUpdatedVpcLink",
    "SecurityGroupIds": [
        "sg1234",
        "sg5678"
    ],
    "SubnetIds": [
        "subnet-aaaa",
        "subnet-bbbb"
    ],
    "Tags": {},
    "VpcLinkId": "abcd123",
    "VpcLinkStatus": "AVAILABLE",
    "VpcLinkStatusMessage": "VPC link is ready to route traffic",
    "VpcLinkVersion": "V2"
}
```

For more information, see Working with VPC links for HTTP APIs in the *Amazon API Gateway Developer Guide*.

- For API details, see UpdateVpcLink in *Amazon CLI Command Reference*.

API Gateway Management API examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with API Gateway Management API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`delete-connection`

The following code example shows how to use `delete-connection`.

Amazon CLI

To delete a WebSocket connection

The following `delete-connection` example disconnects a client from the specified WebSocket API.

```
aws apigatewaymanagementapi delete-connection \
    --connection-id L0SM9cOFvHcCIhw= \
    --endpoint-url https://aabbccddee.execute-api.us-west-2.amazonaws.com/prod
```

This command produces no output.

For more information, see Use @connections commands in your backend service in the *Amazon API Gateway Developer Guide*.

- For API details, see DeleteConnection in *Amazon CLI Command Reference*.

`get-connection`

The following code example shows how to use `get-connection`.

Amazon CLI

To get information about a WebSocket connection

The following `get-connection` example describes a connection to the specified WebSocket API.

```
aws apigatewaymanagementapi get-connection \
    --connection-id L0SM9cOFvHcCIhw= \
    --endpoint-url https://aabbccddee.execute-api.us-west-2.amazonaws.com/prod
```

Output:

```
{
    "ConnectedAt": "2020-04-30T20:10:33.236Z",
    "Identity": {
        "SourceIp": "192.0.2.1"
    },
    "LastActiveAt": "2020-04-30T20:10:42.997Z"
}
```

For more information, see Use @connections commands in your backend service in the *Amazon API Gateway Developer Guide*.

- For API details, see GetConnection in *Amazon CLI Command Reference*.

`post-to-connection`

The following code example shows how to use `post-to-connection`.

Amazon CLI

To send data to a WebSocket connection

The following `post-to-connection` example sends a message to a client that's connected to the specified WebSocket API.

```
aws apigatewaymanagementapi post-to-connection \
    --connection-id L0SM9cOFvHcCIhw= \
    --data "Hello from API Gateway!" \
    --endpoint-url https://aabbccddee.execute-api.us-west-2.amazonaws.com/prod
```

This command produces no output.

For more information, see Use @connections commands in your backend service in the *Amazon API Gateway Developer Guide*.

- For API details, see PostToConnection in *Amazon CLI Command Reference*.

App Mesh examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with App Mesh.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-mesh`

The following code example shows how to use `create-mesh`.

Amazon CLI

Example 1: To create a new service mesh

The following `create-mesh` example creates a service mesh.

```
aws appmesh create-mesh \
    --mesh-name app1
```

Output:

```
{
    "mesh":{
        "meshName":"app1",
        "metadata":{
            "arn":"arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
            "createdAt":1563809909.282,
            "lastUpdatedAt":1563809909.282,
            "uid":"a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version":1
        },
        "spec":{},
        "status":{
            "status":"ACTIVE"
        }
    }
}
```

Example 2: To create a new service mesh with multiple tags

The following `create-mesh` example creates a service mesh with multiple tags.

```
aws appmesh create-mesh \
    --mesh-name app2 \
    --tags key=key1,value=value1 key=key2,value=value2 key=key3,value=value3
```

Output:

`create-route`

The following code example shows how to use `create-route`.

Amazon CLI

To create a new gRPC route

The following `create-route` example uses a JSON input file to create a gRPC route. GRPC traffic that has metadata that starts with 123 is routed to a virtual node named serviceBgrpc. If there are specific gRPC, HTTP, or TCP failures when attempting to communicate with the target of the route, the route is retried three times. There is a 15 second delay between each retry attempt.

```
aws appmesh create-route \
    --cli-input-json file://create-route-grpc.json
```

Contents of `create-route-grpc.json`:

```
{
    "meshName" : "apps",
    "routeName" : "grpcRoute",
    "spec" : {
       "grpcRoute" : {
          "action" : {
             "weightedTargets" : [
                {
                   "virtualNode" : "serviceBgrpc",
                   "weight" : 100
                }
             ]
          },
          "match" : {
             "metadata" : [
                {
                   "invert" : false,
                   "match" : {
                      "prefix" : "123"
                   },
                   "name" : "myMetadata"
                }
             ],
             "methodName" : "GetColor",
             "serviceName" : "com.amazonaws.services.ColorService"
          },
          "retryPolicy" : {
             "grpcRetryEvents" : [ "deadline-exceeded" ],
             "httpRetryEvents" : [ "server-error", "gateway-error" ],
             "maxRetries" : 3,
             "perRetryTimeout" : {
                "unit" : "s",
                "value" : 15
             },
             "tcpRetryEvents" : [ "connection-error" ]
          }
       },
       "priority" : 100
    },
    "virtualRouterName" : "serviceBgrpc"
}
```

Output:

```
{
    "route": {

    }
}
```

To create a new HTTP or HTTP/2 route

The following `create-route` example uses a JSON input file to create an HTTP/2 route. To create an HTTP route, replace http2Route with httpRoute under spec. All HTTP/2 traffic addressed to any URL prefix that has a header value that starts with 123 is routed to a virtual node named serviceBhttp2. If there are specific HTTP or TCP failures when attempting to communicate with the target of the route, the route is retried three times. There is a 15 second delay between each retry attempt.

```
aws appmesh create-route \
    --cli-input-json file://create-route-http2.json
```

Contents of `create-route-http2.json`:

```
{
    "meshName": "apps",
    "routeName": "http2Route",
    "spec": {
        "http2Route": {
            "action": {
                "weightedTargets": [
                    {
                        "virtualNode": "serviceBhttp2",
```

```
                        "weight": 100
                    }
                ]
            },
            "match": {
                "headers": [
                    {
                        "invert": false,
                        "match": {
                            "prefix": "123"
                        },
                        "name": "clientRequestId"
                    }
                ],
                "method": "POST",
                "prefix": "/",
                "scheme": "http"
            },
            "retryPolicy": {
                "httpRetryEvents": [
                    "server-error",
                    "gateway-error"
                ],
                "maxRetries": 3,
                "perRetryTimeout": {
                    "unit": "s",
                    "value": 15
                },
                "tcpRetryEvents": [
                    "connection-error"
                ]
            }
        },
        "priority": 200
    },
    "virtualRouterName": "serviceBhttp2"
}
```

Output:

```
{

                    },
                    "tcpRetryEvents": [
```

```
                        "connection-error"
                    ]
                }
            },
            "priority": 200
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "serviceBhttp2"
    }
}
```

To create a new TCP route

The following `create-route` example uses a JSON input file to create a TCP route. 75 percent of traffic is routed to a virtual node named serviceBtcp, and 25 percent of traffic is routed to a virtual node named serviceBv2tcp. Specifying different weightings for different targets is an effective way to do a deployment of a new version of an application. You can adjust the weights so that eventually, 100 percent of all traffic is routed to a target that has the new version of an application.

```
aws appmesh create-route \
    --cli-input-json file://create-route-tcp.json
```

Contents of create-route-tcp.json:

```
{
    "meshName": "apps",
    "routeName": "tcpRoute",
    "spec": {
        "priority": 300,
        "tcpRoute": {
            "action": {
                "weightedTargets": [
                    {
                        "virtualNode": "serviceBtcp",
                        "weight": 75
                    },
                    {
                        "virtualNode": "serviceBv2tcp",
                        "weight": 25
```

```
                    }
                ]
            }
        }
    },
    "virtualRouterName": "serviceBtcp"
}
```

Output:

```
{
    "route": {
        "meshName": "apps",
        "metadata": {
            "arn": "arn:aws:appmesh:us-west-2:123456789012:mesh/apps/virtualRouter/
serviceBtcp/route/tcpRoute",
            "createdAt": 1572011436.26,
            "lastUpdatedAt": 1572011436.26,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "routeName": "tcpRoute",
        "spec": {
            "priority": 300,
            "tcpRoute": {
                "action": {
                    "weightedTargets": [
                        {
                            "virtualNode": "serviceBtcp",
                            "weight": 75
                        },
                        {
                            "virtualNode": "serviceBv2tcp",
                            "weight": 25
                        }
                    ]
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "serviceBtcp"
```

```
    }
}
```

For more information, see Routes in the *Amazon App Mesh User Guide*.

- For API details, see CreateRoute in *Amazon CLI Command Reference*.

`create-virtual-gateway`

The following code example shows how to use `create-virtual-gateway`.

Amazon CLI

To create a new virtual gateway

The following `create-virtual-gateway` example uses a JSON input file to create a virtual gateway with a listener for HTTP using port 9080.

```
aws appmesh create-virtual-gateway \
    --mesh-name meshName \
    --virtual-gateway-name virtualGatewayName \
    --cli-input-json file://create-virtual-gateway.json
```

Contents of `create-virtual-gateway.json`:

```
{
    "spec": {
      "listeners": [
        {
          "portMapping": {
            "port": 9080,
            "protocol": "http"
          }
        }
      ]
    }
}
```

Output:

```
{
```

```
    "virtualGateway": {
        "meshName": "meshName",
        "metadata": {
            "arn": "arn:aws:appmesh:us-west-2:123456789012:mesh/meshName/
virtualGateway/virtualGatewayName",
            "createdAt": "2022-04-06T10:42:42.015000-05:00",
            "lastUpdatedAt": "2022-04-06T10:42:42.015000-05:00",
            "meshOwner": "123456789012",
            "resourceOwner": "123456789012",
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "listeners": [
                {
                    "portMapping": {
                        "port": 9080,
                        "protocol": "http"
                    }
                }
            ]
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualGatewayName": "virtualGatewayName"
    }
}
```

For more information, see Virtual Gateways in the *Amazon App Mesh User Guide*.

- For API details, see CreateVirtualGateway in *Amazon CLI Command Reference*.

`create-virtual-node`

The following code example shows how to use `create-virtual-node`.

Amazon CLI

Example 1: To create a new virtual node that uses DNS for discovery

The following `create-virtual-node` example uses a JSON input file to create a virtual node that uses DNS for service discovery.

```
aws appmesh create-virtual-node \
    --cli-input-json file://create-virtual-node-dns.json
```

Contents of `create-virtual-node-dns.json`:

```
{
    "meshName": "app1",
    "spec": {
        "listeners": [
            {
                "portMapping": {
                    "port": 80,
                    "protocol": "http"
                }
            }
        ],
        "serviceDiscovery": {
            "dns": {
                "hostname": "serviceBv1.svc.cluster.local"
            }
        }
    },
    "virtualNodeName": "vnServiceBv1"
}
```

Output:

```
{
    "virtualNode": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceBv1",
            "createdAt": 1563810019.874,
            "lastUpdatedAt": 1563810019.874,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "listeners": [
                {
                    "portMapping": {
```

```
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ],
            "serviceDiscovery": {
                "dns": {
                    "hostname": "serviceBv1.svc.cluster.local"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualNodeName": "vnServiceBv1"
    }
}
```

Example 2: To create a new virtual node that uses Amazon Cloud Map for discovery

The following `create-virtual-node` example uses a JSON input file to create a virtual node that uses Amazon Cloud Map for service discovery.

```
aws appmesh create-virtual-node \
    --cli-input-json file://create-virtual-node-cloud-map.json
```

Contents of `create-virtual-node-cloud-map.json`:

```
{
    "meshName": "app1",
    "spec": {
        "backends": [
            {
                "virtualService": {
                    "virtualServiceName": "serviceA.svc.cluster.local"
                }
            }
        ],
        "listeners": [
            {
                "portMapping": {
                    "port": 80,
                    "protocol": "http"
```

```
                }
            }
        ],
        "serviceDiscovery": {
            "awsCloudMap": {
                "attributes": [
                    {
                        "key": "Environment",
                        "value": "Testing"
                    }
                ],
                "namespaceName": "namespace1",
                "serviceName": "serviceA"
            }
        }
    },
    "virtualNodeName": "vnServiceA"
}
```

Output:

```
{
    "virtualNode": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceA",
            "createdAt": 1563810859.465,

            "version": 1
        },
        "spec": {
            "backends": [
                {
                    "virtualService": {
                        "virtualServiceName": "serviceA.svc.cluster.local"
                    }
                }
            ],
            "listeners": [
                {
                    "portMapping": {
```

```
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ],
            "serviceDiscovery": {
                "awsCloudMap": {
                    "attributes": [
                        {
                            "key": "Environment",
                            "value": "Testing"
                        }
                    ],
                    "namespaceName": "namespace1",
                    "serviceName": "serviceA"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualNodeName": "vnServiceA"
    }
}
```

For more information, see Virtual Nodes in the *Amazon App Mesh User Guide*.

- For API details, see CreateVirtualNode in *Amazon CLI Command Reference*.

`create-virtual-router`

The following code example shows how to use `create-virtual-router`.

Amazon CLI

To create a new virtual router

The following `create-virtual-router` example uses a JSON input file to create a virtual router with a listener for HTTP using port 80.

```
aws appmesh create-virtual-router \
    --cli-input-json file://create-virtual-router.json
```

Contents of `create-virtual-router.json`:

```
{
    "meshName": "app1",
    "spec": {
        "listeners": [
            {
                "portMapping": {
                    "port": 80,
                    "protocol": "http"
                }
            }
        ]
    },
    "virtualRouterName": "vrServiceB"
}
```

Output:

```
{
    "virtualRouter": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB",
            "createdAt": 1563810546.59,
            "lastUpdatedAt": 1563810546.59,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "listeners": [
                {
                    "portMapping": {
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ]
        },
        "status": {
            "status": "ACTIVE"
        },
```

```
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Virtual Routers in the *Amazon App Mesh User Guide*.

- For API details, see CreateVirtualRouter in *Amazon CLI Command Reference*.

`create-virtual-service`

The following code example shows how to use `create-virtual-service`.

Amazon CLI

Example 1: To create a new virtual service with a virtual node provider

The following `create-virtual-service` example uses a JSON input file to create a virtual service with a virtual node provider.

```
aws appmesh create-virtual-service \
    --cli-input-json file://create-virtual-service-virtual-node.json
```

Contents of `create-virtual-service-virtual-node.json`:

```
{
    "meshName": "app1",
    "spec": {
        "provider": {
            "virtualNode": {
                "virtualNodeName": "vnServiceA"
            }
        }
    },
    "virtualServiceName": "serviceA.svc.cluster.local"
}
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
```

```
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceA.svc.cluster.local",
            "createdAt": 1563810859.474,
            "lastUpdatedAt": 1563810967.179,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "spec": {
            "provider": {
                "virtualNode": {
                    "virtualNodeName": "vnServiceA"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualServiceName": "serviceA.svc.cluster.local"
    }
}
```

For more information, see Virtual Node in the *Amazon App Mesh User Guide*.

Example 2: To create a new virtual service with a virtual router provider

The following `create-virtual-service` example uses a JSON input file to create a virtual service with a virtual router provider.

```
aws appmesh create-virtual-service \
    --cli-input-json file://create-virtual-service-virtual-router.json
```

Contents of `create-virtual-service-virtual-router.json`:

```
{
    "meshName": "app1",
    "spec": {
        "provider": {
            "virtualRouter": {
                "virtualRouterName": "vrServiceB"
            }
        }
    },
```

```
    "virtualServiceName": "serviceB.svc.cluster.local"
}
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceB.svc.cluster.local",
            "createdAt": 1563908363.999,
            "lastUpdatedAt": 1563908363.999,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "provider": {
                "virtualRouter": {
                    "virtualRouterName": "vrServiceB"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualServiceName": "serviceB.svc.cluster.local"
    }
}
```

For more information, see Virtual Services<https://docs.aws.amazon.com/app-mesh/latest/userguide/virtual_services.html> in the *Amazon App Mesh User Guide*

- For API details, see CreateVirtualService in *Amazon CLI Command Reference*.

`delete-mesh`

The following code example shows how to use `delete-mesh`.

Amazon CLI

To delete a service mesh

The following `delete-mesh` example deletes the specified service mesh.

```
aws appmesh delete-mesh \
    --mesh-name app1
```

Output:

```
{
    "mesh": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
            "createdAt": 1563809909.282,
            "lastUpdatedAt": 1563824981.248,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "spec": {
            "egressFilter": {
                "type": "ALLOW_ALL"
            }
        },
        "status": {
            "status": "DELETED"
        }
    }
}
```

For more information, see Service Meshes in the *Amazon App Mesh User Guide*.

- For API details, see DeleteMesh in *Amazon CLI Command Reference*.

`delete-route`

The following code example shows how to use `delete-route`.

Amazon CLI

To delete a route

The following `delete-route` example deletes the specified route.

```
aws appmesh delete-route \
```

```
    --mesh-name app1 \
    --virtual-router-name vrServiceB \
    --route-name toVnServiceB-weighted
```

Output:

```
{
    "route": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB/route/toVnServiceB-weighted",
            "createdAt": 1563811384.015,
            "lastUpdatedAt": 1563823915.936,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 3
        },
        "routeName": "toVnServiceB-weighted",
        "spec": {
            "httpRoute": {
                "action": {
                    "weightedTargets": [
                        {
                            "virtualNode": "vnServiceBv1",
                            "weight": 80
                        },
                        {
                            "virtualNode": "vnServiceBv2",
                            "weight": 20
                        }
                    ]
                },
                "match": {
                    "prefix": "/"
                }
            }
        },
        "status": {
            "status": "DELETED"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Routes in the *Amazon App Mesh User Guide*.

- For API details, see DeleteRoute in *Amazon CLI Command Reference*.

`delete-virtual-node`

The following code example shows how to use `delete-virtual-node`.

Amazon CLI

To delete a virtual node

The following `delete-virtual-node` example deletes the specified virtual node.

```
aws appmesh delete-virtual-node \
    --mesh-name app1 \
    --virtual-node-name vnServiceBv2
```

Output:

```
{
    "virtualNode": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceBv2",
            "createdAt": 1563810117.297,
            "lastUpdatedAt": 1563824700.678,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "spec": {
            "backends": [],
            "listeners": [
                {
                    "portMapping": {
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ],
            "serviceDiscovery": {
                "dns": {
```

```
                    "hostname": "serviceBv2.svc.cluster.local"
                }
            }
        },
        "status": {
            "status": "DELETED"
        },
        "virtualNodeName": "vnServiceBv2"
    }
}
```

For more information, see Virtual Nodes in the *Amazon App Mesh User Guide*.

- For API details, see DeleteVirtualNode in *Amazon CLI Command Reference*.

`delete-virtual-router`

The following code example shows how to use `delete-virtual-router`.

Amazon CLI

To delete a virtual router

The following `delete-virtual-router` example deletes the specified virtual router.

```
aws appmesh delete-virtual-router \
    --mesh-name app1 \
    --virtual-router-name vrServiceB
```

Output:

```
{
    "virtualRouter": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB",
            "createdAt": 1563810546.59,
            "lastUpdatedAt": 1563824253.467,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 3
        },
```

```
        "spec": {
            "listeners": [
                {
                    "portMapping": {
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ]
        },
        "status": {
            "status": "DELETED"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Virtual Routers in the *Amazon App Mesh User Guide*.

- For API details, see DeleteVirtualRouter in *Amazon CLI Command Reference*.

`delete-virtual-service`

The following code example shows how to use `delete-virtual-service`.

Amazon CLI

To delete a virtual service

The following `delete-virtual-service` example deletes the specified virtual service.

```
aws appmesh delete-virtual-service \
    --mesh-name app1 \
    --virtual-service-name serviceB.svc.cluster.local
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceB.svc.cluster.local",
```

```
            "createdAt": 1563908363.999,
            "lastUpdatedAt": 1563913940.866,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 3
        },
        "spec": {},
        "status": {
            "status": "DELETED"
        },
        "virtualServiceName": "serviceB.svc.cluster.local"
    }
}
```

For more information, see Virtual Service in the *Amazon App Mesh User Guide*.

- For API details, see DeleteVirtualService in *Amazon CLI Command Reference*.

`describe-mesh`

The following code example shows how to use `describe-mesh`.

Amazon CLI

To describe a service mesh

The following `describe-mesh` example returns details about the specified service mesh.

```
aws appmesh describe-mesh \
    --mesh-name app1
```

Output:

```
{
    "mesh": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
            "createdAt": 1563809909.282,

For more information, see Service Meshes in the *Amazon App Mesh User Guide*.

- For API details, see DescribeMesh in *Amazon CLI Command Reference*.

`describe-route`

The following code example shows how to use `describe-route`.

Amazon CLI

To describe a route

The following `describe-route` example returns details about the specified route.

```
aws appmesh describe-route \
    --mesh-name app1 \
    --virtual-router-name vrServiceB \
    --route-name toVnServiceB-weighted
```

Output:

```
{
    "route": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB/route/toVnServiceB-weighted",
            "createdAt": 1563811384.015,
            "lastUpdatedAt": 1563811384.015,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "routeName": "toVnServiceB-weighted",
        "spec": {
            "httpRoute": {
```

```
                "action": {
                    "weightedTargets": [
                        {
                            "virtualNode": "vnServiceBv1",
                            "weight": 90
                        },
                        {
                            "virtualNode": "vnServiceBv2",
                            "weight": 10
                        }
                    ]
                },
                "match": {
                    "prefix": "/"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Routes in the *Amazon App Mesh User Guide*.

- For API details, see DescribeRoute in *Amazon CLI Command Reference*.

`describe-virtual-node`

The following code example shows how to use `describe-virtual-node`.

Amazon CLI

To describe a virtual node

The following `describe-virtual-node` example returns details about the specified virtual node.

```
aws appmesh describe-virtual-node \
    --mesh-name app1 \
    --virtual-node-name vnServiceBv1
```

Output:

```
{
    "virtualNode": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceBv1",
            "createdAt": 1563810019.874,
            "lastUpdatedAt": 1563810019.874,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "backends": [],
            "listeners": [
                {
                    "portMapping": {
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ],
            "serviceDiscovery": {
                "dns": {
                    "hostname": "serviceBv1.svc.cluster.local"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualNodeName": "vnServiceBv1"
    }
}
```

For more information, see Virtual Nodes in the *Amazon App Mesh User Guide*.

- For API details, see DescribeVirtualNode in *Amazon CLI Command Reference*.

`describe-virtual-router`

The following code example shows how to use `describe-virtual-router`.

Amazon CLI

To describe a virtual router

The following `describe-virtual-router` example returns details about the specified virtual router.

```
aws appmesh describe-virtual-router \
    --mesh-name app1 \
    --virtual-router-name vrServiceB
```

Output:

```
{
    "virtualRouter": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB",
            "createdAt": 1563810546.59,
            "lastUpdatedAt": 1563810546.59,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "listeners": [
                {
                    "portMapping": {
                        "port": 80,
                        "protocol": "http"
                    }
                }
            ]
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Virtual Routers in the *Amazon App Mesh User Guide*.

- For API details, see DescribeVirtualRouter in *Amazon CLI Command Reference*.

`describe-virtual-service`

The following code example shows how to use `describe-virtual-service`.

Amazon CLI

To describe a virtual service

The following `describe-virtual-service` example returns details about the specified virtual service.

```
aws appmesh describe-virtual-service \
    --mesh-name app1 \
    --virtual-service-name serviceB.svc.cluster.local
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceB.svc.cluster.local",
            "createdAt": 1563908363.999,
            "lastUpdatedAt": 1563908363.999,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 1
        },
        "spec": {
            "provider": {
                "virtualRouter": {
                    "virtualRouterName": "vrServiceB"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualServiceName": "serviceB.svc.cluster.local"
    }
```

```
}
```

For more information, see Virtual Services in the *Amazon App Mesh User Guide*.

- For API details, see DescribeVirtualService in *Amazon CLI Command Reference*.

`list-meshes`

The following code example shows how to use `list-meshes`.

Amazon CLI

To list service meshes

The following `list-meshes` example lists all of the service meshes in the current Amazon Region.

```
aws appmesh list-meshes
```

Output:

```
{
    "meshes": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
            "meshName": "app1"
        }
    ]
}
```

For more information, see Service Meshes in the *Amazon App Mesh User Guide*.

- For API details, see ListMeshes in *Amazon CLI Command Reference*.

`list-routes`

The following code example shows how to use `list-routes`.

Amazon CLI

To list routes

The following `list-routes` example lists all of the routes for the specified virtual router.

```
aws appmesh list-routes \
    --mesh-name app1 \
    --virtual-router-name vrServiceB
```

Output:

```
{
    "routes": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB/route/toVnServiceB",
            "meshName": "app1",
            "routeName": "toVnServiceB-weighted",
            "virtualRouterName": "vrServiceB"
        }
    ]
}
```

For more information, see Routes in the *Amazon App Mesh User Guide*.

- For API details, see ListRoutes in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags for a resource

The following `list-tags-for-resource` example lists all of the tags assigned to the specified resource.

```
aws appmesh list-tags-for-resource \
    --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1
```

Output:

```
{
```

```
    "tags": [
        {
            "key": "key1",
            "value": "value1"
        },
        {
            "key": "key2",
            "value": "value2"
        },
        {
            "key": "key3",
            "value": "value3"
        }
    ]
}
```

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`list-virtual-nodes`

The following code example shows how to use `list-virtual-nodes`.

Amazon CLI

To list virtual nodes

The following `list-virtual-nodes` example lists all of the virtual nodes in the specified service mesh.

```
aws appmesh list-virtual-nodes \
    --mesh-name app1
```

Output:

```
{
    "virtualNodes": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceBv1",
            "meshName": "app1",
            "virtualNodeName": "vnServiceBv1"
        },
```

```
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualNode/
vnServiceBv2",
            "meshName": "app1",
            "virtualNodeName": "vnServiceBv2"
        }
    ]
}
```

For more information, see Virtual Nodes in the *Amazon App Mesh User Guide*.

- For API details, see ListVirtualNodes in *Amazon CLI Command Reference*.

`list-virtual-routers`

The following code example shows how to use `list-virtual-routers`.

Amazon CLI

To list virtual routers

The following `list-virtual-routers` example lists all of the virtual routers in the specified service mesh.

```
aws appmesh list-virtual-routers \
    --mesh-name app1
```

Output:

```
{
    "virtualRouters": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB",
            "meshName": "app1",
            "virtualRouterName": "vrServiceB"
        }
    ]
}
```

For more information, see Virtual Routers in the *Amazon App Mesh User Guide*.

- For API details, see ListVirtualRouters in *Amazon CLI Command Reference*.

`list-virtual-services`

The following code example shows how to use `list-virtual-services`.

Amazon CLI

To list virtual services

The following `list-virtual-services` example lists all of the virtual services in the specified service mesh.

```
aws appmesh list-virtual-services \
    --mesh-name app1
```

Output:

```
{
    "virtualServices": [
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceA.svc.cluster.local",
            "meshName": "app1",
            "virtualServiceName": "serviceA.svc.cluster.local"
        },
        {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceB.svc.cluster.local",
            "meshName": "app1",
            "virtualServiceName": "serviceB.svc.cluster.local"
        }
    ]
}
```

For more information, see Virtual Services in the *Amazon App Mesh User Guide*.

- For API details, see ListVirtualServices in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resource

The following `tag-resource` example adds the tag `key1` with the value `value1` to the specified resource.

```
aws appmesh tag-resource \
    --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1 \
    --tags key=key1,value=value1
```

This command produces no output.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To untag a resource

The following `untag-resource` example removes a tag with the key `key1` from the specified resource.

```
aws appmesh untag-resource \
    --resource-arn arn:aws:appmesh:us-east-1:123456789012:mesh/app1 \
    --tag-keys key1
```

This command produces no output.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-mesh`

The following code example shows how to use `update-mesh`.

Amazon CLI

To update a service mesh

The following `update-mesh` example uses a JSON input file to update a service mesh to allow all external egress traffic to be forwarded through the Envoy proxy untouched.

```
aws appmesh update-mesh \
    --cli-input-json file://update-mesh.json
```

Contents of `update-mesh.json`:

```
{
    "meshName": "app1",
    "spec": {
        "egressFilter": {
            "type": "ALLOW_ALL"
        }
    }
}
```

Output:

```
{
    "mesh": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1",
            "createdAt": 1563809909.282,
            "lastUpdatedAt": 1563812829.687,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "spec": {
            "egressFilter": {
                "type": "ALLOW_ALL"
            }
        },
        "status": {
            "status": "ACTIVE"
        }
    }
}
```

For more information, see Service Meshes in the *Amazon App Mesh User Guide*.

- For API details, see UpdateMesh in *Amazon CLI Command Reference*.

`update-route`

The following code example shows how to use `update-route`.

Amazon CLI

To update a route

The following `update-route` example uses a JSON input file to update the weights for a route.

```
aws appmesh update-route \
    --cli-input-json file://update-route-weighted.json
```

Contents of `update-route-weighted.json`:

```
{
    "meshName": "app1",
    "routeName": "toVnServiceB-weighted",
    "spec": {
        "httpRoute": {
            "action": {
                "weightedTargets": [
                    {
                        "virtualNode": "vnServiceBv1",
                        "weight": 80
                    },
                    {
                        "virtualNode": "vnServiceBv2",
                        "weight": 20
                    }
                ]
            },
            "match": {
                "prefix": "/"
            }
        }
    },
    "virtualRouterName": "vrServiceB"
}
```

Output:

```
{
    "route": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB/route/toVnServiceB-weighted",
            "createdAt": 1563811384.015,
            "lastUpdatedAt": 1563819600.022,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "routeName": "toVnServiceB-weighted",
        "spec": {
            "httpRoute": {
                "action": {
                    "weightedTargets": [
                        {
                            "virtualNode": "vnServiceBv1",
                            "weight": 80
                        },
                        {
                            "virtualNode": "vnServiceBv2",
                            "weight": 20
                        }
                    ]
                },
                "match": {
                    "prefix": "/"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Routes in the *Amazon App Mesh User Guide*.

- For API details, see UpdateRoute in *Amazon CLI Command Reference*.

update-virtual-node

The following code example shows how to use update-virtual-node.

Amazon CLI

To update a virtual node

The following update-virtual-node example uses a JSON input file to add a health check to a virtual node.

```
aws appmesh update-virtual-node \
    --cli-input-json file://update-virtual-node.json
```

Contents of update-virtual-node.json:

```
{
    "clientToken": "500",
    "meshName": "app1",
    "spec": {
        "listeners": [
            {
                "healthCheck": {
                    "healthyThreshold": 5,
                    "intervalMillis": 10000,
                    "path": "/",
                    "port": 80,
                    "protocol": "http",
                    "timeoutMillis": 3000,
                    "unhealthyThreshold": 3
                },
                "portMapping": {
                    "port": 80,
                    "protocol": "http"
                }
            }
        ],
        "serviceDiscovery": {
            "dns": {
                "hostname": "serviceBv1.svc.cluster.local"
            }
        }
    },
```

```
    "virtualNodeName": "vnServiceBv1"
}
```

`update-virtual-router`

The following code example shows how to use `update-virtual-router`.

Amazon CLI

To update a virtual router

The following `update-virtual-router` example uses a JSON input file to update a virtual router listener port.

```
aws appmesh update-virtual-router \
    --cli-input-json file://update-virtual-router.json
```

Contents of `update-virtual-router.json`:

```
{
    "meshName": "app1",
    "spec": {
        "listeners": [
            {
                "portMapping": {
                    "port": 8080,
                    "protocol": "http"
                }
            }
        ]
    },
    "virtualRouterName": "vrServiceB"
}
```

Output:

```
{
```

```
    "virtualRouter": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualRouter/
vrServiceB",
            "createdAt": 1563810546.59,
            "lastUpdatedAt": 1563819431.352,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 2
        },
        "spec": {
            "listeners": [
                {
                    "portMapping": {
                        "port": 8080,
                        "protocol": "http"
                    }
                }
            ]
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualRouterName": "vrServiceB"
    }
}
```

For more information, see Virtual Routers in the *Amazon App Mesh User Guide*.

- For API details, see UpdateVirtualRouter in *Amazon CLI Command Reference*.

`update-virtual-service`

The following code example shows how to use `update-virtual-service`.

Amazon CLI

To update a virtual service

The following `update-virtual-service` example uses a JSON input file to update a virtual service to use a virtual router provider.

```
aws appmesh update-virtual-service \
```

```
    --cli-input-json file://update-virtual-service.json
```

Contents of `update-virtual-service.json`:

```
{
    "meshName": "app1",
    "spec": {
        "provider": {
            "virtualRouter": {
                "virtualRouterName": "vrServiceA"
            }
        }
    },
    "virtualServiceName": "serviceA.svc.cluster.local"
}
```

Output:

```
{
    "virtualService": {
        "meshName": "app1",
        "metadata": {
            "arn": "arn:aws:appmesh:us-east-1:123456789012:mesh/app1/virtualService/
serviceA.svc.cluster.local",
            "createdAt": 1563810859.474,
            "lastUpdatedAt": 1563820257.411,
            "uid": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "version": 3
        },
        "spec": {
            "provider": {
                "virtualRouter": {
                    "virtualRouterName": "vrServiceA"
                }
            }
        },
        "status": {
            "status": "ACTIVE"
        },
        "virtualServiceName": "serviceA.svc.cluster.local"
    }
}
```

For more information, see Virtual Services in the *Amazon App Mesh User Guide*.

- For API details, see UpdateVirtualService in *Amazon CLI Command Reference*.

App Runner examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with App Runner.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-custom-domain`

The following code example shows how to use `associate-custom-domain`.

Amazon CLI

To associate a domain name and the www subdomain with a service

The following `associate-custom-domain` example associates a custom domain name that you control with an App Runner service. The domain name is the root domain `example.com`, including the special-case subdomain `www.example.com`.

```
aws apprunner associate-custom-domain \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
```

```
    "DomainName": "example.com",
    "EnableWWWSubdomain": true
}
```

Output:

```
{
    "CustomDomain": {
        "CertificateValidationRecords": [
            {
                "Name": "_70d3f50a94f7c72dc28784cf55db2f6b.example.com",
                "Status": "PENDING_VALIDATION",
                "Type": "CNAME",
                "Value": "_1270c137383c6307b6832db02504c4b0.bsgbmzkfwj.acm-
validations.aws."
            },
            {
                "Name": "_287870d3f50a94f7c72dc4cf55db2f6b.www.example.com",
                "Status": "PENDING_VALIDATION",
                "Type": "CNAME",
                "Value": "_832db01270c137383c6307b62504c4b0.mzkbsgbfwj.acm-
validations.aws."
            }
        ],
        "DomainName": "example.com",
        "EnableWWWSubdomain": true,
        "Status": "CREATING"
    },
    "DNSTarget": "psbqam834h.us-east-1.awsapprunner.com",
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

- For API details, see AssociateCustomDomain in *Amazon CLI Command Reference*.

`create-auto-scaling-configuration`

The following code example shows how to use `create-auto-scaling-configuration`.

Amazon CLI

To create a high availability auto scaling configuration

The following `create-auto-scaling-configuration` example creates an auto scaling configuration optimized for high availability by setting `MinSize` to 5. With this configuration, App Runner attempts to spread your service instances over the most Availability Zones possible, up to five, depending on the Amazon Region.

The call returns an `AutoScalingConfiguration` object with the other settings set to their defaults. In the example, this is the first call to create a configuration named `high-availability`. The revision is set to 1, and it's the latest revision.

```
aws apprunner create-auto-scaling-configuration \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "AutoScalingConfigurationName": "high-availability",
    "MinSize": 5
}
```

Output:

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-
availability/1/2f50e7656d7819fead0f59672e68042e",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 1,
        "CreatedAt": "2020-11-03T00:29:17Z",
        "Latest": true,
        "Status": "ACTIVE",
        "MaxConcurrency": 100,
        "MaxSize": 50,
        "MinSize": 5
    }
}
```

- For API details, see CreateAutoScalingConfiguration in *Amazon CLI Command Reference*.

`create-connection`

The following code example shows how to use `create-connection`.

Amazon CLI

To create a GitHub connection

The following `create-connection` example creates a connection to a private GitHub code repository. The connection status after a successful call is `PENDING_HANDSHAKE`. This is because an authentication handshake with the provider still hasn't happened. Complete the handshake using the App Runner console.

```
aws apprunner create-connection \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ConnectionName": "my-github-connection",
    "ProviderType": "GITHUB"
}
```

Output:

```
{
    "Connection": {
        "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/my-
github-connection",
        "ConnectionName": "my-github-connection",
        "Status": "PENDING_HANDSHAKE",
        "CreatedAt": "2020-11-03T00:32:51Z",
        "ProviderType": "GITHUB"
    }
}
```

For more information, see Managing App Runner connections in the *Amazon App Runner Developer Guide*.

- For API details, see CreateConnection in *Amazon CLI Command Reference*.

`create-service`

The following code example shows how to use `create-service`.

Amazon CLI

Example 1: To create a source code repository service

The following `create-service` example creates an App Runner service based on a Python source code repository.

```
aws apprunner create-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceName": "python-app",
    "SourceConfiguration": {
        "AuthenticationConfiguration": {
            "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/
my-github-connection/e7656250f67242d7819feade6800f59e"
        },
        "AutoDeploymentsEnabled": true,
        "CodeRepository": {
            "RepositoryUrl": "https://github.com/my-account/python-hello",
            "SourceCodeVersion": {
                "Type": "BRANCH",
                "Value": "main"
            },
            "CodeConfiguration": {
                "ConfigurationSource": "API",
                "CodeConfigurationValues": {
                    "Runtime": "PYTHON_3",
                    "BuildCommand": "pip install -r requirements.txt",
                    "StartCommand": "python server.py",
                    "Port": "8080",
                    "RuntimeEnvironmentVariables": [
                        {
                            "NAME": "Jane"
                        }
                    ]
                }
```

```
            }
        }
    },
    "InstanceConfiguration": {
        "CPU": "1 vCPU",
        "Memory": "3 GB"
    }
}
```

Output:

```
{

                        "RuntimeEnvironmentVariables": [
                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
```

```
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

Example 2: To create a source code repository service

The following `create-service` example creates an App Runner service based on a Python source code repository.

```
aws apprunner create-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceName": "python-app",
    "SourceConfiguration": {
        "AuthenticationConfiguration": {
            "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/
my-github-connection/e7656250f67242d7819feade6800f59e"
        },
        "AutoDeploymentsEnabled": true,
        "CodeRepository": {
            "RepositoryUrl": "https://github.com/my-account/python-hello",
            "SourceCodeVersion": {
                "Type": "BRANCH",
                "Value": "main"
            },
            "CodeConfiguration": {
                "ConfigurationSource": "API",
                "CodeConfigurationValues": {
                    "Runtime": "PYTHON_3",
```

```
                    "BuildCommand": "pip install -r requirements.txt",
                    "StartCommand": "python server.py",
                    "Port": "8080",
                    "RuntimeEnvironmentVariables": [
                        {
                            "NAME": "Jane"
                        }
                    ]
                }
            }
        },
    "InstanceConfiguration": {
        "CPU": "1 vCPU",
        "Memory": "3 GB"
    }
}
```

                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

Example 3: To create a source image repository service

The following `create-service` example creates an App Runner service based on an image stored in Elastic Container Registry (ECR).

```
aws apprunner create-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceName": "golang-container-app",
    "SourceConfiguration": {
        "AuthenticationConfiguration": {
            "AccessRoleArn": "arn:aws:iam::123456789012:role/my-ecr-role"
        },
        "AutoDeploymentsEnabled": true,
        "ImageRepository": {
```

```
            "ImageIdentifier": "123456789012.dkr.ecr.us-east-1.amazonaws.com/golang-
app:latest",
            "ImageConfiguration": {
                "Port": "8080",
                "RuntimeEnvironmentVariables": [
                    {
                        "NAME": "Jane"
                    }
                ]
            },
            "ImageRepositoryType": "ECR"
        }
    },
    "InstanceConfiguration": {
        "CPU": "1 vCPU",
        "Memory": "3 GB"
    }
}
```

Output:

```
{
    "OperationId": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
    "Service": {
        "CreatedAt": "2020-11-06T23:15:30Z",
        "UpdatedAt": "2020-11-06T23:15:30Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/golang-
container-app/51728f8a20ce46d39b25398a6c8e9d1a",
        "ServiceId": "51728f8a20ce46d39b25398a6c8e9d1a",
        "ServiceName": "golang-container-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
                "AccessRoleArn": "arn:aws:iam::123456789012:role/my-ecr-role"
            },
            "AutoDeploymentsEnabled": true,
            "ImageRepository": {
                "ImageIdentifier": "123456789012.dkr.ecr.us-east-1.amazonaws.com/
golang-app:latest",
                "ImageConfiguration": {
                    "Port": "8080",
                    "RuntimeEnvironmentVariables": [
                        {
```

```
                            "NAME": "Jane"
                        }
                    ]
                },
                "ImageRepositoryType": "ECR"
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

- For API details, see CreateService in *Amazon CLI Command Reference*.

`delete-auto-scaling-configuration`

The following code example shows how to use `delete-auto-scaling-configuration`.

Amazon CLI

Example 1: To delete the latest active revision of an auto scaling configuration

The following `delete-auto-scaling-configuration` example deletes the latest active revision of an App Runner auto scaling configuration. To delete the latest active revision, specify an Amazon Resource Name (ARN) that ends with the configuration name, without the revision component.

In the example, two revisions exist before this action. Therefore, revision 2 (the latest) is deleted. However, it now shows `"Latest": false`, because, after being deleted, it isn't the latest active revision anymore.

```
aws apprunner delete-auto-scaling-configuration \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability"
```

```
}
```

Output:

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability/2/
e76562f50d78042e819fead0f59672e6",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 2,
        "CreatedAt": "2021-02-25T17:42:59Z",
        "DeletedAt": "2021-03-02T08:07:06Z",
        "Latest": false,
        "Status": "INACTIVE",
        "MaxConcurrency": 30,
        "MaxSize": 90,
        "MinSize": 5
    }
}
```

Example 2: To delete a specific revision of an auto scaling configuration

The following `delete-auto-scaling-configuration` example deletes a specific revision of an App Runner auto scaling configuration. To delete a specific revision, specify an ARN that includes the revision number.

In the example, several revisions exist before this action. The action deletes revision 1.

```
aws apprunner delete-auto-scaling-configuration \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability/1"
}
```

Output:

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-
availability/1/2f50e7656d7819fead0f59672e68042e",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 1,
        "CreatedAt": "2020-11-03T00:29:17Z",
        "DeletedAt": "2021-03-02T08:07:06Z",
        "Latest": false,
        "Status": "INACTIVE",
        "MaxConcurrency": 100,
        "MaxSize": 50,
        "MinSize": 5
    }
}
```

- For API details, see DeleteAutoScalingConfiguration in *Amazon CLI Command Reference*.

`delete-connection`

The following code example shows how to use `delete-connection`.

Amazon CLI

To delete a connection

The following `delete-connection` example deletes an App Runner connection. The connection status after a successful call is `DELETED`. This is because the connection is no longer available.

```
aws apprunner delete-connection \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/my-github-
connection"
}
```

Output:

```
{
    "Connection": {
        "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/my-
github-connection",
        "ConnectionName": "my-github-connection",
        "Status": "DELETED",
        "CreatedAt": "2020-11-03T00:32:51Z",
        "ProviderType": "GITHUB"
    }
}
```

- For API details, see DeleteConnection in *Amazon CLI Command Reference*.

`delete-service`

The following code example shows how to use `delete-service`.

Amazon CLI

To delete a service

The following `delete-service` example deletes an App Runner service.

```
aws apprunner delete-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "OperationId": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
    "Service": {
        "CreatedAt": "2020-11-20T19:05:25Z",
```

```
        "UpdatedAt": "2020-11-20T19:05:25Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceName": "python-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
                "ConnectionArn": "arn:aws:apprunner:us-
east-1:123456789012:connection/my-github-connection/
e7656250f67242d7819feade6800f59e"
            },
            "AutoDeploymentsEnabled": true,
            "CodeRepository": {
                "CodeConfiguration": {
                    "CodeConfigurationValues": {
                        "BuildCommand": "pip install -r requirements.txt",
                        "Port": "8080",
                        "Runtime": "PYTHON_3",
                        "RuntimeEnvironmentVariables": [
                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

- For API details, see DeleteService in *Amazon CLI Command Reference*.

describe-auto-scaling-configuration

The following code example shows how to use `describe-auto-scaling-configuration`.

Amazon CLI

Example 1: To describe the latest active revision of an auto scaling configuration

The following `describe-auto-scaling-configuration` example gets a description of the latest active revision of an App Runner auto scaling configuration. To describe the latest active revision, specify an ARN that ends with the configuration name, without the revision component.

In the example, two revisions exist. Therefore, revision 2 (the latest) is described. The resulting object shows `"Latest": true`.

```
aws apprunner describe-auto-scaling-configuration \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability"
}
```

Output:

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability/2/
e76562f50d78042e819fead0f59672e6",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 2,
        "CreatedAt": "2021-02-25T17:42:59Z",
        "Latest": true,
        "Status": "ACTIVE",
        "MaxConcurrency": 30,
        "MaxSize": 90,
        "MinSize": 5
```

```
    }
}
```

Example 2: To describe a specific revision of an auto scaling configuration

The following `describe-auto-scaling-configuration` example get a description of a specific revision of an App Runner auto scaling configuration. To describe a specific revision, specify an ARN that includes the revision number.

In the example, several revisions exist and revision 1 is queried. The resulting object shows `"Latest": false`.

```
aws apprunner describe-auto-scaling-configuration \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability/1"
}
```

Output:

```
{
    "AutoScalingConfiguration": {
        "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-
availability/1/2f50e7656d7819fead0f59672e68042e",
        "AutoScalingConfigurationName": "high-availability",
        "AutoScalingConfigurationRevision": 1,
        "CreatedAt": "2020-11-03T00:29:17Z",
        "Latest": false,
        "Status": "ACTIVE",
        "MaxConcurrency": 100,
        "MaxSize": 50,
        "MinSize": 5
    }
}
```

- For API details, see DescribeAutoScalingConfiguration in *Amazon CLI Command Reference*.

describe-custom-domains

The following code example shows how to use `describe-custom-domains`.

Amazon CLI

To get descriptions of custom domain names associated with a service

The following `describe-custom-domains` example get descriptions and status of the custom domain names associated with an App Runner service.

```
aws apprunner describe-custom-domains \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
    "DomainName": "example.com",
    "EnableWWWSubdomain": true
}
```

Output:

```
{
    "CustomDomains": [
        {
            "CertificateValidationRecords": [
                {
                    "Name": "_70d3f50a94f7c72dc28784cf55db2f6b.example.com",
                    "Status": "PENDING_VALIDATION",
                    "Type": "CNAME",
                    "Value": "_1270c137383c6307b6832db02504c4b0.bsgbmzkfwj.acm-
validations.aws."
                },
                {
                    "Name": "_287870d3f50a94f7c72dc4cf55db2f6b.www.example.com",
                    "Status": "PENDING_VALIDATION",
                    "Type": "CNAME",
                    "Value": "_832db01270c137383c6307b62504c4b0.mzkbsgbfwj.acm-
validations.aws."
```

```
                }
            ],
            "DomainName": "example.com",
            "EnableWWWSubdomain": true,
            "Status": "PENDING_CERTIFICATE_DNS_VALIDATION"
        },
        {
            "CertificateValidationRecords": [
                {
                    "Name": "_a94f784c70d3f507c72dc28f55db2f6b.deals.example.com",
                    "Status": "SUCCESS",
                    "Type": "CNAME",
                    "Value": "_2db02504c1270c137383c6307b6834b0.bsgbmzkfwj.acm-
validations.aws."
                }
            ],
            "DomainName": "deals.example.com",
            "EnableWWWSubdomain": false,
            "Status": "ACTIVE"
        }
    ],
    "DNSTarget": "psbqam834h.us-east-1.awsapprunner.com",
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

- For API details, see DescribeCustomDomains in *Amazon CLI Command Reference*.

`describe-service`

The following code example shows how to use `describe-service`.

Amazon CLI

To describe a service

The following `describe-service` example gets a description of an App Runner service.

```
aws apprunner describe-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "Service": {
        "CreatedAt": "2020-11-20T19:05:25Z",
        "UpdatedAt": "2020-11-20T19:05:25Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceName": "python-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
                "ConnectionArn": "arn:aws:apprunner:us-
east-1:123456789012:connection/my-github-connection/
e7656250f67242d7819feade6800f59e"
            },
            "AutoDeploymentsEnabled": true,
            "CodeRepository": {
                "CodeConfiguration": {
                    "CodeConfigurationValues": {
                        "BuildCommand": "pip install -r requirements.txt",
                        "Port": "8080",
                        "Runtime": "PYTHON_3",
                        "RuntimeEnvironmentVariables": [
                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
```

```
            }
        },
        "Status": "RUNNING",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

- For API details, see DescribeService in *Amazon CLI Command Reference*.

`disassociate-custom-domain`

The following code example shows how to use `disassociate-custom-domain`.

Amazon CLI

To disassociate a domain name from a service

The following `disassociate-custom-domain` example disassociates the domain `example.com` from an App Runner service. The call also disassociates the subdomain `www.example.com` that was associated together with the root domain.

```
aws apprunner disassociate-custom-domain \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
    "DomainName": "example.com"
}
```

Output:

```
{
    "CustomDomain": {
        "CertificateValidationRecords": [
            {
```

app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

- For API details, see DisassociateCustomDomain in *Amazon CLI Command Reference*.

`list-auto-scaling-configurations`

The following code example shows how to use `list-auto-scaling-configurations`.

Amazon CLI

To get a paginated listing of App Runner auto scaling configurations

The following `list-auto-scaling-configurations` example lists all App Runner auto scaling configurations in your Amazon account. Up to five auto scaling configurations are listed in each response. `AutoScalingConfigurationName` and `LatestOnly` aren't specified. Their defaults cause the latest revision of all active configurations to be listed.

In this example, the response includes two results and there aren't additional ones, so no `NextToken` is returned.

```
aws apprunner list-auto-scaling-configurations \
```

```
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "MaxResults": 5
}
```

Output:

```
{
    "AutoScalingConfigurationSummaryList": [
        {
            "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/high-availability/2/
e76562f50d78042e819fead0f59672e6",
            "AutoScalingConfigurationName": "high-availability",
            "AutoScalingConfigurationRevision": 2
        },
        {
            "AutoScalingConfigurationArn": "arn:aws:apprunner:us-
east-1:123456789012:autoscalingconfiguration/low-
cost/1/50d7804e7656fead0f59672e62f2e819",
            "AutoScalingConfigurationName": "low-cost",
            "AutoScalingConfigurationRevision": 1
        }
    ]
}
```

- For API details, see ListAutoScalingConfigurations in *Amazon CLI Command Reference*.

`list-connections`

The following code example shows how to use `list-connections`.

Amazon CLI

Example 1: To list all connections

The following `list-connections` example lists all App Runner connections in the Amazon account.

```
aws apprunner list-connections
```

Output:

```
{
    "ConnectionSummaryList": [
        {
            "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/
my-github-connection",
            "ConnectionName": "my-github-connection",
            "Status": "AVAILABLE",
            "CreatedAt": "2020-11-03T00:32:51Z",
            "ProviderType": "GITHUB"
        },
        {
            "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/
my-github-org-connection",
            "ConnectionName": "my-github-org-connection",
            "Status": "AVAILABLE",
            "CreatedAt": "2020-11-03T02:54:17Z",
            "ProviderType": "GITHUB"
        }
    ]
}
```

Example 2: To list a connection by name

The following `list-connections` example lists a connection by its name.

```
aws apprunner list-connections \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ConnectionName": "my-github-org-connection"
}
```

Output:

```
{
```

```
    "ConnectionSummaryList": [
        {
            "ConnectionArn": "arn:aws:apprunner:us-east-1:123456789012:connection/
my-github-org-connection",
            "ConnectionName": "my-github-org-connection",
            "Status": "AVAILABLE",
            "CreatedAt": "2020-11-03T02:54:17Z",
            "ProviderType": "GITHUB"
        }
    ]
}
```

- For API details, see ListConnections in *Amazon CLI Command Reference*.

`list-operations`

The following code example shows how to use `list-operations`.

Amazon CLI

To list operations that occurred on a servicee

The following `list-operations` example lists all operations that occurred on an App Runner service so far. In this example, the service is new and only a single operation of type `CREATE_SERVICE` has occurred.

```
aws apprunner list-operations \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "OperationSummaryList": [
        {
            "EndedAt": 1606156217,
```

```
            "Id": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
            "StartedAt": 1606156014,
            "Status": "SUCCEEDED",
            "TargetArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
            "Type": "CREATE_SERVICE",
            "UpdatedAt": 1606156217
        }
    ]
}
```

- For API details, see ListOperations in *Amazon CLI Command Reference*.

`list-services`

The following code example shows how to use `list-services`.

Amazon CLI

To get a paginated listing of App Runner services

The following `list-services` example lists all App Runner services in the Amazon account. Up to two services are listed in each response. This example shows the first request. The response includes two results and a token that can be used in the next request. When a subsequent response doesn't include a token, all services have been listed.

```
aws apprunner list-services \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "MaxResults": 2
}
```

Output:

```
{
    "NextToken":
 "eyJDdXN0b21lckFjY291bnRJZCI6IjI3MDIwNTQwMjg0NSIsIlNlcnZpY2VTdGF0dXNDb2RlIjoiUFJPVklTU9OU
    "ServiceSummaryList": [
```

```
        {
            "CreatedAt": "2020-11-20T19:05:25Z",
            "UpdatedAt": "2020-11-23T12:41:37Z",
            "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
            "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
            "ServiceName": "python-app",
            "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
            "Status": "RUNNING"
        },
        {
            "CreatedAt": "2020-11-06T23:15:30Z",
            "UpdatedAt": "2020-11-23T13:21:22Z",
            "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/golang-
container-app/ab8f94cfe29a460fb8760afd2ee87555",
            "ServiceId": "ab8f94cfe29a460fb8760afd2ee87555",
            "ServiceName": "golang-container-app",
            "ServiceUrl": "e2m8rrrx33.us-east-1.awsapprunner.com",
            "Status": "RUNNING"
        }
    ]
}
```

- For API details, see ListServices in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags associated with an App Runner service

The following `list-tags-for-resource` example lists all the tags that are associated with an App Runner service.

```
aws apprunner list-tags-for-resource \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
```

```
    "ResourceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "Tags": [
        {
            "Key": "Department",
            "Value": "Retail"
        },
        {
            "Key": "CustomerId",
            "Value": "56439872357912"
        }
    ]
}
```

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`pause-service`

The following code example shows how to use `pause-service`.

Amazon CLI

To pause a service

The following `pause-service` example pauses an App Runner service.

```
aws apprunner pause-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "OperationId": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
    "Service": {
        "CreatedAt": "2020-11-20T19:05:25Z",
        "UpdatedAt": "2020-11-23T12:41:37Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceName": "python-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
                "ConnectionArn": "arn:aws:apprunner:us-
east-1:123456789012:connection/my-github-connection/
e7656250f67242d7819feade6800f59e"
            },
            "AutoDeploymentsEnabled": true,
            "CodeRepository": {
                "CodeConfiguration": {
                    "CodeConfigurationValues": {
                        "BuildCommand": "pip install -r requirements.txt",
                        "Port": "8080",
                        "Runtime": "PYTHON_3",
                        "RuntimeEnvironmentVariables": [
                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
```

```
            "Memory": "3 GB"
        }
    }
}
```

- For API details, see PauseService in *Amazon CLI Command Reference*.

`resume-service`

The following code example shows how to use `resume-service`.

Amazon CLI

To resume a service

The following `resume-service` example resumes an App Runner service.

```
aws apprunner resume-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "OperationId": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
    "Service": {
        "CreatedAt": "2020-11-20T19:05:25Z",
        "UpdatedAt": "2020-11-23T12:41:37Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceName": "python-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
```

```
                "ConnectionArn": "arn:aws:apprunner:us-
east-1:123456789012:connection/my-github-connection/
e7656250f67242d7819feade6800f59e"
            },
            "AutoDeploymentsEnabled": true,
            "CodeRepository": {
                "CodeConfiguration": {
                    "CodeConfigurationValues": {
                        "BuildCommand": "pip install -r requirements.txt",
                        "Port": "8080",
                        "Runtime": "PYTHON_3",
                        "RuntimeEnvironmentVariables": [
                            {
                                "NAME": "Jane"
                            }
                        ],
                        "StartCommand": "python server.py"
                    },
                    "ConfigurationSource": "Api"
                },
                "RepositoryUrl": "https://github.com/my-account/python-hello",
                "SourceCodeVersion": {
                    "Type": "BRANCH",
                    "Value": "main"
                }
            }
        },
        "Status": "OPERATION_IN_PROGRESS",
        "InstanceConfiguration": {
            "CPU": "1 vCPU",
            "Memory": "3 GB"
        }
    }
}
```

- For API details, see ResumeService in *Amazon CLI Command Reference*.

`start-deployment`

The following code example shows how to use `start-deployment`.

Amazon CLI

To initiate a manual deployment

The following `start-deployment` example performs a manual deployment to an App Runner service.

```
aws apprunner start-deployment \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa"
}
```

Output:

```
{
    "OperationId": "853a7d5b-fc9f-4730-831b-fd8037ab832a"
}
```

- For API details, see StartDeployment in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add tags to an App Runner service

The following `tag-resource` example adds two tags to an App Runner service.

```
aws apprunner tag-resource \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ResourceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
    "Tags": [
        {
            "Key": "Department",
            "Value": "Retail"
        },
        {
            "Key": "CustomerId",
            "Value": "56439872357912"
        }
    ]
}
```

This command produces no output.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from an App Runner service

The following `untag-resource` example removes two tags from an App Runner service.

```
aws apprunner untag-resource \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ResourceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
    "TagKeys": [
        "Department",
        "CustomerId"
    ]
```

```
}
```

This command produces no output.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-service`

The following code example shows how to use `update-service`.

Amazon CLI

To update memory size

The following `update-service` example updates the memory size of instances (scaling units) of an App Runner service to 2048 MiB.

When the call succeeds, App Runner starts an asynchronous update process. The `Service` structure that's returned by the call reflects the new memory value that's being applied by this call.

```
aws apprunner update-service \
    --cli-input-json file://input.json
```

Contents of `input.json`:

```
{
    "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
    "InstanceConfiguration": {
        "Memory": "4 GB"
    }
}
```

Output:

```
{
    "OperationId": "17fe9f55-7e91-4097-b243-fcabbb69a4cf",
    "Service": {
        "CreatedAt": "2020-11-20T19:05:25Z",
```

```
        "UpdatedAt": "2020-11-23T12:41:37Z",
        "ServiceArn": "arn:aws:apprunner:us-east-1:123456789012:service/python-
app/8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceId": "8fe1e10304f84fd2b0df550fe98a71fa",
        "ServiceName": "python-app",
        "ServiceUrl": "psbqam834h.us-east-1.awsapprunner.com",
        "SourceConfiguration": {
            "AuthenticationConfiguration": {
                "ConnectionArn": "arn:aws:apprunner:us-
east-1:123456789012:connection/my-github-connection/
e7656250f67242d7819feade6800f59e"

- For API details, see UpdateService in *Amazon CLI Command Reference*.

Amazon AppConfig examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon AppConfig.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-application`

The following code example shows how to use `create-application`.

Amazon CLI

To create an application

The following `create-application` example creates an application in Amazon AppConfig.

```
aws appconfig create-application \
    --name "example-application" \
    --description "An application used for creating an example."
```

Output:

```
{
    "Description": "An application used for creating an example.",
    "Id": "339ohji",
    "Name": "example-application"
}
```

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see CreateApplication in *Amazon CLI Command Reference*.

`create-configuration-profile`

The following code example shows how to use `create-configuration-profile`.

Amazon CLI

To create a configuration profile

The following `create-configuration-profile` example creates a configuration profile using a configuration stored in Parameter Store, a capability of Systems Manager.

```
aws appconfig create-configuration-profile \
    --application-id "339ohji" \
    --name "Example-Configuration-Profile" \
    --location-uri "ssm-parameter://Example-Parameter" \
    --retrieval-role-arn "arn:aws:iam::111122223333:role/Example-App-Config-Role"
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Description": null,
    "Id": "ur8hx2f",
    "LocationUri": "ssm-parameter://Example-Parameter",
    "Name": "Example-Configuration-Profile",
    "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role",
    "Type": null,
    "Validators": null
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see CreateConfigurationProfile in *Amazon CLI Command Reference*.

`create-environment`

The following code example shows how to use `create-environment`.

Amazon CLI

To create an environment

The following `create-environment` example creates an Amazon AppConfig environment named Example-Environment using the application you created using create-application.

```
aws appconfig create-environment \
    --application-id "339ohji" \
    --name "Example-Environment"
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Description": null,
    "Id": "54j1r29",
    "Monitors": null,
    "Name": "Example-Environment",
    "State": "ReadyForDeployment"
}
```

For more information, see Step 2: Creating an environment in the *Amazon AppConfig User Guide*.

- For API details, see CreateEnvironment in *Amazon CLI Command Reference*.

`create-extension-association`

The following code example shows how to use `create-extension-association`.

Amazon CLI

To create an extension association

The following `create-extension-association` example creates a new extension association in Amazon AppConfig.

```
aws appconfig create-extension-association \
    --region us-west-2 \
    --extension-identifier S3-backup-extension \
    --resource-identifier "arn:aws:appconfig:us-west-2:123456789012:application/
Finance" \
    --parameters S3bucket=FinanceConfigurationBackup
```

Output:

```
{
  "Id": "a1b2c3d4",
  "ExtensionArn": "arn:aws:appconfig:us-west-2:123456789012:extension/S3-backup-
extension/1",
  "ResourceArn": "arn:aws:appconfig:us-west-2:123456789012:application/Finance",
  "Parameters": {
    "S3bucket": "FinanceConfigurationBackup"
  },
  "ExtensionVersionNumber": 1
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see CreateExtensionAssociation in *Amazon CLI Command Reference*.

`create-extension`

The following code example shows how to use `create-extension`.

Amazon CLI

To create an extension

The following `create-extension` example creates a new extension in Amazon AppConfig.

```
aws appconfig create-extension \
    --region us-west-2 \
    --name S3-backup-extension \
    --
actions PRE_CREATE_HOSTED_CONFIGURATION_VERSION=[{Name=S3backup,Uri=arn:aws:lambda:us-
west-2:123456789012:function:s3backupfunction,RoleArn=arn:aws:iam::123456789012:role/
appconfigextensionrole}] \
    --parameters S3bucket={Required=true}
```

Output:

```
{
    "Id": "1A2B3C4D",
```

```
    "Name": "S3-backup-extension",
    "VersionNumber": 1,
    "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/1A2B3C4D/1",
    "Actions": {
        "PRE_CREATE_HOSTED_CONFIGURATION_VERSION": [
            {
                "Name": "S3backup",
                "Uri": "arn:aws:lambda:us-
west-2:123456789012:function:s3backupfunction",
                "RoleArn": "arn:aws:iam::123456789012:role/appconfigextensionrole"
            }
        ]
    },
    "Parameters": {
        "S3bucket": {
            "Required": true
        }
    }
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see CreateExtension in *Amazon CLI Command Reference*.

`create-hosted-configuration-version`

The following code example shows how to use `create-hosted-configuration-version`.

Amazon CLI

To create a hosted configuration version

The following `create-hosted-configuration-version` example creates a new configuration in the Amazon AppConfig hosted configuration store. The configuration content must first be converted to base64.

```
aws appconfig create-hosted-configuration-version \
    --application-id "339ohji" \
    --configuration-profile-id "ur8hx2f" \
    --
content eyAiTmFtZSI6ICJFeGFtcGxlQXBwbGljYXRpb24iLCAiSWQiOiBFeGFtcGxlSUQsICJSYW5rIjogNyB9
 \
```

```
    --content-type "application/json" \
    configuration_version_output_file
```

Contents of `configuration_version_output_file`:

```
{ "Name": "ExampleApplication", "Id": ExampleID, "Rank": 7 }
```

Output:

```
{
    "ApplicationId": "339ohji",
    "ConfigurationProfileId": "ur8hx2f",
    "VersionNumber": "1",
    "ContentType": "application/json"
}
```

For more information, see About the Amazon AppConfig hosted configuration store in the *Amazon Appconfig User Guide*.

- For API details, see CreateHostedConfigurationVersion in *Amazon CLI Command Reference*.

`delete-application`

The following code example shows how to use `delete-application`.

Amazon CLI

To delete an application

The following `delete-application` example deletes the specified application.

```
aws appconfig delete-application \
--application-id 339ohji
```

This command produces no output.

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see DeleteApplication in *Amazon CLI Command Reference*.

`delete-configuration-profile`

The following code example shows how to use `delete-configuration-profile`.

Amazon CLI

To delete a configuration profile

The following `delete-configuration-profile` example deletes the specified configuration profile.

```
aws appconfig delete-configuration-profile \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f
```

This command produces no output.

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see DeleteConfigurationProfile in *Amazon CLI Command Reference*.

`delete-deployment-strategy`

The following code example shows how to use `delete-deployment-strategy`.

Amazon CLI

To delete a deployment strategy

The following `delete-deployment-strategy` example deletes the specified deployment strategy.

```
aws appconfig delete-deployment-strategy \
    --deployment-strategy-id 1225qzk
```

This command produces no output.

For more information, see Step 4: Creating a deployment strategy in the *Amazon AppConfig User Guide*.

- For API details, see DeleteDeploymentStrategy in *Amazon CLI Command Reference*.

`delete-environment`

The following code example shows how to use `delete-environment`.

Amazon CLI

To delete an environment

The following `delete-environment` example deletes the specified application environment.

```
aws appconfig delete-environment \
    --application-id 339ohji \
    --environment-id 54j1r29
```

This command produces no output.

For more information, see Step 2: Creating an environment in the *Amazon AppConfig User Guide*.

- For API details, see DeleteEnvironment in *Amazon CLI Command Reference*.

`delete-extension-association`

The following code example shows how to use `delete-extension-association`.

Amazon CLI

To delete an extension association

The following `delete-extension-association` example deletes an extension association from Amazon AppConfig.

```
aws appconfig delete-extension-association \
    --region us-west-2 \
    --extension-association-id a1b2c3d4
```

This command produces no output.

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see DeleteExtensionAssociation in *Amazon CLI Command Reference*.

`delete-extension`

The following code example shows how to use `delete-extension`.

Amazon CLI

To delete an extension

The following `delete-extension` example deletes an extension from Amazon AppConfig.

```
aws appconfig delete-extension \
    --region us-west-2 \
    --extension-identifier S3-backup-extension
```

This command produces no output.

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see DeleteExtension in *Amazon CLI Command Reference*.

`delete-hosted-configuration-version`

The following code example shows how to use `delete-hosted-configuration-version`.

Amazon CLI

To delete a hosted configuration version

The following `delete-hosted-configuration-version` example deletes a configuration version hosted in the Amazon AppConfig hosted configuration store.

```
aws appconfig delete-hosted-configuration-version \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f \
    --version-number 1
```

Output:: This command produces no output.

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see DeleteHostedConfigurationVersion in *Amazon CLI Command Reference*.

`get-application`

The following code example shows how to use `get-application`.

Amazon CLI

To list details of an application

The following `get-application` example lists the details of the specified application.

```
aws appconfig get-application \
    --application-id 339ohji
```

Output:

```
{
    "Description": "An application used for creating an example.",
    "Id": "339ohji",
    "Name": "example-application"
}
```

For more information, see How Amazon AppConfig works in the *Amazon AppConfig User Guide*.

- For API details, see GetApplication in *Amazon CLI Command Reference*.

`get-configuration-profile`

The following code example shows how to use `get-configuration-profile`.

Amazon CLI

To retrieve configuration profile details

The following `get-configuration-profile` example returns the details of the specified configuration profile.

```
aws appconfig get-configuration-profile \
    --application-id 339ohji \
```

```
    --configuration-profile-id ur8hx2f
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "ur8hx2f",
    "Name": "Example-Configuration-Profile",
    "LocationUri": "ssm-parameter://Example-Parameter",
    "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role"
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see GetConfigurationProfile in *Amazon CLI Command Reference*.

`get-configuration`

The following code example shows how to use `get-configuration`.

Amazon CLI

To retrieve configuration details

The following `get-configuration` example returns the configuration details of the example application. On subsequent calls to get-configuration use the `client-configuration-version` parameter to only update the configuration of your application if the version has changed. Only updating the configuration when the version has changed avoids excess charges incurred by calling get-configuration.

```
aws appconfig get-configuration \
    --application "example-application" \
    --environment "Example-Environment" \
    --configuration "Example-Configuration-Profile" \
    --client-id "test-id" \
    configuration-output-file
```

Contents of `configuration-output-file`:

```
{ "Name": "ExampleApplication", "Id": ExampleID, "Rank": 7 }
```

Output:

```
{
    "ConfigurationVersion": "1",
    "ContentType": "application/json"
}
```

For more information, see Step 6: Receiving the configuration in the *Amazon AppConfig User Guide*.

- For API details, see GetConfiguration in *Amazon CLI Command Reference*.

`get-deployment-strategy`

The following code example shows how to use `get-deployment-strategy`.

Amazon CLI

To retrieve details of a deployment strategy

The following `get-deployment-strategy` example lists the details of the specified deployment strategy.

```
aws appconfig get-deployment-strategy \
    --deployment-strategy-id 1225qzk
```

Output:

```
{
    "Id": "1225qzk",
    "Name": "Example-Deployment",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 0,
    "ReplicateTo": "SSM_DOCUMENT"
}
```

For more information, see Step 4: Creating a deployment strategy in the *Amazon AppConfig User Guide*.

- For API details, see GetDeploymentStrategy in *Amazon CLI Command Reference*.

`get-deployment`

The following code example shows how to use `get-deployment`.

Amazon CLI

To retrieve deployment details

The following `get-deployment` example lists details of the deployment to the application in the specified environment and deployment.

```
aws appconfig get-deployment \
    --application-id 339ohji \
    --environment-id 54j1r29 \
    --deployment-number 1
```

Output:

```
{
    "ApplicationId": "339ohji",
    "EnvironmentId": "54j1r29",
    "DeploymentStrategyId": "1225qzk",
    "ConfigurationProfileId": "ur8hx2f",
    "DeploymentNumber": 1,
    "ConfigurationName": "Example-Configuration-Profile",
    "ConfigurationLocationUri": "ssm-parameter://Example-Parameter",
    "ConfigurationVersion": "1",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 0,
    "State": "COMPLETE",
    "EventLog": [
        {
            "EventType": "DEPLOYMENT_COMPLETED",
            "TriggeredBy": "APPCONFIG",
            "Description": "Deployment completed",

    "CompletedAt": "2021-09-17T21:59:03.888000+00:00"
}
```

For more information, see Step 5: Deploying a configuration in the *Amazon AppConfig User Guide*.

- For API details, see GetDeployment in *Amazon CLI Command Reference*.

`get-environment`

The following code example shows how to use `get-environment`.

Amazon CLI

To retrieve environment details

The following `get-environment` example returns the details and state of the specified environment.

```
aws appconfig get-environment \
    --application-id 339ohji \
    --environment-id 54j1r29
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "54j1r29",
    "Name": "Example-Environment",
    "State": "ReadyForDeployment"
}
```

For more information, see Step 2: Creating an environment in the *Amazon AppConfig User Guide*.

- For API details, see GetEnvironment in *Amazon CLI Command Reference*.

`get-extension-association`

The following code example shows how to use `get-extension-association`.

Amazon CLI

To get extension association details

The following `get-extension-association` example displays information about an extension association.

```
aws appconfig get-extension-association \
```

```
    --region us-west-2 \
    --extension-association-id a1b2c3d4
```

Output:

```
{
    "Id": "a1b2c3d4",
    "ExtensionArn": "arn:aws:appconfig:us-west-2:123456789012:extension/S3-backup-
extension/1",
    "ResourceArn": "arn:aws:appconfig:us-west-2:123456789012:application/Finance",
    "Parameters": {
        "S3bucket": "FinanceConfigurationBackup"
    },
    "ExtensionVersionNumber": 1
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see GetExtensionAssociation in *Amazon CLI Command Reference*.

`get-extension`

The following code example shows how to use `get-extension`.

Amazon CLI

To get extension details

The following `get-extension` example displays information about an extension.

```
aws appconfig get-extension \
    --region us-west-2 \
    --extension-identifier S3-backup-extension
```

Output:

```
{
    "Id": "1A2B3C4D",
    "Name": "S3-backup-extension",
    "VersionNumber": 1,
```

```
    "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/S3-backup-
extension/1",
    "Actions": {
        "PRE_CREATE_HOSTED_CONFIGURATION_VERSION": [
            {
                "Name": "S3backup",
                "Uri": "arn:aws:lambda:us-
west-2:123456789012:function:S3backupfunction",
                "RoleArn": "arn:aws:iam::123456789012:role/appconfigextensionrole"
            }
        ]
    },
    "Parameters": {
        "S3bucket": {
            "Required": true
        }
    }
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see GetExtension in *Amazon CLI Command Reference*.

`get-hosted-configuration-version`

The following code example shows how to use `get-hosted-configuration-version`.

Amazon CLI

To retreive hosted configuration details

The following `get-hosted-configuration-version` example retrieves the configuration details of the Amazon AppConfig hosted configuration.

```
aws appconfig get-hosted-configuration-version \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f \
    --version-number 1 \
    hosted-configuration-version-output
```

Contents of `hosted-configuration-version-output`:

```
{ "Name": "ExampleApplication", "Id": ExampleID, "Rank": 7 }
```

Output:

```
{
    "ApplicationId": "339ohji",
    "ConfigurationProfileId": "ur8hx2f",
    "VersionNumber": "1",
    "ContentType": "application/json"
}
```

For more information, see About the Amazon AppConfig hosted configuration store in the *Amazon AppConfig User Guide*.

- For API details, see GetHostedConfigurationVersion in *Amazon CLI Command Reference*.

`list-applications`

The following code example shows how to use `list-applications`.

Amazon CLI

To list the available applications

The following `list-applications` example lists the available applications in your Amazon account.

```
aws appconfig list-applications
```

Output:

```
{
    "Items": [
        {
            "Id": "339ohji",
            "Name": "test-application",
            "Description": "An application used for creating an example."
        },
        {
            "Id": "rwalwu7",
```

```
            "Name": "Test-Application"
        }
    ]
}
```

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see ListApplications in *Amazon CLI Command Reference*.

`list-configuration-profiles`

The following code example shows how to use `list-configuration-profiles`.

Amazon CLI

To list the available configuration profiles

The following `list-configuration-profiles` example lists the available configuration profiles for the specified application.

```
aws appconfig list-configuration-profiles \
    --application-id 339ohji
```

Output:

```
{
    "Items": [
        {
            "ApplicationId": "339ohji",
            "Id": "ur8hx2f",
            "Name": "Example-Configuration-Profile",
            "LocationUri": "ssm-parameter://Example-Parameter"
        }
    ]
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see ListConfigurationProfiles in *Amazon CLI Command Reference*.

`list-deployment-strategies`

The following code example shows how to use `list-deployment-strategies`.

Amazon CLI

To list the available deployment strategies

The following `list-deployment-strategies` example lists the available deployment strategies in your Amazon account.

```
aws appconfig list-deployment-strategies
```

Output:

```
{
    "Items": [
        {
            "Id": "1225qzk",
            "Name": "Example-Deployment",
            "DeploymentDurationInMinutes": 15,
            "GrowthType": "LINEAR",
            "GrowthFactor": 25.0,
            "FinalBakeTimeInMinutes": 0,
            "ReplicateTo": "SSM_DOCUMENT"
        },
        {
            "Id": "AppConfig.AllAtOnce",
            "Name": "AppConfig.AllAtOnce",
            "Description": "Quick",
            "DeploymentDurationInMinutes": 0,
            "GrowthType": "LINEAR",
            "GrowthFactor": 100.0,
            "FinalBakeTimeInMinutes": 10,
            "ReplicateTo": "NONE"
        },
        {
            "Id": "AppConfig.Linear50PercentEvery30Seconds",
            "Name": "AppConfig.Linear50PercentEvery30Seconds",
            "Description": "Test/Demo",
            "DeploymentDurationInMinutes": 1,
            "GrowthType": "LINEAR",
            "GrowthFactor": 50.0,
```

```
            "FinalBakeTimeInMinutes": 1,
            "ReplicateTo": "NONE"
        },
        {
            "Id": "AppConfig.Canary10Percent20Minutes",
            "Name": "AppConfig.Canary10Percent20Minutes",
            "Description": "AWS Recommended",
            "DeploymentDurationInMinutes": 20,
            "GrowthType": "EXPONENTIAL",
            "GrowthFactor": 10.0,
            "FinalBakeTimeInMinutes": 10,
            "ReplicateTo": "NONE"
        }
    ]
}
```

For more information, see Step 4: Creating a deployment strategy in the *Amazon AppConfig User Guide*.

- For API details, see ListDeploymentStrategies in *Amazon CLI Command Reference*.

`list-deployments`

The following code example shows how to use `list-deployments`.

Amazon CLI

To list the available deployments

The following `list-deployments` example lists the available deployments in your Amazon account for the specified application and environment.

```
aws appconfig list-deployments \
    --application-id 339ohji \
    --environment-id 54j1r29
```

Output:

```
{
    "Items": [
        {
            "DeploymentNumber": 1,
```

```
            "ConfigurationName": "Example-Configuration-Profile",
            "ConfigurationVersion": "1",
            "DeploymentDurationInMinutes": 15,
            "GrowthType": "LINEAR",
            "GrowthFactor": 25.0,
            "FinalBakeTimeInMinutes": 0,
            "State": "COMPLETE",
            "PercentageComplete": 100.0,
            "StartedAt": "2021-09-17T21:43:54.205000+00:00",
            "CompletedAt": "2021-09-17T21:59:03.888000+00:00"
        }
    ]
}
```

For more information, see Step 5: Deploying a configuration in the *Amazon AppConfig User Guide*.

- For API details, see ListDeployments in *Amazon CLI Command Reference*.

`list-environments`

The following code example shows how to use `list-environments`.

Amazon CLI

To list the available environments

The following `list-environments` example lists the available environments in your Amazon account for the specified application.

```
aws appconfig list-environments \
    --application-id 339ohji
```

Output:

```
{
    "Items": [
        {
            "ApplicationId": "339ohji",
            "Id": "54j1r29",
            "Name": "Example-Environment",
            "State": "ReadyForDeployment"
```

```
        }
    ]
}
```

For more information, see Step 2: Creating an environment in the *Amazon AppConfig User Guide*.

- For API details, see ListEnvironments in *Amazon CLI Command Reference*.

`list-extension-associations`

The following code example shows how to use `list-extension-associations`.

Amazon CLI

To list all Amazon AppConfig extension associations in your Amazon account for an Amazon Region

The following `list-extension-associations` example lists all Amazon AppConfig extension associations for the current Amazon account in a specific Amazon Region.

```
aws appconfig list-extension-associations \
    --region us-west-2
```

Output:

```
{
    "Items": [
        {
            "Id": "a1b2c3d4",
            "ExtensionArn": "arn:aws:appconfig:us-west-2:123456789012:extension/S3-
backup-extension/1",
            "ResourceArn": "arn:aws:appconfig:us-west-2:123456789012:application/
Finance"
        }
    ]
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see ListExtensionAssociations in *Amazon CLI Command Reference*.

`list-extensions`

The following code example shows how to use `list-extensions`.

Amazon CLI

To list all Amazon AppConfig extensions in your Amazon account for an Amazon Region

The following `list-extensions` example lists all Amazon AppConfig extensions for the current Amazon account in a specific Amazon Region. The command returns custom and Amazon authored extensions.

```
aws appconfig list-extensions \
    --region us-west-2
```

Output:

```
{
    "Items": [
        {
            "Id": "1A2B3C4D",
            "Name": "S3-backup-extension",
            "VersionNumber": 1,
            "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/1A2B3C4D/1"
        },
        {
            "Id": "AWS.AppConfig.FeatureFlags",
            "Name": "AppConfig Feature Flags Helper",
            "VersionNumber": 1,
            "Arn": "arn:aws:appconfig:us-west-2::extension/
AWS.AppConfig.FeatureFlags/1",
            "Description": "Validates AppConfig feature flag data automatically
 against a JSON schema that includes structure and constraints. Also transforms
 feature flag data prior to sending to the client. This extension is automatically
 associated to configuration profiles with type \"AWS.AppConfig.FeatureFlags\"."
        },
        {
            "Id": "AWS.AppConfig.JiraIntegration",
            "Name": "AppConfig integration with Atlassian Jira",
            "VersionNumber": 1,
            "Arn": "arn:aws:appconfig:us-west-2::extension/
AWS.AppConfig.JiraIntegration/1",
```

```
            "Description": "Exports feature flag data from AWS AppConfig into
 Jira. The lifecycle of each feature flag in AppConfig is tracked in Jira as an
 individual issue. Customers can see in Jira when flags are updated, turned on or
 off. Works in conjunction with the AppConfig app in the Atlassian Marketplace and
 is automatically associated to configuration profiles configured within that app."
        },
        {
            "Id": "AWS.AppConfig.DeploymentNotificationsToEventBridge",
            "Name": "AppConfig deployment events to Amazon EventBridge",
            "VersionNumber": 1,
            "Arn": "arn:aws:appconfig:us-west-2::extension/
AWS.AppConfig.DeploymentNotificationsToEventBridge/1",
            "Description": "Sends events to Amazon EventBridge when a deployment
 of configuration data in AppConfig is started, completed, or rolled back. Can
 be associated to the following resources in AppConfig: Application, Environment,
 Configuration Profile."
        },
        {
            "Id": "AWS.AppConfig.DeploymentNotificationsToSqs",
            "Name": "AppConfig deployment events to Amazon SQS",
            "VersionNumber": 1,
            "Arn": "arn:aws:appconfig:us-west-2::extension/
AWS.AppConfig.DeploymentNotificationsToSqs/1",
            "Description": "Sends messages to the configured Amazon SQS queue when
 a deployment of configuration data in AppConfig is started, completed, or rolled
 back. Can be associated to the following resources in AppConfig: Application,
 Environment, Configuration Profile."
        },
        {
            "Id": "AWS.AppConfig.DeploymentNotificationsToSns",
            "Name": "AppConfig deployment events to Amazon SNS",
            "VersionNumber": 1,
            "Description": "Sends events to the configured Amazon SNS topic when
 a deployment of configuration data in AppConfig is started, completed, or rolled
 back. Can be associated to the following resources in AppConfig: Application,
 Environment, Configuration Profile."
        }
    ]
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see ListExtensions in *Amazon CLI Command Reference*.

`list-hosted-configuration-versions`

The following code example shows how to use `list-hosted-configuration-versions`.

Amazon CLI

To list the available hosted configuration versions

The following `list-hosted-configuration-versions` example lists the configurations versions hosted in the Amazon AppConfig hosted configuration store for the specified application and configuration profile.

```
aws appconfig list-hosted-configuration-versions \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f
```

Output:

```
{
    "Items": [
        {
            "ApplicationId": "339ohji",
            "ConfigurationProfileId": "ur8hx2f",
            "VersionNumber": 1,
            "ContentType": "application/json"
        }
    ]
}
```

For more information, see About the Amazon AppConfig hosted configuration store in the *Amazon AppConfig User Guide*.

- For API details, see ListHostedConfigurationVersions in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list the tags of an application

The following `list-tags-for-resource` example lists the tags of a specified application.

```
aws appconfig list-tags-for-resource \
    --resource-arn arn:aws:appconfig:us-east-1:682428703967:application/339ohji
```

Output:

```
{
    "Tags": {
        "group1": "1"
    }
}
```

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`start-deployment`

The following code example shows how to use `start-deployment`.

Amazon CLI

To start a configuration deployment

The following `start-deployment` example starts a deployment to the application using the specified environment, deployment strategy, and configuration profile.

```
aws appconfig start-deployment \
    --application-id 339ohji \
    --environment-id 54j1r29 \
    --deployment-strategy-id 1225qzk \
    --configuration-profile-id ur8hx2f \
    --configuration-version 1
```

Output:

```
{
    "ApplicationId": "339ohji",
```

```
    "EnvironmentId": "54j1r29",
    "DeploymentStrategyId": "1225qzk",
    "ConfigurationProfileId": "ur8hx2f",
    "DeploymentNumber": 1,
    "ConfigurationName": "Example-Configuration-Profile",
    "ConfigurationLocationUri": "ssm-parameter://Example-Parameter",
    "ConfigurationVersion": "1",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 0,
    "State": "DEPLOYING",
    "EventLog": [
        {
            "EventType": "DEPLOYMENT_STARTED",
            "TriggeredBy": "USER",
            "Description": "Deployment started",
            "OccurredAt": "2021-09-17T21:43:54.205000+00:00"
        }
    ],
    "PercentageComplete": 0.0,
    "StartedAt": "2021-09-17T21:43:54.205000+00:00"
}
```

For more information, see Step 5: Deploying a configuration in the *Amazon AppConfig User Guide*.

- For API details, see StartDeployment in *Amazon CLI Command Reference*.

`stop-deployment`

The following code example shows how to use `stop-deployment`.

Amazon CLI

To stop configuration deployment

The following `stop-deployment` example stops the deployment of an application configuration to the specified environment.

```
aws appconfig stop-deployment \
    --application-id 339ohji \
    --environment-id 54j1r29 \
```

```
    --deployment-number 2
```

Output:

```
{
    "DeploymentNumber": 0,
    "DeploymentDurationInMinutes": 0,
    "GrowthFactor": 0.0,
    "FinalBakeTimeInMinutes": 0,
    "PercentageComplete": 0.0
}
```

For more information, see Step 5: Deploying a configuration in the *Amazon AppConfig User Guide*.

- For API details, see StopDeployment in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag an application

The following `tag-resource` example tags an application resource.

```
aws appconfig tag-resource \
    --resource-arn arn:aws:appconfig:us-east-1:682428703967:application/339ohji \
    --tags '{"group1" : "1"}'
```

This command produces no output.

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove a tag from an application

The following `untag-resource` example removes the group1 tag from the specified application.

```
aws appconfig untag-resource \
    --resource-arn arn:aws:appconfig:us-east-1:111122223333:application/339ohji \
    --tag-keys '["group1"]'
```

This command produces no output.

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-application`

The following code example shows how to use `update-application`.

Amazon CLI

To update an application

The following `update-application` example updates the name of the specified application.

```
aws appconfig update-application \
    --application-id 339ohji \
    --name "Example-Application"
```

Output:

```
{
    "Id": "339ohji",
    "Name": "Example-Application",
    "Description": "An application used for creating an example."
}
```

For more information, see Step 1: Creating an Amazon AppConfig application in the *Amazon AppConfig User Guide*.

- For API details, see UpdateApplication in *Amazon CLI Command Reference*.

`update-configuration-profile`

The following code example shows how to use `update-configuration-profile`.

Amazon CLI

To update a configuration profile

The following `update-configuration-profile` example updates the description of the specified configuration profile.

```
aws appconfig update-configuration-profile \
    --application-id 339ohji \
    --configuration-profile-id ur8hx2f \
    --description "Configuration profile used for examples."
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "ur8hx2f",
    "Name": "Example-Configuration-Profile",
    "Description": "Configuration profile used for examples.",
    "LocationUri": "ssm-parameter://Example-Parameter",
    "RetrievalRoleArn": "arn:aws:iam::111122223333:role/Example-App-Config-Role"
}
```

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see UpdateConfigurationProfile in *Amazon CLI Command Reference*.

`update-deployment-strategy`

The following code example shows how to use `update-deployment-strategy`.

Amazon CLI

To update a deployment strategy

The following `update-deployment-strategy` example updates final bake time to 20 minutes in the specified deployment strategy.

```
aws appconfig update-deployment-strategy \
    --deployment-strategy-id 1225qzk \
    --final-bake-time-in-minutes 20
```

Output:

```
{
    "Id": "1225qzk",
    "Name": "Example-Deployment",
    "DeploymentDurationInMinutes": 15,
    "GrowthType": "LINEAR",
    "GrowthFactor": 25.0,
    "FinalBakeTimeInMinutes": 20,
    "ReplicateTo": "SSM_DOCUMENT"
}
```

For more information, see Step 4: Creating a deployment strategy in the *Amazon AppConfig User Guide*.

- For API details, see UpdateDeploymentStrategy in *Amazon CLI Command Reference*.

`update-environment`

The following code example shows how to use `update-environment`.

Amazon CLI

To update an environment

The following `update-environment` example updates an environment's description.

```
aws appconfig update-environment \
    --application-id 339ohji \
    --environment-id 54j1r29 \
    --description "An environment for examples."
```

Output:

```
{
    "ApplicationId": "339ohji",
    "Id": "54j1r29",
    "Name": "Example-Environment",
    "Description": "An environment for examples.",
    "State": "RolledBack"
}
```

For more information, see Step 2: Creating an environment in the *Amazon AppConfig User Guide*.

- For API details, see UpdateEnvironment in *Amazon CLI Command Reference*.

`update-extension-association`

The following code example shows how to use `update-extension-association`.

Amazon CLI

To update an Amazon AppConfig extension association

The following `update-extension-association` example adds a new parameter value to an extension association in Amazon AppConfig.

```
aws appconfig update-extension-association \
    --region us-west-2 \
    --extension-association-id a1b2c3d4 \
    --parameters S3bucket=FinanceMobileApp
```

Output:

```
{
    "Id": "a1b2c3d4",
    "ExtensionArn": "arn:aws:appconfig:us-west-2:123456789012:extension/S3-backup-
extension/1",
    "ResourceArn": "arn:aws:appconfig:us-west-2:123456789012:application/Finance",
    "Parameters": {
        "S3bucket": "FinanceMobileApp"
    },
    "ExtensionVersionNumber": 1
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see UpdateExtensionAssociation in *Amazon CLI Command Reference*.

`update-extension`

The following code example shows how to use `update-extension`.

Amazon CLI

To update an Amazon AppConfig extension

The following `update-extension` example adds an additional parameter Key to an extension in Amazon AppConfig.

```
aws appconfig update-extension \
    --region us-west-2 \
    --extension-identifier S3-backup-extension \
    --parameters S3bucket={Required=true},CampaignID={Required=false}
```

Output:

```
{
    "Id": "1A2B3C4D",
    "Name": "S3-backup-extension",
    "VersionNumber": 1,
    "Arn": "arn:aws:appconfig:us-west-2:123456789012:extension/1A2B3C4D/1",
    "Actions": {
        "PRE_CREATE_HOSTED_CONFIGURATION_VERSION": [
            {
                "Name": "S3backup",
                "Uri": "arn:aws:lambda:us-
west-2:123456789012:function:S3backupfunction",
                "RoleArn": "arn:aws:iam::123456789012:role/appconfigextensionrole"
            }
        ]
    },
    "Parameters": {
        "CampaignID": {
            "Required": false
        },
```

```
        "S3bucket": {
            "Required": true
        }
    }
}
```

For more information, see Working with Amazon AppConfig extensions in the *Amazon AppConfig User Guide*.

- For API details, see UpdateExtension in *Amazon CLI Command Reference*.

`validate-configuration`

The following code example shows how to use `validate-configuration`.

Amazon CLI

To validate a configuration

The following `validate-configuration` example uses the validators in a configuration profile to validate a configuration.

```
aws appconfig validate-configuration \
    --application-id abc1234 \
    --configuration-profile-id ur8hx2f \
    --configuration-version 1
```

The command produces no output.

For more information, see Step 3: Creating a configuration and a configuration profile in the *Amazon AppConfig User Guide*.

- For API details, see ValidateConfiguration in *Amazon CLI Command Reference*.

Application Auto Scaling examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Application Auto Scaling.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`delete-scaling-policy`

The following code example shows how to use `delete-scaling-policy`.

Amazon CLI

To delete a scaling policy

This example deletes a scaling policy for the Amazon ECS service web-app running in the default cluster.

Command:

```
aws application-autoscaling delete-scaling-policy --policy-name web-app-cpu-lt-25 --
scalable-dimension ecs:service:DesiredCount --resource-id service/default/web-app --
service-namespace ecs
```

- For API details, see DeleteScalingPolicy in *Amazon CLI Command Reference*.

`delete-scheduled-action`

The following code example shows how to use `delete-scheduled-action`.

Amazon CLI

To delete a scheduled action

The follwing `delete-scheduled-action` example deletes the specified scheduled action from the specified Amazon AppStream 2.0 fleet:

```
aws application-autoscaling delete-scheduled-action \
    --service-namespace appstream \
    --scalable-dimension appstream:fleet:DesiredCapacity \
```

```
    --resource-id fleet/sample-fleet \
    --scheduled-action-name my-recurring-action
```

This command produces no output.

For more information, see Scheduled Scaling in the *Application Auto Scaling User Guide*.

- For API details, see DeleteScheduledAction in *Amazon CLI Command Reference*.

`deregister-scalable-target`

The following code example shows how to use `deregister-scalable-target`.

Amazon CLI

To deregister a scalable target

This example deregisters a scalable target for an Amazon ECS service called web-app that is running in the default cluster.

Command:

```
aws application-autoscaling deregister-scalable-target --service-namespace ecs --
scalable-dimension ecs:service:DesiredCount --resource-id service/default/web-app
```

This example deregisters a scalable target for a custom resource. The custom-resource-id.txt file contains a string that identifies the Resource ID, which, for a custom resource, is the path to the custom resource through your Amazon API Gateway endpoint.

Command:

```
aws application-autoscaling deregister-scalable-target --service-namespace custom-
resource --scalable-dimension custom-resource:ResourceType:Property --resource-
id file://~/custom-resource-id.txt
```

Contents of custom-resource-id.txt file:

```
https://example.execute-api.us-west-2.amazonaws.com/prod/
scalableTargetDimensions/1-23456789
```

- For API details, see DeregisterScalableTarget in *Amazon CLI Command Reference*.

`describe-scalable-targets`

The following code example shows how to use `describe-scalable-targets`.

Amazon CLI

To describe scalable targets

The following `describe-scalable-targets` example describes the scalable targets for the `ecs` service namespace.

```
aws application-autoscaling describe-scalable-targets \
    --service-namespace ecs
```

Output:

```
{
    "ScalableTargets": [
        {
            "ServiceNamespace": "ecs",
            "ScalableDimension": "ecs:service:DesiredCount",
            "ResourceId": "service/default/web-app",
            "MinCapacity": 1,
            "MaxCapacity": 10,
            "RoleARN": "arn:aws:iam::123456789012:role/
aws-service-role/ecs.application-autoscaling.amazonaws.com/
AWSServiceRoleForApplicationAutoScaling_ECSService",
            "CreationTime": 1462558906.199,
            "SuspendedState": {
                "DynamicScalingOutSuspended": false,
                "ScheduledScalingSuspended": false,
                "DynamicScalingInSuspended": false
            },
            "ScalableTargetARN": "arn:aws:application-autoscaling:us-
west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
        }
    ]
}
```

For more information, see Amazon services that you can use with Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see DescribeScalableTargets in *Amazon CLI Command Reference*.

describe-scaling-activities

The following code example shows how to use `describe-scaling-activities`.

Amazon CLI

Example 1: To describe scaling activities for the specified Amazon ECS service

The following `describe-scaling-activities` example describes the scaling activities for an Amazon ECS service called `web-app` that is running in the `default` cluster. The output shows a scaling activity initiated by a scaling policy.

```
aws application-autoscaling describe-scaling-activities \
    --service-namespace ecs \
    --resource-id service/default/web-app
```

Output:

```
{
    "ScalingActivities": [
        {
            "ScalableDimension": "ecs:service:DesiredCount",
            "Description": "Setting desired count to 1.",
            "ResourceId": "service/default/web-app",
            "ActivityId": "e6c5f7d1-dbbb-4a3f-89b2-51f33e766399",
            "StartTime": 1462575838.171,
            "ServiceNamespace": "ecs",
            "EndTime": 1462575872.111,
            "Cause": "monitor alarm web-app-cpu-lt-25 in state ALARM triggered
 policy web-app-cpu-lt-25",
            "StatusMessage": "Successfully set desired count to 1. Change
 successfully fulfilled by ecs.",
            "StatusCode": "Successful"
        }
    ]
}
```

For more information, see Scaling activities for Application Auto Scaling in the *Application Auto Scaling User Guide*.

Example 2: To describe scaling activities for the specified DynamoDB table

The following `describe-scaling-activities` example describes the scaling activities for a DynamoDB table called `TestTable`. The output shows scaling activities initiated by two different scheduled actions.

```
aws application-autoscaling describe-scaling-activities \
    --service-namespace dynamodb \
    --resource-id table/TestTable
```

Output:

```
{
    "ScalingActivities": [
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "Description": "Setting write capacity units to 10.",
            "ResourceId": "table/my-table",
            "ActivityId": "4d1308c0-bbcf-4514-a673-b0220ae38547",
            "StartTime": 1561574415.086,
            "ServiceNamespace": "dynamodb",
            "EndTime": 1561574449.51,
            "Cause": "maximum capacity was set to 10",
            "StatusMessage": "Successfully set write capacity units to 10. Change
 successfully fulfilled by dynamodb.",
            "StatusCode": "Successful"
        },
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "Description": "Setting min capacity to 5 and max capacity to 10",
            "ResourceId": "table/my-table",
            "ActivityId": "f2b7847b-721d-4e01-8ef0-0c8d3bacc1c7",
            "StartTime": 1561574414.644,
            "ServiceNamespace": "dynamodb",
            "Cause": "scheduled action name my-second-scheduled-action was
 triggered",
            "StatusMessage": "Successfully set min capacity to 5 and max capacity to
 10",
            "StatusCode": "Successful"
        },
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "Description": "Setting write capacity units to 15.",
            "ResourceId": "table/my-table",
            "ActivityId": "d8ea4de6-9eaa-499f-b466-2cc5e681ba8b",
```

```
            "StartTime": 1561574108.904,
            "ServiceNamespace": "dynamodb",
            "EndTime": 1561574140.255,
            "Cause": "minimum capacity was set to 15",
            "StatusMessage": "Successfully set write capacity units to 15. Change
 successfully fulfilled by dynamodb.",
            "StatusCode": "Successful"
        },
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "Description": "Setting min capacity to 15 and max capacity to 20",
            "ResourceId": "table/my-table",
            "ActivityId": "3250fd06-6940-4e8e-bb1f-d494db7554d2",
            "StartTime": 1561574108.512,
            "ServiceNamespace": "dynamodb",
            "Cause": "scheduled action name my-first-scheduled-action was
 triggered",
            "StatusMessage": "Successfully set min capacity to 15 and max capacity
 to 20",
            "StatusCode": "Successful"
        }
    ]
}
```

For more information, see Scaling activities for Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see DescribeScalingActivities in *Amazon CLI Command Reference*.

`describe-scaling-policies`

The following code example shows how to use `describe-scaling-policies`.

Amazon CLI

To describe scaling policies

This example command describes the scaling policies for the ecs service namespace.

Command:

```
aws application-autoscaling describe-scaling-policies --service-namespace ecs
```

Output:

```
{
    "ScalingPolicies": [
        {
            "PolicyName": "web-app-cpu-gt-75",
            "ScalableDimension": "ecs:service:DesiredCount",
            "ResourceId": "service/default/web-app",
            "CreationTime": 1462561899.23,
            "StepScalingPolicyConfiguration": {
                "Cooldown": 60,
                "StepAdjustments": [
                    {
                        "ScalingAdjustment": 200,
                        "MetricIntervalLowerBound": 0.0
                    }
                ],
                "AdjustmentType": "PercentChangeInCapacity"
            },
            "PolicyARN": "arn:aws:autoscaling:us-
west-2:012345678910:scalingPolicy:6d8972f3-efc8-437c-92d1-6270f29a66e7:resource/ecs/
service/default/web-app:policyName/web-app-cpu-gt-75",
            "PolicyType": "StepScaling",
            "Alarms": [
                {
                    "AlarmName": "web-app-cpu-gt-75",
                    "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:web-app-cpu-gt-75"
                }
            ],
            "ServiceNamespace": "ecs"
        },
        {
            "PolicyName": "web-app-cpu-lt-25",
            "ScalableDimension": "ecs:service:DesiredCount",
            "ResourceId": "service/default/web-app",
            "CreationTime": 1462562575.099,
            "StepScalingPolicyConfiguration": {
                "Cooldown": 1,
                "StepAdjustments": [
                    {
                        "ScalingAdjustment": -50,
                        "MetricIntervalUpperBound": 0.0
                    }
```

```
                ],
                "AdjustmentType": "PercentChangeInCapacity"
            },
            "PolicyARN": "arn:aws:autoscaling:us-
west-2:012345678910:scalingPolicy:6d8972f3-efc8-437c-92d1-6270f29a66e7:resource/ecs/
service/default/web-app:policyName/web-app-cpu-lt-25",
            "PolicyType": "StepScaling",
            "Alarms": [
                {
                    "AlarmName": "web-app-cpu-lt-25",
                    "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:web-app-cpu-lt-25"
                }
            ],
            "ServiceNamespace": "ecs"
        }
    ]
}
```

- For API details, see DescribeScalingPolicies in *Amazon CLI Command Reference*.

`describe-scheduled-actions`

The following code example shows how to use `describe-scheduled-actions`.

Amazon CLI

To describe scheduled actions

The following `describe-scheduled-actions` example displays details for the scheduled actions for the specified service namespace:

```
aws application-autoscaling describe-scheduled-actions \
    --service-namespace dynamodb
```

Output:

```
{
    "ScheduledActions": [
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
```

```
            "Schedule": "at(2019-05-20T18:35:00)",
            "ResourceId": "table/my-table",
            "CreationTime": 1561571888.361,
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledAction:2d36aa3b-cdf9-4565-b290-81db519b227d:resource/
dynamodb/table/my-table:scheduledActionName/my-first-scheduled-action",
            "ScalableTargetAction": {
                "MinCapacity": 15,
                "MaxCapacity": 20
            },
            "ScheduledActionName": "my-first-scheduled-action",
            "ServiceNamespace": "dynamodb"
        },
        {
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
            "Schedule": "at(2019-05-20T18:40:00)",
            "ResourceId": "table/my-table",
            "CreationTime": 1561571946.021,
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledAction:2d36aa3b-cdf9-4565-b290-81db519b227d:resource/
dynamodb/table/my-table:scheduledActionName/my-second-scheduled-action",
            "ScalableTargetAction": {
                "MinCapacity": 5,
                "MaxCapacity": 10
            },
            "ScheduledActionName": "my-second-scheduled-action",
            "ServiceNamespace": "dynamodb"
        }
    ]
}
```

For more information, see Scheduled Scaling in the *Application Auto Scaling User Guide*.

- For API details, see DescribeScheduledActions in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list the tags for a scalable target

The following `list-tags-for-resource` example lists the tag key names and values that are attached to the scalable target specified by its ARN.

```
aws application-autoscaling list-tags-for-resource \
    --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123
```

Output:

```
{
    "Tags": {
        "environment": "production"
    }
}
```

For more information, see Tagging support for Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`put-scaling-policy`

The following code example shows how to use `put-scaling-policy`.

Amazon CLI

Example 1: To apply a target tracking scaling policy with a predefined metric specification

The following `put-scaling-policy` example applies a target tracking scaling policy with a predefined metric specification to an Amazon ECS service called web-app in the default cluster. The policy keeps the average CPU utilization of the service at 75 percent, with scale-out and scale-in cooldown periods of 60 seconds. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf.

```
aws application-autoscaling put-scaling-policy --service-namespace ecs \
--scalable-dimension ecs:service:DesiredCount \
--resource-id service/default/web-app \
--policy-name cpu75-target-tracking-scaling-policy --policy-
type TargetTrackingScaling \
--target-tracking-scaling-policy-configuration file://config.json
```

This example assumes that you have a config.json file in the current directory with the following contents:

```
{
     "TargetValue": 75.0,
     "PredefinedMetricSpecification": {
         "PredefinedMetricType": "ECSServiceAverageCPUUtilization"
     },
     "ScaleOutCooldown": 60,
    "ScaleInCooldown": 60
}
```

Output:

```
{
    "PolicyARN": "arn:aws:autoscaling:us-west-2:012345678910:scalingPolicy:6d8972f3-
efc8-437c-92d1-6270f29a66e7:resource/ecs/service/default/web-app:policyName/cpu75-
target-tracking-scaling-policy",
    "Alarms": [
        {
            "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-
b46e-434a-a60f-3b36d653feca",
            "AlarmName": "TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-
b46e-434a-a60f-3b36d653feca"
        },
        {
            "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:TargetTracking-service/default/web-app-AlarmLow-1b437334-
d19b-4a63-a812-6c67aaf2910d",
            "AlarmName": "TargetTracking-service/default/web-app-AlarmLow-1b437334-
d19b-4a63-a812-6c67aaf2910d"
        }
    ]
}
```

Example 2: To apply a target tracking scaling policy with a customized metric specification

The following `put-scaling-policy` example applies a target tracking scaling policy with a customized metric specification to an Amazon ECS service called web-app in the default cluster. The policy keeps the average utilization of the service at 75 percent, with scale-out and

scale-in cooldown periods of 60 seconds. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf.

```
aws application-autoscaling put-scaling-policy --service-namespace ecs \
--scalable-dimension ecs:service:DesiredCount \
--resource-id service/default/web-app \
--policy-name cms75-target-tracking-scaling-policy
--policy-type TargetTrackingScaling \
--target-tracking-scaling-policy-configuration file://config.json
```

This example assumes that you have a config.json file in the current directory with the following contents:

```
{
    "TargetValue":75.0,
    "CustomizedMetricSpecification":{
        "MetricName":"MyUtilizationMetric",
        "Namespace":"MyNamespace",
        "Dimensions": [
            {
                "Name":"MyOptionalMetricDimensionName",
                "Value":"MyOptionalMetricDimensionValue"
            }
        ],
        "Statistic":"Average",
        "Unit":"Percent"
    },
    "ScaleOutCooldown": 60,
    "ScaleInCooldown": 60
}
```

Output:

```
{
    "PolicyARN": "arn:aws:autoscaling:us-west-2:012345678910:scalingPolicy:
 8784a896-b2ba-47a1-b08c-27301cc499a1:resource/ecs/service/default/web-
app:policyName/cms75-target-tracking-scaling-policy",
    "Alarms": [
        {
            "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:TargetTracking-service/default/web-app-
AlarmHigh-9bc77b56-0571-4276-ba0f-d4178882e0a0",
```

```
            "AlarmName": "TargetTracking-service/default/web-app-
AlarmHigh-9bc77b56-0571-4276-ba0f-d4178882e0a0"
        },
        {
            "AlarmARN": "arn:aws:cloudwatch:us-
west-2:012345678910:alarm:TargetTracking-service/default/web-app-
AlarmLow-9b6ad934-6d37-438e-9e05-02836ddcbdc4",
            "AlarmName": "TargetTracking-service/default/web-app-
AlarmLow-9b6ad934-6d37-438e-9e05-02836ddcbdc4"
        }
    ]
}
```

Example 3: To apply a target tracking scaling policy for scale out only

The following `put-scaling-policy` example applies a target tracking scaling policy to an Amazon ECS service called `web-app` in the default cluster. The policy is used to scale out the ECS service when the `RequestCountPerTarget` metric from the Application Load Balancer exceeds the threshold. The output contains the ARN and name of the CloudWatch alarm created on your behalf.

```
aws application-autoscaling put-scaling-policy \
    --service-namespace ecs \
    --scalable-dimension ecs:service:DesiredCount \
    --resource-id service/default/web-app \
    --policy-name alb-scale-out-target-tracking-scaling-policy \
    --policy-type TargetTrackingScaling \
    --target-tracking-scaling-policy-configuration file://config.json
```

Contents of `config.json`:

```
{
     "TargetValue": 1000.0,
     "PredefinedMetricSpecification": {
         "PredefinedMetricType": "ALBRequestCountPerTarget",
         "ResourceLabel": "app/EC2Co-EcsEl-1TKLTMITMM0EO/f37c06a68c1748aa/
targetgroup/EC2Co-Defau-LDNM7Q3ZH1ZN/6d4ea56ca2d6a18d"
     },
     "ScaleOutCooldown": 60,
    "ScaleInCooldown": 60,
    "DisableScaleIn": true
}
```

Output:

```
{
    "PolicyARN": "arn:aws:autoscaling:us-west-2:123456789012:scalingPolicy:6d8972f3-
efc8-437c-92d1-6270f29a66e7:resource/ecs/service/default/web-app:policyName/alb-
scale-out-target-tracking-scaling-policy",
    "Alarms": [
        {
            "AlarmName": "TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-
b46e-434a-a60f-3b36d653feca",
            "AlarmARN": "arn:aws:cloudwatch:us-
west-2:123456789012:alarm:TargetTracking-service/default/web-app-AlarmHigh-d4f0770c-
b46e-434a-a60f-3b36d653feca"
        }
    ]
}
```

For more information, see Target Tracking Scaling Policies for Application Auto Scaling in the *Amazon Application Auto Scaling User Guide*.

- For API details, see PutScalingPolicy in *Amazon CLI Command Reference*.

`put-scheduled-action`

The following code example shows how to use `put-scheduled-action`.

Amazon CLI

To add a scheduled action to a DynamoDB table

This example adds a scheduled action to a DynamoDB table called TestTable to scale out on a recurring schedule. On the specified schedule (every day at 12:15pm UTC), if the current capacity is below the value specified for MinCapacity, Application Auto Scaling scales out to the value specified by MinCapacity.

Command:

```
aws application-autoscaling put-scheduled-action --service-namespace dynamodb
 --scheduled-action-name my-recurring-action --schedule "cron(15 12 * * ? *)" --
resource-id table/TestTable --scalable-dimension dynamodb:table:WriteCapacityUnits
 --scalable-target-action MinCapacity=6
```

For more information, see Scheduled Scaling in the *Application Auto Scaling User Guide*.

- For API details, see PutScheduledAction in *Amazon CLI Command Reference*.

`register-scalable-target`

The following code example shows how to use `register-scalable-target`.

Amazon CLI

Example 1: To register an ECS service as a scalable target

The following `register-scalable-target` example registers an Amazon ECS service with Application Auto Scaling. It also adds a tag with the key name `environment` and the value `production` to the scalable target.

```
aws application-autoscaling register-scalable-target \
    --service-namespace ecs \
    --scalable-dimension ecs:service:DesiredCount \
    --resource-id service/default/web-app \
    --min-capacity 1 --max-capacity 10 \
    --tags environment=production
```

Output:

```
{
    "ScalableTargetARN": "arn:aws:application-autoscaling:us-
west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}
```

For examples for other Amazon services and custom resources, see the topics in Amazon services that you can use with Application Auto Scaling in the *Application Auto Scaling User Guide*.

Example 2: To suspend scaling activities for a scalable target

The following `register-scalable-target` example suspends scaling activities for an existing scalable target.

```
aws application-autoscaling register-scalable-target \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:ReadCapacityUnits \
```

```
    --resource-id table/my-table \
    --suspended-
state DynamicScalingInSuspended=true,DynamicScalingOutSuspended=true,ScheduledScalingSuspend
```

Output:

```
{
    "ScalableTargetARN": "arn:aws:application-autoscaling:us-
west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}
```

For more information, see Suspending and resuming scaling for Application Auto Scaling in the *Application Auto Scaling User Guide*.

Example 3: To resume scaling activities for a scalable target

The following `register-scalable-target` example resumes scaling activities for an existing scalable target.

```
aws application-autoscaling register-scalable-target \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:ReadCapacityUnits \
    --resource-id table/my-table \
    --suspended-
state DynamicScalingInSuspended=false,DynamicScalingOutSuspended=false,ScheduledScalingSuspe
```

Output:

```
{
    "ScalableTargetARN": "arn:aws:application-autoscaling:us-
west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123"
}
```

For more information, see Suspending and resuming scaling for Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see RegisterScalableTarget in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add a tag to a scalable target

The following `tag-resource` example adds a tag with the key name `environment` and the value `production` to the scalable target specified by its ARN.

```
aws application-autoscaling tag-resource \
    --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123 \
    --tags environment=production
```

This command produces no output.

For more information, see Tagging support for Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove a tag from a scalable target

The following `untag-resource` example removes the tag pair with the key name `environment` from the scalable target specified by its ARN.

```
aws application-autoscaling untag-resource \
    --resource-arn arn:aws:application-autoscaling:us-west-2:123456789012:scalable-target/1234abcd56ab78cd901ef1234567890ab123 \
    --tag-keys "environment"
```

This command produces no output.

For more information, see Tagging support for Application Auto Scaling in the *Application Auto Scaling User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

Application Discovery Service examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Application Discovery Service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

- Actions

Actions

`describe-agents`

The following code example shows how to use `describe-agents`.

Amazon CLI

Describe agents with specified collectionStatus states

This example command describes collection agents with collection status of "STARTED" or "STOPPED".

Command:

```
aws discovery describe-agents --filters
 name="collectionStatus",values="STARTED","STOPPED",condition="EQUALS" --max-
results 3
```

Output:

```
{
       "Snapshots": [
      {
            "version": "1.0.40.0",
            "agentType": "EC2",
            "hostName": "ip-172-31-40-234",
            "collectionStatus": "STOPPED",
```

```
            "agentNetworkInfoList": [
                {
                    "macAddress": "06:b5:97:14:fc:0d",
                    "ipAddress": "172.31.40.234"
                }
            ],
            "health": "UNKNOWN",
            "agentId": "i-003305c02a776e883",
            "registeredTime": "2016-12-09T19:05:06Z",
            "lastHealthPingTime": "2016-12-09T19:05:10Z"
        },
        {
            "version": "1.0.40.0",
            "agentType": "EC2",
            "hostName": "ip-172-31-39-64",
            "collectionStatus": "STARTED",
            "agentNetworkInfoList": [
                {
                    "macAddress": "06:a1:0e:c7:b2:73",
                    "ipAddress": "172.31.39.64"
                }
            ],
            "health": "SHUTDOWN",
            "agentId": "i-003a5e5e2b36cf8bd",
            "registeredTime": "2016-11-16T16:36:25Z",
            "lastHealthPingTime": "2016-11-16T16:47:37Z"
        }
    ]
}
```

- For API details, see DescribeAgents in *Amazon CLI Command Reference*.

`describe-configurations`

The following code example shows how to use `describe-configurations`.

Amazon CLI

Describe selected asset configurations

This example command describes the configurations of two specified servers. The action detects the type of asset from the configuration ID. Only one type of asset is allowed per command.

Command:

```
aws discovery describe-configurations --configuration-ids "d-
server-099385097ef9fbcfb" "d-server-0c4f2dd1fee22c6c1"
```

Output:

```
{
    "configurations": [
        {
                "server.performance.maxCpuUsagePct": "0.0",
                "server.performance.maxDiskReadIOPS": "0.0",
                "server.performance.avgCpuUsagePct": "0.0",
                "server.type": "EC2",
                "server.performance.maxNetworkReadsPerSecondInKB": "0.19140625",
                "server.hostName": "ip-172-31-35-152",

        }
    ]
}
```

Describe selected asset configurations

This example command describes the configurations of two specified applications. The action detects the type of asset from the configuration ID. Only one type of asset is allowed per command.

Command:

```
aws discovery describe-configurations --configuration-ids "d-
application-0ac39bc0e4fad0e42" "d-application-02444a45288013764q"
```

Output:

```
{
    "configurations": [
        {
                "application.serverCount": "0",
                "application.name": "Application-12345",
                "application.lastModifiedTime": "2016-12-13 23:53:27.0",
                "application.description": "",
                "application.timeOfCreation": "2016-12-13 23:53:27.0",
                "application.configurationId": "d-application-0ac39bc0e4fad0e42"
        },
        {
                "application.serverCount": "0",
                "application.name": "Application-67890",
                "application.lastModifiedTime": "2016-12-13 23:53:33.0",
```

```
                "application.description": "",
                "application.timeOfCreation": "2016-12-13 23:53:33.0",
                "application.configurationId": "d-application-02444a45288013764"
        }
    ]
}
```

- For API details, see DescribeConfigurations in *Amazon CLI Command Reference*.

`list-configurations`

The following code example shows how to use `list-configurations`.

Amazon CLI

To list all of the discovered servers meeting a set of filter conditions

This example command lists discovered servers matching either of two hostname patterns and not running Ubuntu.

Command:

```
aws discovery list-configurations --configuration-type SERVER --filters
 name="server.hostName",values="172-31-35","172-31-42",condition="CONTAINS"
 name="server.osName",values="Ubuntu",condition="NOT_CONTAINS"
```

Output:

```
{
    "configurations": [
      {
            "server.osVersion": "3.14.48-33.39.amzn1.x86_64",
            "server.type": "EC2",
            "server.hostName": "ip-172-31-42-208",
            "server.timeOfCreation": "2016-10-28 23:44:30.0",
            "server.configurationId": "d-server-099385097ef9fbcfb",
            "server.osName": "Linux - Amazon Linux AMI release 2015.03",
            "server.agentId": "i-c142b99e"
        },
        {
            "server.osVersion": "3.14.48-33.39.amzn1.x86_64",
```

```
            "server.type": "EC2",
            "server.hostName": "ip-172-31-35-152",
            "server.timeOfCreation": "2016-10-28 23:44:00.0",
            "server.configurationId": "d-server-0c4f2dd1fee22c6c1",
            "server.osName": "Linux - Amazon Linux AMI release 2015.03",
            "server.agentId": "i-4447bc1b"
        }
    ]
}
```

- For API details, see ListConfigurations in *Amazon CLI Command Reference*.

AppRegistry examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with AppRegistry.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-attribute-group`

The following code example shows how to use `associate-attribute-group`.

Amazon CLI

To associate an attribute group

The following `associate-attribute-group` example associates a specific attribute group in your Amazon account to a specific application in your Amazon account.

```
aws servicecatalog-appregistry associate-attribute-group \
```

```
    --application "ExampleApplication" \
    --attribute-group "ExampleAttributeGroup"
```

Output:

```
{
    "applicationArn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/0ars38r6btoohvpvd9gqrptt9l",
    "attributeGroupArn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl"
}
```

For more information, see Associating and disassociating attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see AssociateAttributeGroup in *Amazon CLI Command Reference*.

`create-application`

The following code example shows how to use `create-application`.

Amazon CLI

To create an application

The following `create-application` example creates a new application in your Amazon account.

```
aws servicecatalog-appregistry create-application \
    --name "ExampleApplication"
```

Output:

```
{
    "application": {
        "id": "0ars38r6btoohvpvd9gqrptt9l",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/0ars38r6btoohvpvd9gqrptt9l",
        "name": "ExampleApplication",
        "creationTime": "2023-02-28T21:10:10.820000+00:00",
```

```
        "lastUpdateTime": "2023-02-28T21:10:10.820000+00:00",
        "tags": {}
    }
}
```

For more information, see Creating applications in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see CreateApplication in *Amazon CLI Command Reference*.

`create-attribute-group`

The following code example shows how to use `create-attribute-group`.

Amazon CLI

To create an attribute group

The following `create-attribute-group` example creates a new attribute group in your Amazon account.

```
aws servicecatalog-appregistry create-attribute-group \
    --name "ExampleAttributeGroup" \
    --attributes '{"SomeKey1":"SomeValue1","SomeKey2":"SomeValue2"}'
```

Output:

```
{
    "attributeGroup": {
        "id": "01sj5xdwhbw54kejwnt09fnpcl",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl",
        "name": "ExampleAttributeGroup",

        "tags": {}
    }
}
```

For more information, see Creating attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see CreateAttributeGroup in *Amazon CLI Command Reference*.

`delete-application`

The following code example shows how to use `delete-application`.

Amazon CLI

To delete an application

The following `delete-application` example deletes a specific application in your Amazon account.

```
aws servicecatalog-appregistry delete-application \
    --application "ExampleApplication3"
```

Output:

```
{
    "application": {
        "id": "055gw7aynr1i5mbv7kjwzx5945",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/055gw7aynr1i5mbv7kjwzx5945",
        "name": "ExampleApplication3",
        "creationTime": "2023-02-28T22:06:28.228000+00:00",
        "lastUpdateTime": "2023-02-28T22:06:28.228000+00:00"
    }
}
```

For more information, see Deleting applications in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see DeleteApplication in *Amazon CLI Command Reference*.

`delete-attribute-group`

The following code example shows how to use `delete-attribute-group`.

Amazon CLI

Example 8: To delete an attribute group

The following `delete-attribute-group` example deletes a specific attribute group in your Amazon account.

```
aws servicecatalog-appregistry delete-attribute-group \
    --attribute-group "ExampleAttributeGroup3"
```

Output:

```
{
    "attributeGroup": {
        "id": "011ge6y3emyjijt8dw8jn6r0hv",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/011ge6y3emyjijt8dw8jn6r0hv",
        "name": "ExampleAttributeGroup3",
        "creationTime": "2023-02-28T22:05:35.224000+00:00",
        "lastUpdateTime": "2023-02-28T22:05:35.224000+00:00"
    }
}
```

For more information, see Deleting attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see DeleteAttributeGroup in *Amazon CLI Command Reference*.

`get-application`

The following code example shows how to use `get-application`.

Amazon CLI

To get an application

The following `get-application` example retrieves metadata information about a specific application in your Amazon account.

```
aws servicecatalog-appregistry get-application \
    --application "ExampleApplication"
```

Output:

```
{
```

```
    "id": "0ars38r6btoohvpvd9gqrptt9l",
    "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/0ars38r6btoohvpvd9gqrptt9l",
    "name": "ExampleApplication",
    "creationTime": "2023-02-28T21:10:10.820000+00:00",
    "lastUpdateTime": "2023-02-28T21:10:10.820000+00:00",
    "associatedResourceCount": 0,
    "tags": {
        "aws:servicecatalog:applicationName": "ExampleApplication"
    },
    "integrations": {
        "resourceGroup": {
            "state": "CREATE_COMPLETE",
            "arn": "arn:aws:resource-groups:us-west-2:813737243517:group/
AWS_AppRegistry_Application-ExampleApplication"
        }
    }
}
```

For more information, see Using Application details in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see GetApplication in *Amazon CLI Command Reference*.

`get-attribute-group`

The following code example shows how to use `get-attribute-group`.

Amazon CLI

To get an attribute group

The following `get-attribute-group` example retrieves a specific attribute group in your Amazon account.

```
aws servicecatalog-appregistry get-attribute-group \
    --attribute-group "ExampleAttributeGroup"
```

Output:

```
{
    "id": "01sj5xdwhbw54kejwnt09fnpcl",
```

```
    "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl",
    "name": "ExampleAttributeGroup",
    "attributes": "{\"SomeKey1\":\"SomeValue1\",\"SomeKey2\":\"SomeValue2\"}",
    "creationTime": "2023-02-28T20:38:01.389000+00:00",
    "lastUpdateTime": "2023-02-28T20:38:01.389000+00:00",
    "tags": {
        "aws:servicecatalog:attributeGroupName": "ExampleAttributeGroup"
    }
}
```

For more information, see Managing metadata for attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see GetAttributeGroup in *Amazon CLI Command Reference*.

`list-applications`

The following code example shows how to use `list-applications`.

Amazon CLI

To list applications

The following `list-applications` example retrieves a list of all the applications in your Amazon account.

```
aws servicecatalog-appregistry list-applications
```

Output:

```
{
    "applications": [
        {
            "id": "03axw94pjfj3uan00tcgbrxnkw",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/03axw94pjfj3uan00tcgbrxnkw",
            "name": "ExampleApplication2",
            "creationTime": "2023-02-28T21:59:34.094000+00:00",
            "lastUpdateTime": "2023-02-28T21:59:34.094000+00:00"
        },
        {
```

```
            "id": "055gw7aynr1i5mbv7kjwzx5945",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/055gw7aynr1i5mbv7kjwzx5945",
            "name": "ExampleApplication3",
            "creationTime": "2023-02-28T22:06:28.228000+00:00",
            "lastUpdateTime": "2023-02-28T22:06:28.228000+00:00"
        },
        {
            "id": "0ars38r6btoohvpvd9gqrptt9l",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/0ars38r6btoohvpvd9gqrptt9l",
            "name": "ExampleApplication",
            "description": "This is an example application",
            "creationTime": "2023-02-28T21:10:10.820000+00:00",
            "lastUpdateTime": "2023-02-28T21:24:19.729000+00:00"
        }
    ]
}
```

For more information, see Viewing application details in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see ListApplications in *Amazon CLI Command Reference*.

`list-associated-attribute-groups`

The following code example shows how to use `list-associated-attribute-groups`.

Amazon CLI

To list associated attribute groups

The following `list-associated-attribute-groups` example retrieves a list of all attribute groups in your Amazon account that are associated with a specific application in your Amazon account.

```
aws servicecatalog-appregistry list-associated-attribute-groups \
    --application "ExampleApplication"
```

Output:

```
{
```

```
    "attributeGroups": [
        "01sj5xdwhbw54kejwnt09fnpcl"
    ]
}
```

For more information, see Associating and disassociating attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see ListAssociatedAttributeGroups in *Amazon CLI Command Reference*.

`list-attribute-groups-for-application`

The following code example shows how to use `list-attribute-groups-for-application`.

Amazon CLI

To list attribute groups for an application

The following `list-attribute-groups-for-application` example lists the details of all attribute groups in your Amazon account that are associated with a specific application in your Amazon account.

```
aws servicecatalog-appregistry list-attribute-groups-for-application \
    --application "ExampleApplication"
```

Output:

```
{
    "attributeGroupsDetails": [
        {
            "id": "01sj5xdwhbw54kejwnt09fnpcl",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl",
            "name": "ExampleAttributeGroup"
        }
    ]
}
```

For more information, see Viewing attribute group details in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see ListAttributeGroupsForApplication in *Amazon CLI Command Reference*.

`list-attribute-groups`

The following code example shows how to use `list-attribute-groups`.

Amazon CLI

To list attribute groups

The following `list-attribute-groups` example retrieves a list of all attribute groups in your Amazon account.

```
aws servicecatalog-appregistry list-attribute-groups
```

Output:

```
{
    "attributeGroups": [
        {
            "id": "011ge6y3emyjijt8dw8jn6r0hv",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/011ge6y3emyjijt8dw8jn6r0hv",
            "name": "ExampleAttributeGroup3",
            "creationTime": "2023-02-28T22:05:35.224000+00:00",
            "lastUpdateTime": "2023-02-28T22:05:35.224000+00:00"
        },
        {
            "id": "01sj5xdwhbw54kejwnt09fnpcl",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl",
            "name": "ExampleAttributeGroup",
            "description": "This is an example attribute group",
            "creationTime": "2023-02-28T20:38:01.389000+00:00",
            "lastUpdateTime": "2023-02-28T21:02:04.559000+00:00"
        },
        {
            "id": "03n1yffgq6d18vwrzxf0c70nm3",
            "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/03n1yffgq6d18vwrzxf0c70nm3",
            "name": "ExampleAttributeGroup2",
            "creationTime": "2023-02-28T21:57:30.687000+00:00",
            "lastUpdateTime": "2023-02-28T21:57:30.687000+00:00"
        }
    ]
```

```
}
```

For more information, see Viewing attribute group details in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see ListAttributeGroups in *Amazon CLI Command Reference*.

`update-application`

The following code example shows how to use `update-application`.

Amazon CLI

To update an application

The following `update-application` example updates a specific application in your Amazon account to include a description.

```
aws servicecatalog-appregistry update-application \
    --application "ExampleApplication" \
    --description "This is an example application"
```

Output:

```
{
    "application": {
        "id": "0ars38r6btoohvpvd9gqrptt9l",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/
applications/0ars38r6btoohvpvd9gqrptt9l",
        "name": "ExampleApplication",
        "description": "This is an example application",
        "creationTime": "2023-02-28T21:10:10.820000+00:00",
        "lastUpdateTime": "2023-02-28T21:24:19.729000+00:00",
        "tags": {
            "aws:servicecatalog:applicationName": "ExampleApplication"
        }
    }
}
```

For more information, see Editing applications in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see UpdateApplication in *Amazon CLI Command Reference*.

update-attribute-group

The following code example shows how to use update-attribute-group.

Amazon CLI

To update an attribute group

The following update-attribute-group example updates a specific attribute group in your Amazon account to include a descritption.

```
aws servicecatalog-appregistry update-attribute-group \
    --attribute-group "ExampleAttributeGroup" \
    --description "This is an example attribute group"
```

Output:

```
{
    "attributeGroup": {
        "id": "01sj5xdwhbw54kejwnt09fnpcl",
        "arn": "arn:aws:servicecatalog:us-west-2:813737243517:/attribute-
groups/01sj5xdwhbw54kejwnt09fnpcl",
        "name": "ExampleAttributeGroup",
        "description": "This is an example attribute group",
        "creationTime": "2023-02-28T20:38:01.389000+00:00",
        "lastUpdateTime": "2023-02-28T21:02:04.559000+00:00",
        "tags": {
            "aws:servicecatalog:attributeGroupName": "ExampleAttributeGroup"
        }
    }
}
```

For more information, see Editing attribute groups in the *Amazon Service Catalog AppRegistry Administrator Guide*.

- For API details, see UpdateAttributeGroup in *Amazon CLI Command Reference*.

Athena examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Athena.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`batch-get-named-query`

The following code example shows how to use `batch-get-named-query`.

Amazon CLI

To return information about more than one query

The following `batch-get-named-query` example returns information about the named queries that have the specified IDs.

```
aws athena batch-get-named-query \
    --named-query-ids a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 a1b2c3d4-5678-90ab-cdef-EXAMPLE22222 a1b2c3d4-5678-90ab-cdef-EXAMPLE33333
```

Output:

```
{
    "NamedQueries": [
        {
            "Name": "Flights Select Query",
            "Description": "Sample query to get the top 10 airports with the most number of departures since 2000",
            "Database": "sampledb",
            "QueryString": "SELECT origin, count(*) AS total_departures\nFROM \nflights_parquet\nWHERE year >= '2000'\nGROUP BY origin\nORDER BY total_departures DESC\nLIMIT 10;",
            "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "WorkGroup": "primary"
        },
```

```
        {
            "Name": "Load flights table partitions",
            "Description": "Sample query to load flights table partitions using MSCK
 REPAIR TABLE statement",
            "Database": "sampledb",
            "QueryString": "MSCK REPAIR TABLE flights_parquet;",
            "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "WorkGroup": "primary"
        },
        {
            "Name": "CloudFront Select Query",
            "Description": "Sample query to view requests per operating system
 during a particular time frame",
            "Database": "sampledb",
            "QueryString": "SELECT os, COUNT(*) count FROM cloudfront_logs WHERE
 date BETWEEN date '2014-07-05' AND date '2014-08-05' GROUP BY os;",
            "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
            "WorkGroup": "primary"
        }
    ],
    "UnprocessedNamedQueryIds": []
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see BatchGetNamedQuery in *Amazon CLI Command Reference*.

`batch-get-query-execution`

The following code example shows how to use `batch-get-query-execution`.

Amazon CLI

To return information about one or more query executions

The following `batch-get-query-execution` example returns query execution information for the queries that have the specified query IDs.

```
aws athena batch-get-query-execution \
    --query-execution-ids a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 a1b2c3d4-5678-90ab-
cdef-EXAMPLE22222
```

Output:

```
{
    "QueryExecutions": [
        {
            "QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",

            },
            "WorkGroup": "AthenaAdmin"
        }
    ],
    "UnprocessedQueryExecutionIds": []
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see BatchGetQueryExecution in *Amazon CLI Command Reference*.

`create-data-catalog`

The following code example shows how to use `create-data-catalog`.

Amazon CLI

To create a data catalog

The following `create-data-catalog` example creates the `dynamo_db_catalog` data catalog.

```
aws athena create-data-catalog \
    --name dynamo_db_catalog \
    --type LAMBDA \
    --description "DynamoDB Catalog" \
    --parameters function=arn:aws:lambda:us-
west-2:111122223333:function:dynamo_db_lambda
```

This command produces no output. To see the result, use `aws athena get-data-catalog --name dynamo_db_catalog`.

For more information, see Registering a Catalog: create-data-catalog in the *Amazon Athena User Guide*.

- For API details, see CreateDataCatalog in *Amazon CLI Command Reference*.

`create-named-query`

The following code example shows how to use `create-named-query`.

Amazon CLI

To create a named query

The following `create-named-query` example creates a saved query in the `AthenaAdmin` workgroup that queries the `flights_parquet` table for flights from Seattle to New York in January, 2016 whose departure and arrival were both delayed by more than ten minutes. Because the airport code values in the table are strings that include double quotes (for example, "SEA"), they are escaped by backslashes and surrounded by single quotes.

```
aws athena create-named-query \
    --name "SEA to JFK delayed flights Jan 2016" \
    --description "Both arrival and departure delayed more than 10 minutes." \
    --database sampledb \
    --query-string "SELECT flightdate, carrier, flightnum, origin, dest,
 depdelayminutes, arrdelayminutes FROM sampledb.flights_parquet WHERE yr = 2016 AND
 month = 1 AND origin = '\"SEA\"' AND dest = '\"JFK\"' AND depdelayminutes > 10 AND
 arrdelayminutes > 10" \
    --work-group AthenaAdmin
```

Output:

```
{
    "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see CreateNamedQuery in *Amazon CLI Command Reference*.

`create-work-group`

The following code example shows how to use `create-work-group`.

Amazon CLI

To create a workgroup

The following `create-work-group` example creates a workgroup called `Data_Analyst_Group` that has the query results output location `s3://amzn-s3-demo-bucket`. The command creates a workgroup that overrides client configuration settings, which includes the query results output location. The command also enables CloudWatch metrics and adds three key-value tag pairs to the workgroup to distinguish it from other workgroups. Note that the `--configuration` argument has no spaces before the commas that separate its options.

```
aws athena create-work-group \
    --name Data_Analyst_Group \
    --configuration ResultConfiguration={OutputLocation="s3://amzn-s3-demo-
bucket"},EnforceWorkGroupConfiguration="true",PublishCloudWatchMetricsEnabled="true"
 \
    --description "Workgroup for data analysts" \
    --tags Key=Division,Value=West Key=Location,Value=Seattle Key=Team,Value="Big
 Data"
```

This command produces no output. To see the results, use `aws athena get-work-group --work-group Data_Analyst_Group`.

For more information, see Managing Workgroups in the *Amazon Athena User Guide*.

- For API details, see CreateWorkGroup in *Amazon CLI Command Reference*.

`delete-data-catalog`

The following code example shows how to use `delete-data-catalog`.

Amazon CLI

To delete a data catalog

The following `delete-data-catalog` example deletes the `UnusedDataCatalog` data catalog.

```
aws athena delete-data-catalog \
    --name UnusedDataCatalog
```

This command produces no output.

For more information, see Deleting a Catalog: delete-data-catalog in the *Amazon Athena User Guide*.

- For API details, see DeleteDataCatalog in *Amazon CLI Command Reference*.

`delete-named-query`

The following code example shows how to use `delete-named-query`.

Amazon CLI

To delete a named query

The following `delete-named-query` example deletes the named query that has the specified ID.

```
aws athena delete-named-query \
    --named-query-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see DeleteNamedQuery in *Amazon CLI Command Reference*.

`delete-work-group`

The following code example shows how to use `delete-work-group`.

Amazon CLI

To delete a workgroup

The following `delete-work-group` example deletes the `TeamB` workgroup.

```
aws athena delete-work-group \
```

```
    --work-group TeamB
```

This command produces no output. To confirm the deletion, use `aws athena list-work-groups`.

For more information, see Managing Workgroups in the *Amazon Athena User Guide*.

- For API details, see DeleteWorkGroup in *Amazon CLI Command Reference*.

`get-data-catalog`

The following code example shows how to use `get-data-catalog`.

Amazon CLI

To return information about a data catalog

The following `get-data-catalog` example returns information about the `dynamo_db_catalog` data catalog.

```
aws athena get-data-catalog \
    --name dynamo_db_catalog
```

Output:

```
{
    "DataCatalog": {
        "Name": "dynamo_db_catalog",
        "Description": "DynamoDB Catalog",
        "Type": "LAMBDA",
        "Parameters": {
            "catalog": "dynamo_db_catalog",
            "metadata-function": "arn:aws:lambda:us-
west-2:111122223333:function:dynamo_db_lambda",
            "record-function": "arn:aws:lambda:us-
west-2:111122223333:function:dynamo_db_lambda"
        }
    }
}
```

For more information, see Showing Catalog Details: get-data-catalog in the *Amazon Athena User Guide*.

- For API details, see GetDataCatalog in *Amazon CLI Command Reference*.

`get-database`

The following code example shows how to use `get-database`.

Amazon CLI

To return information about a database in a data catalog

The following `get-database` example returns information about the `sampledb` database in the `AwsDataCatalog` data catalog.

```
aws athena get-database \
    --catalog-name AwsDataCatalog \
    --database-name sampledb
```

Output:

```
{
    "Database": {
        "Name": "sampledb",
        "Description": "Sample database",
        "Parameters": {
            "CreatedBy": "Athena",
            "EXTERNAL": "TRUE"
        }
    }
}
```

For more information, see Showing Database Details: get-database in the *Amazon Athena User Guide*.

- For API details, see GetDatabase in *Amazon CLI Command Reference*.

`get-named-query`

The following code example shows how to use `get-named-query`.

Amazon CLI

To return a named query

The following `get-named-query` example returns information about the query that has the specified ID.

```
aws athena get-named-query \
    --named-query-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "NamedQuery": {
        "Name": "CloudFront Logs - SFO",
        "Description": "Shows successful GET request data for SFO",
        "Database": "default",
        "QueryString": "select date, location, browser, uri, status from
 cloudfront_logs where method = 'GET' and status = 200 and location like 'SFO%'
 limit 10",
        "NamedQueryId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "WorkGroup": "AthenaAdmin"
    }
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see GetNamedQuery in *Amazon CLI Command Reference*.

`get-query-execution`

The following code example shows how to use `get-query-execution`.

Amazon CLI

To return information about a query execution

The following `get-query-execution` example returns information about the query that has the specified query ID.

```
aws athena get-query-execution \
    --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "QueryExecution": {
        "QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "Query": "select date, location, browser, uri, status from cloudfront_logs
 where method = 'GET
' and status = 200 and location like 'SFO%' limit 10",
        "StatementType": "DML",
        "ResultConfiguration": {
            "OutputLocation": "s3://amzn-s3-demo-bucket/a1b2c3d4-5678-90ab-cdef-
EXAMPLE11111.csv"
        },
        "QueryExecutionContext": {
            "Database": "mydatabase",
            "Catalog": "awsdatacatalog"
        },
        "Status": {
            "State": "SUCCEEDED",
            "SubmissionDateTime": 1593469842.665,
            "CompletionDateTime": 1593469846.486
        },
        "Statistics": {
            "EngineExecutionTimeInMillis": 3600,
            "DataScannedInBytes": 203089,
            "TotalExecutionTimeInMillis": 3821,
            "QueryQueueTimeInMillis": 267,
            "QueryPlanningTimeInMillis": 1175
        },
        "WorkGroup": "AthenaAdmin"
    }
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see GetQueryExecution in *Amazon CLI Command Reference*.

`get-query-results`

The following code example shows how to use `get-query-results`.

Amazon CLI

To return the results of a query

The following `get-query-results` example returns the results of the query that has the specified query ID.

```
aws athena get-query-results \
    --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "ResultSet": {
        "Rows": [
            {
                "Data": [
                    {
                        "VarCharValue": "date"
                    },
                    {
                        "VarCharValue": "location"
                    },
                    {
                        "VarCharValue": "browser"
                    },
                    {
                        "VarCharValue": "uri"
                    },
                    {
                        "VarCharValue": "status"
                    }
                ]
            },
            {
                "Data": [
                    {
                        "VarCharValue": "2014-07-05"
                    },
                    {
                        "VarCharValue": "SFO4"
                    },

- For API details, see GetQueryResults in *Amazon CLI Command Reference*.

`get-table-metadata`

The following code example shows how to use `get-table-metadata`.

Amazon CLI

To return metadata information about a table

The following `get-table-metadata` example returns metadata information about the `counties` table, including including column names and their datatypes, from the `sampledb` database of the `AwsDataCatalog` data catalog.

```
aws athena get-table-metadata \
    --catalog-name AwsDataCatalog \
    --database-name sampledb \
    --table-name counties
```

Output:

```
{
    "TableMetadata": {
        "Name": "counties",
        "CreateTime": 1593559968.0,
        "LastAccessTime": 0.0,
        "TableType": "EXTERNAL_TABLE",
        "Columns": [
            {
                "Name": "name",
                "Type": "string",
                "Comment": "from deserializer"
            },
            {
                "Name": "boundaryshape",
                "Type": "binary",
                "Comment": "from deserializer"
            },
            {
                "Name": "motto",
                "Type": "string",
                "Comment": "from deserializer"
            },
            {
                "Name": "population",
                "Type": "int",
                "Comment": "from deserializer"
            }
        ],
        "PartitionKeys": [],
        "Parameters": {
            "EXTERNAL": "TRUE",
            "inputformat": "com.esri.json.hadoop.EnclosedJsonInputFormat",
```

```

 "org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat",
            "serde.param.serialization.format": "1",
            "serde.serialization.lib": "com.esri.hadoop.hive.serde.JsonSerde",
            "transient_lastDdlTime": "1593559968"
        }
    }
}
```

For more information, see Showing Table Details: get-table-metadata in the *Amazon Athena User Guide*.

- For API details, see GetTableMetadata in *Amazon CLI Command Reference*.

`get-work-group`

The following code example shows how to use `get-work-group`.

Amazon CLI

To return information about a workgroup

The following `get-work-group` example returns information about the `AthenaAdmin` workgroup.

```
aws athena get-work-group \
    --work-group AthenaAdmin
```

Output:

```
{
    "WorkGroup": {
        "Name": "AthenaAdmin",
        "State": "ENABLED",
        "Configuration": {
            "ResultConfiguration": {
                "OutputLocation": "s3://amzn-s3-demo-bucket/"
            },
            "EnforceWorkGroupConfiguration": false,
            "PublishCloudWatchMetricsEnabled": true,
            "RequesterPaysEnabled": false
        },
```

```
        "Description": "Workgroup for Athena administrators",
        "CreationTime": 1573677174.105
    }
}
```

For more information, see Managing Workgroups in the *Amazon Athena User Guide*.

- For API details, see GetWorkGroup in *Amazon CLI Command Reference*.

`list-data-catalogs`

The following code example shows how to use `list-data-catalogs`.

Amazon CLI

To list the data catalogs registered with Athena

The following `list-data-catalogs` example lists the data catalogs registered with Athena.

```
aws athena list-data-catalogs
```

Output:

```
{
    "DataCatalogsSummary": [
        {
            "CatalogName": "AwsDataCatalog",
            "Type": "GLUE"
        },
        {
            "CatalogName": "cw_logs_catalog",
            "Type": "LAMBDA"
        },
        {
            "CatalogName": "cw_metrics_catalog",
            "Type": "LAMBDA"
        }
    ]
}
```

For more information, see Listing Registered Catalogs: list-data-catalogs in the *Amazon Athena User Guide*.

- For API details, see ListDataCatalogs in *Amazon CLI Command Reference*.

`list-databases`

The following code example shows how to use `list-databases`.

Amazon CLI

To list the databases in a data catalog

The following `list-databases` example lists the databases in the `AwsDataCatalog` data catalog.

```
aws athena list-databases \
    --catalog-name AwsDataCatalog
```

Output:

```
{
    "DatabaseList": [
        {
            "Name": "default"
        },
        {
            "Name": "mydatabase"
        },
        {
            "Name": "newdb"
        },
        {
            "Name": "sampledb",
            "Description": "Sample database",
            "Parameters": {
                "CreatedBy": "Athena",
                "EXTERNAL": "TRUE"
            }
        },
        {
            "Name": "webdata"
        }
    ]
}
```

For more information, see Listing Databases in a Catalog: list-databases in the *Amazon Athena User Guide*.

- For API details, see ListDatabases in *Amazon CLI Command Reference*.

`list-named-queries`

The following code example shows how to use `list-named-queries`.

Amazon CLI

To list the named queries for a workgroup

The following `list-named-queries` example lists the named queries for the `AthenaAdmin` workgroup.

```
aws athena list-named-queries \
    --work-group AthenaAdmin
```

Output:

```
{
    "NamedQueryIds": [
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333"
    ]
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see ListNamedQueries in *Amazon CLI Command Reference*.

`list-query-executions`

The following code example shows how to use `list-query-executions`.

Amazon CLI

To list the query IDs of the queries in a specified workgroup

The following `list-query-executions` example lists a maximum of ten of the query IDs in the `AthenaAdmin` workgroup.

```
aws athena list-query-executions \
    --work-group AthenaAdmin \
    --max-items 10
```

Output:

```
{
    "QueryExecutionIds": [
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11110",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11114",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11115",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11116",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11117",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11118",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11119"
    ],
    "NextToken": "eyJOZXh0VG9rZW4iOiBudWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQiOiAxMH0="
}
```

For more information, see Working with Query Results, Output Files, and Query History in the *Amazon Athena User Guide*.

- For API details, see ListQueryExecutions in *Amazon CLI Command Reference*.

`list-table-metadata`

The following code example shows how to use `list-table-metadata`.

Amazon CLI

To list the metadata for tables in the specified database of a data catalog

The following `list-table-metadata` example returns metadata information for a maximum of two tables in the `geography` database of the `AwsDataCatalog` data catalog.

```
aws athena list-table-metadata \
```

```
    --catalog-name AwsDataCatalog \
    --database-name geography \
    --max-items 2
```

Output:

```
{
    "TableMetadataList": [
        {
            "Name": "country_codes",
            "CreateTime": 1586553454.0,
            "TableType": "EXTERNAL_TABLE",
            "Columns": [
                {
                    "Name": "country",
                    "Type": "string",
                    "Comment": "geo id"
                },
                {
                    "Name": "alpha-2 code",
                    "Type": "string",
                    "Comment": "geo id2"
                },
                {
                    "Name": "alpha-3 code",

- For API details, see ListTableMetadata in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

Example 1: To list the tags for a workgroup

The following `list-tags-for-resource` example lists the tags for the `Data_Analyst_Group` workgroup.

```
aws athena list-tags-for-resource \
    --resource-arn arn:aws:athena:us-west-2:111122223333:workgroup/
Data_Analyst_Group
```

Output:

```
{
    "Tags": [
        {
            "Key": "Division",
            "Value": "West"
        },
        {
            "Key": "Team",
            "Value": "Big Data"
        },
        {
            "Key": "Location",
            "Value": "Seattle"
        }
    ]
}
```

Example 2: To list the tags for a data catalog

The following `list-tags-for-resource` example lists the tags for the dynamo_db_catalog data catalog.

```
aws athena list-tags-for-resource \
    --resource-arn arn:aws:athena:us-west-2:111122223333:datacatalog/
dynamo_db_catalog
```

Output:

```
{
    "Tags": [
        {
            "Key": "Division",
            "Value": "Mountain"
        },
        {
```

```
            "Key": "Organization",
            "Value": "Retail"
        },
        {
            "Key": "Product_Line",
            "Value": "Shoes"
        },
        {
            "Key": "Location",
            "Value": "Denver"
        }
    ]
}
```

For more information, see Listing the tags for a resource: list-tags-for-resource in the *Amazon Athena User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`list-work-groups`

The following code example shows how to use `list-work-groups`.

Amazon CLI

To list workgroups

The following `list-work-groups` example lists the workgroups in the current account.

```
aws athena list-work-groups
```

Output:

```
{
    "WorkGroups": [
        {
            "Name": "Data_Analyst_Group",
            "State": "ENABLED",
            "Description": "",
            "CreationTime": 1578006683.016
        },
        {
```

```
            "Name": "AthenaAdmin",
            "State": "ENABLED",
            "Description": "",
            "CreationTime": 1573677174.105
        },
        {
            "Name": "primary",
            "State": "ENABLED",
            "Description": "",
            "CreationTime": 1567465222.723
        }
    ]
}
```

For more information, see Managing Workgroups in the *Amazon Athena User Guide*.

- For API details, see ListWorkGroups in *Amazon CLI Command Reference*.

`start-query-execution`

The following code example shows how to use `start-query-execution`.

Amazon CLI

Example 1: To run a query in a workgroup on the specified table in the specified database and data catalog

The following `start-query-execution` example uses the `AthenaAdmin` workgroup to run a query on the `cloudfront_logs` table in the `cflogsdatabase` in the `AwsDataCatalog` data catalog.

```
aws athena start-query-execution \
    --query-string "select date, location, browser, uri, status from cloudfront_logs
 where method = 'GET' and status = 200 and location like 'SFO%' limit 10" \
    --work-group "AthenaAdmin" \
    --query-execution-context Database=cflogsdatabase,Catalog=AwsDataCatalog
```

Output:

```
{
"QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
```

```
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

Example 2: To run a query that uses a specified workgroup to create a database in the specified data catalog

The following `start-query-execution` example uses the `AthenaAdmin` workgroup to create the database `newdb` in the default data catalog `AwsDataCatalog`.

```
aws athena start-query-execution \
    --query-string "create database if not exists newdb" \
    --work-group "AthenaAdmin"
```

Output:

```
{
"QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11112"
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

Example 3: To run a query that creates a view on a table in the specified database and data catalog

The following `start-query-execution` example uses a SELECT statement on the `cloudfront_logs` table in the `cflogsdatabase` to create the view `cf10`.

```
aws athena start-query-execution \
    --query-string  "CREATE OR REPLACE VIEW cf10 AS SELECT * FROM cloudfront_logs
 limit 10" \
    --query-execution-context Database=cflogsdatabase
```

Output:

```
{
"QueryExecutionId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11113"
```

```
}
```

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see StartQueryExecution in *Amazon CLI Command Reference*.

`stop-query-execution`

The following code example shows how to use `stop-query-execution`.

Amazon CLI

To stop a running query

The following `stop-query-execution` example stops the query that has the specified query ID.

```
aws athena stop-query-execution \
    --query-execution-id a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

This command produces no output.

For more information, see Running SQL Queries Using Amazon Athena in the *Amazon Athena User Guide*.

- For API details, see StopQueryExecution in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add a tag to a resource

The following `tag-resource` example adds three tags to the dynamo_db_catalog data catalog.

```
aws athena tag-resource \
```

```
    --resource-arn arn:aws:athena:us-west-2:111122223333:datacatalog/
dynamo_db_catalog \
    --
tags Key=Organization,Value=Retail Key=Division,Value=Mountain Key=Product_Line,Value=Shoes
```

This command produces no output. To see the result, use `aws athena list-tags-for-resource --resource-arn arn:aws:athena:us-west-2:111122223333:datacatalog/dynamo_db_catalog`.

For more information, see Adding tags to a resource: tag-resource in the *Amazon Athena User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove a tag from a resource

The following `untag-resource` example removes the `Specialization` and `Focus` keys and their associated values from the `dynamo_db_catalog` data catalog resource.

```
aws athena untag-resource \
    --resource-arn arn:aws:athena:us-west-2:111122223333:datacatalog/
dynamo_db_catalog \
    --tag-keys Specialization Focus
```

This command produces no output. To see the results, use the `list-tags-for-resource` command.

For more information, see Removing tags from a resource: untag-resource in the *Amazon Athena User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-data-catalog`

The following code example shows how to use `update-data-catalog`.

Amazon CLI

To update a data catalog

The following `update-data-catalog` example updates the Lambda function and description of the `cw_logs_catalog` data catalog.

```
aws athena update-data-catalog \
    --name cw_logs_catalog \
    --type LAMBDA \
    --description "New CloudWatch Logs Catalog" \
    --function=arn:aws:lambda:us-west-2:111122223333:function:new_cw_logs_lambda
```

This command produces no output. To see the result, use `aws athena get-data-catalog --name cw_logs_catalog`.

For more information, see Updating a Catalog: update-data-catalog in the *Amazon Athena User Guide*.

- For API details, see UpdateDataCatalog in *Amazon CLI Command Reference*.

`update-work-group`

The following code example shows how to use `update-work-group`.

Amazon CLI

To update a workgroup

The following `update-work-group` example disables the `Data_Analyst_Group` workgroup. Users cannot run or create queries in the disabled workgroup, but can still view metrics, data usage limit controls, workgroup settings, query history, and saved queries.

```
aws athena update-work-group \
    --work-group Data_Analyst_Group \
    --state DISABLED
```

This command produces no output. To verify the change in state, use `aws athena get-work-group --work-group Data_Analyst_Group` and check the `State` property in the output.

For more information, see Managing Workgroups in the *Amazon Athena User Guide*.

- For API details, see UpdateWorkGroup in *Amazon CLI Command Reference*.

Auto Scaling examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Auto Scaling.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`attach-instances`

The following code example shows how to use `attach-instances`.

Amazon CLI

To attach an instance to an Auto Scaling group

This example attaches the specified instance to the specified Auto Scaling group.

```
aws autoscaling attach-instances \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg
```

This command produces no output.

- For API details, see AttachInstances in *Amazon CLI Command Reference*.

`attach-load-balancer-target-groups`

The following code example shows how to use `attach-load-balancer-target-groups`.

Amazon CLI

To attach a target group to an Auto Scaling group

This example attaches the specified target group to the specified Auto Scaling group.

```
aws autoscaling attach-load-balancer-target-groups \
    --auto-scaling-group-name my-asg \
    --target-group-arns arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see AttachLoadBalancerTargetGroups in *Amazon CLI Command Reference*.

`attach-load-balancers`

The following code example shows how to use `attach-load-balancers`.

Amazon CLI

To attach a Classic Load Balancer to an Auto Scaling group

This example attaches the specified Classic Load Balancer to the specified Auto Scaling group.

```
aws autoscaling attach-load-balancers \
    --load-balancer-names my-load-balancer \
    --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see AttachLoadBalancers in *Amazon CLI Command Reference*.

`cancel-instance-refresh`

The following code example shows how to use `cancel-instance-refresh`.

Amazon CLI

To cancel an instance refresh

The following `cancel-instance-refresh` example cancels an in-progress instance refresh for the specified Auto Scaling group.

```
aws autoscaling cancel-instance-refresh \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see Cancel an instance refresh in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see CancelInstanceRefresh in *Amazon CLI Command Reference*.

`complete-lifecycle-action`

The following code example shows how to use `complete-lifecycle-action`.

Amazon CLI

To complete the lifecycle action

This example notifies Amazon EC2 Auto Scaling that the specified lifecycle action is complete so that it can finish launching or terminating the instance.

```
aws autoscaling complete-lifecycle-action \
    --lifecycle-hook-name my-launch-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-action-result CONTINUE \
    --lifecycle-action-token bcd2f1b8-9a78-44d3-8a7a-4dd07d7cf635
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see CompleteLifecycleAction in *Amazon CLI Command Reference*.

`create-auto-scaling-group`

The following code example shows how to use `create-auto-scaling-group`.

Amazon CLI

Example 1: To create an Auto Scaling group

The following `create-auto-scaling-group` example creates an Auto Scaling group in subnets in multiple Availability Zones within a Region. The instances launch with the default version of the specified launch template. Note that defaults are used for most other settings, such as the termination policies and health check configuration.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-template LaunchTemplateId=lt-1234567890abcde12 \
    --min-size 1 \
    --max-size 5 \
    --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Auto Scaling groups in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To attach an Application Load Balancer, Network Load Balancer, or Gateway Load Balancer

This example specifies the ARN of a target group for a load balancer that supports the expected traffic. The health check type specifies `ELB` so that when Elastic Load Balancing reports an instance as unhealthy, the Auto Scaling group replaces it. The command also defines a health check grace period of `600` seconds. The grace period helps prevent premature termination of newly launched instances.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-template LaunchTemplateId=lt-1234567890abcde12 \
    --target-group-arns arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/my-targets/943f017f100becff \
```

```
    --health-check-type ELB \
    --health-check-grace-period 600 \
    --min-size 1 \
    --max-size 5 \
    --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To specify a placement group and use the latest version of the launch template

This example launches instances into a placement group within a single Availability Zone. This can be useful for low-latency groups with HPC workloads. This example also specifies the minimum size, maximum size, and desired capacity of the group.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-template LaunchTemplateId=lt-1234567890abcde12,Version='$Latest' \
    --min-size 1 \
    --max-size 5 \
    --desired-capacity 3 \
    --placement-group my-placement-group \
    --vpc-zone-identifier "subnet-6194ea3b"
```

This command produces no output.

For more information, see Placement groups in the *Amazon EC2 User Guide for Linux Instances*.

Example 4: To specify a single instance Auto Scaling group and use a specific version of the launch template

This example creates an Auto Scaling group with minimum and maximum capacity set to 1 to enforce that one instance will be running. The command also specifies v1 of a launch template in which the ID of an existing ENI is specified. When you use a launch template that specifies an existing ENI for eth0, you must specify an Availability Zone for the Auto Scaling group that matches the network interface, without also specifying a subnet ID in the request.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg-single-instance \
```

```
    --launch-template LaunchTemplateName=my-template-for-auto-scaling,Version='1' \
    --min-size 1 \
    --max-size 1 \
    --availability-zones us-west-2a
```

This command produces no output.

For more information, see Auto Scaling groups in the *Amazon EC2 Auto Scaling User Guide*.

Example 5: To specify a different termination policy

This example creates an Auto Scaling group using a launch configuration and sets the termination policy to terminate the oldest instances first. The command also applies a tag to the group and its instances, with a key of `Role` and a value of `WebServer`.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-configuration-name my-lc \
    --min-size 1 \
    --max-size 5 \
    --termination-policies "OldestInstance" \
    --tags "ResourceId=my-asg,ResourceType=auto-scaling-
group,Key=Role,Value=WebServer,PropagateAtLaunch=true" \
    --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Working with Amazon EC2 Auto Scaling termination policies in the *Amazon EC2 Auto Scaling User Guide*.

Example 6: To specify a launch lifecycle hook

This example creates an Auto Scaling group with a lifecycle hook that supports a custom action at instance launch.

```
aws autoscaling create-auto-scaling-group \
    --cli-input-json file://~/config.json
```

Contents of `config.json` file:

```
{
```

```
    "AutoScalingGroupName": "my-asg",
    "LaunchTemplate": {
        "LaunchTemplateId": "lt-1234567890abcde12"
    },
    "LifecycleHookSpecificationList": [{
        "LifecycleHookName": "my-launch-hook",
        "LifecycleTransition": "autoscaling:EC2_INSTANCE_LAUNCHING",
        "NotificationTargetARN": "arn:aws:sqs:us-west-2:123456789012:my-sqs-queue",
        "RoleARN": "arn:aws:iam::123456789012:role/my-notification-role",
        "NotificationMetadata": "SQS message metadata",
        "HeartbeatTimeout": 4800,
        "DefaultResult": "ABANDON"
    }],
    "MinSize": 1,
    "MaxSize": 5,
    "VPCZoneIdentifier": "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782",
    "Tags": [{
        "ResourceType": "auto-scaling-group",
        "ResourceId": "my-asg",
        "PropagateAtLaunch": true,
        "Value": "test",
        "Key": "environment"
    }]
}
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

Example 7: To specify a termination lifecycle hook

This example creates an Auto Scaling group with a lifecycle hook that supports a custom action at instance termination.

```
aws autoscaling create-auto-scaling-group \
    --cli-input-json file://~/config.json
```

Contents of `config.json`:

```
{
    "AutoScalingGroupName": "my-asg",
```

```
    "LaunchTemplate": {
        "LaunchTemplateId": "lt-1234567890abcde12"
    },
    "LifecycleHookSpecificationList": [{
        "LifecycleHookName": "my-termination-hook",
        "LifecycleTransition": "autoscaling:EC2_INSTANCE_TERMINATING",
        "HeartbeatTimeout": 120,
        "DefaultResult": "CONTINUE"
    }],
    "MinSize": 1,
    "MaxSize": 5,
    "TargetGroupARNs": [
        "arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/my-
targets/73e2d6bc24d8a067"
    ],
    "VPCZoneIdentifier": "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
}
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

Example 8: To specify a custom termination policy

This example creates an Auto Scaling group that specifies a custom Lambda function termination policy that tells Amazon EC2 Auto Scaling which instances are safe to terminate on scale in.

```
aws autoscaling create-auto-scaling-group \
    --auto-scaling-group-name my-asg-single-instance \
    --launch-template LaunchTemplateName=my-template-for-auto-scaling \
    --min-size 1 \
    --max-size 5 \
    --termination-policies "arn:aws:lambda:us-
west-2:123456789012:function:HelloFunction:prod" \
    --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Creating a custom termination policy with Lambda in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see CreateAutoScalingGroup in *Amazon CLI Command Reference*.

`create-launch-configuration`

The following code example shows how to use `create-launch-configuration`.

Amazon CLI

Example 1: To create a launch configuration

This example creates a simple launch configuration.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large
```

This command produces no output.

For more information, see Creating a launch configuration in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To create a launch configuration with a security group, key pair, and bootrapping script

This example creates a launch configuration with a security group, a key pair, and a bootrapping script contained in the user data.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --security-groups sg-eb2af88example \
    --key-name my-key-pair \
    --user-data file://myuserdata.txt
```

This command produces no output.

For more information, see Creating a launch configuration in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To create a launch configuration with an IAM role

This example creates a launch configuration with the instance profile name of an IAM role.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --iam-instance-profile my-autoscaling-role
```

This command produces no output.

For more information, see IAM role for applications that run on Amazon EC2 instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 4: To create a launch configuration with detailed monitoring enabled

This example creates a launch configuration with EC2 detailed monitoring enabled, which sends EC2 metrics to CloudWatch in 1-minute periods.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --instance-monitoring Enabled=true
```

This command produces no output.

For more information, see Configuring monitoring for Auto Scaling instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 5: To create a launch configuration that launches Spot Instances

This example creates a launch configuration that uses Spot Instances as the only purchase option.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --spot-price "0.50"
```

This command produces no output.

For more information, see Requesting Spot Instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 6: To create a launch configuration using an EC2 instance

This example creates a launch configuration based on the attributes of an existing instance. It overrides the placement tenancy and whether a public IP address is set by including the `--placement-tenancy` and `--no-associate-public-ip-address` options.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc-from-instance \
    --instance-id i-0123a456700123456 \
    --instance-type m5.large \
    --no-associate-public-ip-address \
    --placement-tenancy dedicated
```

This command produces no output.

For more information, see Creating a launch configuration using an EC2 instance in the *Amazon EC2 Auto Scaling User Guide*.

Example 7: To create a launch configuration with a block device mapping for an Amazon EBS volume

This example creates a launch configuration with a block device mapping for an Amazon EBS gp3 volume with the device name `/dev/sdh` and a volume size of 20.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --block-device-mappings '[{"DeviceName":"/dev/sdh","Ebs":
{"VolumeSize":20,"VolumeType":"gp3"}}]'
```

This command produces no output.

For more information, see EBS in the *Amazon EC2 Auto Scaling API Reference*.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the Amazon CLI in the *Amazon Command Line Interface User Guide*.

Example 8: To create a launch configuration with a block device mapping for an instance store volume

This example creates a launch configuration with `ephemeral1` as an instance store volume with the device name `/dev/sdc`.

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --block-device-mappings '[{"DeviceName":"/dev/sdc","VirtualName":"ephemeral1"}]'
```

This command produces no output.

For more information, see BlockDeviceMapping in the *Amazon EC2 Auto Scaling API Reference*.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the Amazon CLI in the *Amazon Command Line Interface User Guide*.

Example 9: To create a launch configuration and suppress a block device from attaching at launch time

This example creates a launch configuration that suppresses a block device specified by the block device mapping of the AMI (for example, `/dev/sdf`).

```
aws autoscaling create-launch-configuration \
    --launch-configuration-name my-lc \
    --image-id ami-04d5cc9b88example \
    --instance-type m5.large \
    --block-device-mappings '[{"DeviceName":"/dev/sdf","NoDevice":""}]'
```

This command produces no output.

For more information, see BlockDeviceMapping in the *Amazon EC2 Auto Scaling API Reference*.

For information about the syntax for quoting JSON-formatted parameter values, see Using quotation marks with strings in the Amazon CLI in the *Amazon Command Line Interface User Guide*.

- For API details, see CreateLaunchConfiguration in *Amazon CLI Command Reference*.

`create-or-update-tags`

The following code example shows how to use `create-or-update-tags`.

Amazon CLI

To create or update tags for an Auto Scaling group

This example adds two tags to the specified Auto Scaling group.

```
aws autoscaling create-or-update-tags \
    --tags ResourceId=my-asg,ResourceType=auto-scaling-
group,Key=Role,Value=WebServer,PropagateAtLaunch=true ResourceId=my-
asg,ResourceType=auto-scaling-group,Key=Dept,Value=Research,PropagateAtLaunch=true
```

This command produces no output.

For more information, see Tagging Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see CreateOrUpdateTags in *Amazon CLI Command Reference*.

`delete-auto-scaling-group`

The following code example shows how to use `delete-auto-scaling-group`.

Amazon CLI

Example 1: To delete the specified Auto Scaling group

This example deletes the specified Auto Scaling group.

```
aws autoscaling delete-auto-scaling-group \
    --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see Deleting your Auto Scaling infrastructure in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To force delete the specified Auto Scaling group

To delete the Auto Scaling group without waiting for the instances in the group to terminate, use the `--force-delete` option.

```
aws autoscaling delete-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --force-delete
```

This command produces no output.

For more information, see Deleting your Auto Scaling infrastructure in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DeleteAutoScalingGroup in *Amazon CLI Command Reference*.

`delete-launch-configuration`

The following code example shows how to use `delete-launch-configuration`.

Amazon CLI

To delete a launch configuration

This example deletes the specified launch configuration.

```
aws autoscaling delete-launch-configuration \
    --launch-configuration-name my-launch-config
```

This command produces no output.

For more information, see Deleting your Auto Scaling infrastructure in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DeleteLaunchConfiguration in *Amazon CLI Command Reference*.

`delete-lifecycle-hook`

The following code example shows how to use `delete-lifecycle-hook`.

Amazon CLI

To delete a lifecycle hook

This example deletes the specified lifecycle hook.

```
aws autoscaling delete-lifecycle-hook \
    --lifecycle-hook-name my-lifecycle-hook \
    --auto-scaling-group-name my-asg
```

This command produces no output.

- For API details, see DeleteLifecycleHook in *Amazon CLI Command Reference*.

`delete-notification-configuration`

The following code example shows how to use `delete-notification-configuration`.

Amazon CLI

To delete an Auto Scaling notification

This example deletes the specified notification from the specified Auto Scaling group.

```
aws autoscaling delete-notification-configuration \
    --auto-scaling-group-name my-asg \
    --topic-arn arn:aws:sns:us-west-2:123456789012:my-sns-topic
```

This command produces no output.

For more information, see Delete the notification configuration in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DeleteNotificationConfiguration in *Amazon CLI Command Reference*.

`delete-policy`

The following code example shows how to use `delete-policy`.

Amazon CLI

To delete a scaling policy

This example deletes the specified scaling policy.

```
aws autoscaling delete-policy \
    --auto-scaling-group-name my-asg \
```

```
    --policy-name alb1000-target-tracking-scaling-policy
```

This command produces no output.

- For API details, see DeletePolicy in *Amazon CLI Command Reference*.

`delete-scheduled-action`

The following code example shows how to use `delete-scheduled-action`.

Amazon CLI

To delete a scheduled action from an Auto Scaling group

This example deletes the specified scheduled action from the specified Auto Scaling group.

```
aws autoscaling delete-scheduled-action \
    --auto-scaling-group-name my-asg \
    --scheduled-action-name my-scheduled-action
```

This command produces no output.

- For API details, see DeleteScheduledAction in *Amazon CLI Command Reference*.

`delete-tags`

The following code example shows how to use `delete-tags`.

Amazon CLI

To delete a tag from an Auto Scaling group

This example deletes the specified tag from the specified Auto Scaling group.

```
aws autoscaling delete-tags \
    --tags ResourceId=my-asg,ResourceType=auto-scaling-group,Key=Dept,Value=Research
```

This command produces no output.

For more information, see Tagging Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DeleteTags in *Amazon CLI Command Reference*.

`delete-warm-pool`

The following code example shows how to use `delete-warm-pool`.

Amazon CLI

Example 1: To delete a warm pool

The following example deletes the warm pool for the specified Auto Scaling group.

```
aws autoscaling delete-warm-pool \
    --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see Warm pools for Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To force delete a warm pool

To delete the warm pool without waiting for its instances to terminate, use the `--force-delete` option.

```
aws autoscaling delete-warm-pool \
    --auto-scaling-group-name my-asg \
    --force-delete
```

This command produces no output.

For more information, see Warm pools for Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DeleteWarmPool in *Amazon CLI Command Reference*.

`describe-account-limits`

The following code example shows how to use `describe-account-limits`.

Amazon CLI

To describe your Amazon EC2 Auto Scaling account limits

This example describes the Amazon EC2 Auto Scaling limits for your Amazon account.

```
aws autoscaling describe-account-limits
```

Output:

```
{
    "NumberOfLaunchConfigurations": 5,
    "MaxNumberOfLaunchConfigurations": 100,
    "NumberOfAutoScalingGroups": 3,
    "MaxNumberOfAutoScalingGroups": 20
}
```

For more information, see Amazon EC2 Auto Scaling service quotas in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeAccountLimits in *Amazon CLI Command Reference*.

`describe-adjustment-types`

The following code example shows how to use `describe-adjustment-types`.

Amazon CLI

To describe the available scaling adjustment types

This example describes the available adjustment types.

```
aws autoscaling describe-adjustment-types
```

Output:

```
{
    "AdjustmentTypes": [
        {
            "AdjustmentType": "ChangeInCapacity"
        },
        {
            "AdjustmentType": "ExactCapacity"
        },
        {
```

```
            "AdjustmentType": "PercentChangeInCapacity"
        }
    ]
}
```

For more information, see Scaling adjustment types in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeAdjustmentTypes in *Amazon CLI Command Reference*.

`describe-auto-scaling-groups`

The following code example shows how to use `describe-auto-scaling-groups`.

Amazon CLI

Example 1: To describe the specified Auto Scaling group

This example describes the specified Auto Scaling group.

```
aws autoscaling describe-auto-scaling-groups \
    --auto-scaling-group-names my-asg
```

Output:

```
{
    "AutoScalingGroups": [
        {
            "AutoScalingGroupName": "my-asg",
            "AutoScalingGroupARN": "arn:aws:autoscaling:us-
west-2:123456789012:autoScalingGroup:930d940e-891e-4781-

                    "ProtectedFromScaleIn": false,
                    "LaunchTemplate": {
                        "LaunchTemplateName": "my-launch-template",
                        "Version": "1",
                        "LaunchTemplateId": "lt-1234567890abcde12"
                    }
                }
            ],
            "CreatedTime": "2023-10-28T02:39:22.152Z",
            "SuspendedProcesses": [],
            "VPCZoneIdentifier": "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782",
            "EnabledMetrics": [],
            "Tags": [],
            "TerminationPolicies": [
                "Default"
            ],
            "NewInstancesProtectedFromScaleIn": false,
            "ServiceLinkedRoleARN":"arn",
            "TrafficSources": []
        }
    ]
}
```

Example 2: To describe the first 100 specified Auto Scaling group

This example describes the specified Auto Scaling groups. It allows you to specify up to 100 group names.

```
aws autoscaling describe-auto-scaling-groups \
```

```
    --max-items 100 \
    --auto-scaling-group-names "group1" "group2" "group3" "group4"
```

See example 1 for sample output.

Example 3: To describe an Auto Scaling group in the specified region

This example describes the Auto Scaling groups in the specified region, up to a maximum of 75 groups.

```
aws autoscaling describe-auto-scaling-groups \
    --max-items 75 \
    --region us-east-1
```

See example 1 for sample output.

Example 4: To describe the specified number of Auto Scaling group

To return a specific number of Auto Scaling groups, use the `--max-items` option.

```
aws autoscaling describe-auto-scaling-groups \
    --max-items 1
```

See example 1 for sample output.

If the output includes a `NextToken` field, there are more groups. To get the additional groups, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-auto-scaling-groups \
    --starting-token Z3M3LMPEXAMPLE
```

See example 1 for sample output.

Example 5: To describe Auto Scaling groups that use launch configurations

This example uses the `--query` option to describe Auto Scaling groups that use launch configurations.

```
aws autoscaling describe-auto-scaling-groups \
    --query 'AutoScalingGroups[?LaunchConfigurationName!=`null`]'
```

Output:

```
[
    {
        "AutoScalingGroupName": "my-asg",
        "AutoScalingGroupARN": "arn:aws:autoscaling:us-
west-2:123456789012:autoScalingGroup:930d940e-891e-4781-
a11a-7b0acd480f03:autoScalingGroupName/my-asg",
        "LaunchConfigurationName": "my-lc",
        "MinSize": 0,
        "MaxSize": 1,
        "DesiredCapacity": 1,
        "DefaultCooldown": 300,
        "AvailabilityZones": [
            "us-west-2a",
            "us-west-2b",
            "us-west-2c"
        ],
        "LoadBalancerNames": [],
        "TargetGroupARNs": [],
        "HealthCheckType": "EC2",
        "HealthCheckGracePeriod": 0,
        "Instances": [
            {
                "InstanceId": "i-088c57934a6449037",
                "InstanceType": "t2.micro",
                "AvailabilityZone": "us-west-2c",
                "HealthStatus": "Healthy",
                "LifecycleState": "InService",
                "LaunchConfigurationName": "my-lc",
                "ProtectedFromScaleIn": false
            }
        ],
        "CreatedTime": "2023-10-28T02:39:22.152Z",
        "SuspendedProcesses": [],
        "VPCZoneIdentifier": "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782",
        "EnabledMetrics": [],
        "Tags": [],
        "TerminationPolicies": [
            "Default"
        ],
        "NewInstancesProtectedFromScaleIn": false,
        "ServiceLinkedRoleARN":"arn",
        "TrafficSources": []
```

```
    }
]
```

For more information, see Filter Amazon CLI output in the *Amazon Command Line Interface User Guide*.

- For API details, see DescribeAutoScalingGroups in *Amazon CLI Command Reference*.

`describe-auto-scaling-instances`

The following code example shows how to use `describe-auto-scaling-instances`.

Amazon CLI

Example 1: To describe one or more instances

This example describes the specified instance.

```
aws autoscaling describe-auto-scaling-instances \
    --instance-ids i-06905f55584de02da
```

Output:

```
{
    "AutoScalingInstances": [
        {
            "InstanceId": "i-06905f55584de02da",
            "InstanceType": "t2.micro",
            "AutoScalingGroupName": "my-asg",
            "AvailabilityZone": "us-west-2b",
            "LifecycleState": "InService",
            "HealthStatus": "HEALTHY",
            "ProtectedFromScaleIn": false,
            "LaunchTemplate": {
                "LaunchTemplateId": "lt-1234567890abcde12",
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            }
        }
    ]
}
```

Example 2: To describe one or more instances

This example uses the `--max-items` option to specify how many instances to return with this call.

```
aws autoscaling describe-auto-scaling-instances \
    --max-items 1
```

If the output includes a `NextToken` field, there are more instances. To get the additional instances, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-auto-scaling-instances \
    --starting-token Z3M3LMPEXAMPLE
```

See example 1 for sample output.

Example 3: To describe instances that use launch configurations

This example uses the `--query` option to describe instances that use launch configurations.

```
aws autoscaling describe-auto-scaling-instances \
    --query 'AutoScalingInstances[?LaunchConfigurationName!=`null`]'
```

Output:

```
[
    {
        "InstanceId": "i-088c57934a6449037",
        "InstanceType": "t2.micro",
        "AutoScalingGroupName": "my-asg",
        "AvailabilityZone": "us-west-2c",
        "LifecycleState": "InService",
        "HealthStatus": "HEALTHY",
        "LaunchConfigurationName": "my-lc",
        "ProtectedFromScaleIn": false
    }
]
```

For more information, see Filter Amazon CLI output in the *Amazon Command Line Interface User Guide*.

- For API details, see DescribeAutoScalingInstances in *Amazon CLI Command Reference*.

`describe-auto-scaling-notification-types`

The following code example shows how to use `describe-auto-scaling-notification-types`.

Amazon CLI

To describe the available notification types

This example describes the available notification types.

```
aws autoscaling describe-auto-scaling-notification-types
```

Output:

```
{
    "AutoScalingNotificationTypes": [
        "autoscaling:EC2_INSTANCE_LAUNCH",
        "autoscaling:EC2_INSTANCE_LAUNCH_ERROR",
        "autoscaling:EC2_INSTANCE_TERMINATE",
        "autoscaling:EC2_INSTANCE_TERMINATE_ERROR",
        "autoscaling:TEST_NOTIFICATION"
    ]
}
```

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeAutoScalingNotificationTypes in *Amazon CLI Command Reference*.

`describe-instance-refreshes`

The following code example shows how to use `describe-instance-refreshes`.

Amazon CLI

To describe instance refreshes

The following `describe-instance-refreshes` example returns a description of all instance refresh requests for the specified Auto Scaling group, including the status message and (if available) the status reason.

```
aws autoscaling describe-instance-refreshes \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "InstanceRefreshes": [
        {
            "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b",
            "AutoScalingGroupName": "my-asg",
            "Status": "InProgress",
            "StatusReason": "Waiting for instances to warm up before continuing. For
 example: 0e69cc3f05f825f4f is warming up.",
            "EndTime": "2023-03-23T16:42:55Z",
            "PercentageComplete": 0,
            "InstancesToUpdate": 0,
    "Preferences": {
                "MinHealthyPercentage": 100,
                "InstanceWarmup": 300,
                "CheckpointPercentages": [
                    50
                ],
                "CheckpointDelay": 3600,
                "SkipMatching": false,
                "AutoRollback": true,
                "ScaleInProtectedInstances": "Ignore",
                "StandbyInstances": "Ignore"
            }
        },
        {
            "InstanceRefreshId": "dd7728d0-5bc4-4575-96a3-1b2c52bf8bb1",
            "AutoScalingGroupName": "my-asg",
            "Status": "Successful",
            "EndTime": "2022-06-02T16:53:37Z",
            "PercentageComplete": 100,
            "InstancesToUpdate": 0,
    "Preferences": {
                "MinHealthyPercentage": 90,
                "InstanceWarmup": 300,
                "SkipMatching": true,
                "AutoRollback": true,
                "ScaleInProtectedInstances": "Ignore",
                "StandbyInstances": "Ignore"
```

```
            }
        }
    ]
}
```

For more information, see Check the status of an instance refresh in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeInstanceRefreshes in *Amazon CLI Command Reference*.

`describe-launch-configurations`

The following code example shows how to use `describe-launch-configurations`.

Amazon CLI

Example 1: To describe the specified launch configuration

This example describes the specified launch configuration.

```
aws autoscaling describe-launch-configurations \
    --launch-configuration-names my-launch-config
```

Output:

```
{
    "LaunchConfigurations": [
        {
            "LaunchConfigurationName": "my-launch-config",
            "LaunchConfigurationARN": "arn:aws:autoscaling:us-
west-2:123456789012:launchConfiguration:98d3b196-4cf9-4e88-8ca1-8547c24ced8b:launchConfigura
my-launch-config",
            "ImageId": "ami-0528a5175983e7f28",
            "KeyName": "my-key-pair-uswest2",
            "SecurityGroups": [
                "sg-05eaec502fcdadc2e"
            ],
            "ClassicLinkVPCSecurityGroups": [],
            "UserData": "",
            "InstanceType": "t2.micro",
            "KernelId": "",
            "RamdiskId": "",
```

```
            "BlockDeviceMappings": [
                {
                    "DeviceName": "/dev/xvda",
                    "Ebs": {
                        "SnapshotId": "snap-06c1606ba5ca274b1",
                        "VolumeSize": 8,
                        "VolumeType": "gp2",
                        "DeleteOnTermination": true,
                        "Encrypted": false
                    }
                }
            ],
            "InstanceMonitoring": {
                "Enabled": true
            },
            "CreatedTime": "2020-10-28T02:39:22.321Z",
            "EbsOptimized": false,
            "AssociatePublicIpAddress": true,
            "MetadataOptions": {
                "HttpTokens": "required",
                "HttpPutResponseHopLimit": 1,
                "HttpEndpoint": "disabled"
            }
        }
    ]
}
```

Example 2: To describe a specified number of launch configurations

To return a specific number of launch configurations, use the `--max-items` option.

```
aws autoscaling describe-launch-configurations \
    --max-items 1
```

If the output includes a `NextToken` field, there are more launch configurations. To get the additional launch configurations, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-launch-configurations \
    --starting-token Z3M3LMPEXAMPLE
```

- For API details, see DescribeLaunchConfigurations in *Amazon CLI Command Reference*.

`describe-lifecycle-hook-types`

The following code example shows how to use `describe-lifecycle-hook-types`.

Amazon CLI

To describe the available lifecycle hook types

This example describes the available lifecycle hook types.

```
aws autoscaling describe-lifecycle-hook-types
```

Output:

```
{
    "LifecycleHookTypes": [
        "autoscaling:EC2_INSTANCE_LAUNCHING",
        "autoscaling:EC2_INSTANCE_TERMINATING"
    ]
}
```

- For API details, see DescribeLifecycleHookTypes in *Amazon CLI Command Reference*.

`describe-lifecycle-hooks`

The following code example shows how to use `describe-lifecycle-hooks`.

Amazon CLI

To describe your lifecycle hooks

This example describes the lifecycle hooks for the specified Auto Scaling group.

```
aws autoscaling describe-lifecycle-hooks \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "LifecycleHooks": [
        {
```

```
            "GlobalTimeout": 3000,
            "HeartbeatTimeout": 30,
            "AutoScalingGroupName": "my-asg",
            "LifecycleHookName": "my-launch-hook",
            "DefaultResult": "ABANDON",
            "LifecycleTransition": "autoscaling:EC2_INSTANCE_LAUNCHING"
        },
        {
            "GlobalTimeout": 6000,
            "HeartbeatTimeout": 60,
            "AutoScalingGroupName": "my-asg",
            "LifecycleHookName": "my-termination-hook",
            "DefaultResult": "CONTINUE",
            "LifecycleTransition": "autoscaling:EC2_INSTANCE_TERMINATING"
        }
    ]
}
```

- For API details, see DescribeLifecycleHooks in *Amazon CLI Command Reference*.

`describe-load-balancer-target-groups`

The following code example shows how to use `describe-load-balancer-target-groups`.

Amazon CLI

To describe the load balancer target groups for an Auto Scaling group

This example describes the load balancer target groups attached to the specified Auto Scaling group.

```
aws autoscaling describe-load-balancer-target-groups \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "LoadBalancerTargetGroups": [
        {
            "LoadBalancerTargetGroupARN": "arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067",
            "State": "Added"
```

```
        }
    ]
}
```

- For API details, see DescribeLoadBalancerTargetGroups in *Amazon CLI Command Reference*.

`describe-load-balancers`

The following code example shows how to use `describe-load-balancers`.

Amazon CLI

To describe the Classic Load Balancers for an Auto Scaling group

This example describes the Classic Load Balancers for the specified Auto Scaling group.

```
aws autoscaling describe-load-balancers \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "LoadBalancers": [
        {
            "State": "Added",
            "LoadBalancerName": "my-load-balancer"
        }
    ]
}
```

- For API details, see DescribeLoadBalancers in *Amazon CLI Command Reference*.

`describe-metric-collection-types`

The following code example shows how to use `describe-metric-collection-types`.

Amazon CLI

To describe the available metric collection types

This example describes the available metric collection types.

```
aws autoscaling describe-metric-collection-types
```

Output:

```
{
    "Metrics": [
        {
            "Metric": "GroupMinSize"
        },
        {
            "Metric": "GroupMaxSize"
        },
        {
            "Metric": "GroupDesiredCapacity"
        },
        {
            "Metric": "GroupInServiceInstances"
        },
        {
            "Metric": "GroupInServiceCapacity"
        },
        {
            "Metric": "GroupPendingInstances"
        },
        {
            "Metric": "GroupPendingCapacity"
        },
        {
            "Metric": "GroupTerminatingInstances"
        },
        {
            "Metric": "GroupTerminatingCapacity"
        },
        {
            "Metric": "GroupStandbyInstances"
        },
        {
            "Metric": "GroupStandbyCapacity"
        },
        {
            "Metric": "GroupTotalInstances"
        },
        {
```

```
            "Metric": "GroupTotalCapacity"
        }
    ],
    "Granularities": [
        {
            "Granularity": "1Minute"
        }
    ]
}
```

For more information, see Auto Scaling group metrics in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeMetricCollectionTypes in *Amazon CLI Command Reference*.

`describe-notification-configurations`

The following code example shows how to use `describe-notification-configurations`.

Amazon CLI

Example 1: To describe the notification configurations of a specified group

This example describes the notification configurations for the specified Auto Scaling group.

```
aws autoscaling describe-notification-configurations \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "NotificationConfigurations": [
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
            "TopicARN": "arn:aws:sns:us-west-2:123456789012:my-sns-topic-2"
        },
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
            "TopicARN": "arn:aws:sns:us-west-2:123456789012:my-sns-topic"
        }
    ]
```

```
}
```

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the *Amazon EC2 Auto Scaling User Guide*.

Example 1: To describe a specified number of notification configurations

To return a specific number of notification configurations, use the `max-items` parameter.

```
aws autoscaling describe-notification-configurations \
    --auto-scaling-group-name my-auto-scaling-group \
    --max-items 1
```

Output:

```
{
    "NotificationConfigurations": [
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
            "TopicARN": "arn:aws:sns:us-west-2:123456789012:my-sns-topic-2"
        },
        {
            "AutoScalingGroupName": "my-asg",
            "NotificationType": "autoscaling:TEST_NOTIFICATION",
            "TopicARN": "arn:aws:sns:us-west-2:123456789012:my-sns-topic"
        }
    ]
}
```

If the output includes a `NextToken` field, there are more notification configurations. To get the additional notification configurations, use the value of this field with the `starting-token` parameter in a subsequent call as follows.

```
aws autoscaling describe-notification-configurations \
    --auto-scaling-group-name my-asg \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeNotificationConfigurations in *Amazon CLI Command Reference*.

describe-policies

The following code example shows how to use `describe-policies`.

Amazon CLI

Example 1: To describe the scaling policies of a specified group

This example describes the scaling policies for the specified Auto Scaling group.

```
aws autoscaling describe-policies \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "ScalingPolicies": [
        {
            "AutoScalingGroupName": "my-asg",
            "PolicyName": "alb1000-target-tracking-scaling-policy",
            "PolicyARN": "arn:aws:autoscaling:us-
west-2:123456789012:scalingPolicy:3065d9c8-9969-4bec-
bb6a-3fbe5550fde6:autoScalingGroupName/my-asg:policyName/alb1000-target-tracking-
scaling-policy",
            "PolicyType": "TargetTrackingScaling",
            "StepAdjustments": [],
            "Alarms": [
                {
                    "AlarmName": "TargetTracking-my-asg-
AlarmHigh-924887a9-12d7-4e01-8686-6f844d13a196",
                    "AlarmARN": "arn:aws:cloudwatch:us-
west-2:123456789012:alarm:TargetTracking-my-asg-
AlarmHigh-924887a9-12d7-4e01-8686-6f844d13a196"
                },
                {
                    "AlarmName": "TargetTracking-my-asg-AlarmLow-f96f899d-b8e7-4d09-
a010-c1aaa35da296",
                    "AlarmARN": "arn:aws:cloudwatch:us-
west-2:123456789012:alarm:TargetTracking-my-asg-AlarmLow-f96f899d-b8e7-4d09-a010-

                    "AlarmARN": "arn:aws:cloudwatch:us-
west-2:123456789012:alarm:TargetTracking-my-asg-AlarmLow-bd681c67-fc18-4c56-8468-
fb8e413009c9"
                }
            ],
            "TargetTrackingConfiguration": {
                "PredefinedMetricSpecification": {
                    "PredefinedMetricType": "ASGAverageCPUUtilization"
                },
                "TargetValue": 40.0,
                "DisableScaleIn": false
            },
            "Enabled": true
        }
    ]
```

```
}
```

For more information, see Dynamic scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To describe the scaling policies of a specified name

To return specific scaling policies, use the `--policy-names` option.

```
aws autoscaling describe-policies \
    --auto-scaling-group-name my-asg \
    --policy-names cpu40-target-tracking-scaling-policy
```

See example 1 for sample output.

For more information, see Dynamic scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To describe a number of scaling policies

To return a specific number of policies, use the `--max-items` option.

```
aws autoscaling describe-policies \
    --auto-scaling-group-name my-asg \
    --max-items 1
```

See example 1 for sample output.

If the output includes a `NextToken` field, use the value of this field with the `--starting-token` option in a subsequent call to get the additional policies.

```
aws autoscaling describe-policies --auto-scaling-group-name my-asg --starting-
token Z3M3LMPEXAMPLE
```

For more information, see Dynamic scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribePolicies in *Amazon CLI Command Reference*.

`describe-scaling-activities`

The following code example shows how to use `describe-scaling-activities`.

Amazon CLI

Example 1: To describe scaling activities for the specified group

This example describes the scaling activities for the specified Auto Scaling group.

```
aws autoscaling describe-scaling-activities \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "f9f2d65b-f1f2-43e7-b46d-d86756459699",
            "Description": "Launching a new EC2 instance: i-0d44425630326060f",
            "AutoScalingGroupName": "my-asg",
            "Cause": "At 2020-10-30T19:35:51Z a user request update of
 AutoScalingGroup constraints to min: 0, max: 16, desired: 16 changing the desired
 capacity from 0 to 16.  At 2020-10-30T19:36:07Z an instance was started in response
 to a difference between desired and actual capacity, increasing the capacity from 0
 to 16.",
            "StartTime": "2020-10-30T19:36:09.766Z",
            "EndTime": "2020-10-30T19:36:41Z",
            "StatusCode": "Successful",
            "Progress": 100,
            "Details": "{\"Subnet ID\":\"subnet-5ea0c127\",\"Availability Zone\":
\"us-west-2b\"}"
        }
    ]
}
```

For more information, see Verify a scaling activity for an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To describe the scaling activities for a deleted group

To describe scaling activities after the Auto Scaling group has been deleted, add the `--include-deleted-groups` option.

```
aws autoscaling describe-scaling-activities \
    --auto-scaling-group-name my-asg \
```

```
    --include-deleted-groups
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "e1f5de0e-f93e-1417-34ac-092a76fba220",
            "Description": "Launching a new EC2 instance.  Status Reason: Your Spot
 request price of 0.001 is lower than the minimum required Spot request fulfillment
 price of 0.0031. Launching EC2 instance failed.",
            "AutoScalingGroupName": "my-asg",
            "Cause": "At 2021-01-13T20:47:24Z a user request update of
 AutoScalingGroup constraints to min: 1, max: 5, desired: 3 changing the desired
 capacity from 0 to 3.  At 2021-01-13T20:47:27Z an instance was started in response
 to a difference between desired and actual capacity, increasing the capacity from 0
 to 3.",
            "StartTime": "2021-01-13T20:47:30.094Z",
            "EndTime": "2021-01-13T20:47:30Z",
            "StatusCode": "Failed",
            "StatusMessage": "Your Spot request price of 0.001 is lower than the
 minimum required Spot request fulfillment price of 0.0031. Launching EC2 instance
 failed.",
            "Progress": 100,
            "Details": "{\"Subnet ID\":\"subnet-5ea0c127\",\"Availability Zone\":
\"us-west-2b\"}",
            "AutoScalingGroupState": "Deleted",
            "AutoScalingGroupARN": "arn:aws:autoscaling:us-
west-2:123456789012:autoScalingGroup:283179a2-
f3ce-423d-93f6-66bb518232f7:autoScalingGroupName/my-asg"
        }
    ]
}
```

For more information, see Troubleshoot Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To describe a specified number of scaling activities

To return a specific number of activities, use the `--max-items` option.

```
aws autoscaling describe-scaling-activities \
```

```
    --max-items 1
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "f9f2d65b-f1f2-43e7-b46d-d86756459699",
            "Description": "Launching a new EC2 instance: i-0d44425630326060f",
            "AutoScalingGroupName": "my-asg",
            "Cause": "At 2020-10-30T19:35:51Z a user request update of
 AutoScalingGroup constraints to min: 0, max: 16, desired: 16 changing the desired
 capacity from 0 to 16.  At 2020-10-30T19:36:07Z an instance was started in response
 to a difference between desired and actual capacity, increasing the capacity from 0
 to 16.",
            "StartTime": "2020-10-30T19:36:09.766Z",
            "EndTime": "2020-10-30T19:36:41Z",
            "StatusCode": "Successful",
            "Progress": 100,
            "Details": "{\"Subnet ID\":\"subnet-5ea0c127\",\"Availability Zone\":
\"us-west-2b\"}"
        }
    ]
}
```

If the output includes a `NextToken` field, there are more activities. To get the additional activities, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-scaling-activities \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see Verify a scaling activity for an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeScalingActivities in *Amazon CLI Command Reference*.

`describe-scaling-process-types`

The following code example shows how to use `describe-scaling-process-types`.

Amazon CLI

To describe the available process types

This example describes the available process types.

```
aws autoscaling describe-scaling-process-types
```

Output:

```
{
    "Processes": [
        {
            "ProcessName": "AZRebalance"
        },
        {
            "ProcessName": "AddToLoadBalancer"
        },
        {
            "ProcessName": "AlarmNotification"
        },
        {
            "ProcessName": "HealthCheck"
        },
        {
            "ProcessName": "InstanceRefresh"
        },
        {
            "ProcessName": "Launch"
        },
        {
            "ProcessName": "ReplaceUnhealthy"
        },
        {
            "ProcessName": "ScheduledActions"
        },
        {
            "ProcessName": "Terminate"
        }
    ]
}
```

For more information, see Suspending and resuming scaling processes in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeScalingProcessTypes in *Amazon CLI Command Reference*.

`describe-scheduled-actions`

The following code example shows how to use `describe-scheduled-actions`.

Amazon CLI

Example 1: To describe all scheduled actions

This example describes all your scheduled actions.

```
aws autoscaling describe-scheduled-actions
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To describe scheduled actions for the specified group

To describe the scheduled actions for a specific Auto Scaling group, use the `--auto-scaling-group-name` option.

```
aws autoscaling describe-scheduled-actions \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To describe the specified scheduled action

To describe a specific scheduled action, use the `--scheduled-action-names` option.

```
aws autoscaling describe-scheduled-actions \
    --scheduled-action-names my-recurring-action
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
```

```
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 4: To describe scheduled actions with a specified start time

To describe the scheduled actions that start at a specific time, use the `--start-time` option.

```
aws autoscaling describe-scheduled-actions \
    --start-time "2023-12-01T04:00:00Z"
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
```

```
    ]
}
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 5: To describe scheduled actions that end at a specified time

To describe the scheduled actions that end at a specific time, use the `--end-time` option.

```
aws autoscaling describe-scheduled-actions \
    --end-time "2023-12-01T04:00:00Z"
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 6: To describe a specified number of scheduled actions

To return a specific number of scheduled actions, use the `--max-items` option.

```
aws autoscaling describe-scheduled-actions \
    --auto-scaling-group-name my-asg \
```

```
    --max-items 1
```

Output:

```
{
    "ScheduledUpdateGroupActions": [
        {
            "AutoScalingGroupName": "my-asg",
            "ScheduledActionName": "my-recurring-action",
            "Recurrence": "30 0 1 1,6,12 *",
            "ScheduledActionARN": "arn:aws:autoscaling:us-
west-2:123456789012:scheduledUpdateGroupAction:8e86b655-b2e6-4410-8f29-
b4f094d6871c:autoScalingGroupName/my-asg:scheduledActionName/my-recurring-action",
            "StartTime": "2023-12-01T04:00:00Z",
            "Time": "2023-12-01T04:00:00Z",
            "MinSize": 1,
            "MaxSize": 6,
            "DesiredCapacity": 4,
            "TimeZone": "America/New_York"
        }
    ]
}
```

If the output includes a `NextToken` field, there are more scheduled actions. To get the additional scheduled actions, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-scheduled-actions \
    --auto-scaling-group-name my-asg \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeScheduledActions in *Amazon CLI Command Reference*.

`describe-tags`

The following code example shows how to use `describe-tags`.

Amazon CLI

To describe all tags

This example describes all your tags.

```
aws autoscaling describe-tags
```

Output:

```
{
    "Tags": [
        {
            "ResourceType": "auto-scaling-group",
            "ResourceId": "my-asg",
            "PropagateAtLaunch": true,
            "Value": "Research",
            "Key": "Dept"
        },
        {
            "ResourceType": "auto-scaling-group",
            "ResourceId": "my-asg",
            "PropagateAtLaunch": true,
            "Value": "WebServer",
            "Key": "Role"
        }
    ]
}
```

For more information, see Tagging Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To describe tags for a specified group

To describe tags for a specific Auto Scaling group, use the `--filters` option.

```
aws autoscaling describe-tags --filters Name=auto-scaling-group,Values=my-asg
```

For more information, see Tagging Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To describe the specified number of tags

To return a specific number of tags, use the `--max-items` option.

```
aws autoscaling describe-tags \
    --max-items 1
```

If the output includes a `NextToken` field, there are more tags. To get the additional tags, use the value of this field with the `--starting-token` option in a subsequent call as follows.

```
aws autoscaling describe-tags \
    --filters Name=auto-scaling-group,Values=my-asg \
    --starting-token Z3M3LMPEXAMPLE
```

For more information, see Tagging Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeTags in *Amazon CLI Command Reference*.

`describe-termination-policy-types`

The following code example shows how to use `describe-termination-policy-types`.

Amazon CLI

To describe available termination policy types

This example describes the available termination policy types.

```
aws autoscaling describe-termination-policy-types
```

Output:

```
{
    "TerminationPolicyTypes": [
        "AllocationStrategy",
        "ClosestToNextInstanceHour",
        "Default",
        "NewestInstance",
        "OldestInstance",
        "OldestLaunchConfiguration",
        "OldestLaunchTemplate"
    ]
}
```

For more information, see Controlling which Auto Scaling instances terminate during scale in in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeTerminationPolicyTypes in *Amazon CLI Command Reference*.

`describe-warm-pool`

The following code example shows how to use `describe-warm-pool`.

Amazon CLI

To describe a warm pool

This example describes the warm pool for the specified Auto Scaling group.

```
aws autoscaling describe-warm-pool \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "WarmPoolConfiguration": {
        "MinSize": 2,
        "PoolState": "Stopped"
    },
    "Instances": [
        {
            "InstanceId": "i-070a5bbc7e7f40dc5",
            "InstanceType": "t2.micro",
            "AvailabilityZone": "us-west-2c",
            "LifecycleState": "Warmed:Pending",
            "HealthStatus": "Healthy",
            "LaunchTemplate": {
                "LaunchTemplateId": "lt-00a731f6e9fa48610",
                "LaunchTemplateName": "my-template-for-auto-scaling",
                "Version": "6"
            }
        },
        {
            "InstanceId": "i-0b52f061814d3bd2d",
            "InstanceType": "t2.micro",
            "AvailabilityZone": "us-west-2b",
            "LifecycleState": "Warmed:Pending",
```

```
            "HealthStatus": "Healthy",
            "LaunchTemplate": {
                "LaunchTemplateId": "lt-00a731f6e9fa48610",
                "LaunchTemplateName": "my-template-for-auto-scaling",
                "Version": "6"
            }
        }
    ]
}
```

For more information, see Warm pools for Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DescribeWarmPool in *Amazon CLI Command Reference*.

`detach-instances`

The following code example shows how to use `detach-instances`.

Amazon CLI

To detach an instance from an Auto Scaling group

This example detaches the specified instance from the specified Auto Scaling group.

```
aws autoscaling detach-instances \
    --instance-ids i-030017cfa84b20135 \
    --auto-scaling-group-name my-asg \
    --should-decrement-desired-capacity
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "5091cb52-547a-47ce-a236-c9ccbc2cb2c9",
            "AutoScalingGroupName": "my-asg",
            "Description": "Detaching EC2 instance: i-030017cfa84b20135",
            "Cause": "At 2020-10-31T17:35:04Z instance i-030017cfa84b20135 was
 detached in response to a user request, shrinking the capacity from 2 to 1.",
            "StartTime": "2020-04-12T15:02:16.179Z",
            "StatusCode": "InProgress",
```

```
            "Progress": 50,
            "Details": "{\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":
\"us-west-2c\"}"
        }
    ]
}
```

- For API details, see DetachInstances in *Amazon CLI Command Reference*.

`detach-load-balancer-target-groups`

The following code example shows how to use `detach-load-balancer-target-groups`.

Amazon CLI

To detach a load balancer target group from an Auto Scaling group

This example detaches the specified load balancer target group from the specified Auto Scaling group.

```
aws autoscaling detach-load-balancer-target-groups \
    --auto-scaling-group-name my-asg \
    --target-group-arns arn:aws:elasticloadbalancing:us-
west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067
```

This command produces no output

For more information, see Attaching a load balancer to your Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DetachLoadBalancerTargetGroups in *Amazon CLI Command Reference*.

`detach-load-balancers`

The following code example shows how to use `detach-load-balancers`.

Amazon CLI

To detach a Classic Load Balancer from an Auto Scaling group

This example detaches the specified Classic Load Balancer from the specified Auto Scaling group.

```
aws autoscaling detach-load-balancers \
    --load-balancer-names my-load-balancer \
    --auto-scaling-group-name my-asg
```

This command produces no output.

For more information, see Attaching a load balancer to your Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DetachLoadBalancers in *Amazon CLI Command Reference*.

`disable-metrics-collection`

The following code example shows how to use `disable-metrics-collection`.

Amazon CLI

To disable metrics collection for an Auto Scaling group

This example disables collection of the `GroupDesiredCapacity` metric for the specified Auto Scaling group.

```
aws autoscaling disable-metrics-collection \
    --auto-scaling-group-name my-asg \
    --metrics GroupDesiredCapacity
```

This command produces no output.

For more information, see Monitoring CloudWatch metrics for your Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see DisableMetricsCollection in *Amazon CLI Command Reference*.

`enable-metrics-collection`

The following code example shows how to use `enable-metrics-collection`.

Amazon CLI

Example 1: To enable metrics collection for an Auto Scaling group

This example enables data collection for the specified Auto Scaling group.

```
aws autoscaling enable-metrics-collection \
    --auto-scaling-group-name my-asg \
    --granularity "1Minute"
```

This command produces no output.

For more information, see Monitoring CloudWatch metrics for your Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To collect data for the specified metric for an Auto Scaling group

To collect data for a specific metric, use the `--metrics` option.

```
aws autoscaling enable-metrics-collection \
    --auto-scaling-group-name my-asg \
    --metrics GroupDesiredCapacity --granularity "1Minute"
```

This command produces no output.

For more information, see Monitoring CloudWatch metrics for your Auto Scaling groups and instances in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see EnableMetricsCollection in *Amazon CLI Command Reference*.

`enter-standby`

The following code example shows how to use `enter-standby`.

Amazon CLI

To move instances into standby mode

This example puts the specified instance into standby mode. This is useful for updating or troubleshooting an instance that is currently in service.

```
aws autoscaling enter-standby \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg \
```

```
    --should-decrement-desired-capacity
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "ffa056b4-6ed3-41ba-ae7c-249dfae6eba1",
            "AutoScalingGroupName": "my-asg",
            "Description": "Moving EC2 instance to Standby: i-061c63c5eb45f0416",
            "Cause": "At 2020-10-31T20:31:00Z instance i-061c63c5eb45f0416 was moved
 to standby in response to a user request, shrinking the capacity from 1 to 0.",
            "StartTime": "2020-10-31T20:31:00.949Z",
            "StatusCode": "InProgress",
            "Progress": 50,
            "Details": "{\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":
\"us-west-2c\"}"
        }
    ]
}
```

For more information, see Amazon EC2 Auto Scaling instance lifecycle in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see EnterStandby in *Amazon CLI Command Reference*.

`execute-policy`

The following code example shows how to use `execute-policy`.

Amazon CLI

To execute a scaling policy

This example executes the scaling policy named `my-step-scale-out-policy` for the specified Auto Scaling group.

```
aws autoscaling execute-policy \
    --auto-scaling-group-name my-asg \
    --policy-name  my-step-scale-out-policy \
    --metric-value 95 \
```

```
    --breach-threshold 80
```

This command produces no output.

For more information, see Step and simple scaling policies in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see ExecutePolicy in *Amazon CLI Command Reference*.

`exit-standby`

The following code example shows how to use `exit-standby`.

Amazon CLI

To move instances out of standby mode

This example moves the specified instance out of standby mode.

```
aws autoscaling exit-standby \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "142928e1-a2dc-453a-9b24-b85ad6735928",
            "AutoScalingGroupName": "my-asg",
            "Description": "Moving EC2 instance out of Standby:
 i-061c63c5eb45f0416",
            "Cause": "At 2020-10-31T20:32:50Z instance i-061c63c5eb45f0416 was moved
 out of standby in response to a user request, increasing the capacity from 0 to
 1.",
            "StartTime": "2020-10-31T20:32:50.222Z",
            "StatusCode": "PreInService",
            "Progress": 30,
            "Details": "{\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":
\"us-west-2c\"}"
        }
    ]
```

```
}
```

For more information, see Temporarily removing instances from your Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see ExitStandby in *Amazon CLI Command Reference*.

`put-lifecycle-hook`

The following code example shows how to use `put-lifecycle-hook`.

Amazon CLI

Example 1: To create a lifecycle hook

This example creates a lifecycle hook that will invoke on any newly launched instances, with a timeout of 4800 seconds. This is useful for keeping the instances in a wait state until the user data scripts have finished, or for invoking an Amazon Lambda function using EventBridge.

```
aws autoscaling put-lifecycle-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-hook-name my-launch-hook \
    --lifecycle-transition autoscaling:EC2_INSTANCE_LAUNCHING \
    --heartbeat-timeout 4800
```

This command produces no output. If a lifecycle hook with the same name already exists, it will be overwritten by the new lifecycle hook.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To send an Amazon SNS email message to notify you of instance state transitions

This example creates a lifecycle hook with the Amazon SNS topic and IAM role to use to receive notification at instance launch.

```
aws autoscaling put-lifecycle-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-hook-name my-launch-hook \
```

```
    --lifecycle-transition autoscaling:EC2_INSTANCE_LAUNCHING \
    --notification-target-arn arn:aws:sns:us-west-2:123456789012:my-sns-topic \
    --role-arn arn:aws:iam::123456789012:role/my-auto-scaling-role
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To publish a message to an Amazon SQS queue

This example creates a lifecycle hook that publishes a message with metadata to the specified Amazon SQS queue.

```
aws autoscaling put-lifecycle-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-hook-name my-launch-hook \
    --lifecycle-transition autoscaling:EC2_INSTANCE_LAUNCHING \
    --notification-target-arn arn:aws:sqs:us-west-2:123456789012:my-sqs-queue \
    --role-arn arn:aws:iam::123456789012:role/my-notification-role \
    --notification-metadata "SQS message metadata"
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see PutLifecycleHook in *Amazon CLI Command Reference*.

`put-notification-configuration`

The following code example shows how to use `put-notification-configuration`.

Amazon CLI

To add a notification

This example adds the specified notification to the specified Auto Scaling group.

```
aws autoscaling put-notification-configuration \
    --auto-scaling-group-name my-asg \
```

```
    --topic-arn arn:aws:sns:us-west-2:123456789012:my-sns-topic \
    --notification-type autoscaling:TEST_NOTIFICATION
```

This command produces no output.

For more information, see Getting Amazon SNS notifications when your Auto Scaling group scales in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see PutNotificationConfiguration in *Amazon CLI Command Reference*.

`put-scaling-policy`

The following code example shows how to use `put-scaling-policy`.

Amazon CLI

To add a target tracking scaling policy to an Auto Scaling group

The following `put-scaling-policy` example applies a target tracking scaling policy to the specified Auto Scaling group. The output contains the ARNs and names of the two CloudWatch alarms created on your behalf. If a scaling policy with the same name already exists, it will be overwritten by the new scaling policy.

```
aws autoscaling put-scaling-policy --auto-scaling-group-name my-asg \
  --policy-name alb1000-target-tracking-scaling-policy \
  --policy-type TargetTrackingScaling \
  --target-tracking-configuration file://config.json
```

Contents of `config.json`:

```
{
     "TargetValue": 1000.0,
     "PredefinedMetricSpecification": {
          "PredefinedMetricType": "ALBRequestCountPerTarget",
          "ResourceLabel": "app/my-alb/778d41231b141a0f/targetgroup/my-alb-target-
group/943f017f100becff"
     }
}
```

Output:

```
{
     "PolicyARN": "arn:aws:autoscaling:region:account-id:scalingPolicy:228f02c2-
c665-4bfd-aaac-8b04080bea3c:autoScalingGroupName/my-asg:policyName/alb1000-target-
tracking-scaling-policy",
     "Alarms": [
         {
             "AlarmARN": "arn:aws:cloudwatch:region:account-id:alarm:TargetTracking-
my-asg-AlarmHigh-fc0e4183-23ac-497e-9992-691c9980c38e",
             "AlarmName": "TargetTracking-my-asg-AlarmHigh-
fc0e4183-23ac-497e-9992-691c9980c38e"
         },
         {
             "AlarmARN": "arn:aws:cloudwatch:region:account-id:alarm:TargetTracking-
my-asg-AlarmLow-61a39305-ed0c-47af-bd9e-471a352ee1a2",
             "AlarmName": "TargetTracking-my-asg-AlarmLow-61a39305-ed0c-47af-
bd9e-471a352ee1a2"
         }
     ]
 }
```

For more examples, see Example scaling policies for the Amazon Command Line Interface (Amazon CLI) in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see PutScalingPolicy in *Amazon CLI Command Reference*.

`put-scheduled-update-group-action`

The following code example shows how to use `put-scheduled-update-group-action`.

Amazon CLI

Example 1: To add a scheduled action to an Auto Scaling group

This example adds the specified scheduled action to the specified Auto Scaling group.

```
aws autoscaling put-scheduled-update-group-action \
    --auto-scaling-group-name my-asg \
    --scheduled-action-name my-scheduled-action \
    --start-time "2023-05-12T08:00:00Z" \
    --min-size 2 \
    --max-size 6 \
    --desired-capacity 4
```

This command produces no output. If a scheduled action with the same name already exists, it will be overwritten by the new scheduled action.

For more examples, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To specify a recurring schedule

This example creates a scheduled action to scale on a recurring schedule that is scheduled to execute at 00:30 hours on the first of January, June, and December every year.

```
aws autoscaling put-scheduled-update-group-action \
    --auto-scaling-group-name my-asg \
    --scheduled-action-name my-recurring-action \
    --recurrence "30 0 1 1,6,12 *" \
    --min-size 2 \
    --max-size 6 \
    --desired-capacity 4
```

This command produces no output. If a scheduled action with the same name already exists, it will be overwritten by the new scheduled action.

For more examples, see Scheduled scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see PutScheduledUpdateGroupAction in *Amazon CLI Command Reference*.

`put-warm-pool`

The following code example shows how to use `put-warm-pool`.

Amazon CLI

To create a warm pool

The following example creates a warm pool for the specified Auto Scaling group.

```
aws autoscaling put-warm-pool \
    --auto-scaling-group-name my-asg \
    --min-size 2
```

This command produces no output. If a warm pool already exists, it will be updated.

For more information, see Warm pools for Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see PutWarmPool in *Amazon CLI Command Reference*.

`record-lifecycle-action-heartbeat`

The following code example shows how to use `record-lifecycle-action-heartbeat`.

Amazon CLI

To record a lifecycle action heartbeat

This example records a lifecycle action heartbeat to keep the instance in a pending state.

```
aws autoscaling record-lifecycle-action-heartbeat \
    --lifecycle-hook-name my-launch-hook \
    --auto-scaling-group-name my-asg \
    --lifecycle-action-token bcd2f1b8-9a78-44d3-8a7a-4dd07d7cf635
```

This command produces no output.

For more information, see Amazon EC2 Auto Scaling lifecycle hooks in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see RecordLifecycleActionHeartbeat in *Amazon CLI Command Reference*.

`resume-processes`

The following code example shows how to use `resume-processes`.

Amazon CLI

To resume suspended processes

This example resumes the specified suspended scaling process for the specified Auto Scaling group.

```
aws autoscaling resume-processes \
    --auto-scaling-group-name my-asg \
    --scaling-processes AlarmNotification
```

This command produces no output.

For more information, see Suspending and resuming scaling processes in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see ResumeProcesses in *Amazon CLI Command Reference*.

`rollback-instance-refresh`

The following code example shows how to use `rollback-instance-refresh`.

Amazon CLI

To roll back an instance refresh

The following `rollback-instance-refresh` example rolls back an in-progress instance refresh for the specified Auto Scaling group.

```
aws autoscaling rollback-instance-refresh \
    --auto-scaling-group-name my-asg
```

Output:

```
{
    "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see Undo changes with a rollback in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see RollbackInstanceRefresh in *Amazon CLI Command Reference*.

`set-desired-capacity`

The following code example shows how to use `set-desired-capacity`.

Amazon CLI

To set the desired capacity for an Auto Scaling group

This example sets the desired capacity for the specified Auto Scaling group.

```
aws autoscaling set-desired-capacity \
    --auto-scaling-group-name my-asg \
```

```
    --desired-capacity 2 \
    --honor-cooldown
```

This command returns to the prompt if successful.

- For API details, see SetDesiredCapacity in *Amazon CLI Command Reference*.

`set-instance-health`

The following code example shows how to use `set-instance-health`.

Amazon CLI

To set the health status of an instance

This example sets the health status of the specified instance to `Unhealthy`.

```
aws autoscaling set-instance-health \
    --instance-id i-061c63c5eb45f0416 \
    --health-status Unhealthy
```

This command produces no output.

- For API details, see SetInstanceHealth in *Amazon CLI Command Reference*.

`set-instance-protection`

The following code example shows how to use `set-instance-protection`.

Amazon CLI

Example 1: To enable the instance protection setting for an instance

This example enables instance protection for the specified instance.

```
aws autoscaling set-instance-protection \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg --protected-from-scale-in
```

This command produces no output.

Example 2: To disable the instance protection setting for an instance

This example disables instance protection for the specified instance.

```
aws autoscaling set-instance-protection \
    --instance-ids i-061c63c5eb45f0416 \
    --auto-scaling-group-name my-asg \
    --no-protected-from-scale-in
```

This command produces no output.

- For API details, see SetInstanceProtection in *Amazon CLI Command Reference*.

`start-instance-refresh`

The following code example shows how to use `start-instance-refresh`.

Amazon CLI

Example 1: To start an instance refresh using command line parameters

The following `start-instance-refresh` example starts an instance refresh using command line arguments. The optional `preferences` parameter specifies an `InstanceWarmup` of `60` seconds and a `MinHealthyPercentage` of `50` percent.

```
aws autoscaling start-instance-refresh \
    --auto-scaling-group-name my-asg \
    --preferences '{"InstanceWarmup": 60, "MinHealthyPercentage": 50}'
```

Output:

```
{
    "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see Start an instance refresh in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To start an instance refresh using a JSON file

The following `start-instance-refresh` example starts an instance refresh using a JSON file. You can specify the Auto Scaling group and define your desired configuration and preferences in a JSON file, as shown in the following example.

```
aws autoscaling start-instance-refresh \
    --cli-input-json file://config.json
```

Contents of `config.json`:

```
{
    "AutoScalingGroupName": "my-asg",
    "DesiredConfiguration": {
        "LaunchTemplate": {
            "LaunchTemplateId": "lt-068f72b729example",
            "Version": "$Default"
        }
    },
    "Preferences": {
        "InstanceWarmup": 60,
        "MinHealthyPercentage": 50,
        "AutoRollback": true,
        "ScaleInProtectedInstances": Ignore,
        "StandbyInstances": Terminate
    }
}
```

Output:

```
{
    "InstanceRefreshId": "08b91cf7-8fa6-48af-b6a6-d227f40f1b9b"
}
```

For more information, see Start an instance refresh in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see StartInstanceRefresh in *Amazon CLI Command Reference*.

`suspend-processes`

The following code example shows how to use `suspend-processes`.

Amazon CLI

To suspend Auto Scaling processes

This example suspends the specified scaling process for the specified Auto Scaling group.

```
aws autoscaling suspend-processes \
    --auto-scaling-group-name my-asg \
    --scaling-processes AlarmNotification
```

This command produces no output.

For more information, see Suspending and resuming scaling processes in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see SuspendProcesses in *Amazon CLI Command Reference*.

`terminate-instance-in-auto-scaling-group`

The following code example shows how to use `terminate-instance-in-auto-scaling-group`.

Amazon CLI

To terminate an instance in an Auto Scaling group

This example terminates the specified instance from the specified Auto Scaling group without updating the size of the group. Amazon EC2 Auto Scaling launches a replacement instance after the specified instance terminates.

```
aws autoscaling terminate-instance-in-auto-scaling-group \
    --instance-id i-061c63c5eb45f0416 \
    --no-should-decrement-desired-capacity
```

Output:

```
{
    "Activities": [
        {
            "ActivityId": "8c35d601-793c-400c-fcd0-f64a27530df7",
            "AutoScalingGroupName": "my-asg",
            "Description": "Terminating EC2 instance: i-061c63c5eb45f0416",
            "Cause": "",
            "StartTime": "2020-10-31T20:34:25.680Z",
            "StatusCode": "InProgress",
            "Progress": 0,
            "Details": "{\"Subnet ID\":\"subnet-6194ea3b\",\"Availability Zone\":
\"us-west-2c\"}"
```

```
        }
    ]
}
```

- For API details, see TerminateInstanceInAutoScalingGroup in *Amazon CLI Command Reference*.

`update-auto-scaling-group`

The following code example shows how to use `update-auto-scaling-group`.

Amazon CLI

Example 1: To update the size limits of an Auto Scaling group

This example updates the specified Auto Scaling group with a minimum size of 2 and a maximum size of 10.

```
aws autoscaling update-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --min-size 2 \
    --max-size 10
```

This command produces no output.

For more information, see Setting capacity limits for your Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

Example 2: To add Elastic Load Balancing health checks and specify which Availability Zones and subnets to use

This example updates the specified Auto Scaling group to add Elastic Load Balancing health checks. This command also updates the value of `--vpc-zone-identifier` with a list of subnet IDs in multiple Availability Zones.

```
aws autoscaling update-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --health-check-type ELB \
    --health-check-grace-period 600 \
    --vpc-zone-identifier "subnet-5ea0c127,subnet-6194ea3b,subnet-c934b782"
```

This command produces no output.

For more information, see Elastic Load Balancing and Amazon EC2 Auto Scaling in the *Amazon EC2 Auto Scaling User Guide*.

Example 3: To update the placement group and termination policy

This example updates the placement group and termination policy to use.

```
aws autoscaling update-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --placement-group my-placement-group \
    --termination-policies "OldestInstance"
```

This command produces no output.

For more information, see Auto Scaling groups in the *Amazon EC2 Auto Scaling User Guide*.

Example 4: To use the latest version of the launch template

This example updates the specified Auto Scaling group to use the latest version of the specified launch template.

```
aws autoscaling update-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-template LaunchTemplateId=lt-1234567890abcde12,Version='$Latest'
```

This command produces no output.

For more information, see Launch templates in the *Amazon EC2 Auto Scaling User Guide*.

Example 5: To use a specific version of the launch template

This example updates the specified Auto Scaling group to use a specific version of a launch template instead of the latest or default version.

```
aws autoscaling update-auto-scaling-group \
    --auto-scaling-group-name my-asg \
    --launch-template LaunchTemplateName=my-template-for-auto-scaling,Version='2'
```

This command produces no output.

For more information, see Launch templates in the *Amazon EC2 Auto Scaling User Guide*.

Example 6: To define a mixed instances policy and enable capacity rebalancing

This example updates the specified Auto Scaling group to use a mixed instances policy and enables capacity rebalancing. This structure lets you specify groups with Spot and On-Demand capacities and use different launch templates for different architectures.

```
aws autoscaling update-auto-scaling-group \
    --cli-input-json file://~/config.json
```

Contents of `config.json`:

```
{
    "AutoScalingGroupName": "my-asg",
    "CapacityRebalance": true,
    "MixedInstancesPolicy": {
        "LaunchTemplate": {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template-for-x86",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c6g.large",
                    "LaunchTemplateSpecification": {
                        "LaunchTemplateName": "my-launch-template-for-arm",
                        "Version": "$Latest"
                    }
                },
                {
                    "InstanceType": "c5.large"
                },
                {
                    "InstanceType": "c5a.large"
                }
            ]
        },
        "InstancesDistribution": {
            "OnDemandPercentageAboveBaseCapacity": 50,
            "SpotAllocationStrategy": "capacity-optimized"
        }
    }
}
```

This command produces no output.

For more information, see Auto Scaling groups with multiple instance types and purchase options in the *Amazon EC2 Auto Scaling User Guide*.

- For API details, see UpdateAutoScalingGroup in *Amazon CLI Command Reference*.

Auto Scaling Plans examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Auto Scaling Plans.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

- Actions

Actions

`create-scaling-plan`

The following code example shows how to use `create-scaling-plan`.

Amazon CLI

To create a scaling plan

The following `create-scaling-plan` example creates a scaling plan named `my-scaling-plan` using an already-created JSON file (named config.json). The structure of the scaling plan includes a scaling instruction for an Auto Scaling group named `my-asg`. It specifies the `TagFilters` property as the application source and enables predictive scaling and dynamic scaling.

```
aws autoscaling-plans create-scaling-plan \
    --scaling-plan-name my-scaling-plan \
    --cli-input-json file://~/config.json
```

Contents of `config.json` file:

```
{
    "ApplicationSource": {
        "TagFilters": [
            {
                "Key": "purpose",
                "Values": [
                    "my-application"
                ]
            }
        ]
    },
    "ScalingInstructions": [
        {
            "ServiceNamespace": "autoscaling",
            "ResourceId": "autoScalingGroup/my-asg",
            "ScalableDimension": "autoscaling:autoScalingGroup:DesiredCapacity",
            "ScheduledActionBufferTime": 300,
            "PredictiveScalingMaxCapacityBehavior":
 "SetForecastCapacityToMaxCapacity",
            "PredictiveScalingMode": "ForecastAndScale",
            "PredefinedLoadMetricSpecification": {
                "PredefinedLoadMetricType": "ASGTotalCPUUtilization"
            },
            "ScalingPolicyUpdateBehavior": "ReplaceExternalPolicies",
            "MinCapacity": 1,
            "MaxCapacity": 4,
            "TargetTrackingConfigurations": [
                {
                    "PredefinedScalingMetricSpecification": {
                        "PredefinedScalingMetricType": "ASGAverageCPUUtilization"
                    },
                    "TargetValue": 50
                }
            ]
        }
    ]
}
```

Output:

```
{
```

```
"ScalingPlanVersion": 1
}
```

For more information, see the Amazon Auto Scaling User Guide.

- For API details, see CreateScalingPlan in *Amazon CLI Command Reference*.

`delete-scaling-plan`

The following code example shows how to use `delete-scaling-plan`.

Amazon CLI

To delete a scaling plan

The following `delete-scaling-plan` example deletes the specified scaling plan.

```
aws autoscaling-plans delete-scaling-plan \
    --scaling-plan-name my-scaling-plan \
    --scaling-plan-version 1
```

This command produces no output.

For more information, see the Amazon Auto Scaling User Guide.

- For API details, see DeleteScalingPlan in *Amazon CLI Command Reference*.

`describe-scaling-plan-resources`

The following code example shows how to use `describe-scaling-plan-resources`.

Amazon CLI

To describe the scalable resources for a scaling plan

The following `describe-scaling-plan-resources` example displays details about the single scalable resource (an Auto Scaling group) that is associated with the specified scaling plan.

```
aws autoscaling-plans describe-scaling-plan-resources \
    --scaling-plan-name my-scaling-plan \
```

```
    --scaling-plan-version 1
```

Output:

```
{
    "ScalingPlanResources": [
        {
            "ScalableDimension": "autoscaling:autoScalingGroup:DesiredCapacity",
            "ScalingPlanVersion": 1,
            "ResourceId": "autoScalingGroup/my-asg",
            "ScalingStatusCode": "Active",
            "ScalingStatusMessage": "Target tracking scaling policies have been
 applied to the resource.",
            "ScalingPolicies": [
                {
                    "PolicyName": "AutoScaling-my-asg-b1ab65ae-4be3-4634-bd64-
c7471662b251",
                    "PolicyType": "TargetTrackingScaling",
                    "TargetTrackingConfiguration": {
                        "PredefinedScalingMetricSpecification": {
                            "PredefinedScalingMetricType":
 "ALBRequestCountPerTarget",
                            "ResourceLabel": "app/my-alb/f37c06a68c1748aa/
targetgroup/my-target-group/6d4ea56ca2d6a18d"
                        },
                        "TargetValue": 40.0
                    }
                }
            ],
            "ServiceNamespace": "autoscaling",
            "ScalingPlanName": "my-scaling-plan"
        }
    ]
}
```

For more information, see What Is Amazon Auto Scaling? in the *Amazon Auto Scaling User Guide*.

- For API details, see DescribeScalingPlanResources in *Amazon CLI Command Reference*.

`describe-scaling-plans`

The following code example shows how to use `describe-scaling-plans`.

Amazon CLI

To describe a scaling plan

The following `describe-scaling-plans` example displays the details of the specified scaling plan.

```
aws autoscaling-plans describe-scaling-plans \
    --scaling-plan-names scaling-plan-with-asg-and-ddb
```

Output:

```
{
    "ScalingPlans": [
        {
            "LastMutatingRequestTime": 1565388443.963,
            "ScalingPlanVersion": 1,
            "CreationTime": 1565388443.963,
            "ScalingInstructions": [
                {

    ]
}
```

For more information, see What Is Amazon Auto Scaling? in the *Amazon Auto Scaling User Guide*.

- For API details, see DescribeScalingPlans in *Amazon CLI Command Reference*.

`get-scaling-plan-resource-forecast-data`

The following code example shows how to use `get-scaling-plan-resource-forecast-data`.

Amazon CLI

To retrieve load forecast data

This example retrieves load forecast data for a scalable resource (an Auto Scaling group) that is associated with the specified scaling plan.

```
aws autoscaling-plans get-scaling-plan-resource-forecast-data \
    --scaling-plan-name my-scaling-plan \
    --scaling-plan-version 1 \
    --service-namespace "autoscaling" \
    --resource-id autoScalingGroup/my-asg \
    --scalable-dimension "autoscaling:autoScalingGroup:DesiredCapacity" \
    --forecast-data-type "LoadForecast" \
    --start-time "2019-08-30T00:00:00Z" \
    --end-time "2019-09-06T00:00:00Z"
```

Output:

```
{
    "Datapoints": [...]
}
```

For more information, see What Is Amazon Auto Scaling in the *Amazon Auto Scaling User Guide*.

- For API details, see GetScalingPlanResourceForecastData in *Amazon CLI Command Reference*.

`update-scaling-plan`

The following code example shows how to use `update-scaling-plan`.

Amazon CLI

To update a scaling plan

The following `update-scaling-plan` example modifies the scaling metric for an Auto Scaling group in the specified scaling plan.

```
aws autoscaling-plans update-scaling-plan \
    --scaling-plan-name my-scaling-plan \
    --scaling-plan-version 1 \
    --scaling-instructions
 '{"ScalableDimension":"autoscaling:autoScalingGroup:DesiredCapacity","ResourceId":"autoScal
my-asg","ServiceNamespace":"autoscaling","TargetTrackingConfigurations":
[{"PredefinedScalingMetricSpecification":
 {"PredefinedScalingMetricType":"ALBRequestCountPerTarget","ResourceLabel":"app/my-
alb/f37c06a68c1748aa/targetgroup/my-target-
group/6d4ea56ca2d6a18d"},"TargetValue":40.0}],"MinCapacity": 1,"MaxCapacity": 10}'
```

This command produces no output.

For more information, see What Is Amazon Auto Scaling? in the *Amazon Auto Scaling User Guide*.

- For API details, see UpdateScalingPlan in *Amazon CLI Command Reference*.

Amazon Backup examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Backup.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-backup-plan`

The following code example shows how to use `create-backup-plan`.

Amazon CLI

To create a backup plan

The following `create-backup-plan` example creates the specified backup plan with a 35 day retention.

```
aws backup create-backup-plan \
--backup-plan "{\"BackupPlanName\":\"Example-Backup-Plan\",\"Rules\":[{\"RuleName\":
\"DailyBackups\",\"ScheduleExpression\":\"cron(0 5 ? * * *)\",\"StartWindowMinutes
\":480,\"TargetBackupVaultName\":\"Default\",\"Lifecycle\":{\"DeleteAfterDays
\":35}}]}"
```

Output:

```
{
    "BackupPlanId": "1fa3895c-a7f5-484a-a371-2dd6a1a9f729",
    "BackupPlanArn": "arn:aws:backup:us-west-2:123456789012:backup-plan:1fa3895c-
a7f5-484a-a371-2dd6a1a9f729",
    "CreationDate": 1568928754.747,
    "VersionId": "ZjQ2ZTI5YWQtZDg5Yi00MzYzLWJmZTAtMDI1MzhlMDhjYjEz"
}
```

For more information, see Creating a Backup Plan in the *Amazon Backup Developer Guide*.

- For API details, see CreateBackupPlan in *Amazon CLI Command Reference*.

`create-backup-vault`

The following code example shows how to use `create-backup-vault`.

Amazon CLI

To create a backup vault

The following `create-backup-vault` example creates a backup vault with the specified name.

```
aws backup create-backup-vault
    --backup-vault-name sample-vault
```

This command produces no output. Output:

```
{
    "BackupVaultName": "sample-vault",
    "BackupVaultArn": "arn:aws:backup:us-west-2:123456789012:backup-vault:sample-
vault",
    "CreationDate": 1568928338.385
}
```

For more information, see Creating a Backup Vault in the *Amazon Backup Developer Guide*.

- For API details, see CreateBackupVault in *Amazon CLI Command Reference*.

`get-backup-plan-from-template`

The following code example shows how to use `get-backup-plan-from-template`.

Amazon CLI

To get an existing backup plan from a template

The following `get-backup-plan-from-template` example gets an existing backup plan from a template that specifies a daily backup with a 35 day retention.

```
aws backup get-backup-plan-from-template \
    --backup-plan-template-id "87c0c1ef-254d-4180-8fef-2e76a2c38aaa"
```

Output:

```
{
    "BackupPlanDocument": {
        "Rules": [
            {
                "RuleName": "DailyBackups",
                "ScheduleExpression": "cron(0 5 ? * * *)",
                "StartWindowMinutes": 480,
                "Lifecycle": {
                    "DeleteAfterDays": 35
                }
            }
        ]
    }
}
```

For more information, see Creating a Backup Plan in the *Amazon Backup Developer Guide*.

- For API details, see GetBackupPlanFromTemplate in *Amazon CLI Command Reference*.

`get-backup-plan`

The following code example shows how to use `get-backup-plan`.

Amazon CLI

To get the details of a backup plan

The following `get-backup-plan` example displays the details of the specified backup plan.

```
aws backup get-backup-plan \
    --backup-plan-id "fcbf5d8f-bd77-4f3a-9c97-f24fb3d373a5"
```

Output:

```
{
    "BackupPlan": {
        "BackupPlanName": "Example-Backup-Plan",
        "Rules": [
            {
                "RuleName": "DailyBackups",
                "TargetBackupVaultName": "Default",
                "ScheduleExpression": "cron(0 5 ? * * *)",
```

```
                "StartWindowMinutes": 480,
                "CompletionWindowMinutes": 10080,
                "Lifecycle": {
                    "DeleteAfterDays": 35
                },
                "RuleId": "70e0ccdc-e9df-4e83-82ad-c1e5a9471cc3"
            }
        ]
    },
    "BackupPlanId": "fcbf5d8f-bd77-4f3a-9c97-f24fb3d373a5",
    "BackupPlanArn": "arn:aws:backup:us-west-2:123456789012:backup-plan:fcbf5d8f-
bd77-4f3a-9c97-f24fb3d373a5",
    "VersionId": "NjQ2ZTZkODktMGVhNy00MmQ0LWE4YjktZTkwNTQ3OTkyYTcw",
    "CreationDate": 1568926091.57
}
```

For more information, see Creating a Backup Plan in the *Amazon Backup Developer Guide*.

- For API details, see GetBackupPlan in *Amazon CLI Command Reference*.

`list-backup-jobs`

The following code example shows how to use `list-backup-jobs`.

Amazon CLI

Example 1: To list all backup jobs

The following `list-backup-jobs` example returns metadata about your backup jobs in your Amazon account.

```
aws backup list-backup-jobs
```

Output:

```
{
    "BackupJobs": [
        {
            "BackupJobId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "BackupVaultName": "Default",
            "BackupVaultArn": "arn:aws:backup:us-west-2:123456789012:backup-
vault:Default",
```

```
            "ResourceArn": "arn:aws:ec2:us-west-2:123456789012:instance/
i-12345678901234567",
            "CreationDate": 1600721892.929,
            "State": "CREATED",
            "PercentDone": "0.0",
            "IamRoleArn": "arn:aws:iam::123456789012:role/service-role/
AWSBackupDefaultServiceRole",
            "StartBy": 1600725492.929,
            "ResourceType": "EC2"
        },
        {
            "BackupJobId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "BackupVaultName": "Default",
            "BackupVaultArn": "arn:aws:backup:us-west-2:123456789012:backup-
vault:Default",
            "RecoveryPointArn": "arn:aws:backup:us-west-2:123456789012:recovery-
point:a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
            "ResourceArn": "arn:aws:elasticfilesystem:us-west-2:123456789012:file-
system/fs-12345678",
            "CreationDate": 1600721724.77,
            "CompletionDate": 1600721744.488,
            "State": "COMPLETED",
            "PercentDone": "100.0",
            "BackupSizeInBytes": 71,
            "IamRoleArn": "arn:aws:iam::123456789012:role/service-role/
AWSBackupDefaultServiceRole",
            "StartBy": 1600725324.77,
            "ResourceType": "EFS"
        }
    ]
}
```

For more information, see Creating a Backup in the *Amazon Backup Developer Guide*.

Example 2: To list completed backup jobs

The following `list-backup-jobs` example returns metadata about your completed backup jobs in your Amazon account.

```
aws backup list-backup-jobs \
    --by-state COMPLETED
```

Output:

```
{
    "BackupJobs": [
        {
            "BackupJobId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "BackupVaultName": "Default",
            "BackupVaultArn": "arn:aws:backup:us-west-2:123456789012:backup-
vault:Default",
            "RecoveryPointArn": "arn:aws:backup:us-west-2:123456789012:recovery-
point:a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
            "ResourceArn": "arn:aws:elasticfilesystem:us-west-2:123456789012:file-
system/fs-12345678",
            "CreationDate": 1600721724.77,
            "CompletionDate": 1600721744.488,
            "State": "COMPLETED",
            "PercentDone": "100.0",
            "BackupSizeInBytes": 71,
            "IamRoleArn": "arn:aws:iam::123456789012:role/service-role/
AWSBackupDefaultServiceRole",
            "StartBy": 1600725324.77,
            "ResourceType": "EFS"
        }
    ]
}
```

For more information, see Creating a Backup in the *Amazon Backup Developer Guide*.

- For API details, see ListBackupJobs in *Amazon CLI Command Reference*.

Amazon Batch examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Batch.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`cancel-job`

The following code example shows how to use `cancel-job`.

Amazon CLI

To cancel a job

This example cancels a job with the specified job ID.

Command:

```
aws batch cancel-job --job-id bcf0b186-a532-4122-842e-2ccab8d54efb --
reason "Cancelling job."
```

- For API details, see CancelJob in *Amazon CLI Command Reference*.

`create-compute-environment`

The following code example shows how to use `create-compute-environment`.

Amazon CLI

To create a managed compute environment with On-Demand instances

This example creates a managed compute environment with specific C4 instance types that are launched on demand. The compute environment is called C4OnDemand.

Command:

```
aws batch create-compute-environment --cli-input-json file://<path_to_json_file>/
C4OnDemand.json
```

JSON file format:

```
{
  "computeEnvironmentName": "C4OnDemand",
  "type": "MANAGED",
  "state": "ENABLED",
  "computeResources": {
```

```
    "type": "EC2",
    "minvCpus": 0,
    "maxvCpus": 128,
    "desiredvCpus": 48,
    "instanceTypes": [
      "c4.large",
      "c4.xlarge",
      "c4.2xlarge",
      "c4.4xlarge",
      "c4.8xlarge"
    ],
    "subnets": [
      "subnet-220c0e0a",
      "subnet-1a95556d",
      "subnet-978f6dce"
    ],
    "securityGroupIds": [
      "sg-cf5093b2"
    ],
    "ec2KeyPair": "id_rsa",
    "instanceRole": "ecsInstanceRole",
    "tags": {
      "Name": "Batch Instance - C4OnDemand"
    }
  },
  "serviceRole": "arn:aws:iam::012345678910:role/AWSBatchServiceRole"
}
```

Output:

```
{
    "computeEnvironmentName": "C4OnDemand",
    "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-
environment/C4OnDemand"
}
```

To create a managed compute environment with Spot Instances

This example creates a managed compute environment with the M4 instance type that is launched when the Spot bid price is at or below 20% of the On-Demand price for the instance type. The compute environment is called M4Spot.

Command:

```
aws batch create-compute-environment --cli-input-json file://<path_to_json_file>/
M4Spot.json
```

JSON file format:

```
{
  "computeEnvironmentName": "M4Spot",
  "type": "MANAGED",
  "state": "ENABLED",
  "computeResources": {
    "type": "SPOT",
    "spotIamFleetRole": "arn:aws:iam::012345678910:role/aws-ec2-spot-fleet-role",
    "minvCpus": 0,
    "maxvCpus": 128,
    "desiredvCpus": 4,
    "instanceTypes": [
      "m4"
    ],
    "bidPercentage": 20,
    "subnets": [
      "subnet-220c0e0a",
      "subnet-1a95556d",
      "subnet-978f6dce"
    ],
    "securityGroupIds": [
      "sg-cf5093b2"
    ],
    "ec2KeyPair": "id_rsa",
    "instanceRole": "ecsInstanceRole",
    "tags": {
      "Name": "Batch Instance - M4Spot"
    }
  },
  "serviceRole": "arn:aws:iam::012345678910:role/AWSBatchServiceRole"
}
```

Output:

```
{
    "computeEnvironmentName": "M4Spot",
    "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-
environment/M4Spot"
```

```
}
```

- For API details, see CreateComputeEnvironment in *Amazon CLI Command Reference*.

`create-job-queue`

The following code example shows how to use `create-job-queue`.

Amazon CLI

To create a low priority job queue with a single compute environment

This example creates a job queue called LowPriority that uses the M4Spot compute environment.

Command:

```
aws batch create-job-queue --cli-input-json file://<path_to_json_file>/
LowPriority.json
```

JSON file format:

```
{
  "jobQueueName": "LowPriority",
  "state": "ENABLED",
  "priority": 10,
  "computeEnvironmentOrder": [
    {
      "order": 1,
      "computeEnvironment": "M4Spot"
    }
  ]
}
```

Output:

```
{
    "jobQueueArn": "arn:aws:batch:us-east-1:012345678910:job-queue/LowPriority",
    "jobQueueName": "LowPriority"
}
```

To create a high priority job queue with two compute environments

This example creates a job queue called HighPriority that uses the C4OnDemand compute environment with an order of 1 and the M4Spot compute environment with an order of 2. The scheduler will attempt to place jobs on the C4OnDemand compute environment first.

Command:

```
aws batch create-job-queue --cli-input-json file://<path_to_json_file>/
HighPriority.json
```

JSON file format:

```
{
  "jobQueueName": "HighPriority",
  "state": "ENABLED",
  "priority": 1,
  "computeEnvironmentOrder": [
    {
      "order": 1,
      "computeEnvironment": "C4OnDemand"
    },
    {
      "order": 2,
      "computeEnvironment": "M4Spot"
    }
  ]
}
```

Output:

```
{
    "jobQueueArn": "arn:aws:batch:us-east-1:012345678910:job-queue/HighPriority",
    "jobQueueName": "HighPriority"
}
```

- For API details, see CreateJobQueue in *Amazon CLI Command Reference*.

`delete-compute-environment`

The following code example shows how to use `delete-compute-environment`.

Amazon CLI

To delete a compute environment

This example deletes the P2OnDemand compute environment.

Command:

```
aws batch delete-compute-environment --compute-environment P2OnDemand
```

- For API details, see DeleteComputeEnvironment in *Amazon CLI Command Reference*.

`delete-job-queue`

The following code example shows how to use `delete-job-queue`.

Amazon CLI

To delete a job queue

This example deletes the GPGPU job queue.

Command:

```
aws batch delete-job-queue --job-queue GPGPU
```

- For API details, see DeleteJobQueue in *Amazon CLI Command Reference*.

`deregister-job-definition`

The following code example shows how to use `deregister-job-definition`.

Amazon CLI

To deregister a job definition

This example deregisters a job definition called sleep10.

Command:

```
aws batch deregister-job-definition --job-definition sleep10
```

- For API details, see DeregisterJobDefinition in *Amazon CLI Command Reference*.

describe-compute-environments

The following code example shows how to use `describe-compute-environments`.

Amazon CLI

To describe a compute environment

This example describes the P2OnDemand compute environment.

Command:

```
aws batch describe-compute-environments --compute-environments P2OnDemand
```

Output:

```
{
    "computeEnvironments": [
        {
            "status": "VALID",
            "serviceRole": "arn:aws:iam::012345678910:role/AWSBatchServiceRole",
            "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-
environment/P2OnDemand",
            "computeResources": {
                "subnets": [
                    "subnet-220c0e0a",
                    "subnet-1a95556d",
                    "subnet-978f6dce"
                ],
                "tags": {
                    "Name": "Batch Instance - P2OnDemand"
                },
                "desiredvCpus": 48,
                "minvCpus": 0,
                "instanceTypes": [
                    "p2"
                ],
                "securityGroupIds": [
                    "sg-cf5093b2"
                ],
                "instanceRole": "ecsInstanceRole",
                "maxvCpus": 128,
                "type": "EC2",
                "ec2KeyPair": "id_rsa"
```

```
            },
            "statusReason": "ComputeEnvironment Healthy",
            "ecsClusterArn": "arn:aws:ecs:us-east-1:012345678910:cluster/
P2OnDemand_Batch_2c06f29d-d1fe-3a49-879d-42394c86effc",
            "state": "ENABLED",
            "computeEnvironmentName": "P2OnDemand",
            "type": "MANAGED"
        }
    ]
}
```

- For API details, see DescribeComputeEnvironments in *Amazon CLI Command Reference*.

`describe-job-definitions`

The following code example shows how to use `describe-job-definitions`.

Amazon CLI

To describe active job definitions

This example describes all of your active job definitions.

Command:

```
aws batch describe-job-definitions --status ACTIVE
```

Output:

```
{
    "jobDefinitions": [
        {
            "status": "ACTIVE",
            "jobDefinitionArn": "arn:aws:batch:us-east-1:012345678910:job-
definition/sleep60:1",
            "containerProperties": {
                "mountPoints": [],
                "parameters": {},
                "image": "busybox",
                "environment": {},
                "vcpus": 1,
                "command": [
                    "sleep",
```

```
                    "60"
                ],
                "volumes": [],
                "memory": 128,
                "ulimits": []
            },
            "type": "container",
            "jobDefinitionName": "sleep60",
            "revision": 1
        }
    ]
}
```

- For API details, see DescribeJobDefinitions in *Amazon CLI Command Reference*.

`describe-job-queues`

The following code example shows how to use `describe-job-queues`.

Amazon CLI

To describe a job queue

This example describes the HighPriority job queue.

Command:

```
aws batch describe-job-queues --job-queues HighPriority
```

Output:

```
{
    "jobQueues": [
        {
            "status": "VALID",
            "jobQueueArn": "arn:aws:batch:us-east-1:012345678910:job-queue/
HighPriority",
            "computeEnvironmentOrder": [
                {
                    "computeEnvironment": "arn:aws:batch:us-
east-1:012345678910:compute-environment/C4OnDemand",
                    "order": 1
                }
```

```
            ],
            "statusReason": "JobQueue Healthy",
            "priority": 1,
            "state": "ENABLED",
            "jobQueueName": "HighPriority"
        }
    ]
}
```

- For API details, see DescribeJobQueues in *Amazon CLI Command Reference*.

`describe-jobs`

The following code example shows how to use `describe-jobs`.

Amazon CLI

To describe a job

The following `describe-jobs` example describes a job with the specified job ID.

```
aws batch describe-jobs \
    --jobs bcf0b186-a532-4122-842e-2ccab8d54efb
```

Output:

```
{
    "jobs": [
        {
            "status": "SUBMITTED",
            "container": {
                "mountPoints": [],
                "image": "busybox",
                "environment": [],
                "vcpus": 1,
                "command": [
                    "sleep",
                    "60"
                ],
                "volumes": [],
                "memory": 128,
                "ulimits": []
```

```
            },
            "parameters": {},
            "jobDefinition": "arn:aws:batch:us-east-1:012345678910:job-definition/
sleep60:1",
            "jobQueue": "arn:aws:batch:us-east-1:012345678910:job-queue/
HighPriority",
            "jobId": "bcf0b186-a532-4122-842e-2ccab8d54efb",
            "dependsOn": [],
            "jobName": "example",
            "createdAt": 1480483387803
        }
    ]
}
```

- For API details, see DescribeJobs in *Amazon CLI Command Reference*.

`list-jobs`

The following code example shows how to use `list-jobs`.

Amazon CLI

To list running jobs

This example lists the running jobs in the HighPriority job queue.

Command:

```
aws batch list-jobs --job-queue HighPriority
```

Output:

```
{
    "jobSummaryList": [
        {
            "jobName": "example",
            "jobId": "e66ff5fd-a1ff-4640-b1a2-0b0a142f49bb"
        }
    ]
}
```

To list submitted jobs

This example lists jobs in the HighPriority job queue that are in the SUBMITTED job status.

Command:

```
aws batch list-jobs --job-queue HighPriority --job-status SUBMITTED
```

Output:

```
{
    "jobSummaryList": [
        {
            "jobName": "example",
            "jobId": "68f0c163-fbd4-44e6-9fd1-25b14a434786"
        }
    ]
}
```

- For API details, see ListJobs in *Amazon CLI Command Reference*.

`register-job-definition`

The following code example shows how to use `register-job-definition`.

Amazon CLI

To register a job definition

This example registers a job definition for a simple container job.

Command:

```
aws batch register-job-definition --job-definition-name sleep30 --type container --
container-properties '{ "image": "busybox", "vcpus": 1, "memory": 128, "command":
 [ "sleep", "30"]}'
```

Output:

```
{
    "jobDefinitionArn": "arn:aws:batch:us-east-1:012345678910:job-definition/
sleep30:1",
    "jobDefinitionName": "sleep30",
    "revision": 1
```

```
}
```

- For API details, see RegisterJobDefinition in *Amazon CLI Command Reference*.

`submit-job`

The following code example shows how to use `submit-job`.

Amazon CLI

To submit a job

This example submits a simple container job called example to the HighPriority job queue.

Command:

```
aws batch submit-job --job-name example --job-queue HighPriority  --job-
definition sleep60
```

Output:

```
{
    "jobName": "example",
    "jobId": "876da822-4198-45f2-a252-6cea32512ea8"
}
```

- For API details, see SubmitJob in *Amazon CLI Command Reference*.

`terminate-job`

The following code example shows how to use `terminate-job`.

Amazon CLI

To terminate a job

This example terminates a job with the specified job ID.

Command:

```
aws batch terminate-job --job-id 61e743ed-35e4-48da-b2de-5c8333821c84 --
reason "Terminating job."
```

- For API details, see TerminateJob in *Amazon CLI Command Reference*.

`update-compute-environment`

The following code example shows how to use `update-compute-environment`.

Amazon CLI

To update a compute environment

This example disables the P2OnDemand compute environment so it can be deleted.

Command:

```
aws batch update-compute-environment --compute-environment P2OnDemand --
state DISABLED
```

Output:

```
{
    "computeEnvironmentName": "P2OnDemand",
    "computeEnvironmentArn": "arn:aws:batch:us-east-1:012345678910:compute-
environment/P2OnDemand"
}
```

- For API details, see UpdateComputeEnvironment in *Amazon CLI Command Reference*.

`update-job-queue`

The following code example shows how to use `update-job-queue`.

Amazon CLI

To update a job queue

This example disables a job queue so that it can be deleted.

Command:

```
aws batch update-job-queue --job-queue GPGPU --state DISABLED
```

Output:

```
{
    "jobQueueArn": "arn:aws:batch:us-east-1:012345678910:job-queue/GPGPU",
    "jobQueueName": "GPGPU"
}
```

- For API details, see UpdateJobQueue in *Amazon CLI Command Reference*.

Amazon Budgets examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Budgets.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-budget`

The following code example shows how to use `create-budget`.

Amazon CLI

To create a Cost and Usage budget

The following `create-budget` command creates a Cost and Usage budget.

```
aws budgets create-budget \
    --account-id 111122223333 \
    --budget file://budget.json \
    --notifications-with-subscribers file://notifications-with-subscribers.json
```

Contents of `budget.json`:

```
{
    "BudgetLimit": {
        "Amount": "100",
        "Unit": "USD"
    },
    "BudgetName": "Example Tag Budget",
    "BudgetType": "COST",
    "CostFilters": {
        "TagKeyValue": [
            "user:Key$value1",
            "user:Key$value2"
        ]
    },
    "CostTypes": {
        "IncludeCredit": true,
        "IncludeDiscount": true,
        "IncludeOtherSubscription": true,
        "IncludeRecurring": true,
        "IncludeRefund": true,
        "IncludeSubscription": true,
        "IncludeSupport": true,
        "IncludeTax": true,
        "IncludeUpfront": true,
        "UseBlended": false
    },
    "TimePeriod": {
        "Start": 1477958399,
        "End": 3706473600
    },
    "TimeUnit": "MONTHLY"
}
```

Contents of `notifications-with-subscribers.json`:

```
[
    {
        "Notification": {
            "ComparisonOperator": "GREATER_THAN",
            "NotificationType": "ACTUAL",
            "Threshold": 80,
            "ThresholdType": "PERCENTAGE"
        },
        "Subscribers": [
```

```
            {
                "Address": "example@example.com",
                "SubscriptionType": "EMAIL"
            }
        ]
    }
]
```

- For API details, see CreateBudget in *Amazon CLI Command Reference*.

`create-notification`

The following code example shows how to use `create-notification`.

Amazon CLI

To create a notification for the specified Cost and Usage budget

This example creates a notification for the specified Cost and Usage budget.

Command:

```
aws budgets create-notification --account-id 111122223333 --budget-name "Example
 Budget" --
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
 --subscriber SubscriptionType=EMAIL,Address=example@example.com
```

- For API details, see CreateNotification in *Amazon CLI Command Reference*.

`create-subscriber`

The following code example shows how to use `create-subscriber`.

Amazon CLI

To create a subscriber for a notification associated with a Cost and Usage budget

This example creates a subscriber for the specified notification.

Command:

```
aws budgets create-subscriber --account-id 111122223333 --budget-name "Example
 Budget" --
```

```
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
 --subscriber SubscriptionType=EMAIL,Address=example@example.com
```

- For API details, see CreateSubscriber in *Amazon CLI Command Reference*.

`delete-budget`

The following code example shows how to use `delete-budget`.

Amazon CLI

To delete a Cost and Usage budget

This example deletes the specified Cost and Usage budget.

Command:

```
aws budgets delete-budget --account-id 111122223333 --budget-name "Example Budget"
```

- For API details, see DeleteBudget in *Amazon CLI Command Reference*.

`delete-notification`

The following code example shows how to use `delete-notification`.

Amazon CLI

To delete a notification from a budget

This example deletes the specified notification from the specified budget.

Command:

```
aws budgets delete-notification --account-id 111122223333 --budget-name "Example
 Budget" --
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
```

- For API details, see DeleteNotification in *Amazon CLI Command Reference*.

`delete-subscriber`

The following code example shows how to use `delete-subscriber`.

Amazon CLI

To delete a subscriber from a notification

This example deletes the specified subscriber from the specified notification.

Command:

```
aws budgets delete-subscriber --account-id 111122223333 --budget-name "Example
 Budget" --
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
 --subscriber SubscriptionType=EMAIL,Address=example@example.com
```

- For API details, see DeleteSubscriber in *Amazon CLI Command Reference*.

`describe-budget`

The following code example shows how to use `describe-budget`.

Amazon CLI

To retrieve a budget associated with an account

This example retrieves the specified Cost and Usage budget.

Command:

```
aws budgets describe-budget --account-id 111122223333 --budget-name "Example Budget"
```

Output:

```
{
   "Budget": {
       "CalculatedSpend": {
           "ForecastedSpend": {
               "Amount": "2641.548000000000229192664846777915954589843 75",
               "Unit": "USD"
           },
           "ActualSpend": {
               "Amount": "604.456000000000017280399333685636520385742 1875",
               "Unit": "USD"
```

```
            }
        },
        "BudgetType": "COST",
        "BudgetLimit": {
            "Amount": "100",
            "Unit": "USD"
        },
        "BudgetName": "Example Budget",
        "CostTypes": {
            "IncludeOtherSubscription": true,
            "IncludeUpfront": true,
            "IncludeRefund": true,
            "UseBlended": false,
            "IncludeDiscount": true,
            "UseAmortized": false,
            "IncludeTax": true,
            "IncludeCredit": true,
            "IncludeSupport": true,
            "IncludeRecurring": true,
            "IncludeSubscription": true
        },
        "TimeUnit": "MONTHLY",
        "TimePeriod": {
            "Start": 1477958399.0,
            "End": 3706473600.0
        },
        "CostFilters": {
            "AZ": [
                "us-east-1"
            ]
        }
    }
}
```

- For API details, see [DescribeBudget](#) in *Amazon CLI Command Reference*.

`describe-budgets`

The following code example shows how to use `describe-budgets`.

Amazon CLI

To retrieve the budgets associated with an account

This example retrieves the Cost and Usage budgets for an account.

Command:

```
aws budgets describe-budgets --account-id 111122223333 --max-results 20
```

Output:

```
{
   "Budgets": [
       {
           "CalculatedSpend": {
               "ForecastedSpend": {
                   "Amount": "2641.548000000000229192664846777915954589843 75",
                   "Unit": "USD"
               },
               "ActualSpend": {
                   "Amount": "604.456000000000017280399333685636520385742 1875",
                   "Unit": "USD"
               }
           },
           "BudgetType": "COST",
           "BudgetLimit": {
               "Amount": "100",
               "Unit": "USD"
           },
           "BudgetName": "Example Budget",
           "CostTypes": {
               "IncludeOtherSubscription": true,
               "IncludeUpfront": true,
               "IncludeRefund": true,
               "UseBlended": false,
               "IncludeDiscount": true,
               "UseAmortized": false,
               "IncludeTax": true,
               "IncludeCredit": true,
               "IncludeSupport": true,
               "IncludeRecurring": true,
               "IncludeSubscription": true
           },
           "TimeUnit": "MONTHLY",
           "TimePeriod": {
               "Start": 1477958399.0,
```

```
                "End": 3706473600.0
            },
            "CostFilters": {
                "AZ": [
                    "us-east-1"
                ]
            }
        }
    ]
}
```

- For API details, see DescribeBudgets in *Amazon CLI Command Reference*.

`describe-notifications-for-budget`

The following code example shows how to use `describe-notifications-for-budget`.

Amazon CLI

To retrieve the notifications for a budget

This example retrieves the notifications for a Cost and Usage budget.

Command:

```
aws budgets describe-notifications-for-budget --account-id 111122223333 --budget-
name "Example Budget" --max-results 5
```

Output:

```
{
    "Notifications": [
        {
            "Threshold": 80.0,
            "ComparisonOperator": "GREATER_THAN",
            "NotificationType": "ACTUAL"
        }
    ]
}
```

- For API details, see DescribeNotificationsForBudget in *Amazon CLI Command Reference*.

`describe-subscribers-for-notification`

The following code example shows how to use `describe-subscribers-for-notification`.

Amazon CLI

To retrieve the subscribers for a budget notification

This example retrieves the subscribers for a Cost and Usage budget notification.

Command:

```
aws budgets describe-subscribers-for-notification --
account-id 111122223333 --budget-name "Example Budget" --
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
 --max-results 5
```

Output:

```
{
   "Subscribers": [
       {
           "SubscriptionType": "EMAIL",
           "Address": "example2@example.com"
       },
       {
           "SubscriptionType": "EMAIL",
           "Address": "example@example.com"
       }
   ]
}
```

- For API details, see DescribeSubscribersForNotification in *Amazon CLI Command Reference*.

`update-budget`

The following code example shows how to use `update-budget`.

Amazon CLI

To replace a budget for a Cost and Usage budget

This example replaces a Cost and Usage budget with a new budget.

Command:

```
aws budgets update-budget --account-id 111122223333 --new-budget file://new-budget.json
```

new-budget.json:

```
{
    "BudgetLimit": {
       "Amount": "100",
       "Unit": "USD"
    },
    "BudgetName": "Example Budget",
    "BudgetType": "COST",
    "CostFilters": {
       "AZ" : [ "us-east-1" ]
    },
    "CostTypes": {
       "IncludeCredit": false,
       "IncludeDiscount": true,
       "IncludeOtherSubscription": true,
       "IncludeRecurring": true,
       "IncludeRefund": true,
       "IncludeSubscription": true,
       "IncludeSupport": true,
       "IncludeTax": true,
       "IncludeUpfront": true,
       "UseBlended": false,
       "UseAmortized": true
    },
    "TimePeriod": {
       "Start": 1477958399,
       "End": 3706473600
    },
    "TimeUnit": "MONTHLY"
 }
```

- For API details, see UpdateBudget in *Amazon CLI Command Reference*.

`update-notification`

The following code example shows how to use `update-notification`.

Amazon CLI

To replace a notification for a Cost and Usage budget

This example replaces an 80% notification for a Cost and Usage budget with a 90% notification.

Command:

```
aws budgets update-notification --account-id 111122223333 --budget-name "Example
 Budget" --old-notification
  NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdType=PERCENT
 --new-notification
  NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=90,ThresholdType=PERCENT
```

- For API details, see UpdateNotification in *Amazon CLI Command Reference*.

`update-subscriber`

The following code example shows how to use `update-subscriber`.

Amazon CLI

To replace a subscriber for a Cost and Usage budget

This example replaces the subscriber for a Cost and Usage budget.

Command:

```
aws budgets update-subscriber --account-id 111122223333 --budget-name "Example
 Budget" --
notification NotificationType=ACTUAL,ComparisonOperator=GREATER_THAN,Threshold=80,ThresholdT
 --old-subscriber SubscriptionType=EMAIL,Address=example@example.com --new-
subscriber SubscriptionType=EMAIL,Address=example2@example.com
```

- For API details, see UpdateSubscriber in *Amazon CLI Command Reference*.

Amazon Chime examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Chime.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-phone-number-with-user`

The following code example shows how to use `associate-phone-number-with-user`.

Amazon CLI

To associate a phone number with a user

The following `associate-phone-number-with-user` example associates the specified phone number with a user.

```
aws chime associate-phone-number-with-user \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --user-id 1ab2345c-67de-8901-f23g-45h678901j2k \
    --e164-phone-number "+12065550100"
```

This command produces no output.

For more information, see Managing User Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see AssociatePhoneNumberWithUser in *Amazon CLI Command Reference*.

`associate-signin-delegate-groups-with-account`

The following code example shows how to use `associate-signin-delegate-groups-with-account`.

Amazon CLI

To associate sign-in delegate groups

The following `associate-signin-delegate-groups-with-account` example associates the specified sign-in delegate group with the specified Amazon Chime account.

```
aws chime associate-signin-delegate-groups-with-account \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --signin-delegate-groups GroupName=my_users
```

This command produces no output.

For more information, see Managing User Access and Permissions in the *Amazon Chime Administration Guide*.

- For API details, see AssociateSigninDelegateGroupsWithAccount in *Amazon CLI Command Reference*.

`batch-create-room-membership`

The following code example shows how to use `batch-create-room-membership`.

Amazon CLI

To create multiple room memberships

The following `batch-create-room-membership` example adds multiple users to a chat room as chat room members. It also assigns administrator and member roles to the users.

```
aws chime batch-create-room-membership \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \
    --membership-item-list "MemberId=1ab2345c-67de-8901-
f23g-45h678901j2k,Role=Administrator" "MemberId=2ab2345c-67de-8901-
f23g-45h678901j2k,Role=Member"
```

Output:

```
{
    "ResponseMetadata": {
        "RequestId": "169ba401-d886-475f-8b3f-e01eac6fadfb",
        "HTTPStatusCode": 201,
        "HTTPHeaders": {
            "x-amzn-requestid": "169ba401-d886-475f-8b3f-e01eac6fadfb",
```

```
            "content-type": "application/json",
            "content-length": "13",
            "date": "Mon, 02 Dec 2019 22:46:58 GMT",
            "connection": "keep-alive"
        },
        "RetryAttempts": 0
    },
    "Errors": []
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see BatchCreateRoomMembership in *Amazon CLI Command Reference*.

`batch-delete-phone-number`

The following code example shows how to use `batch-delete-phone-number`.

Amazon CLI

To delete multiple phone numbers

The following `batch-delete-phone-number` example deletes all of the specified phone numbers.

```
aws chime batch-delete-phone-number \
    --phone-number-ids "%2B12065550100" "%2B12065550101"
```

This command produces no output. Output:

```
{
    "PhoneNumberErrors": []
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see BatchDeletePhoneNumber in *Amazon CLI Command Reference*.

`batch-suspend-user`

The following code example shows how to use `batch-suspend-user`.

Amazon CLI

To suspend multiple users

The following `batch-suspend-user` example suspends the listed users from the specified Amazon Chime account.

```
aws chime batch-suspend-user \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --user-id-list "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE" "a1b2c3d4-5678-90ab-
cdef-33333EXAMPLE" "a1b2c3d4-5678-90ab-cdef-44444EXAMPLE"
```

Output:

```
{
    "UserErrors": []
}
```

- For API details, see BatchSuspendUser in *Amazon CLI Command Reference*.

`batch-unsuspend-user`

The following code example shows how to use `batch-unsuspend-user`.

Amazon CLI

To unsuspend multiple users

The following `batch-unsuspend-user` example removes any previous suspension for the listed users on the specified Amazon Chime account.

```
aws chime batch-unsuspend-user \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --user-id-list "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE" "a1b2c3d4-5678-90ab-
cdef-33333EXAMPLE" "a1b2c3d4-5678-90ab-cdef-44444EXAMPLE"
```

Output:

```
{
    "UserErrors": []
}
```

- For API details, see BatchUnsuspendUser in *Amazon CLI Command Reference*.

`batch-update-phone-number`

The following code example shows how to use `batch-update-phone-number`.

Amazon CLI

To update several phone number product types at the same time

The following `batch-update-phone-number` example updates the product types for all of the specified phone numbers.

```
aws chime batch-update-phone-number \
    --update-phone-number-request-items PhoneNumberId=
%2B12065550100,ProductType=BusinessCalling PhoneNumberId=
%2B12065550101,ProductType=BusinessCalling
```

Output:

```
{
    "PhoneNumberErrors": []
}
```

To update several phone number calling names at the same time

The following `batch-update-phone-number` example updates the calling names for all of the specified phone numbers.

```
aws chime batch-update-phone-number \
    --update-phone-number-request-items PhoneNumberId=
%2B14013143874,CallingName=phonenumber1 PhoneNumberId=
%2B14013144061,CallingName=phonenumber2
```

Output:

```
{
    "PhoneNumberErrors": []
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see BatchUpdatePhoneNumber in *Amazon CLI Command Reference*.

`batch-update-user`

The following code example shows how to use `batch-update-user`.

Amazon CLI

To update multiple users in a single command

The following `batch-update-user` example updates the `LicenseType` for each of the listed users in the specified Amazon Chime account.

```
aws chime batch-update-user \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
    --update-user-request-items "UserId=a1b2c3d4-5678-90ab-
cdef-22222EXAMPLE,LicenseType=Basic" "UserId=a1b2c3d4-5678-90ab-
cdef-33333EXAMPLE,LicenseType=Basic"
```

Output:

```
{
    "UserErrors": []
}
```

- For API details, see BatchUpdateUser in *Amazon CLI Command Reference*.

`create-account`

The following code example shows how to use `create-account`.

Amazon CLI

To create an account

The following `create-account` example creates an Amazon Chime account under the administrator's Amazon account.

```
aws chime create-account \
    --name MyChimeAccount
```

Output:

```
{
    "Account": {
        "AwsAccountId": "111122223333",
        "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "Name": "MyChimeAccount",
        "AccountType": "Team",
        "CreatedTimestamp": "2019-01-04T17:11:22.003Z",
        "DefaultLicense": "Pro",
        "SupportedLicenses": [
            "Basic",
            "Pro"
        ],
        "SigninDelegateGroups": [
            {
                "GroupName": "myGroup"
            },
        ]
    }
}
```

For more information, see Getting Started in the *Amazon Chime Administration Guide*.

- For API details, see CreateAccount in *Amazon CLI Command Reference*.

`create-bot`

The following code example shows how to use `create-bot`.

Amazon CLI

To create an Amazon Chime bot

The following `create-bot` example creates a bot for the specified Amazon Chime Enterprise account.

```
aws chime create-bot \
```

```
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --display-name "myBot" \
    --domain "example.com"
```

Output:

```
{
    "Bot": {
        "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "DisplayName": "myBot (Bot)",
        "BotType": "ChatBot",
        "Disabled": false,
        "CreatedTimestamp": "2019-09-09T18:05:56.749Z",
        "UpdatedTimestamp": "2019-09-09T18:05:56.749Z",
        "BotEmail": "myBot-chimebot@example.com",
        "SecurityToken": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY"
    }
}
```

For more information, see Integrate a Chat Bot with Amazon Chime in the *Amazon Chime Developer Guide*.

- For API details, see CreateBot in *Amazon CLI Command Reference*.

`create-phone-number-order`

The following code example shows how to use `create-phone-number-order`.

Amazon CLI

To create a phone number order

The following `create-phone-number-order` example creates a phone number order for the specified phone numbers.

```
aws chime create-phone-number-order \
    --product-type VoiceConnector \
    --e164-phone-numbers "+12065550100" "+12065550101" "+12065550102"
```

Output:

```
{
    "PhoneNumberOrder": {
        "PhoneNumberOrderId": "abc12345-de67-89f0-123g-h45i678j9012",
        "ProductType": "VoiceConnector",
        "Status": "Processing",
        "OrderedPhoneNumbers": [
            {
                "E164PhoneNumber": "+12065550100",
                "Status": "Processing"
            },
            {
               "E164PhoneNumber": "+12065550101",
               "Status": "Processing"
            },
            {
              "E164PhoneNumber": "+12065550102",
              "Status": "Processing"
            }
        ],
        "CreatedTimestamp": "2019-08-09T21:35:21.427Z",
        "UpdatedTimestamp": "2019-08-09T21:35:22.408Z"
    }
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see CreatePhoneNumberOrder in *Amazon CLI Command Reference*.

`create-room-membership`

The following code example shows how to use `create-room-membership`.

Amazon CLI

To create a room membership

The following `create-room-membership` example adds the specified user to the chat room as a chat room member.

```
aws chime create-room-membership \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
```

```
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \
    --member-id 1ab2345c-67de-8901-f23g-45h678901j2k
```

Output:

```
{
    "RoomMembership": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Member": {
            "MemberId": "1ab2345c-67de-8901-f23g-45h678901j2k",
            "MemberType": "User",
            "Email": "janed@example.com",
            "FullName": "Jane Doe",
            "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45"
        },
        "Role": "Member",
        "InvitedBy": "arn:aws:iam::111122223333:user/alejandro",
        "UpdatedTimestamp": "2019-12-02T22:36:41.969Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see CreateRoomMembership in *Amazon CLI Command Reference*.

`create-room`

The following code example shows how to use `create-room`.

Amazon CLI

To create a chat room

The following `create-room` example creates a chat room for the specified Amazon Chime account.

```
aws chime create-room \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --name chatRoom
```

Output:

```
{
    "Room": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Name": "chatRoom",
        "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",
        "CreatedBy": "arn:aws:iam::111122223333:user/alejandro",
        "CreatedTimestamp": "2019-12-02T22:29:31.549Z",
        "UpdatedTimestamp": "2019-12-02T22:29:31.549Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see CreateRoom in *Amazon CLI Command Reference*.

`create-user`

The following code example shows how to use `create-user`.

Amazon CLI

To create a user profile for a shared device

The following `create-user` example creates a shared device profile for the specified email address.

```
aws chime create-user \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --email roomdevice@example.com \
    --user-type SharedDevice
```

Output:

```
{
    "User": {
        "UserId": "1ab2345c-67de-8901-f23g-45h678901j2k",
        "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",
        "PrimaryEmail": "roomdevice@example.com",
        "DisplayName": "Room Device",
        "LicenseType": "Pro",
        "UserType": "SharedDevice",
        "UserRegistrationStatus": "Registered",
```

```
        "RegisteredOn": "2020-01-15T22:38:09.806Z",
        "AlexaForBusinessMetadata": {
            "IsAlexaForBusinessEnabled": false
        }
    }
}
```

For more information, see Preparing for Setup in the *Amazon Chime Administration Guide*.

- For API details, see CreateUser in *Amazon CLI Command Reference*.

`delete-account`

The following code example shows how to use `delete-account`.

Amazon CLI

To delete an account

The following `delete-account` example deletes the specified account.

```
aws chime delete-account --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
```

This command produces no output.

For more information, see Deleting Your Account in the *Amazon Chime Administration Guide*.

- For API details, see DeleteAccount in *Amazon CLI Command Reference*.

`delete-phone-number`

The following code example shows how to use `delete-phone-number`.

Amazon CLI

To delete a phone number

The following `delete-phone-number` example moves the specified phone number into the deletion queue.

```
aws chime delete-phone-number \
```

```
    --phone-number-id "+12065550100"
```

This command produces no output.

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see DeletePhoneNumber in *Amazon CLI Command Reference*.

`delete-room-membership`

The following code example shows how to use `delete-room-membership`.

Amazon CLI

To remove a user as a member of a chat room

The following `delete-room-membership` example removes the specified member from the specified chat room.

```
aws chime delete-room-membership \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \
    --member-id 1ab2345c-67de-8901-f23g-45h678901j2k
```

This command produces no output.

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see DeleteRoomMembership in *Amazon CLI Command Reference*.

`delete-room`

The following code example shows how to use `delete-room`.

Amazon CLI

To delete a chat room

The following `delete-room` example deletes the specified chat room and removes the chat room memberships.

```
aws chime delete-room \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j
```

This command produces no output.

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see DeleteRoom in *Amazon CLI Command Reference*.

`disassociate-phone-number-from-user`

The following code example shows how to use `disassociate-phone-number-from-user`.

Amazon CLI

To disassociate a phone number from a user

The following `disassociate-phone-number-from-user` example disassociates a phone number from the specified user.

```
aws chime disassociate-phone-number-from-user \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --user-id 1ab2345c-67de-8901-f23g-45h678901j2k
```

This command produces no output.

For more information, see Managing User Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see DisassociatePhoneNumberFromUser in *Amazon CLI Command Reference*.

`disassociate-signin-delegate-groups-from-account`

The following code example shows how to use `disassociate-signin-delegate-groups-from-account`.

Amazon CLI

To disassociate sign-in delegate groups

The following `disassociate-signin-delegate-groups-from-account` example disassociates the specified sign-in delegate group from the specified Amazon Chime account.

```
aws chime disassociate-signin-delegate-groups-from-account \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --group-names "my_users"
```

This command produces no output.

For more information, see Managing User Access and Permissions in the *Amazon Chime Administration Guide*.

- For API details, see DisassociateSigninDelegateGroupsFromAccount in *Amazon CLI Command Reference*.

`get-account-settings`

The following code example shows how to use `get-account-settings`.

Amazon CLI

To retrieve settings for an account

The following `get-account-settings` example retrieves the account settings for the specified account.

```
aws chime get-account-settings --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
```

Output:

```
{
    "AccountSettings": {
        "DisableRemoteControl": false,
        "EnableDialOut": false
    }
}
```

For more information, see Managing Your Amazon Chime Accounts in the *Amazon Chime Administration Guide*.

- For API details, see GetAccountSettings in *Amazon CLI Command Reference*.

`get-account`

The following code example shows how to use `get-account`.

Amazon CLI

To retrieve the details for an account

The following `get-account` example retrieves the details for the specified Amazon Chime account.

```
aws chime get-account \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
```

Output:

```
{
    "Account": {
        "AwsAccountId": "111122223333",
        "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "Name": "EnterpriseDirectory",
        "AccountType": "EnterpriseDirectory",
        "CreatedTimestamp": "2018-12-20T18:38:02.181Z",
        "DefaultLicense": "Pro",
        "SupportedLicenses": [
            "Basic",
            "Pro"
        ],
        "SigninDelegateGroups": [
            {
                "GroupName": "myGroup"
            },
        ]
    }
}
```

For more information, see Managing Your Amazon Chime Accounts in the *Amazon Chime Administration Guide*.

- For API details, see GetAccount in *Amazon CLI Command Reference*.

`get-bot`

The following code example shows how to use `get-bot`.

Amazon CLI

To retrieve details about a bot

The following `get-bot` example displays the details for the specified bot.

```
aws chime get-bot \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --bot-id 123abcd4-5ef6-789g-0h12-34j56789012k
```

Output:

```
{
    "Bot": {
        "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "DisplayName": "myBot (Bot)",
        "BotType": "ChatBot",
        "Disabled": false,
        "CreatedTimestamp": "2019-09-09T18:05:56.749Z",

        "BotEmail": "myBot-chimebot@example.com",
        "SecurityToken": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY"
    }
}
```

For more information, see Update Chat Bots in the *Amazon Chime Developer Guide*.

- For API details, see GetBot in *Amazon CLI Command Reference*.

`get-global-settings`

The following code example shows how to use `get-global-settings`.

Amazon CLI

To get global settings

The following `get-global-settings` example retrieves the S3 bucket names used to store call detail records for Amazon Chime Business Calling and Amazon Chime Voice Connectors associated with the administrator's Amazon account.

```
aws chime get-global-settings
```

Output:

```
{
    "BusinessCalling": {
        "CdrBucket": "s3bucket"
    },
    "VoiceConnector": {
        "CdrBucket": "s3bucket"
    }
}
```

For more information, see Managing Global Settings in the *Amazon Chime Administration Guide*.

- For API details, see GetGlobalSettings in *Amazon CLI Command Reference*.

`get-phone-number-order`

The following code example shows how to use `get-phone-number-order`.

Amazon CLI

To get details for a phone number order

The following `get-phone-number-order` example displays the details of the specified phone number order.

```
aws chime get-phone-number-order \
    --phone-number-order-id abc12345-de67-89f0-123g-h45i678j9012
```

Output:

```
{
    "PhoneNumberOrder": {
        "PhoneNumberOrderId": "abc12345-de67-89f0-123g-h45i678j9012",
        "ProductType": "VoiceConnector",
```

```
        "Status": "Partial",
        "OrderedPhoneNumbers": [
            {
              "E164PhoneNumber": "+12065550100",
              "Status": "Acquired"
            },
            {
                "E164PhoneNumber": "+12065550101",
                "Status": "Acquired"
            },
            {
                "E164PhoneNumber": "+12065550102",
                "Status": "Failed"
            }
        ],
        "CreatedTimestamp": "2019-08-09T21:35:21.427Z",
        "UpdatedTimestamp": "2019-08-09T21:35:31.926Z"
    }
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see GetPhoneNumberOrder in *Amazon CLI Command Reference*.

`get-phone-number-settings`

The following code example shows how to use `get-phone-number-settings`.

Amazon CLI

To retrieve an outbound calling name

The following `get-phone-number-settings` example retrieves the default outbound calling name for the calling user's Amazon account.

```
aws chime get-phone-number-settings
```

This command produces no output. Output:

```
{
    "CallingName": "myName",
```

```
    "CallingNameUpdatedTimestamp": "2019-10-28T18:56:42.911Z"
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see GetPhoneNumberSettings in *Amazon CLI Command Reference*.

`get-phone-number`

The following code example shows how to use `get-phone-number`.

Amazon CLI

To get phone number details

The following `get-phone-number` example displays the details of the specified phone number.

```
aws chime get-phone-number \
    --phone-number-id +12065550100
```

Output:

```
{
    "PhoneNumber": {
        "PhoneNumberId": "%2B12065550100",
        "E164PhoneNumber": "+12065550100",
        "Type": "Local",
        "ProductType": "VoiceConnector",
        "Status": "Unassigned",
        "Capabilities": {
            "InboundCall": true,
            "OutboundCall": true,
            "InboundSMS": true,
            "OutboundSMS": true,
            "InboundMMS": true,
            "OutboundMMS": true
        },
       "Associations": [
            {
                "Value": "abcdef1ghij2klmno3pqr4",
                "Name": "VoiceConnectorId",
                "AssociatedTimestamp": "2019-10-28T18:40:37.453Z"
```

```
            }
        ],
        "CallingNameStatus": "UpdateInProgress",
        "CreatedTimestamp": "2019-08-09T21:35:21.445Z",
        "UpdatedTimestamp": "2019-08-09T21:35:31.745Z"
    }
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see GetPhoneNumber in *Amazon CLI Command Reference*.

`get-room`

The following code example shows how to use `get-room`.

Amazon CLI

To get the details about a chat room

The following `get-room` example displays details about the specified chat room.

```
aws chime get-room \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j
```

Output:

```
{
    "Room": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Name": "chatRoom",
        "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",
        "CreatedBy": "arn:aws:iam::111122223333:user/alejandro",
        "CreatedTimestamp": "2019-12-02T22:29:31.549Z",
        "UpdatedTimestamp": "2019-12-02T22:29:31.549Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see GetRoom in *Amazon CLI Command Reference*.

`get-user-settings`

The following code example shows how to use `get-user-settings`.

Amazon CLI

To retrieve user settings

The following `get-user-settings` example displays the specified user settings.

```
aws chime get-user-settings \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --user-id 1ab2345c-67de-8901-f23g-45h678901j2k
```

Output:

```
{
    "UserSettings": {
        "Telephony": {
            "InboundCalling": true,
            "OutboundCalling": true,
            "SMS": true
        }
    }
}
```

For more information, see Managing User Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see GetUserSettings in *Amazon CLI Command Reference*.

`get-user`

The following code example shows how to use `get-user`.

Amazon CLI

To get details about a user

The following `get-user` example retrieves the details for the specified user.

```
aws chime get-user \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
```

```
    --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE
```

Output:

```
{
    "User": {
        "UserId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE",
        "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "PrimaryEmail": "marthar@example.com",
        "DisplayName": "Martha Rivera",
        "LicenseType": "Pro",
        "UserRegistrationStatus": "Registered",
        "RegisteredOn": "2018-12-20T18:45:25.231Z",
        "InvitedOn": "2018-12-20T18:45:25.231Z",
        "AlexaForBusinessMetadata": {
            "IsAlexaForBusinessEnabled": False,
            "AlexaForBusinessRoomArn": "null"
        },
        "PersonalPIN": "XXXXXXXXXX"
    }
}
```

For more information, see Managing Users in the *Amazon Chime Administration Guide*.

- For API details, see GetUser in *Amazon CLI Command Reference*.

`invite-users`

The following code example shows how to use `invite-users`.

Amazon CLI

To invite users to join Amazon Chime

The following `invite-users` example sends an email to invite a user to the specified Amazon Chime account.

```
aws chime invite-users \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --user-email-list "alejandror@example.com" "janed@example.com"
```

Output:

```
{
    "Invites": [
        {
            "InviteId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE",
            "Status": "Pending",
            "EmailAddress": "alejandror@example.com",
            "EmailStatus": "Sent"
        }
        {
            "InviteId": "a1b2c3d4-5678-90ab-cdef-33333EXAMPLE",
            "Status": "Pending",
            "EmailAddress": "janed@example.com",
            "EmailStatus": "Sent"
        }
    ]
}
```

For more information, see Inviting and Suspending Users in the *Amazon Chime Administration Guide*.

- For API details, see InviteUsers in *Amazon CLI Command Reference*.

`list-accounts`

The following code example shows how to use `list-accounts`.

Amazon CLI

To get a list of accounts

The following `list-accounts` example retrieves a list of the Amazon Chime accounts in the administrator's Amazon account.

```
aws chime list-accounts
```

Output:

```
{
    "Accounts": [
        {
            "AwsAccountId": "111122223333",
```

```
            "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
            "Name": "First Chime Account",
            "AccountType": "EnterpriseDirectory",
            "CreatedTimestamp": "2018-12-20T18:38:02.181Z",
            "DefaultLicense": "Pro",
            "SupportedLicenses": [
                "Basic",
                "Pro"
            ],
            "SigninDelegateGroups": [
                {
                    "GroupName": "myGroup"
                },
            ]
        },
        {
            "AwsAccountId": "111122223333",
            "AccountId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE",
            "Name": "Second Chime Account",
            "AccountType": "Team",
            "CreatedTimestamp": "2018-09-04T21:44:22.292Z",
            "DefaultLicense": "Pro",
            "SupportedLicenses": [
                "Basic",
                "Pro"
            ],
            "SigninDelegateGroups": [
                {
                    "GroupName": "myGroup"
                },
            ]
        }
    ]
}
```

For more information, see Managing Your Amazon Chime Accounts in the *Amazon Chime Administration Guide*.

- For API details, see ListAccounts in *Amazon CLI Command Reference*.

`list-bots`

The following code example shows how to use `list-bots`.

Amazon CLI

To retrieve a list of bots

The following `list-bots` example lists the bots associated with the specified Amazon Chime Enterprise account.

```
aws chime list-bots \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45
```

Output:

```
{
    "Bot": {
        "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "DisplayName": "myBot (Bot)",
        "BotType": "ChatBot",
        "Disabled": false,
        "CreatedTimestamp": "2019-09-09T18:05:56.749Z",
        "UpdatedTimestamp": "2019-09-09T18:05:56.749Z",
        "BotEmail": "myBot-chimebot@example.com",
        "SecurityToken": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY"
    }
}
```

For more information, see Use Chat Bots with Amazon Chime in the *Amazon Chime Developer Guide*.

- For API details, see ListBots in *Amazon CLI Command Reference*.

`list-phone-number-orders`

The following code example shows how to use `list-phone-number-orders`.

Amazon CLI

To list phone number orders

The following `list-phone-number-orders` example lists the phone number orders associated with the Amazon Chime administrator's account.

```
aws chime list-phone-number-orders
```

Output:

```
{
    "PhoneNumberOrders": [
        {
            "PhoneNumberOrderId": "abc12345-de67-89f0-123g-h45i678j9012",
            "ProductType": "VoiceConnector",
            "Status": "Partial",
            "OrderedPhoneNumbers": [
                {
                    "E164PhoneNumber": "+12065550100",
                    "Status": "Acquired"
                },
                {
                    "E164PhoneNumber": "+12065550101",
                    "Status": "Acquired"
                },
                {
                    "E164PhoneNumber": "+12065550102",
                    "Status": "Failed"
                }
            ],
            "CreatedTimestamp": "2019-08-09T21:35:21.427Z",
            "UpdatedTimestamp": "2019-08-09T21:35:31.926Z"
        }
        {
            "PhoneNumberOrderId": "cba54321-ed76-09f5-321g-h54i876j2109",
            "ProductType": "BusinessCalling",
            "Status": "Partial",
            "OrderedPhoneNumbers": [
                {
                    "E164PhoneNumber": "+12065550103",
                    "Status": "Acquired"
                },
                {
                    "E164PhoneNumber": "+12065550104",
                    "Status": "Acquired"
                },
                {
                    "E164PhoneNumber": "+12065550105",
                    "Status": "Failed"
```

```
                }
            ],
            "CreatedTimestamp": "2019-08-09T21:35:21.427Z",
            "UpdatedTimestamp": "2019-08-09T21:35:31.926Z"
        }
    ]
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see ListPhoneNumberOrders in *Amazon CLI Command Reference*.

`list-phone-numbers`

The following code example shows how to use `list-phone-numbers`.

Amazon CLI

To list phone numbers for an Amazon Chime account

The following `list-phone-numbers` example lists the phone numbers associated with the administrator's Amazon Chime account.

```
aws chime list-phone-numbers
```

This command produces no output. Output:

```
{
    "PhoneNumbers": [
        {
            "PhoneNumberId": "%2B12065550100",
            "E164PhoneNumber": "+12065550100",
            "Type": "Local",

            "UpdatedTimestamp": "2019-10-28T18:42:07.960Z"
        }
    ]
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see ListPhoneNumbers in *Amazon CLI Command Reference*.

`list-room-memberships`

The following code example shows how to use `list-room-memberships`.

Amazon CLI

To list room memberships

The following `list-room-memberships` example displays a list of the membership details for the specified chat room.

```
aws chime list-room-memberships \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j
```

Output:

```
{
    "RoomMemberships": [
        {
            "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
            "Member": {
                "MemberId": "2ab2345c-67de-8901-f23g-45h678901j2k",
                "MemberType": "User",
                "Email": "zhangw@example.com",
                "FullName": "Zhang Wei",

            "UpdatedTimestamp": "2019-12-02T22:46:58.532Z"
        }
    ]
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see ListRoomMemberships in *Amazon CLI Command Reference*.

`list-rooms`

The following code example shows how to use `list-rooms`.

Amazon CLI

To list chat rooms

The following `list-rooms` example displays a list of chat rooms in the specified account. The list is filtered to only those chat rooms that the specified member belongs to.

```
aws chime list-rooms \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --member-id 1ab2345c-67de-8901-f23g-45h678901j2k
```

Output:

```
{
    "Room": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Name": "teamRoom",
        "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",
        "CreatedBy": "arn:aws:iam::111122223333:user/alejandro",
        "CreatedTimestamp": "2019-12-02T22:29:31.549Z",
        "UpdatedTimestamp": "2019-12-02T22:33:19.310Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see ListRooms in *Amazon CLI Command Reference*.

`list-users`

The following code example shows how to use `list-users`.

Amazon CLI

To list the users in an account

The following `list-users` example lists the users for the specified Amazon Chime account.

```
aws chime list-users --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
```

Output:

```
{
    "Users": [
        {
            "UserId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE",
            "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",

            "UserRegistrationStatus": "Registered",
            "RegisteredOn": "2018-12-20T18:47:15.390Z"
            "AlexaForBusinessMetadata": {
                "IsAlexaForBusinessEnabled": false
            }
        }
    ]
}
```

For more information, see Managing Users in the *Amazon Chime Administration Guide*.

- For API details, see ListUsers in *Amazon CLI Command Reference*.

`logout-user`

The following code example shows how to use `logout-user`.

Amazon CLI

To log out a user

The following `logout-user` example logs out the specified user.

```
aws chime logout-user \
```

```
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE
```

This command produces no output.

- For API details, see LogoutUser in *Amazon CLI Command Reference*.

`regenerate-security-token`

The following code example shows how to use `regenerate-security-token`.

Amazon CLI

To regenerate a security token

The following `regenerate-security-token` example regenerates the security token for the specified bot.

```
aws chime regenerate-security-token \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --bot-id 123abcd4-5ef6-789g-0h12-34j56789012k
```

Output:

```
{
    "Bot": {
        "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "DisplayName": "myBot (Bot)",
        "BotType": "ChatBot",
        "Disabled": false,
        "CreatedTimestamp": "2019-09-09T18:05:56.749Z",
        "UpdatedTimestamp": "2019-09-09T18:05:56.749Z",
        "BotEmail": "myBot-chimebot@example.com",
        "SecurityToken": "je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY"
    }
}
```

For more information, see Authenticate Chat Bot Requests in the *Amazon Chime Developer Guide*.

- For API details, see RegenerateSecurityToken in *Amazon CLI Command Reference*.

`reset-personal-pin`

The following code example shows how to use `reset-personal-pin`.

Amazon CLI

To reset a user's personal meeting PIN

The following `reset-personal-pin` example resets the specified user's personal meeting PIN.

```
aws chime reset-personal-pin \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE
    --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE
```

Output:

```
{
    "User": {
        "UserId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE",
        "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "PrimaryEmail": "mateo@example.com",
        "DisplayName": "Mateo Jackson",
        "LicenseType": "Pro",
        "UserType": "PrivateUser",
        "UserRegistrationStatus": "Registered",
        "RegisteredOn": "2018-12-20T18:45:25.231Z",
        "AlexaForBusinessMetadata": {
            "IsAlexaForBusinessEnabled": False,
            "AlexaForBusinessRoomArn": "null"
        },
        "PersonalPIN": "XXXXXXXXXX"
    }
}
```

For more information, see Changing Personal Meeting PINs in the *Amazon Chime Administration Guide*.

- For API details, see ResetPersonalPin in *Amazon CLI Command Reference*.

`restore-phone-number`

The following code example shows how to use `restore-phone-number`.

Amazon CLI

To restore a phone number

The following `restore-phone-number` example restores the specified phone number from the deletion queue.

```
aws chime restore-phone-number \
    --phone-number-id "+12065550100"
```

Output:

```
{
    "PhoneNumber": {
        "PhoneNumberId": "%2B12065550100",
        "E164PhoneNumber": "+12065550100",
        "Type": "Local",
        "ProductType": "BusinessCalling",
        "Status": "Unassigned",
        "Capabilities": {
            "InboundCall": true,
            "OutboundCall": true,
            "InboundSMS": true,
            "OutboundSMS": true,
            "InboundMMS": true,
            "OutboundMMS": true
        },
        "Associations": [],
        "CreatedTimestamp": "2019-08-09T21:35:21.445Z",
        "UpdatedTimestamp": "2019-08-12T22:06:36.355Z"
    }
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see RestorePhoneNumber in *Amazon CLI Command Reference*.

`search-available-phone-numbers`

The following code example shows how to use `search-available-phone-numbers`.

Amazon CLI

To search available phone numbers

The following `search-available-phone-numbers` example searches available phone numbers by area code.

```
aws chime search-available-phone-numbers \
    --area-code "206"
```

Output:

```
{
    "E164PhoneNumbers": [
        "+12065550100",
        "+12065550101",
        "+12065550102",
        "+12065550103",
        "+12065550104",
        "+12065550105",
        "+12065550106",
        "+12065550107",
        "+12065550108",
        "+12065550109",
    ]
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see SearchAvailablePhoneNumbers in *Amazon CLI Command Reference*.

`update-account-settings`

The following code example shows how to use `update-account-settings`.

Amazon CLI

To update the settings for your account

The following `update-account-settings` example disables the remote control of shared screens for the specified Amazon Chime account.

```
aws chime update-account-settings \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --account-settings DisableRemoteControl=true
```

This command produces no output.

- For API details, see UpdateAccountSettings in *Amazon CLI Command Reference*.

`update-account`

The following code example shows how to use `update-account`.

Amazon CLI

To update an account

The following `update-account` example updates the specified account name.

```
aws chime update-account \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --name MyAccountName
```

Output:

```
{
    "Account": {
        "AwsAccountId": "111122223333",
        "AccountId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "Name": "MyAccountName",
        "AccountType": "Team",
        "CreatedTimestamp": "2018-09-04T21:44:22.292Z",
        "DefaultLicense": "Pro",
        "SupportedLicenses": [
            "Basic",
            "Pro"
        ],
        "SigninDelegateGroups": [
            {
                "GroupName": "myGroup"
            },
        ]
```

```
    }
}
```

For more information, see Renaming Your Account in the *Amazon Chime Administration Guide*.

- For API details, see UpdateAccount in *Amazon CLI Command Reference*.

`update-bot`

The following code example shows how to use `update-bot`.

Amazon CLI

To update a bot

The following `update-bot` example updates the status of the specified bot to stop it from running.

```
aws chime update-bot \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --bot-id 123abcd4-5ef6-789g-0h12-34j56789012k \
    --disabled
```

Output:

```
{
    "Bot": {
        "BotId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "UserId": "123abcd4-5ef6-789g-0h12-34j56789012k",
        "DisplayName": "myBot (Bot)",
        "BotType": "ChatBot",
        "Disabled": true,
        "CreatedTimestamp": "2019-09-09T18:05:56.749Z",
        "UpdatedTimestamp": "2019-09-09T18:05:56.749Z",
        "BotEmail": "myBot-chimebot@example.com",
        "SecurityToken": "je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY"
    }
}
```

For more information, see Update Chat Bots in the *Amazon Chime Developer Guide*.

- For API details, see UpdateBot in *Amazon CLI Command Reference*.

`update-global-settings`

The following code example shows how to use `update-global-settings`.

Amazon CLI

To update global settings

The following `update-global-settings` example updates the S3 bucket used to store call detail records for Amazon Chime Business Calling and Amazon Chime Voice Connectors associated with the administrator's Amazon account.

```
aws chime update-global-settings \
    --business-calling CdrBucket="s3bucket" \
    --voice-connector CdrBucket="s3bucket"
```

This command produces no output.

For more information, see Managing Global Settings in the *Amazon Chime Administration Guide*.

- For API details, see UpdateGlobalSettings in *Amazon CLI Command Reference*.

`update-phone-number-settings`

The following code example shows how to use `update-phone-number-settings`.

Amazon CLI

To update an outbound calling name

The following `update-phone-number-settings` example updates the default outbound calling name for the administrator's Amazon account.

```
aws chime update-phone-number-settings \
    --calling-name "myName"
```

This command produces no output.

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see UpdatePhoneNumberSettings in *Amazon CLI Command Reference*.

`update-phone-number`

The following code example shows how to use `update-phone-number`.

Amazon CLI

Example 1: To update the product type for a phone number

The following `update-phone-number` example updates the specified phone number's product type.

```
aws chime update-phone-number \
    --phone-number-id "+12065550100" \
    --product-type "BusinessCalling"
```

Output:

```
{
    "PhoneNumber": {
        "PhoneNumberId": "%2B12065550100",
        "E164PhoneNumber": "+12065550100",
        "Type": "Local",
        "ProductType": "BusinessCalling",
        "Status": "Unassigned",
        "Capabilities": {
            "InboundCall": true,
            "OutboundCall": true,
            "InboundSMS": true,
            "OutboundSMS": true,
            "InboundMMS": true,
            "OutboundMMS": true
        },
        "Associations": [],
        "CallingName": "phonenumber1",
        "CreatedTimestamp": "2019-08-09T21:35:21.445Z",
        "UpdatedTimestamp": "2019-08-12T21:44:07.591Z"
    }
}
```

Example 2: To update the outbound calling name for a phone number

The following `update-phone-number` example updates the outbound calling name for the specified phone number.

aws chime update-phone-number --phone-number-id "+12065550100" --calling-name "phonenumber2"

Output:

```
{
    "PhoneNumber": {
        "PhoneNumberId": "%2B12065550100",
        "E164PhoneNumber": "+12065550100",
        "Type": "Local",
        "ProductType": "BusinessCalling",
        "Status": "Unassigned",
        "Capabilities": {
            "InboundCall": true,
            "OutboundCall": true,
            "InboundSMS": true,
            "OutboundSMS": true,
            "InboundMMS": true,
            "OutboundMMS": true
        },
        "Associations": [],
        "CallingName": "phonenumber2",
        "CreatedTimestamp": "2019-08-09T21:35:21.445Z",
        "UpdatedTimestamp": "2019-08-12T21:44:07.591Z"
    }
}
```

For more information, see Working with Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see UpdatePhoneNumber in *Amazon CLI Command Reference*.

`update-room-membership`

The following code example shows how to use `update-room-membership`.

Amazon CLI

To update a room membership

The following `update-room-membership` example modifies the role of the specified chat room member to `Administrator`.

```
aws chime update-room-membership \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \
    --member-id 1ab2345c-67de-8901-f23g-45h678901j2k \
    --role Administrator
```

Output:

```
{
    "RoomMembership": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Member": {
            "MemberId": "1ab2345c-67de-8901-f23g-45h678901j2k",
            "MemberType": "User",
            "Email": "sofiamartinez@example.com",
            "FullName": "Sofia Martinez",
            "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45"
        },
        "Role": "Administrator",
        "InvitedBy": "arn:aws:iam::111122223333:user/admin",
        "UpdatedTimestamp": "2019-12-02T22:40:22.931Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see UpdateRoomMembership in *Amazon CLI Command Reference*.

update-room

The following code example shows how to use `update-room`.

Amazon CLI

To update a chat room

The following `update-room` example modifies the name of the specified chat room.

```
aws chime update-room \
```

```
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --room-id abcd1e2d-3e45-6789-01f2-3g45h67i890j \
    --name teamRoom
```

Output:

```
{
    "Room": {
        "RoomId": "abcd1e2d-3e45-6789-01f2-3g45h67i890j",
        "Name": "teamRoom",
        "AccountId": "12a3456b-7c89-012d-3456-78901e23fg45",
        "CreatedBy": "arn:aws:iam::111122223333:user/alejandro",
        "CreatedTimestamp": "2019-12-02T22:29:31.549Z",
        "UpdatedTimestamp": "2019-12-02T22:33:19.310Z"
    }
}
```

For more information, see Creating a Chat Room in the *Amazon Chime User Guide*.

- For API details, see UpdateRoom in *Amazon CLI Command Reference*.

`update-user-settings`

The following code example shows how to use `update-user-settings`.

Amazon CLI

To update user settings

The following `update-user-settings` example enables the specified user to make inbound and outbound calls and send and receive SMS messages.

```
aws chime update-user-settings \
    --account-id 12a3456b-7c89-012d-3456-78901e23fg45 \
    --user-id 1ab2345c-67de-8901-f23g-45h678901j2k \
    --user-settings "Telephony={InboundCalling=true,OutboundCalling=true,SMS=true}"
```

This command produces no output.

For more information, see Managing User Phone Numbers in the *Amazon Chime Administration Guide*.

- For API details, see UpdateUserSettings in *Amazon CLI Command Reference*.

`update-user`

The following code example shows how to use `update-user`.

Amazon CLI

To update user details

This example updates the specified details for the specified user.

Command:

```
aws chime update-user \
    --account-id a1b2c3d4-5678-90ab-cdef-11111EXAMPLE \
    --user-id a1b2c3d4-5678-90ab-cdef-22222EXAMPLE \
    --license-type "Basic"
```

Output:

```
{
    "User": {
        "UserId": "a1b2c3d4-5678-90ab-cdef-22222EXAMPLE"
    }
}
```

- For API details, see UpdateUser in *Amazon CLI Command Reference*.

Cloud Control API examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Cloud Control API.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-resource`

The following code example shows how to use `create-resource`.

Amazon CLI

To create a resource

The following `create-resource` example creates an Amazon::Kinesis::Stream resource, named ResourceExample, with a retention period of 168 hours and a shard count of three.

```
aws cloudcontrol create-resource \
    --type-name AWS::Kinesis::Stream \
    --desired-state "{\"Name\": \"ResourceExample\",\"RetentionPeriodHours\":168,
 \"ShardCount\":3}"
```

Output:

```
{
    "ProgressEvent": {
        "EventTime": 1632506656.706,
        "TypeName": "AWS::Kinesis::Stream",
        "OperationStatus": "IN_PROGRESS",
        "Operation": "CREATE",
        "Identifier": "ResourceExample",
        "RequestToken": "20999d87-e304-4725-ad84-832dcbfd7fc5"
    }
}
```

For more information, see Creating a resource in the *Cloud Control API User Guide*.

- For API details, see CreateResource in *Amazon CLI Command Reference*.

`delete-resource`

The following code example shows how to use `delete-resource`.

Amazon CLI

To delete a resource

The following `delete-resource` example deletes a Amazon::Kinesis::Stream resource with the identifier ResourceExample from your Amazon account.

```
aws cloudcontrol delete-resource \
    --type-name AWS::Kinesis::Stream \
    --identifier ResourceExample
```

Output:

```
{
    "ProgressEvent": {
        "TypeName": "AWS::Kinesis::Stream",
        "Identifier": "ResourceExample",
        "RequestToken": "e48f26ff-d0f9-4ab8-a878-120db1edf111",
        "Operation": "DELETE",
        "OperationStatus": "IN_PROGRESS",
        "EventTime": 1632950300.14
    }
}
```

For more information, see Deleting a resource in the *Cloud Control API User Guide*.

- For API details, see DeleteResource in *Amazon CLI Command Reference*.

`get-resource-request-status`

The following code example shows how to use `get-resource-request-status`.

Amazon CLI

To get the status information of a resource request

The following `get-resource-request-status` example returns status information about the specified resource request.

```
aws cloudcontrol get-resource-request-status \
    --request-token "e1a6b86e-46bd-41ac-bfba-001234567890"
```

Output:

```
{
    "ProgressEvent": {
        "TypeName": "AWS::Kinesis::Stream",
        "Identifier": "Demo",
        "RequestToken": "e1a6b86e-46bd-41ac-bfba-001234567890",
        "Operation": "CREATE",
        "OperationStatus": "FAILED",
        "EventTime": 1632950268.481,
        "StatusMessage": "Resource of type 'AWS::Kinesis::Stream' with identifier
 'Demo' already exists.",
        "ErrorCode": "AlreadyExists"
    }
}
```

For more information, see Managing resource operation requests in the *Cloud Control API User Guide*.

- For API details, see GetResourceRequestStatus in *Amazon CLI Command Reference*.

`get-resource`

The following code example shows how to use `get-resource`.

Amazon CLI

To get the current state of a resource

The following `get-resource` example returns the current state of the Amazon::Kinesis::Stream resource named ResourceExample.

```
aws cloudcontrol get-resource \
    --type-name AWS::Kinesis::Stream \
    --identifier ResourceExample
```

Output:

```
{
    "TypeName": "AWS::Kinesis::Stream",
    "ResourceDescription": {
```

```
        "Identifier": "ResourceExample",
        "Properties": "{\"Arn\":\"arn:aws:kinesis:us-west-2:099908667365:stream/
ResourceExample\",\"RetentionPeriodHours\":168,\"Name\":\"ResourceExample\",
\"ShardCount\":3}"
    }
}
```

For more information, see Reading a resource's current state in the *Cloud Control API User Guide*.

- For API details, see GetResource in *Amazon CLI Command Reference*.

`list-resource-requests`

The following code example shows how to use `list-resource-requests`.

Amazon CLI

To list the active resource operation requests

The following `list-resource-requests` example lists the resource requests for CREATE and UPDATE operations that have failed in your Amazon account.

```
aws cloudcontrol list-resource-requests \
    --resource-request-status-filter Operations=CREATE,OperationStatuses=FAILED
```

Output:

```
{
    "ResourceRequestStatusSummaries": [
        {
            "TypeName": "AWS::Kinesis::Stream",
            "Identifier": "Demo",
            "RequestToken": "e1a6b86e-46bd-41ac-bfba-633abcdfdbd7",
            "Operation": "CREATE",
            "OperationStatus": "FAILED",
            "EventTime": 1632950268.481,
            "StatusMessage": "Resource of type 'AWS::Kinesis::Stream' with
 identifier 'Demo' already exists.",
            "ErrorCode": "AlreadyExists"
        }
    ]
}
```

For more information, see Managing resource operation requests in the *Cloud Control API User Guide*.

- For API details, see ListResourceRequests in *Amazon CLI Command Reference*.

`list-resources`

The following code example shows how to use `list-resources`.

Amazon CLI

To list the resources of a given type

The following `list-resources` example lists the Amazon::Kinesis::Stream resources provisioned in your Amazon account.

```
aws cloudcontrol list-resources \
    --type-name AWS::Kinesis::Stream
```

Output:

```
{
    "TypeName": "AWS::Kinesis::Stream",
    "ResourceDescriptions": [
        {
            "Identifier": "MyKinesisStream",
            "Properties": "{\"Name\":\"MyKinesisStream\"}"
        },
        {
            "Identifier": "AnotherStream",
            "Properties": "{\"Name\":\"AnotherStream\"}"
        }
    ]
}
```

For more information, see Discovering resources in the *Cloud Control API User Guide*.

- For API details, see ListResources in *Amazon CLI Command Reference*.

`update-resource`

The following code example shows how to use `update-resource`.

Amazon CLI

To update the properties of an existing resource

The following `update-resource` example updates the retention policy of an Amazon::Logs::LogGroup resource named ExampleLogGroup to 90 days.

```
aws cloudcontrol update-resource \
    --type-name AWS::Logs::LogGroup \
    --identifier ExampleLogGroup \
    --patch-document "[{\"op\":\"replace\",\"path\":\"/RetentionInDays\",\"value
\":90}]"
```

Output:

```
{
    "ProgressEvent": {
        "EventTime": "2021-08-09T18:17:15.219Z",
        "TypeName": "AWS::Logs::LogGroup",
        "OperationStatus": "IN_PROGRESS",
        "Operation": "UPDATE",
        "Identifier": "ExampleLogGroup",
        "RequestToken": "5f40c577-3534-4b20-9599-0b0123456789"
    }
}
```

For more information, see Updating a resource in the *Cloud Control API User Guide*.

- For API details, see UpdateResource in *Amazon CLI Command Reference*.

Amazon Cloud Map examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Cloud Map.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-http-namespace`

The following code example shows how to use `create-http-namespace`.

Amazon CLI

To create an HTTP namespace

The following `create-http-namespace` example creates an HTTP namespace `example.com`.

```
aws servicediscovery create-http-namespace \
    --name example.com \
    --creator-request-id example-request-id
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information about creating a namespace, see Creating an Amazon Cloud Map namespace to group application services in the *Amazon Cloud Map Developer Guide*.

- For API details, see CreateHttpNamespace in *Amazon CLI Command Reference*.

`create-private-dns-namespace`

The following code example shows how to use `create-private-dns-namespace`.

Amazon CLI

To create a private DNS namespace

The following `create-private-dns-namespace` example creates a private DNS namespace.

```
aws servicediscovery create-private-dns-namespace \
    --name example.com \
    --vpc vpc-1c56417b
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information, see Creating namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see CreatePrivateDnsNamespace in *Amazon CLI Command Reference*.

`create-public-dns-namespace`

The following code example shows how to use `create-public-dns-namespace`.

Amazon CLI

To create an public DNS namespace

The following `create-public-dns-namespace` example creates an public DNS namespace `example.com`.

```
aws servicediscovery create-public-dns-namespace \
    --name example-public-dns.com \
    --creator-request-id example-public-request-id \
    --properties DnsProperties={SOA={TTL=60}}
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`.

For more information about creating a namespace, see Creating an Amazon Cloud Map namespace to group application services in the *Amazon Cloud Map Developer Guide*.

- For API details, see CreatePublicDnsNamespace in *Amazon CLI Command Reference*.

`create-service`

The following code example shows how to use `create-service`.

Amazon CLI

To create a service

The following `create-service` example creates a service.

```
aws servicediscovery create-service \
    --name myservice \
    --namespace-id  ns-ylexjili4cdxy3xm \
    --dns-config "NamespaceId=ns-
ylexjili4cdxy3xm,RoutingPolicy=MULTIVALUE,DnsRecords=[{Type=A,TTL=60}]"
```

Output:

```
{
        "Service": {
        "Id": "srv-p5zdwlg5uvvzjita",
        "Arn": "arn:aws:servicediscovery:us-west-2:803642222207:service/srv-
p5zdwlg5uvvzjita",
        "Name": "myservice",
        "NamespaceId": "ns-ylexjili4cdxy3xm",
        "DnsConfig": {
            "NamespaceId": "ns-ylexjili4cdxy3xm",
            "RoutingPolicy": "MULTIVALUE",
            "DnsRecords": [
                {
                    "Type": "A",
                    "TTL": 60
                }
            ]
        },
        "CreateDate": 1587081768.334,
        "CreatorRequestId": "567c1193-6b00-4308-bd57-ad38a8822d25"
    }
```

```
}
```

For more information, see Creating services in the *Amazon Cloud Map Developer Guide*.

- For API details, see CreateService in *Amazon CLI Command Reference*.

`delete-namespace`

The following code example shows how to use `delete-namespace`.

Amazon CLI

To delete a namespace

The following `delete-namespace` example deletes a namespace.

```
aws servicediscovery delete-namespace \
    --id ns-ylexjili4cdxy3xm
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k98y6drk"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information, see Deleting namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see DeleteNamespace in *Amazon CLI Command Reference*.

`delete-service-attributes`

The following code example shows how to use `delete-service-attributes`.

Amazon CLI

To delete a service attribute

The following `delete-service-attributes` example deletes a service attribute with the key `Port` that is associated with the specified service.

```
aws servicediscovery delete-service-attributes \
    --service-id srv-e4anhexample0004 \
    --attributes Port
```

This command produces no output.

For more information, see Deleting namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see DeleteServiceAttributes in *Amazon CLI Command Reference*.

`delete-service`

The following code example shows how to use `delete-service`.

Amazon CLI

To delete a service

The following `delete-service` example deletes a service.

```
aws servicediscovery delete-service \
    --id srv-p5zdwlg5uvvzjita
```

This command produces no output.

For more information, see Deleting services in the *Amazon Cloud Map Developer Guide*.

- For API details, see DeleteService in *Amazon CLI Command Reference*.

`deregister-instance`

The following code example shows how to use `deregister-instance`.

Amazon CLI

To deregister a service instance

The following `deregister-instance` example deregisters a service instance.

```
aws servicediscovery deregister-instance \
    --service-id srv-p5zdwlg5uvvzjita \
```

```
    --instance-id myservice-53
```

Output:

```
{
    "OperationId": "4yejorelbukcjzpnr6tlmrghsjwpngf4-k98rnaiq"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information, see Deregistering service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see DeregisterInstance in *Amazon CLI Command Reference*.

`discover-instances-revision`

The following code example shows how to use `discover-instances-revision`.

Amazon CLI

To discover the revision of an instance

The following `discover-instances-revision` example discovers the increasing revision of an instance.

```
aws servicediscovery discover-instances-revision \
    --namespace-name example.com \
    --service-name myservice
```

Output:

```
{
    "InstancesRevision": 123456
}
```

For more information, see Amazon Cloud Map service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see DiscoverInstancesRevision in *Amazon CLI Command Reference*.

`discover-instances`

The following code example shows how to use `discover-instances`.

Amazon CLI

To discover registered instances

The following `discover-instances` example discovers registered instances.

```
aws servicediscovery discover-instances \
    --namespace-name example.com \
    --service-name myservice \
    --max-results 10 \
    --health-status ALL
```

Output:

```
{
    "Instances": [
        {
            "InstanceId": "myservice-53",
            "NamespaceName": "example.com",
            "ServiceName": "myservice",
            "HealthStatus": "UNKNOWN",
            "Attributes": {
                "AWS_INSTANCE_IPV4": "172.2.1.3",
                "AWS_INSTANCE_PORT": "808"
            }
        }
    ]
}
```

For more information, see Amazon Cloud Map service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see DiscoverInstances in *Amazon CLI Command Reference*.

`get-instance`

The following code example shows how to use `get-instance`.

Amazon CLI

To get the details of an instance

The following `get-instance` example gets the attributes of a service.

```
aws servicediscovery get-instance \
    --service-id srv-e4anhexample0004
    --instance-id i-abcd1234
```

Output:

```
{
    "Instances": {
        "Id": "arn:aws:servicediscovery:us-west-2:111122223333;:service/srv-
e4anhexample0004",
        "Attributes": {
            "AWS_INSTANCE_IPV4": "192.0.2.44",
            "AWS_INSTANCE_PORT": "80",
            "color": "green",
            "region": "us-west-2",
            "stage": "beta"
        }
    }
}
```

For more information, see Amazon Cloud Map service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetInstance in *Amazon CLI Command Reference*.

`get-instances-health-status`

The following code example shows how to use `get-instances-health-status`.

Amazon CLI

To get the health status of instances associated with a service

The following `get-instances-health-status` example gets the health status of instances associated with the specified service.

```
aws servicediscovery get-instances-health-status \
    --service-id srv-e4anhexample0004
```

Output:

```
{
    "Status": {
        "i-abcd1234": "HEALTHY",
        "i-abcd1235": "UNHEALTHY"
    }
}
```

For more information, see Amazon Cloud Map service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetInstancesHealthStatus in *Amazon CLI Command Reference*.

`get-namespace`

The following code example shows how to use `get-namespace`.

Amazon CLI

To get the details of a namespace

The following `get-namespace` example retrieves information about the specified namespace.

```
aws servicediscovery get-namespace \
    --id ns-e4anhexample0004
```

Output:

```
{
    "Namespaces": {
        "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
e4anhexample0004",
        "CreateDate": "20181118T211712Z",
        "CreatorRequestId": "example-creator-request-id-0001",
        "Description": "Example.com AWS Cloud Map HTTP Namespace",
        "Id": "ns-e4anhexample0004",
        "Name": "example-http.com",
```

```
        "Properties": {
            "DnsProperties": {},
            "HttpProperties": {
                "HttpName": "example-http.com"
            }
        },
        "Type": "HTTP"
    }
}
```

For more information, see Amazon Cloud Map namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetNamespace in *Amazon CLI Command Reference*.

`get-operation`

The following code example shows how to use `get-operation`.

Amazon CLI

To get the result of an operation

The following `get-operation` example gets the result of a namespace creation operation.

```
aws servicediscovery get-operation \
    --operation-id gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd
```

Output:

```
{
    "Operation": {
        "Id": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd",
        "Type": "CREATE_NAMESPACE",
        "Status": "SUCCESS",
        "CreateDate": 1587055860.121,
        "UpdateDate": 1587055900.469,
        "Targets": {
            "NAMESPACE": "ns-ylexjili4cdxy3xm"
        }
    }
}
```

For more information, see Creating an Amazon Cloud Map namespace to group application services in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetOperation in *Amazon CLI Command Reference*.

`get-service-attributes`

The following code example shows how to use `get-service-attributes`.

Amazon CLI

To get the attributes of an service

The following `get-service-attributes` example gets the attributes of a service.

```
aws servicediscovery get-service-attributes \
    --service-id srv-e4anhexample0004
```

Output:

```
{
    "ServiceAttributes": {
        "ServiceArn": "arn:aws:servicediscovery:us-west-2:111122223333;:service/srv-
e4anhexample0004",
        "Attributes": {
            "Port": "80"
        }
    }
}
```

For more information, see Amazon Cloud Map services in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetServiceAttributes in *Amazon CLI Command Reference*.

`get-service`

The following code example shows how to use `get-service`.

Amazon CLI

To get the settings of a service

The following `get-service` example gets the settings of a specified service.

```
aws servicediscovery get-service \
    --id srv-e4anhexample0004
```

Output:

```
{
    "Service": {
        "Id": "srv-e4anhexample0004",
        "Arn": "arn:aws:servicediscovery:us-west-2:111122223333:service/srv-
e4anhexample0004",
        "Name": "test-service",
        "NamespaceId": "ns-e4anhexample0004",
        "DnsConfig": {},
        "Type": "HTTP",
        "CreateDate": "2025-02-24T10:59:02.905000-06:00",
        "CreatorRequestId": "3f50f9d9-b14c-482e-a556-d2a22fe6106d"
    }
}
```

For more information, see Amazon Cloud Map services in the *Amazon Cloud Map Developer Guide*.

- For API details, see GetService in *Amazon CLI Command Reference*.

`list-instances`

The following code example shows how to use `list-instances`.

Amazon CLI

To list service instances

The following `list-instances` example lists service instances.

```
aws servicediscovery list-instances \
    --service-id srv-qzpwvt2tfqcegapy
```

Output:

```
{
```

```
    "Instances": [
        {
            "Id": "i-06bdabbae60f65a4e",
            "Attributes": {
                "AWS_INSTANCE_IPV4": "172.2.1.3",
                "AWS_INSTANCE_PORT": "808"
            }
        }
    ]
}
```

For more information, see Viewing a list of service instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see ListInstances in *Amazon CLI Command Reference*.

`list-namespaces`

The following code example shows how to use `list-namespaces`.

Amazon CLI

To list namespaces

The following `list-namespaces` example lists namespaces.

```
aws servicediscovery list-namespaces
```

Output:

```
{
    "Namespaces": [
        {
            "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
a3ccy2e7e3a7rile",
            "CreateDate": 1585354387.357,
            "Id": "ns-a3ccy2e7e3a7rile",
            "Name": "local",
            "Properties": {
                "DnsProperties": {
                    "HostedZoneId": "Z06752353VBUDTC32S84S"
                },
```

```
                "HttpProperties": {
                    "HttpName": "local"
                 }
            },
            "Type": "DNS_PRIVATE"
        },
        {
            "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
pocfyjtrsmwtvcxx",
            "CreateDate": 1586468974.698,
            "Description": "My second namespace",
            "Id": "ns-pocfyjtrsmwtvcxx",
            "Name": "My-second-namespace",
            "Properties": {
                "DnsProperties": {},
                "HttpProperties": {
                    "HttpName": "My-second-namespace"
                }
            },
            "Type": "HTTP"
        },
        {
            "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-
ylexjili4cdxy3xm",
            "CreateDate": 1587055896.798,
            "Id": "ns-ylexjili4cdxy3xm",
            "Name": "example.com",
            "Properties": {
                "DnsProperties": {
                    "HostedZoneId": "Z09983722P0QME1B3KC8I"
                },
                 "HttpProperties": {
                     "HttpName": "example.com"
                }
            },
            "Type": "DNS_PRIVATE"
        }
    ]
}
```

For more information, see Viewing a list of namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see ListNamespaces in *Amazon CLI Command Reference*.

`list-operations`

The following code example shows how to use `list-operations`.

Amazon CLI

To list operations that meet the specified criteria

The following `list-operations` example lists operations that have a status of `PENDING` or `SUCCESS`.

```
aws servicediscovery list-operations \
    --service-id srv-e4anhexample0004 \
    --filters Name=STATUS,Condition=IN,Values=PENDING,SUCCESS
```

Output:

```
{
    "Operations": [
        {
            "Id": "76yy8ovhpdz0plmjzbsnqgnrqvpv2qdt-kexample",
            "Status": "SUCCESS"
        },
        {
            "Id": "prysnyzpji3u2ciy45nke83x2zanl7yk-dexample",
            "Status": "SUCCESS"
        },
        {
            "Id": "ko4ekftir7kzlbechsh7xvcdgcpk66gh-7example",
            "Status": "PENDING"
        }
    ]
}
```

For more information, see What is Amazon Cloud Map? in the *Amazon Cloud Map Developer Guide*.

- For API details, see ListOperations in *Amazon CLI Command Reference*.

`list-services`

The following code example shows how to use `list-services`.

Amazon CLI

To list services

The following `list-services` example lists services.

```
aws servicediscovery list-services
```

Output:

```
{
    "Services": [
        {
            "Id": "srv-p5zdwlg5uvvzjita",
            "Arn": "arn:aws:servicediscovery:us-west-2:123456789012:service/srv-
p5zdwlg5uvvzjita",
            "Name": "myservice",
            "DnsConfig": {
                "RoutingPolicy": "MULTIVALUE",
                "DnsRecords": [
                    {
                        "Type": "A",
                        "TTL": 60
                    }
                ]
            },
            "CreateDate": 1587081768.334
        }
    ]
}
```

For more information, see Viewing a list of services in the *Amazon Cloud Map Developer Guide*.

- For API details, see ListServices in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags associated with the specified resource

The following `list-tags-for-resource` example lists tags for the specified resource.

```
aws servicediscovery list-tags-for-resource \
    --resource-arn arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-e4anhexample0004
```

Output:

```
{
    "Tags": [
        {
            "Key": "Project",
            "Value": "Zeta"
        },
        {
            "Key": "Department",
            "Value": "Engineering"
        }
    ]
}
```

For more information, see Tagging your Amazon Cloud Map resources in the *Amazon Cloud Map Developer Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`register-instance`

The following code example shows how to use `register-instance`.

Amazon CLI

To register a service instance

The following `register-instance` example registers a service instance.

```
aws servicediscovery register-instance \
    --service-id srv-p5zdwlg5uvvzjita \
    --instance-id myservice-53 \
    --attributes=AWS_INSTANCE_IPV4=172.2.1.3,AWS_INSTANCE_PORT=808
```

Output:

```
{
    "OperationId": "4yejorelbukcjzpnr6tlmrghsjwpngf4-k95yg2u7"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information, see Registering instances in the *Amazon Cloud Map Developer Guide*.

- For API details, see RegisterInstance in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To associate tags with the specified resource

The following `tag-resource` example associates a `Department` tag with the value `Engineering` with the specified namespace.

```
aws servicediscovery tag-resource \
    --resource-arn arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-e4anhexample0004 \
    --tags Key=Department, Value=Engineering
```

This command produces no output.

For more information, see Tagging your Amazon Cloud Map resources in the *Amazon Cloud Map Developer Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from the specified resource

The following `untag-resource` example removes a `Department` tag from the specified namespace.

```
aws servicediscovery untag-resource \
    --resource-arn arn:aws:servicediscovery:us-west-2:123456789012:namespace/ns-e4anhexample0004 \
    --tags Key=Department, Value=Engineering
```

This command produces no output.

For more information, see Tagging your Amazon Cloud Map resources in the *Amazon Cloud Map Developer Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-http-namespace`

The following code example shows how to use `update-http-namespace`.

Amazon CLI

To update an HTTP namespace

The following `update-http-namespace` example updates the specified HTTP namespace's description.

```
aws servicediscovery update-http-namespace \
    --id ns-vh4nbmEXAMPLE \
    --updater-request-id example-request-id \
    --namespace Description="The updated namespace description."
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`. For more information, see get-operation .

For more information, see Amazon Cloud Map namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdateHttpNamespace in *Amazon CLI Command Reference*.

`update-instance-custom-health-status`

The following code example shows how to use `update-instance-custom-health-status`.

Amazon CLI

To update a custom health check

The following `update-instance-custom-health-status` example updates the status of the custom health check for the specified service and example service instance to HEALTHY.

```
aws servicediscovery update-instance-custom-health-status \
    --service-id srv-e4anhexample0004 \
    --instance-id example \
    --status HEALTHY
```

This command produces no output.

For more information, see Amazon Cloud Map service health check configuration in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdateInstanceCustomHealthStatus in *Amazon CLI Command Reference*.

`update-private-dns-namespace`

The following code example shows how to use `update-private-dns-namespace`.

Amazon CLI

To update a private DNS namespace

The following `update-private-dns-namespace` example updates the description of a private DNS namespace.

```
aws servicediscovery update-private-dns-namespace \
    --id ns-bk3aEXAMPLE \
    --updater-request-id example-private-request-id \
    --namespace Description="The updated namespace description."
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`.

For more information, see Amazon Cloud Map namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdatePrivateDnsNamespace in *Amazon CLI Command Reference*.

`update-public-dns-namespace`

The following code example shows how to use `update-public-dns-namespace`.

Amazon CLI

To update a public DNS namespace

The following `update-public-dns-namespace` example updates the description of a public DNS namespace.

```
aws servicediscovery update-public-dns-namespace \
    --id ns-bk3aEXAMPLE \
    --updater-request-id example-public-request-id \
    --namespace Description="The updated namespace description."
```

Output:

```
{
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`.

For more information, see Amazon Cloud Map namespaces in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdatePublicDnsNamespace in *Amazon CLI Command Reference*.

`update-service-attributes`

The following code example shows how to use `update-service-attributes`.

Amazon CLI

To update a service to add an attribute

The following `update-service-attributes` example updates the specified service to add a service attribute with a key `Port` and a value `80`.

```
aws servicediscovery update-service-attributes \
    --service-id srv-e4anhexample0004 \
    --attributes Port=80
```

This command produces no output.

For more information, see Amazon Cloud Map services in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdateServiceAttributes in *Amazon CLI Command Reference*.

`update-service`

The following code example shows how to use `update-service`.

Amazon CLI

To update a service

The following `update-service` example updates a service to update the `DnsConfig` and `HealthCheckConfig` settings.

```
aws servicediscovery update-service \
    --id srv-e4anhexample0004 \
    --service
 "DnsConfig={DnsRecords=[{"Type"="A","TTL"=60}]},HealthCheckConfig={"Type"="HTTP","ResourceP
```

Output:

```
{
```

```
    "OperationId": "gv4g5meo7ndmeh4fqskygvk23d2fijwa-k9302yzd"
}
```

To confirm that the operation succeeded, you can run `get-operation`.

For more information about updating a service, see Updating an Amazon Cloud Map service in the *Amazon Cloud Map Developer Guide*.

- For API details, see UpdateService in *Amazon CLI Command Reference*.

Amazon Cloud9 examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Cloud9.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-environment-ec2`

The following code example shows how to use `create-environment-ec2`.

Amazon CLI

To create an Amazon Cloud9 EC2 development environment

This following `create-environment-ec2` example creates an Amazon Cloud9 development environment with the specified settings, launches an Amazon Elastic Compute Cloud (Amazon EC2) instance, and then connects from the instance to the environment.

```
aws cloud9 create-environment-ec2 \
    --name my-demo-env \
```

```
    --description "My demonstration development environment." \
    --instance-type t2.micro --image-id amazonlinux-2023-x86_64 \
    --subnet-id subnet-1fab8aEX \
    --automatic-stop-time-minutes 60 \
    --owner-arn arn:aws:iam::123456789012:user/MyDemoUser
```

Output:

```
{
    "environmentId": "8a34f51ce1e04a08882f1e811bd706EX"
}
```

For more information, see Creating an EC2 Environment in the *Amazon Cloud9 User Guide*.

- For API details, see CreateEnvironmentEc2 in *Amazon CLI Command Reference*.

`create-environment-membership`

The following code example shows how to use `create-environment-membership`.

Amazon CLI

To add an environment member to an Amazon Cloud9 development environment

This example adds the specified environment member to the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 create-environment-membership --environment-
id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/
AnotherDemoUser --permissions read-write
```

Output:

```
{
  "membership": {
    "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
    "userId": "AIDAJ3LOROMOUXTBSU6EX",
    "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",
    "permissions": "read-write"
```

```
  }
}
```

- For API details, see CreateEnvironmentMembership in *Amazon CLI Command Reference*.

`delete-environment-membership`

The following code example shows how to use `delete-environment-membership`.

Amazon CLI

To delete an environment member from an Amazon Cloud9 development environment

This example deletes the specified environment member from the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 delete-environment-membership --environment-
id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/
AnotherDemoUser
```

Output:

```
None.
```

- For API details, see DeleteEnvironmentMembership in *Amazon CLI Command Reference*.

`delete-environment`

The following code example shows how to use `delete-environment`.

Amazon CLI

To delete an Amazon Cloud9 development environment

This example deletes the specified Amazon Cloud9 development environment. If an Amazon EC2 instance is connected to the environment, also terminates the instance.

Command:

```
aws cloud9 delete-environment --environment-id 8a34f51ce1e04a08882f1e811bd706EX
```

Output:

```
None.
```

- For API details, see DeleteEnvironment in *Amazon CLI Command Reference*.

`describe-environment-memberships`

The following code example shows how to use `describe-environment-memberships`.

Amazon CLI

To gets information about environment members for an Amazon Cloud9 development environment

This example gets information about environment members for the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-memberships --environment-
id 8a34f51ce1e04a08882f1e811bd706EX
```

Output:

```
{
  "memberships": [
    {
      "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
      "userId": "AIDAJ3LOROMOUXTBSU6EX",
      "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",
      "permissions": "read-write"
    },
    {
      "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
      "userId": "AIDAJNUEDQAQWFELJDLEX",
      "userArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "permissions": "owner"
    }
```

```
  ]
}
```

To get information about the owner of an Amazon Cloud9 development environment

This example gets information about the owner of the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-memberships --environment-
id 8a34f51ce1e04a08882f1e811bd706EX --permissions owner
```

Output:

```
{
  "memberships": [
    {
      "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
      "userId": "AIDAJNUEDQAQWFELJDLEX",
      "userArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "permissions": "owner"
    }
  ]
}
```

To get information about an environment member for multiple Amazon Cloud9 development environments

This example gets information about the specified environment member for multiple Amazon Cloud9 development environments.

Command:

```
aws cloud9 describe-environment-memberships --user-
arn arn:aws:iam::123456789012:user/MyDemoUser
```

Output:

```
{
  "memberships": [
```

```
    {
      "environmentId": "10a75714bd494714929e7f5ec4125aEX",
      "lastAccess": 1516213427.0,
      "userId": "AIDAJNUEDQAQWFELJDLEX",
      "userArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "permissions": "owner"
    },
    {
      "environmentId": "1980b80e5f584920801c09086667f0EX",
      "lastAccess": 1516144884.0,
      "userId": "AIDAJNUEDQAQWFELJDLEX",
      "userArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "permissions": "owner"
    }
  ]
}
```

- For API details, see DescribeEnvironmentMemberships in *Amazon CLI Command Reference*.

`describe-environment-status`

The following code example shows how to use `describe-environment-status`.

Amazon CLI

To get status information for an Amazon Cloud9 development environment

This example gets status information for the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 describe-environment-status --environment-
id 685f892f431b45c2b28cb69eadcdb0EX
```

Output:

```
{
  "status": "ready",
  "message": "Environment is ready to use"
}
```

- For API details, see DescribeEnvironmentStatus in *Amazon CLI Command Reference*.

`describe-environments`

The following code example shows how to use `describe-environments`.

Amazon CLI

To get information about Amazon Cloud9 development environments

This example gets information about the specified Amazon Cloud9 development environments.

Command:

```
aws cloud9 describe-environments --environment-
ids 685f892f431b45c2b28cb69eadcdb0EX 349c86d4579e4e7298d500ff57a6b2EX
```

Output:

```
{
  "environments": [
    {
      "id": "685f892f431b45c2b28cb69eadcdb0EX",
      "name": "my-demo-ec2-env",
      "description": "Created from CodeStar.",
      "type": "ec2",
      "arn": "arn:aws:cloud9:us-
east-1:123456789012:environment:685f892f431b45c2b28cb69eadcdb0EX",
      "ownerArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "lifecycle": {
        "status": "CREATED"
      }
    },
    {
      "id": "349c86d4579e4e7298d500ff57a6b2EX",
      "name": my-demo-ssh-env",
      "description": "",
      "type": "ssh",
      "arn": "arn:aws:cloud9:us-
east-1:123456789012:environment:349c86d4579e4e7298d500ff57a6b2EX",
      "ownerArn": "arn:aws:iam::123456789012:user/MyDemoUser",
      "lifecycle": {
```

```
        "status": "CREATED"
      }
    }
  ]
}
```

- For API details, see DescribeEnvironments in *Amazon CLI Command Reference*.

`list-environments`

The following code example shows how to use `list-environments`.

Amazon CLI

To get a list of available Amazon Cloud9 development environment identifiers

This example gets a list of available Amazon Cloud9 development environment identifiers.

Command:

```
aws cloud9 list-environments
```

Output:

```
{
  "environmentIds": [
    "685f892f431b45c2b28cb69eadcdb0EX",
    "1980b80e5f584920801c09086667f0EX"
  ]
}
```

- For API details, see ListEnvironments in *Amazon CLI Command Reference*.

`update-environment-membership`

The following code example shows how to use `update-environment-membership`.

Amazon CLI

To change the settings of an existing environment member for an Amazon Cloud9 development environment

This example changes the settings of the specified existing environment member for the specified Amazon Cloud9 development environment.

Command:

```
aws cloud9 update-environment-membership --environment-
id 8a34f51ce1e04a08882f1e811bd706EX --user-arn arn:aws:iam::123456789012:user/
AnotherDemoUser --permissions read-only
```

Output:

```
{
  "membership": {
    "environmentId": "8a34f51ce1e04a08882f1e811bd706EX",
    "userId": "AIDAJ3LOROMOUXTBSU6EX",
    "userArn": "arn:aws:iam::123456789012:user/AnotherDemoUser",
    "permissions": "read-only"
  }
}
```

- For API details, see UpdateEnvironmentMembership in *Amazon CLI Command Reference*.

`update-environment`

The following code example shows how to use `update-environment`.

Amazon CLI

To change the settings of an existing Amazon Cloud9 development environment

This example changes the specified settings of the specified existing Amazon Cloud9 development environment.

Command:

```
aws cloud9 update-environment --environment-id 8a34f51ce1e04a08882f1e811bd706EX
 --name my-changed-demo-env --description "My changed demonstration development
 environment."
```

Output:

```
None.
```

- For API details, see UpdateEnvironment in *Amazon CLI Command Reference*.

Amazon CloudFormation examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon CloudFormation.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`activate-type`

The following code example shows how to use `activate-type`.

Amazon CLI

To activate a type

The following `activate-type` example activates a public third-party extension, making it available for use in stack templates.

```
aws cloudformation activate-type \
    --region us-west-2 \
    --type RESOURCE \
    --type-name Example::Test::1234567890abcdef0 \
    --type-name-alias Example::Test::Alias
```

Output:

```
{
```

```
    "Arn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/Example-
Test-Alias"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see ActivateType in *Amazon CLI Command Reference*.

`batch-describe-type-configurations`

The following code example shows how to use `batch-describe-type-configurations`.

Amazon CLI

To batch describe a type configuration

The following `batch-describe-type-configurations` example configures the data for the type.

```
aws cloudformation batch-describe-type-configurations \
    --region us-west-2 \
    --type-configuration-identifiers TypeArn="arn:aws:cloudformation:us-
west-2:123456789012:type/resource/Example-Test-
Type,TypeConfigurationAlias=MyConfiguration"
```

Output:

```
{
    "Errors": [],
    "UnprocessedTypeConfigurations": [],
    "TypeConfigurations": [
        {
            "Arn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/
Example-Test-Type",
            "Alias": "MyConfiguration",
            "Configuration": "{\n        \"Example\": {\n            \"ApiKey\":
 \"examplekey\",\n            \"ApplicationKey\": \"examplekey1\",\n
 \"ApiURL\": \"exampleurl\"\n            }\n}",
            "LastUpdated": "2021-10-01T15:25:46.210000+00:00",
            "TypeArn": "arn:aws:cloudformation:us-east-1:123456789012:type/resource/
Example-Test-Type"
```

```
        }
    ]
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see BatchDescribeTypeConfigurations in *Amazon CLI Command Reference*.

`cancel-update-stack`

The following code example shows how to use `cancel-update-stack`.

Amazon CLI

To cancel a stack update that is in progress

The following `cancel-update-stack` command cancels a stack update on the `myteststack` stack:

```
aws cloudformation cancel-update-stack --stack-name myteststack
```

- For API details, see CancelUpdateStack in *Amazon CLI Command Reference*.

`continue-update-rollback`

The following code example shows how to use `continue-update-rollback`.

Amazon CLI

To retry an update rollback

The following `continue-update-rollback` example resumes a rollback operation from a previously failed stack update.

```
aws cloudformation continue-update-rollback \
    --stack-name my-stack
```

This command produces no output.

- For API details, see ContinueUpdateRollback in *Amazon CLI Command Reference*.

`create-change-set`

The following code example shows how to use `create-change-set`.

Amazon CLI

To create a change set

The following `create-change-set` example creates a change set with the `CAPABILITY_IAM` capability. The file `template.yaml` is an Amazon CloudFormation template in the current folder that defines a stack that includes IAM resources.

```
aws cloudformation create-change-set \
    --stack-name my-application \
    --change-set-name my-change-set \
    --template-body file://template.yaml \
    --capabilities CAPABILITY_IAM
```

Output:

```
{
    "Id": "arn:aws:cloudformation:us-west-2:123456789012:changeSet/my-change-set/
bc9555ba-a949-xmpl-bfb8-f41d04ec5784",
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-application/
d0a825a0-e4cd-xmpl-b9fb-061c69e99204"
}
```

- For API details, see CreateChangeSet in *Amazon CLI Command Reference*.

`create-stack-instances`

The following code example shows how to use `create-stack-instances`.

Amazon CLI

To create stack instances

The following `create-stack-instances` example creates instances of a stack set in two accounts and in four regions. The fault tolerance setting ensures that the update is attempted in all accounts and regions, even if some stacks cannot be created.

```
aws cloudformation create-stack-instances \
```

```
    --stack-set-name my-stack-set \
    --accounts 123456789012 223456789012 \
    --regions us-east-1 us-east-2 us-west-1 us-west-2 \
    --operation-preferences FailureToleranceCount=7
```

Output:

```
{
    "OperationId": "d7995c31-83c2-xmpl-a3d4-e9ca2811563f"
}
```

To create a stack set, use the `create-stack-set` command.

- For API details, see CreateStackInstances in *Amazon CLI Command Reference*.

`create-stack-set`

The following code example shows how to use `create-stack-set`.

Amazon CLI

To create a stack set

The following `create-stack-set` example creates a stack set using the specified YAML file temlplate. `template.yaml` is an Amazon CloudFormation template in the current folder that defines a stack.

```
aws cloudformation create-stack-set \
    --stack-set-name my-stack-set \
    --template-body file://template.yaml \
    --description "SNS topic"
```

Output:

```
{
    "StackSetId": "my-stack-set:8d0f160b-d157-xmpl-a8e6-c0ce8e5d8cc1"
}
```

To add stack instances to the stack set, use the `create-stack-instances` command.

- For API details, see CreateStackSet in *Amazon CLI Command Reference*.

`create-stack`

The following code example shows how to use `create-stack`.

Amazon CLI

To create an Amazon CloudFormation stack

The following `create-stacks` command creates a stack with the name `myteststack` using the `sampletemplate.json` template:

```
aws cloudformation create-stack --stack-name myteststack --template-body file://
sampletemplate.json --parameters ParameterKey=KeyPairName,ParameterValue=TestKey
 ParameterKey=SubnetIDs,ParameterValue=SubnetID1\\,SubnetID2
```

Output:

```
{
    "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/
myteststack/466df9e0-0dff-08e3-8e2f-5088487c4896"
}
```

For more information, see Stacks in the *Amazon CloudFormation User Guide*.

- For API details, see CreateStack in *Amazon CLI Command Reference*.

`deactivate-type`

The following code example shows how to use `deactivate-type`.

Amazon CLI

To deactivate a type

The following `deactivate-type` example deactivates a public extension that was previously activated in this account and Region.

```
aws cloudformation deactivate-type \
    --region us-west-2 \
    --type MODULE \
    --type-name Example::Test::Type::MODULE
```

This command produces no output.

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see DeactivateType in *Amazon CLI Command Reference*.

`delete-change-set`

The following code example shows how to use `delete-change-set`.

Amazon CLI

To delete a change set

The following `delete-change-set` example deletes a change set by specifying the change set name and stack name.

```
aws cloudformation delete-change-set \
    --stack-name my-stack \
    --change-set-name my-change-set
```

This command produces no output.

The following `delete-change-set` example deletes a change set by specifying the full ARN of the change set.

```
aws cloudformation delete-change-set \
    --change-set-name arn:aws:cloudformation:us-east-2:123456789012:changeSet/my-change-set/4eca1a01-e285-xmpl-8026-9a1967bfb4b0
```

This command produces no output.

- For API details, see DeleteChangeSet in *Amazon CLI Command Reference*.

`delete-stack-instances`

The following code example shows how to use `delete-stack-instances`.

Amazon CLI

To delete stack instances

The following `delete-stack-instances` example deletes instances of a stack set in two accounts in two regions and terminates the stacks.

```
aws cloudformation delete-stack-instances \
    --stack-set-name my-stack-set \
    --accounts 123456789012 567890123456 \
    --regions us-east-1 us-west-1 \
    --no-retain-stacks
```

Output:

```
{
    "OperationId": "ad49f10c-fd1d-413f-a20a-8de6e2fa8f27"
}
```

To delete an empty stack set, use the `delete-stack-set` command.

- For API details, see DeleteStackInstances in *Amazon CLI Command Reference*.

`delete-stack-set`

The following code example shows how to use `delete-stack-set`.

Amazon CLI

To delete a stack set

The following command deletes the specified empty stack set. The stack set must be empty.

```
aws cloudformation delete-stack-set \
    --stack-set-name my-stack-set
```

This command produces no output.

To delete instances from the stack set, use the `delete-stack-instances` command.

- For API details, see DeleteStackSet in *Amazon CLI Command Reference*.

`delete-stack`

The following code example shows how to use `delete-stack`.

Amazon CLI

To delete a stack

The following `delete-stack` example deletes the specified stack.

```
aws cloudformation delete-stack \
    --stack-name my-stack
```

This command produces no output.

- For API details, see DeleteStack in *Amazon CLI Command Reference*.

`deploy`

The following code example shows how to use `deploy`.

Amazon CLI

Following command deploys template named `template.json` to a stack named `my-new-stack`:

```
aws cloudformation deploy --template-file /path_to_template/template.json
 --stack-name my-new-stack --parameter-overrides Key1=Value1 Key2=Value2 --
tags Key1=Value1 Key2=Value2
```

- For API details, see Deploy in *Amazon CLI Command Reference*.

`deregister-type`

The following code example shows how to use `deregister-type`.

Amazon CLI

To deregister a type version

The following `deregister-type` example removes the specified type version from active use in the CloudFormation registry, so that it can no longer be used in CloudFormation operations.

```
aws cloudformation deregister-type \
    --type RESOURCE \
```

```
    --type-name My::Logs::LogGroup \
    --version-id 00000002
```

This command produces no output.

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see DeregisterType in *Amazon CLI Command Reference*.

`describe-account-limits`

The following code example shows how to use `describe-account-limits`.

Amazon CLI

To get information about your account limits

The following command retrieves a list of regional limits for the current account.

```
aws cloudformation describe-account-limits
```

Output:

```
{
    "AccountLimits": [
        {
            "Name": "StackLimit",
            "Value": 200
        },
        {
            "Name": "StackOutputsLimit",
            "Value": 60
        },
        {
            "Name": "ConcurrentResourcesLimit",
            "Value": 2500
        }
    ]
}
```

- For API details, see DescribeAccountLimits in *Amazon CLI Command Reference*.

`describe-change-set`

The following code example shows how to use `describe-change-set`.

Amazon CLI

To get information about a change set

The following `describe-change-set` example displays the details of the change set specified by change set name and stack name.

```
aws cloudformation describe-change-set \
    --change-set-name my-change-set \
    --stack-name my-stack
```

The following `describe-change-set` example displays the details of the change set specified by the full ARN of the change set:

```
aws cloudformation describe-change-set \
    --change-set-name arn:aws:cloudformation:us-west-2:123456789012:changeSet/my-change-set/bc9555ba-a949-xmpl-bfb8-f41d04ec5784
```

Output:

```
{
    "Changes": [
        {
            "Type": "Resource",
            "ResourceChange": {
                "Action": "Modify",
                "LogicalResourceId": "function",
                "PhysicalResourceId": "my-function-SEZV4XMPL4S5",
                "ResourceType": "AWS::Lambda::Function",
                "Replacement": "False",
                "Scope": [
                    "Properties"
                ],
                "Details": [
                    {
                        "Target": {
                            "Attribute": "Properties",
                            "Name": "Timeout",
```

```
                            "RequiresRecreation": "Never"
                        },
                        "Evaluation": "Static",
                        "ChangeSource": "DirectModification"
                    }
                ]
            }
        }
    ],
    "ChangeSetName": "my-change-set",
    "ChangeSetId": "arn:aws:cloudformation:us-west-2:123456789012:changeSet/my-
change-set/4eca1a01-e285-xmpl-8026-9a1967bfb4b0",
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-stack/

    "RollbackConfiguration": {},
    "Capabilities": [
        "CAPABILITY_IAM"
    ],
    "Tags": null
}
```

- For API details, see DescribeChangeSet in *Amazon CLI Command Reference*.

`describe-publisher`

The following code example shows how to use `describe-publisher`.

Amazon CLI

To describe a publisher

The following `describe-publisher` example configures the information for a publisher.

```
aws cloudformation describe-publisher \
    --region us-west-2 \
```

```
    --publisher-id 000q6TfUovXsEMmgKowxDZLlwqr2QUsh
```

Output:

```
{
    "PublisherId": "000q6TfUovXsEMmgKowxDZLlwqr2QUshd2e75c8c",
    "PublisherStatus": "VERIFIED",
    "IdentityProvider": "AWS_Marketplace",
    "PublisherProfile": "https://aws.amazon.com/marketplace/seller-profile?
id=2c5dc1f0-17cd-4259-8e46-822a83gdtegd"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see DescribePublisher in *Amazon CLI Command Reference*.

`describe-stack-drift-detection-status`

The following code example shows how to use `describe-stack-drift-detection-status`.

Amazon CLI

To check a drift detection operation's status

The following `describe-stack-drift-detection-status` example displays the status of a drift detection operation. Get the by ID running the `detect-stack-drift` command.

```
aws cloudformation describe-stack-drift-detection-status \
    --stack-drift-detection-id 1a229160-e4d9-xmpl-ab67-0a4f93df83d4
```

Output:

```
{
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-stack/
d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
    "StackDriftDetectionId": "1a229160-e4d9-xmpl-ab67-0a4f93df83d4",
    "StackDriftStatus": "DRIFTED",
    "DetectionStatus": "DETECTION_COMPLETE",
    "DriftedStackResourceCount": 1,
    "Timestamp": "2019-10-02T05:54:30.902Z"
}
```

- For API details, see DescribeStackDriftDetectionStatus in *Amazon CLI Command Reference*.

`describe-stack-events`

The following code example shows how to use `describe-stack-events`.

Amazon CLI

To describe stack events

The following `describe-stack-events` example displays the 2 most recent events for the specified stack.

```
aws cloudformation describe-stack-events \
    --stack-name my-stack \
    --max-items 2

{
    "StackEvents": [
        {
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-
stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "EventId": "4e1516d0-e4d6-xmpl-b94f-0a51958a168c",
            "StackName": "my-stack",
            "LogicalResourceId": "my-stack",
            "PhysicalResourceId": "arn:aws:cloudformation:us-
west-2:123456789012:stack/my-stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "ResourceType": "AWS::CloudFormation::Stack",
            "Timestamp": "2019-10-02T05:34:29.556Z",
            "ResourceStatus": "UPDATE_COMPLETE"
        },
        {
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-

            "ResourceStatus": "UPDATE_COMPLETE_CLEANUP_IN_PROGRESS"
        }
```

```
    ],

 "NextToken": "eyJOZXh0VG9XMPLiOiBudWxsLCAiYm90b190cnVuY2F0ZV9hbW91bnQiOiAyfQ=="
}
```

- For API details, see DescribeStackEvents in *Amazon CLI Command Reference*.

`describe-stack-instance`

The following code example shows how to use `describe-stack-instance`.

Amazon CLI

To describe a stack instance

The following command describes an instance of the specified stack set in the specified account and Region. The stack set is in the current region and account, and the instance is in the `us-west-2` region in account 123456789012.:

```
aws cloudformation describe-stack-instance \
    --stack-set-name my-stack-set \
    --stack-instance-account 123456789012 \
    --stack-instance-region us-west-2
```

Output:

```
{
    "StackInstance": {
        "StackSetId": "enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
        "Region": "us-west-2",
        "Account": "123456789012",
        "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/
StackSet-enable-config-e6cac20f-xmpl-46e9-8314-53e0d4591532/4287f9a0-e615-
xmpl-894a-12b31d3117be",
        "ParameterOverrides": [],
        "Status": "OUTDATED",
        "StatusReason": "ResourceLogicalId:ConfigBucket,
 ResourceType:AWS::S3::Bucket, ResourceStatusReason:You have attempted to create
 more buckets than allowed (Service: Amazon S3; Status Code: 400; Error Code:
 TooManyBuckets; Request ID: F7F21CXMPL580224; S3 Extended Request ID: egd/
Fdt89BXMPLyiqbMNljVk55Yqqvi3NYW2nKLUVWhUGEhNfCmZdyj967lhriaG/dWMobSO40o=)."
```

```
    }
}
```

- For API details, see DescribeStackInstance in *Amazon CLI Command Reference*.

`describe-stack-resource-drifts`

The following code example shows how to use `describe-stack-resource-drifts`.

Amazon CLI

To get information about resources that drifted from the stack definition

The following command displays information about drifted resources for the specified stack. To initiate drift detection, use the `detect-stack-drift` command.:

```
aws cloudformation describe-stack-resource-drifts \
    --stack-name my-stack
```

The output shows an Amazon Lambda function that was modified out-of-band:

```
{
    "StackResourceDrifts": [
        {
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-
stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "LogicalResourceId": "function",
            "PhysicalResourceId": "my-function-SEZV4XMPL4S5",
            "ResourceType": "AWS::Lambda::Function",
            "ExpectedProperties": "{\"Description\":\"Write a file to S3.\",
\"Environment\":{\"Variables\":{\"bucket\":\"my-stack-bucket-1vc62xmplgguf
\"}},\"Handler\":\"index.handler\",\"MemorySize\":128,\"Role\":

\":22,\"TracingConfig\":{\"Mode\":\"Active\"}}",
            "PropertyDifferences": [
```

```
                {
                    "PropertyPath": "/MemorySize",
                    "ExpectedValue": "128",
                    "ActualValue": "256",
                    "DifferenceType": "NOT_EQUAL"
                },
                {
                    "PropertyPath": "/Timeout",
                    "ExpectedValue": "900",
                    "ActualValue": "22",
                    "DifferenceType": "NOT_EQUAL"
                }
            ],
            "StackResourceDriftStatus": "MODIFIED",
            "Timestamp": "2019-10-02T05:54:44.064Z"
        }
    ]
}
```

- For API details, see DescribeStackResourceDrifts in *Amazon CLI Command Reference*.

`describe-stack-resource`

The following code example shows how to use `describe-stack-resource`.

Amazon CLI

To get information about a stack resource

The following `describe-stack-resource` example displays details for the resource named `MyFunction` in the specified stack.

```
aws cloudformation describe-stack-resource \
    --stack-name MyStack \
    --logical-resource-id MyFunction
```

Output:

```
{
    "StackResourceDetail": {
        "StackName": "MyStack",
```

```
        "StackId": "arn:aws:cloudformation:us-east-2:123456789012:stack/MyStack/
d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
        "LogicalResourceId": "MyFunction",
        "PhysicalResourceId": "my-function-SEZV4XMPL4S5",
        "ResourceType": "AWS::Lambda::Function",
        "LastUpdatedTimestamp": "2019-10-02T05:34:27.989Z",
        "ResourceStatus": "UPDATE_COMPLETE",
        "Metadata": "{}",
        "DriftInformation": {
            "StackResourceDriftStatus": "IN_SYNC"
        }
    }
}
```

- For API details, see DescribeStackResource in *Amazon CLI Command Reference*.

`describe-stack-resources`

The following code example shows how to use `describe-stack-resources`.

Amazon CLI

To get information about a stack resource

The following `describe-stack-resources` example displays details for the resources in the specified stack.

```
aws cloudformation describe-stack-resources \
    --stack-name my-stack
```

Output:

```
{
    "StackResources": [
        {
            "StackName": "my-stack",
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-
stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "LogicalResourceId": "bucket",
            "PhysicalResourceId": "my-stack-bucket-1vc62xmplgguf",
            "ResourceType": "AWS::S3::Bucket",
            "Timestamp": "2019-10-02T04:34:11.345Z",
```

```
            "ResourceStatus": "CREATE_COMPLETE",
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        },
        {
            "StackName": "my-stack",
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-

            "ResourceStatus": "UPDATE_COMPLETE",
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        },
        {
            "StackName": "my-stack",
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-
stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "LogicalResourceId": "functionRole",
            "PhysicalResourceId": "my-functionRole-HIZXMPLEOM9E",
            "ResourceType": "AWS::IAM::Role",
            "Timestamp": "2019-10-02T04:34:06.350Z",
            "ResourceStatus": "CREATE_COMPLETE",
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        }
    ]
}
```

- For API details, see DescribeStackResources in *Amazon CLI Command Reference*.

`describe-stack-set-operation`

The following code example shows how to use `describe-stack-set-operation`.

Amazon CLI

To get information about a stack set operation

The following describe-stack-set-operation ` example displays details for an update operation on the specified stack set.

```
aws cloudformation describe-stack-set-operation \
    --stack-set-name enable-config \
    --operation-id 35d45ebc-ed88-xmpl-ab59-0197a1fc83a0
```

Output:

```
{
    "StackSetOperation": {
        "OperationId": "35d45ebc-ed88-xmpl-ab59-0197a1fc83a0",
        "StackSetId": "enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
        "Action": "UPDATE",
        "Status": "SUCCEEDED",
        "OperationPreferences": {
            "RegionOrder": [
                "us-east-1",
                "us-west-2",
                "eu-west-1",
                "us-west-1"
            ],
            "FailureToleranceCount": 7,
            "MaxConcurrentCount": 2
        },
        "AdministrationRoleARN": "arn:aws:iam::123456789012:role/
AWSCloudFormationStackSetAdministrationRole",
        "ExecutionRoleName": "AWSCloudFormationStackSetExecutionRole",
        "CreationTimestamp": "2019-10-03T16:28:44.377Z",
        "EndTimestamp": "2019-10-03T16:42:08.607Z"
    }
}
```

- For API details, see DescribeStackSetOperation in *Amazon CLI Command Reference*.

`describe-stack-set`

The following code example shows how to use `describe-stack-set`.

Amazon CLI

To get information about a stack set

The following describe-stack-set` example displays details about the specified stack set.

```
aws cloudformation describe-stack-set \
    --stack-set-name my-stack-set
```

Output:

```
{
    "StackSet": {
        "StackSetName": "my-stack-set",
        "StackSetId": "my-stack-set:296a3360-xmpl-40af-be78-9341e95bf743",
        "Description": "Create an Amazon SNS topic",
        "Status": "ACTIVE",
        "TemplateBody": "AWSTemplateFormatVersion: '2010-09-09'\nDescription: An AWS
 SNS topic\nResources:\n  topic:\n    Type: AWS::SNS::Topic",
        "Parameters": [],
        "Capabilities": [],
        "Tags": [],
        "StackSetARN": "arn:aws:cloudformation:us-west-2:123456789012:stackset/
enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
        "AdministrationRoleARN": "arn:aws:iam::123456789012:role/
AWSCloudFormationStackSetAdministrationRole",
        "ExecutionRoleName": "AWSCloudFormationStackSetExecutionRole"
    }
}
```

- For API details, see DescribeStackSet in *Amazon CLI Command Reference*.

`describe-stacks`

The following code example shows how to use `describe-stacks`.

Amazon CLI

To describe Amazon CloudFormation stacks

The following `describe-stacks` command shows summary information for the `myteststack` stack:

```
aws cloudformation describe-stacks --stack-name myteststack
```

Output:

```
{
    "Stacks":  [
        {
            "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/
myteststack/466df9e0-0dff-08e3-8e2f-5088487c4896",
            "Description": "AWS CloudFormation Sample Template S3_Bucket: Sample
 template showing how to create a publicly accessible S3 bucket. **WARNING** This
 template creates an S3 bucket. You will be billed for the AWS resources used if you
 create a stack from this template.",
            "Tags": [],
            "Outputs": [
                {
                    "Description": "Name of S3 bucket to hold website content",
                    "OutputKey": "BucketName",
                    "OutputValue": "myteststack-s3bucket-jssofi1zie2w"
                }
            ],
            "StackStatusReason": null,
            "CreationTime": "2013-08-23T01:02:15.422Z",
            "Capabilities": [],
            "StackName": "myteststack",
            "StackStatus": "CREATE_COMPLETE",
            "DisableRollback": false
        }
    ]
}
```

For more information, see Stacks in the *Amazon CloudFormation User Guide*.

- For API details, see DescribeStacks in *Amazon CLI Command Reference*.

`describe-type-registration`

The following code example shows how to use `describe-type-registration`.

Amazon CLI

To display type registration information

The following `describe-type-registration` example displays information about the specified type registration, including the type's current status, type, and version.

```
aws cloudformation describe-type-registration \
    --registration-token a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "ProgressStatus": "COMPLETE",
    "TypeArn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/My-Logs-LogGroup",
    "Description": "Deployment is currently in DEPLOY_STAGE of status COMPLETED; ",
    "TypeVersionArn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/My-Logs-LogGroup/00000001"
}
```

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see DescribeTypeRegistration in *Amazon CLI Command Reference*.

`describe-type`

The following code example shows how to use `describe-type`.

Amazon CLI

To display type information

The following `describe-type` example displays information for the specified type.

```
aws cloudformation describe-type \
    --type-name My::Logs::LogGroup \
    --type RESOURCE
```

Output:

```
{
    "SourceUrl": "https://github.com/aws-cloudformation/aws-cloudformation-resource-providers-logs.git",
    "Description": "Customized resource derived from AWS::Logs::LogGroup",
    "TimeCreated": "2019-12-03T23:29:33.321Z",
    "Visibility": "PRIVATE",
```

```
    "TypeName": "My::Logs::LogGroup",
    "LastUpdated": "2019-12-03T23:29:33.321Z",
    "DeprecatedStatus": "LIVE",
    "ProvisioningType": "FULLY_MUTABLE",
    "Type": "RESOURCE",
    "Arn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/My-Logs-
LogGroup/00000001",
    "Schema": "[details omitted]"
}
```

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see DescribeType in *Amazon CLI Command Reference*.

`detect-stack-drift`

The following code example shows how to use `detect-stack-drift`.

Amazon CLI

To detect drifted resources

The following `detect-stack-drift` example initiates drift detection for the specified stack.

```
aws cloudformation detect-stack-drift \
    --stack-name my-stack
```

Output:

```
{
    "StackDriftDetectionId": "1a229160-e4d9-xmpl-ab67-0a4f93df83d4"
}
```

You can then use this ID with the `describe-stack-resource-drifts` command to describe drifted resources.

- For API details, see DetectStackDrift in *Amazon CLI Command Reference*.

`detect-stack-resource-drift`

The following code example shows how to use `detect-stack-resource-drift`.

Amazon CLI

To detect drift for a resource

The following `detect-stack-resource-drift` example checks a resource named `MyFunction` in a stack named `MyStack` for drift:

```
aws cloudformation detect-stack-resource-drift \
   --stack-name MyStack \
   --logical-resource-id MyFunction
```

The output shows an Amazon Lambda function that was modified out-of-band:

```
{
    "StackResourceDrift": {
        "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/MyStack/
d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
        "LogicalResourceId": "MyFunction",
        "PhysicalResourceId": "my-function-SEZV4XMPL4S5",
        "ResourceType": "AWS::Lambda::Function",
        "ExpectedProperties": "{\"Description\":\"Write a file to S3.\",
\"Environment\":{\"Variables\":{\"bucket\":\"my-stack-bucket-1vc62xmplgguf
\"}},\"Handler\":\"index.handler\",\"MemorySize\":128,\"Role\":

\"nodejs10.x\",\"Tags\":[{\"Key\":\"lambda:createdBy\",\"Value\":\"SAM\"}],\"Timeout
\":900,\"TracingConfig\":{\"Mode\":\"Active\"}}",
        "ActualProperties": "{\"Description\":\"Write a file to S3.\",\"Environment
\":{\"Variables\":{\"bucket\":\"my-stack-bucket-1vc62xmplgguf\"}},\"Handler\":
\"index.handler\",\"MemorySize\":256,\"Role\":\"arn:aws:iam::123456789012:role/
my-functionRole-HIZXMPLEOM9E\",\"Runtime\":\"nodejs10.x\",\"Tags\":[{\"Key\":
\"lambda:createdBy\",\"Value\":\"SAM\"}],\"Timeout\":22,\"TracingConfig\":{\"Mode\":
\"Active\"}}",
        "PropertyDifferences": [
            {
                "PropertyPath": "/MemorySize",
                "ExpectedValue": "128",
                "ActualValue": "256",
                "DifferenceType": "NOT_EQUAL"
            },
            {
                "PropertyPath": "/Timeout",
                "ExpectedValue": "900",
                "ActualValue": "22",
```

```
                "DifferenceType": "NOT_EQUAL"
            }
        ],
        "StackResourceDriftStatus": "MODIFIED",
        "Timestamp": "2019-10-02T05:58:47.433Z"
    }
}
```

- For API details, see DetectStackResourceDrift in *Amazon CLI Command Reference*.

`detect-stack-set-drift`

The following code example shows how to use `detect-stack-set-drift`.

Amazon CLI

To detect drift on a stack set and all associated stack instances

The following `detect-stack-set-drift` example initiates drift detection operations on the specified stack set, including all the stack instances associated with that stack set, and returns an operation ID that can be used to track the status of the drift operation.

```
aws cloudformation detect-stack-set-drift \
    --stack-set-name stack-set-drift-example
```

Output:

```
{
    "OperationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
```

For more information, see Detecting Unmanaged Configuration Changes in Stack Sets in the *Amazon CloudFormation Users Guide*.

- For API details, see DetectStackSetDrift in *Amazon CLI Command Reference*.

`estimate-template-cost`

The following code example shows how to use `estimate-template-cost`.

Amazon CLI

To estimate template cost

The following `estimate-template-cost` example generates a cost estimate for a template named `template.yaml` in the current folder.

```
aws cloudformation estimate-template-cost \
    --template-body file://template.yaml
```

Output:

```
{
    "Url": "http://calculator.s3.amazonaws.com/calc5.html?
key=cloudformation/7870825a-xmpl-4def-92e7-c4f8dd360cca"
}
```

- For API details, see EstimateTemplateCost in *Amazon CLI Command Reference*.

`execute-change-set`

The following code example shows how to use `execute-change-set`.

Amazon CLI

To execute a change set

The following `execute-change-set` example executes a change set specified by change set name and stack name.

```
aws cloudformation execute-change-set \
    --change-set-name my-change-set \
    --stack-name my-stack
```

The following `execute-change-set` example executes a change set specified by the full ARN of the change set.

```
aws cloudformation execute-change-set \
    --change-set-name arn:aws:cloudformation:us-west-2:123456789012:changeSet/my-
change-set/bc9555ba-a949-xmpl-bfb8-f41d04ec5784
```

- For API details, see ExecuteChangeSet in *Amazon CLI Command Reference*.

`get-stack-policy`

The following code example shows how to use `get-stack-policy`.

Amazon CLI

To view a stack policy

The following `get-stack-policy` example displays the stack policy for the specified stack. To attach a policy to a stack, use the `set-stack-policy` command.

```
aws cloudformation get-stack-policy \
    --stack-name my-stack
```

Output:

```
{
    "StackPolicyBody": "{\n  \"Statement\" : [\n    {\n      \"Effect\" :
 \"Allow\",\n      \"Action\" : \"Update:*\",\n      \"Principal\": \"*\",\n
     \"Resource\" : \"*\"\n    },\n    {\n      \"Effect\" : \"Deny\",\n
 \"Action\" : \"Update:*\",\n      \"Principal\": \"*\",\n      \"Resource\" :
 \"LogicalResourceId/bucket\"\n    }\n  ]\n}\n"
}
```

- For API details, see GetStackPolicy in *Amazon CLI Command Reference*.

`get-template-summary`

The following code example shows how to use `get-template-summary`.

Amazon CLI

To display a template summary

The following command displays summary information about the resources and metadata for the specified template file.

```
aws cloudformation get-template-summary \
```

```
    --template-body file://template.yaml
```

Output:

```
{
    "Parameters": [],
    "Description": "A VPC and subnets.",
    "ResourceTypes": [
        "AWS::EC2::VPC",
        "AWS::EC2::Subnet",
        "AWS::EC2::Subnet",
        "AWS::EC2::RouteTable",
        "AWS::EC2::VPCEndpoint",
        "AWS::EC2::SubnetRouteTableAssociation",
        "AWS::EC2::SubnetRouteTableAssociation",
        "AWS::EC2::VPCEndpoint"
    ],
    "Version": "2010-09-09"
}
```

- For API details, see GetTemplateSummary in *Amazon CLI Command Reference*.

`get-template`

The following code example shows how to use `get-template`.

Amazon CLI

To view the template body for an Amazon CloudFormation stack

The following `get-template` command shows the template for the `myteststack` stack:

```
aws cloudformation get-template --stack-name myteststack
```

Output:

```
{
    "TemplateBody": {
        "AWSTemplateFormatVersion": "2010-09-09",
        "Outputs": {
            "BucketName": {
```

```
                "Description": "Name of S3 bucket to hold website content",
                "Value": {
                    "Ref": "S3Bucket"
                }
            }
        },
        "Description": "AWS CloudFormation Sample Template S3_Bucket: Sample
 template showing how to create a publicly accessible S3 bucket. **WARNING** This
 template creates an S3 bucket. You will be billed for the AWS resources used if you
 create a stack from this template.",
        "Resources": {
            "S3Bucket": {
                "Type": "AWS::S3::Bucket",
                "Properties": {
                    "AccessControl": "PublicRead"
                }
            }
        }
    }
}
```

- For API details, see GetTemplate in *Amazon CLI Command Reference*.

`list-change-sets`

The following code example shows how to use `list-change-sets`.

Amazon CLI

To list change sets

The following `list-change-sets` example displays a list of the pending change sets for the specified stack.

```
aws cloudformation list-change-sets \
   --stack-name my-stack
```

Output:

```
{
    "Summaries": [
        {
```

```
            "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-
stack/d0a825a0-e4cd-xmpl-b9fb-061c69e99204",
            "StackName": "my-stack",
            "ChangeSetId": "arn:aws:cloudformation:us-west-2:123456789012:changeSet/
my-change-set/70160340-7914-xmpl-bcbf-128a1fa78b5d",
            "ChangeSetName": "my-change-set",
            "ExecutionStatus": "AVAILABLE",
            "Status": "CREATE_COMPLETE",
            "CreationTime": "2019-10-02T05:38:54.297Z"
        }
    ]
}
```

- For API details, see ListChangeSets in *Amazon CLI Command Reference*.

`list-exports`

The following code example shows how to use `list-exports`.

Amazon CLI

To list exports

The following `list-exports` example displays a list of the exports from stacks in the current region.

```
aws cloudformation list-exports
```

Output:

```
{
    "Exports": [
        {
            "ExportingStackId": "arn:aws:cloudformation:us-
west-2:123456789012:stack/private-vpc/99764070-b56c-xmpl-bee8-062a88d1d800",
            "Name": "private-vpc-subnet-a",
            "Value": "subnet-07b410xmplddcfa03"
        },
        {
            "ExportingStackId": "arn:aws:cloudformation:us-
west-2:123456789012:stack/private-vpc/99764070-b56c-xmpl-bee8-062a88d1d800",
            "Name": "private-vpc-subnet-b",
```

```
            "Value": "subnet-075ed3xmplebd2fb1"
        },
        {
            "ExportingStackId": "arn:aws:cloudformation:us-
west-2:123456789012:stack/private-vpc/99764070-b56c-xmpl-bee8-062a88d1d800",
            "Name": "private-vpc-vpcid",
            "Value": "vpc-011d7xmpl100e9841"
        }
    ]
}
```

- For API details, see ListExports in *Amazon CLI Command Reference*.

`list-imports`

The following code example shows how to use `list-imports`.

Amazon CLI

To list imports

The following `list-imports` example lists the stacks that import the specified export. To get the list of available exports, use the `list-exports` command.

```
aws cloudformation list-imports \
    --export-name private-vpc-vpcid
```

Output:

```
{
    "Imports": [
        "my-database-stack"
    ]
}
```

- For API details, see ListImports in *Amazon CLI Command Reference*.

`list-stack-instances`

The following code example shows how to use `list-stack-instances`.

Amazon CLI

To list instances for a stack

The following `list-stack-instances` example lists the instances created from the specified stack set.

```
aws cloudformation list-stack-instances \
    --stack-set-name enable-config
```

The example output includes details about a stack that failed to update due to an error:

```
{
    "Summaries": [
        {
            "StackSetId": "enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
            "Region": "us-west-2",
            "Account": "123456789012",
            "StackId": "arn:aws:cloudformation:ap-northeast-1:123456789012:stack/

ConfigDeliveryChannel-1OJWJ7XD59WR0' because the maximum number of delivery
 channels: 1 is reached. (Service: AmazonConfig; Status Code: 400; Error Code:
 MaxNumberOfDeliveryChannelsExceededException; Request ID: d14b34a0-ef7c-xmpl-
acf8-8a864370ae56)."
        }
    ]
}
```

- For API details, see ListStackInstances in *Amazon CLI Command Reference*.

`list-stack-resources`

The following code example shows how to use `list-stack-resources`.

Amazon CLI

To list resources in a stack

The following command displays the list of resources in the specified stack.

```
aws cloudformation list-stack-resources \
    --stack-name my-stack
```

Output:

```
{
    "StackResourceSummaries": [
        {
            "LogicalResourceId": "bucket",
            "PhysicalResourceId": "my-stack-bucket-1vc62xmplgguf",
            "ResourceType": "AWS::S3::Bucket",
            "LastUpdatedTimestamp": "2019-10-02T04:34:11.345Z",
            "ResourceStatus": "CREATE_COMPLETE",
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        },
        {
            "LogicalResourceId": "function",
            "PhysicalResourceId": "my-function-SEZV4XMPL4S5",
            "ResourceType": "AWS::Lambda::Function",
            "LastUpdatedTimestamp": "2019-10-02T05:34:27.989Z",
            "ResourceStatus": "UPDATE_COMPLETE",
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        },
        {
            "LogicalResourceId": "functionRole",
            "PhysicalResourceId": "my-functionRole-HIZXMPLEOM9E",
            "ResourceType": "AWS::IAM::Role",
            "LastUpdatedTimestamp": "2019-10-02T04:34:06.350Z",
            "ResourceStatus": "CREATE_COMPLETE",
```

```
            "DriftInformation": {
                "StackResourceDriftStatus": "IN_SYNC"
            }
        }
    ]
}
```

- For API details, see ListStackResources in *Amazon CLI Command Reference*.

`list-stack-set-operation-results`

The following code example shows how to use `list-stack-set-operation-results`.

Amazon CLI

To list stack set operation results

The following command displays the results of an update operation on instances in the specified stack set.

```
aws cloudformation list-stack-set-operation-results \
    --stack-set-name enable-config \
    --operation-id 35d45ebc-ed88-xmpl-ab59-0197a1fc83a0
```

Output:

```
{
    "Summaries": [
        {
            "Account": "223456789012",
            "Region": "us-west-2",
            "Status": "SUCCEEDED",
            "AccountGateResult": {
                "Status": "SKIPPED",
                "StatusReason": "Function not found: arn:aws:lambda:eu-
west-1:223456789012:function:AWSCloudFormationStackSetAccountGate"
            }
        },
        {
            "Account": "223456789012",
            "Region": "ap-south-1",
            "Status": "CANCELLED",
```

```
            "StatusReason": "Cancelled since failure tolerance has exceeded"
        }
    ]
}
```

Note: The `SKIPPED` status for `AccountGateResult` is expected for successful operations unless you create an account gate function.

- For API details, see ListStackSetOperationResults in *Amazon CLI Command Reference*.

`list-stack-set-operations`

The following code example shows how to use `list-stack-set-operations`.

Amazon CLI

To list stack set operations

The following `list-stack-set-operations` example displays the list of the most recent operations on the specified stack set.

```
aws cloudformation list-stack-set-operations \
    --stack-set-name my-stack-set
```

Output:

```
{
    "Summaries": [
        {
            "OperationId": "35d45ebc-ed88-xmpl-ab59-0197a1fc83a0",
            "Action": "UPDATE",
            "Status": "SUCCEEDED",
            "CreationTimestamp": "2019-10-03T16:28:44.377Z",
            "EndTimestamp": "2019-10-03T16:42:08.607Z"
        },
        {
            "OperationId": "891aa98f-7118-xmpl-00b2-00954d1dd0d6",
            "Action": "UPDATE",
            "Status": "FAILED",
            "CreationTimestamp": "2019-10-03T15:43:53.916Z",
            "EndTimestamp": "2019-10-03T15:45:58.925Z"
        }
```

```
    ]
}
```

- For API details, see ListStackSetOperations in *Amazon CLI Command Reference*.

`list-stack-sets`

The following code example shows how to use `list-stack-sets`.

Amazon CLI

To list stack sets

The following `list-stack-sets` example displays the list of stack sets in the current region and account.

```
aws cloudformation list-stack-sets
```

Output:

```
{
    "Summaries": [
        {
            "StackSetName": "enable-config",
            "StackSetId": "enable-config:296a3360-xmpl-40af-be78-9341e95bf743",
            "Description": "Enable AWS Config",
            "Status": "ACTIVE"
        }
    ]
}
```

- For API details, see ListStackSets in *Amazon CLI Command Reference*.

`list-stacks`

The following code example shows how to use `list-stacks`.

Amazon CLI

To list Amazon CloudFormation stacks

The following `list-stacks` command shows a summary of all stacks that have a status of `CREATE_COMPLETE`:

```
aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE
```

Output:

```
[
    {
        "StackId": "arn:aws:cloudformation:us-east-1:123456789012:stack/
myteststack/466df9e0-0dff-08e3-8e2f-5088487c4896",
        "TemplateDescription": "AWS CloudFormation Sample Template S3_Bucket: Sample
 template showing how to create a publicly accessible S3 bucket. **WARNING** This
 template creates an S3 bucket. You will be billed for the AWS resources used if you
 create a stack from this template.",
        "StackStatusReason": null,
        "CreationTime": "2013-08-26T03:27:10.190Z",
        "StackName": "myteststack",
        "StackStatus": "CREATE_COMPLETE"
    }
]
```

- For API details, see ListStacks in *Amazon CLI Command Reference*.

`list-type-registrations`

The following code example shows how to use `list-type-registrations`.

Amazon CLI

To list the completed registrations of a type

The following `list-type-registrations` example displays a list of the completed type registrations for the specified type.

```
aws cloudformation list-type-registrations \
    --type RESOURCE \
    --type-name My::Logs::LogGroup \
    --registration-status-filter COMPLETE
```

Output:

```
{
    "RegistrationTokenList": [
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333"
    ]
}
```

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see ListTypeRegistrations in *Amazon CLI Command Reference*.

`list-type-versions`

The following code example shows how to use `list-type-versions`.

Amazon CLI

To list an extension's version

The following `list-type-versions` example returns summary information about the versions of an extension.

```
aws cloudformation list-type-versions \
  --endpoint https://example.com \
  --region us-west-2 \
  --type RESOURCE \
  --type-name My::Resource::Example \
  --publisher-id 123456789012
```

This command produces no output.

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see ListTypeVersions in *Amazon CLI Command Reference*.

`list-types`

The following code example shows how to use `list-types`.

Amazon CLI

To list the private resource types in an account

The following `list-types` example displays a list of the private resource types currently registered in the current Amazon account.

```
aws cloudformation list-types
```

Output:

```
{
    "TypeSummaries": [
        {
            "Description": "WordPress blog resource for internal use",
            "LastUpdated": "2019-12-04T18:28:15.059Z",
            "TypeName": "My::WordPress::BlogExample",
            "TypeArn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/
My-WordPress-BlogExample",
            "DefaultVersionId": "00000005",
            "Type": "RESOURCE"
        },
        {
            "Description": "Customized resource derived from AWS::Logs::LogGroup",
            "LastUpdated": "2019-12-04T18:28:15.059Z",
            "TypeName": "My::Logs::LogGroup",
            "TypeArn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/
My-Logs-LogGroup",
            "DefaultVersionId": "00000003",
            "Type": "RESOURCE"
        }
    ]
}
```

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see ListTypes in *Amazon CLI Command Reference*.

package

The following code example shows how to use `package`.

Amazon CLI

Following command exports a template named `template.json` by uploading local artifacts to S3 bucket `bucket-name` and writes the exported template to `packaged-template.json`:

```
aws cloudformation package --template-file /path_to_template/template.json --s3-
bucket bucket-name --output-template-file packaged-template.json --use-json
```

- For API details, see Package in *Amazon CLI Command Reference*.

`publish-type`

The following code example shows how to use `publish-type`.

Amazon CLI

To publish an extension

The following `publish-type` example publishes the specified extension to the CloudFormation registry as a public extension in this Region.

```
aws cloudformation publish-type \
  --region us-west-2 \
  --type RESOURCE \
  --type-name Example::Test::1234567890abcdef0
```

Output:

```
{
    "PublicTypeArn":"arn:aws:cloudformation:us-west-2::type/
resource/000q6TfUovXsEMmgKowxDZLlwqr2QUshd2e75c8c/Example-
Test-1234567890abcdef0/1.0.0"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see PublishType in *Amazon CLI Command Reference*.

`register-publisher`

The following code example shows how to use `register-publisher`.

Amazon CLI

To register a publisher

The following `register-publisher` example registers a publisher and accepts the terms and condition parameter.

```
aws cloudformation register-publisher \
  --region us-west-2 \
  --accept-terms-and-conditions
```

Output:

```
{
    "PublisherId": "000q6TfUovXsEMmgKowxDZLlwqr2QUshd2e75c8c"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see RegisterPublisher in *Amazon CLI Command Reference*.

`register-type`

The following code example shows how to use `register-type`.

Amazon CLI

To register a resource type

The following `register-type` example registers the specified resource type as a private resource type in the user's account.

```
aws cloudformation register-type \
    --type-name My::Organization::ResourceName \
    --schema-handler-package s3://bucket_name/my-organization-resource_name.zip \
    --type RESOURCE
```

Output:

```
{
    "RegistrationToken": "f5525280-104e-4d35-bef5-8f1f1example"
}
```

For more information, see Registering Resource Providers in the *CloudFormation Command Line Interface User Guide for Type Development*.

- For API details, see RegisterType in *Amazon CLI Command Reference*.

`set-stack-policy`

The following code example shows how to use `set-stack-policy`.

Amazon CLI

To apply a stack policy

The following `set-stack-policy` example disables updates for the specified resource in the specified stack. `stack-policy.json` is a JSON document that defines the operations allowed on resources in the stack.

```
aws cloudformation set-stack-policy \
    --stack-name my-stack \
    --stack-policy-body file://stack-policy.json
```

Output:

```
{
  "Statement" : [
    {
      "Effect" : "Allow",
      "Action" : "Update:*",
      "Principal": "*",
      "Resource" : "*"
    },
    {
      "Effect" : "Deny",
      "Action" : "Update:*",
      "Principal": "*",
```

```
      "Resource" : "LogicalResourceId/bucket"
    }
  ]
}
```

- For API details, see SetStackPolicy in *Amazon CLI Command Reference*.

`set-type-configuration`

The following code example shows how to use `set-type-configuration`.

Amazon CLI

To configure data

The following `set-type-configuration` example specifies the configuration data for a registered CloudFormation extension, in the given account and Region.

```
aws cloudformation set-type-configuration \
    --region us-west-2 \
    --type RESOURCE \
    --type-name Example::Test::Type \
    --configuration-alias default \
    --configuration "{\"CredentialKey\": \"testUserCredential\"}"
```

Output:

```
{
    "ConfigurationArn": "arn:aws:cloudformation:us-west-2:123456789012:type-
configuration/resource/Example-Test-Type/default"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see SetTypeConfiguration in *Amazon CLI Command Reference*.

`set-type-default-version`

The following code example shows how to use `set-type-default-version`.

Amazon CLI

To set a type's default version

The following `set-type-default-version` example sets the specified type version to be used as the default for this type.

```
aws cloudformation set-type-default-version \
    --type RESOURCE \
    --type-name My::Logs::LogGroup \
    --version-id 00000003
```

This command produces no output.

For more information, see Using the CloudFormation Registry in the *Amazon CloudFormation Users Guide*.

- For API details, see SetTypeDefaultVersion in *Amazon CLI Command Reference*.

`signal-resource`

The following code example shows how to use `signal-resource`.

Amazon CLI

To signal a resource

The following `signal-resource` example signals `success` to fulfill the wait condition named `MyWaitCondition` in the stack named `my-stack`.

```
aws cloudformation signal-resource \
    --stack-name my-stack \
    --logical-resource-id MyWaitCondition \
    --unique-id 1234 \
    --status SUCCESS
```

This command produces no output.

- For API details, see SignalResource in *Amazon CLI Command Reference*.

`stop-stack-set-operation`

The following code example shows how to use `stop-stack-set-operation`.

Amazon CLI

To stop a stack set operation

The following `stop-stack-set-operation` example stops an in-progess update operation on the specified stack set.

```
aws cloudformation stop-stack-set-operation \
    --stack-set-name my-stack-set \
    --operation-id 1261cd27-490b-xmpl-ab42-793a896c69e6
```

This command produces no output.

- For API details, see StopStackSetOperation in *Amazon CLI Command Reference*.

`test-type`

The following code example shows how to use `test-type`.

Amazon CLI

To test an extension

The following `test-type` example tests a registered extension to make sure it meets all necessary requirements for being published in the CloudFormation registry.

```
aws cloudformation test-type \
    --arn arn:aws:cloudformation:us-west-2:123456789012:type/resource/Sample-Test-Resource123/00000001
```

Output:

```
{
    "TypeVersionArn": "arn:aws:cloudformation:us-west-2:123456789012:type/resource/Sample-Test-Resource123/00000001"
}
```

For more information, see Using the Amazon CloudFormation registry in the *Amazon CloudFormation User Guide*.

- For API details, see TestType in *Amazon CLI Command Reference*.

update-stack-instances

The following code example shows how to use update-stack-instances.

Amazon CLI

To update stack instances

The following update-stack-instances example retries an update on stack instances in two accounts in two regions with the most recent settings. The specified fault tolerance setting ensures that the update is attempted in all accounts and regions, even if some stacks cannot be updated.

```
aws cloudformation update-stack-instances \
    --stack-set-name my-stack-set \
    --accounts 123456789012 567890123456 \
    --regions us-east-1 us-west-2 \
    --operation-preferences FailureToleranceCount=3
```

Output:

```
{
    "OperationId": "103ebdf2-21ea-xmpl-8892-de5e30733132"
}
```

- For API details, see UpdateStackInstances in *Amazon CLI Command Reference*.

update-stack-set

The following code example shows how to use update-stack-set.

Amazon CLI

To update a stack set

The following update-stack-set example adds a tag with the key name Owner and a value of IT to the stack instances in the specified stack set.

```
aws cloudformation update-stack-set \
    --stack-set-name my-stack-set \
```

```
    --use-previous-template \
    --tags Key=Owner,Value=IT
```

Output:

```
{
    "OperationId": "e2b60321-6cab-xmpl-bde7-530c6f47950e"
}
```

- For API details, see UpdateStackSet in *Amazon CLI Command Reference*.

`update-stack`

The following code example shows how to use `update-stack`.

Amazon CLI

To update Amazon CloudFormation stacks

The following `update-stack` command updates the template and input parameters for the `mystack` stack:

```
aws cloudformation update-stack --stack-name mystack --
template-url https://s3.amazonaws.com/sample/updated.template --
parameters ParameterKey=KeyPairName,ParameterValue=SampleKeyPair
 ParameterKey=SubnetIDs,ParameterValue=SampleSubnetID1\\,SampleSubnetID2
```

The following `update-stack` command updates just the `SubnetIDs` parameter value for the `mystack` stack. If you don't specify a parameter value, the default value that is specified in the template is used:

```
aws cloudformation update-stack --stack-name mystack --
template-url https://s3.amazonaws.com/sample/updated.template
 --parameters ParameterKey=KeyPairName,UsePreviousValue=true
 ParameterKey=SubnetIDs,ParameterValue=SampleSubnetID1\\,UpdatedSampleSubnetID2
```

The following `update-stack` command adds two stack notification topics to the `mystack` stack:

```
aws cloudformation update-stack --stack-name mystack --use-previous-template --
notification-arns "arn:aws:sns:use-east-1:123456789012:mytopic1" "arn:aws:sns:us-
east-1:123456789012:mytopic2"
```

For more information, see Amazon CloudFormation stack updates in the *Amazon CloudFormation User Guide*.

- For API details, see UpdateStack in *Amazon CLI Command Reference*.

`update-termination-protection`

The following code example shows how to use `update-termination-protection`.

Amazon CLI

To enable termination protection

The following `update-termination-protection` example enables termination protection on the specified stack.

```
aws cloudformation update-termination-protection \
    --stack-name my-stack \
    --enable-termination-protection
```

Output:

```
{
    "StackId": "arn:aws:cloudformation:us-west-2:123456789012:stack/my-stack/

`validate-template`

The following code example shows how to use `validate-template`.

Amazon CLI

To validate an Amazon CloudFormation template

The following `validate-template` command validates the `sampletemplate.json` template:

```
aws cloudformation validate-template --template-body file://sampletemplate.json
```

Output:

```
{
    "Description": "AWS CloudFormation Sample Template S3_Bucket: Sample template
 showing how to create a publicly accessible S3 bucket. **WARNING** This template
 creates an S3 bucket. You will be billed for the AWS resources used if you create a
 stack from this template.",
    "Parameters": [],
    "Capabilities": []
}
```

For more information, see Working with Amazon CloudFormation Templates in the *Amazon CloudFormation User Guide*.

- For API details, see ValidateTemplate in *Amazon CLI Command Reference*.

CloudFront examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudFront.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-distribution-tenant-web-acl`

The following code example shows how to use `associate-distribution-tenant-web-acl`.

Amazon CLI

To associate a web ACL with a CloudFront distribution tenant

The following `associate-distribution-tenant-web-acl` example associates a web ACL with a CloudFront distribution with ETag `E13V1IB3VIYABC`.

```
aws cloudfront associate-distribution-tenant-web-acl \
    --id dt_2wjDZi3hD1ivOXf6rpZJO1AB \
    --if-match E13V1IB3VIYABC \
    --web-acl-arn arn:aws:wafv2:us-east-1:123456789012:global/webacl/web-global-example/626900da-5f64-418b-ba9b-743f37123ABC
```

Output:

```
{
    "ETag": "E1VC38T7YXBABC",
    "Id": "dt_2wjDZi3hD1ivOXf6rpZJO1AB",
    "WebACLArn": "arn:aws:wafv2:us-east-1:123456789012:global/webacl/web-global-example/626900da-5f64-418b-ba9b-743f37123ABC"
}
```

For more information, see Use Amazon WAF protections in the *Amazon CloudFront Developer Guide*.

- For API details, see AssociateDistributionTenantWebAcl in *Amazon CLI Command Reference*.

`associate-distribution-web-acl`

The following code example shows how to use `associate-distribution-web-acl`.

Amazon CLI

To associate a web ACL with a CloudFront distribution

The following `associate-distribution-web-acl` example associates a web ACL with a CloudFront distribution.

```
aws cloudfront associate-distribution-web-acl \
    --id E1XNX8R2GOAABC \
    --if-match E2YWS1C2J3OABC \
```

```
    --web-acl-arn arn:aws:wafv2:us-east-1:123456789012:global/webacl/web-global-example/626900da-5f64-418b-ba9b-743f3746cABC
```

Output:

```
{
    "ETag": "E3QE7ED60U0ABC",
    "Id": "E1XNX8R2GOAABC",
    "WebACLArn": "arn:aws:wafv2:us-east-1:123456789012:global/webacl/web-global-example/626900da-5f64-418b-ba9b-743f3746cABC"
}
```

For more information, see Use Amazon WAF protections in the *Amazon CloudFront Developer Guide*.

- For API details, see AssociateDistributionWebAcl in *Amazon CLI Command Reference*.

`create-cloud-front-origin-access-identity`

The following code example shows how to use `create-cloud-front-origin-access-identity`.

Amazon CLI

To create a CloudFront origin access identity

The following example creates a CloudFront origin access identity (OAI) by providing the OAI configuration as a command line argument:

```
aws cloudfront create-cloud-front-origin-access-identity \
    --cloud-front-origin-access-identity-config \
        CallerReference="cli-example",Comment="Example OAI"
```

You can accomplish the same thing by providing the OAI configuration in a JSON file, as shown in the following example:

```
aws cloudfront create-cloud-front-origin-access-identity \
    --cloud-front-origin-access-identity-config file://OAI-config.json
```

The file `OAI-config.json` is a JSON document in the current directory that contains the following:

```
{
    "CallerReference": "cli-example",
    "Comment": "Example OAI"
}
```

Whether you provide the OAI configuration with a command line argument or a JSON file, the output is the same:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/origin-access-identity/
cloudfront/E74FTE3AEXAMPLE",
    "ETag": "E2QWRUHEXAMPLE",
    "CloudFrontOriginAccessIdentity": {
        "Id": "E74FTE3AEXAMPLE",
        "S3CanonicalUserId":
 "cd13868f797c227fbea2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",
        "CloudFrontOriginAccessIdentityConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example OAI"
        }
    }
}
```

- For API details, see CreateCloudFrontOriginAccessIdentity in *Amazon CLI Command Reference*.

`create-connection-group`

The following code example shows how to use `create-connection-group`.

Amazon CLI

To create a connection group in CloudFront

The following `create-connection-group` example creates an enabled connection group, specifies an Anycast static IP list, and disables IPv6.

```
aws cloudfront create-connection-group \
    --name cg-with-anycast-ip-list \
    --no-ipv6-enabled \
    --enabled \
    --anycast-ip-list-id aip_CCkW6gKrDiBD4n78123ABC \
```

```
    --tags "Items=[{Key=abc,Value=123}]"
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "ConnectionGroup": {
        "Id": "cg_2yb6uj74B4PCbfhT31WFdiSABC",
        "Name": "cg-with-anycast-ip-list",
        "Arn": "arn:aws:cloudfront::123456789012:connection-group/
cg_2yb6uj74B4PCbfhT31WFdiSABC",
        "CreatedTime": "2025-06-16T16:25:50.061000+00:00",
        "LastModifiedTime": "2025-06-16T16:25:50.061000+00:00",
        "Tags": {
            "Items": [
                {
                    "Key": "abc",
                    "Value": "123"
                }
            ]
        },
        "Ipv6Enabled": false,
        "RoutingEndpoint": "dj6xusxq65abc.cloudfront.net",
        "AnycastIpListId": "aip_CCkW6gKrDiBD4n78123ABC",
        "Status": "InProgress",
        "Enabled": true,
        "IsDefault": false
    }
}
```

For more information, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see CreateConnectionGroup in *Amazon CLI Command Reference*.

`create-distribution-tenant`

The following code example shows how to use `create-distribution-tenant`.

Amazon CLI

To create a CloudFront distribution tenant

The following `create-distribution-tenant` example creates a CloudFront distribution tenant that specifies customizations to disable WAF, add geo-restrictions, and use another certificate.

```
aws cloudfront create-distribution-tenant \
    --cli-input-json file://tenant.json
```

Contents of `tenant.json`:

```
{
    "DistributionId": "E1XNX8R2GOAABC",
    "Domains": [
        {
            "Domain": "example.com"
        }
    ],
    "Parameters": [
        {
            "Name": "testParam",
            "Value": "defaultValue"
        }
    ],
    "ConnectionGroupId": "cg_2whCJoXMYCjHcxaLGrkllvyABC",
    "Enabled": false,
    "Tags": {
        "Items": [
            {
                "Key": "tag",
                "Value": "tagValue"
            }
        ]
    },
    "Name": "new-tenant-customizations",
    "Customizations": {
        "GeoRestrictions": {
            "Locations": ["DE"],
            "RestrictionType": "whitelist"
        },
        "WebAcl": {
            "Action": "disable"
        },
        "Certificate": {
```

```
            "Arn": "arn:aws:acm:us-east-1:123456789012:certificate/ec53f564-
ea5a-4e4a-a0a2-e3c989449abc"
        }
    }
}
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "DistributionTenant": {
        "Id": "dt_2yN5tYwVbPKr7m2IB69M1yp1AB",
        "DistributionId": "E1XNX8R2GOAABC",
        "Name": "new-tenant-customizations",
        "Arn": "arn:aws:cloudfront::123456789012:distribution-tenant/
dt_2yN5tYwVbPKr7m2IB69M1yp1AB",
        "Domains": [
            {
                "Domain": "example.com",
                "Status": "active"
            }
        ],
        "Tags": {
            "Items": [
                {
                    "Key": "tag",
                    "Value": "tagValue"
                }
            ]
        },
        "Customizations": {
            "WebAcl": {
                "Action": "disable"
            },
            "Certificate": {
                "Arn": "arn:aws:acm:us-east-1:123456789012:certificate/ec53f564-

            },
            "GeoRestrictions": {
                "RestrictionType": "whitelist",
                "Locations": [
                    "DE"
                ]
```

```
            }
        },
        "Parameters": [
            {
                "Name": "testParam",
                "Value": "defaultValue"
            }
        ],
        "ConnectionGroupId": "cg_2whCJoXMYCjHcxaLGrkllvyABC",
        "CreatedTime": "2025-06-11T17:20:06.432000+00:00",
        "LastModifiedTime": "2025-06-11T17:20:06.432000+00:00",
        "Enabled": false,
        "Status": "InProgress"
    }
}
```

For more information, see Create a distribution in the *Amazon CloudFront Developer Guide*.

- For API details, see CreateDistributionTenant in *Amazon CLI Command Reference*.

`create-distribution-with-tags`

The following code example shows how to use `create-distribution-with-tags`.

Amazon CLI

To create a CloudFront distribution with tags

The following `create-distribution-with-tags` example creates a distribution with two tags by providing the distribution configuration and tags in a JSON file named `dist-config-with-tags.json`.

```
aws cloudfront create-distribution-with-tags \
    --distribution-config-with-tags file://dist-config-with-tags.json
```

The file `dist-config-with-tags.json` is a JSON document in the current folder. Note the `Tags` object at the top of the file, which contains two tags:

`Name = ExampleDistributionProject = ExampleProject`

Contents of `dist-config-with-tags.json`:

```
{
```

```
    "Tags": {
        "Items": [
            {
                "Key": "Name",
                "Value": "ExampleDistribution"
            },
            {
                "Key": "Project",
                "Value": "ExampleProject"
            }
        ]
    },
    "DistributionConfig": {
        "CallerReference": "cli-example",
        "Aliases": {
            "Quantity": 0
        },
        "DefaultRootObject": "index.html",
        "Origins": {
            "Quantity": 1,
            "Items": [
                {
                    "Id": "amzn-s3-demo-bucket.s3.amazonaws.com-cli-example",
                    "DomainName": "amzn-s3-demo-bucket.s3.amazonaws.com",
                    "OriginPath": "",
                    "CustomHeaders": {
                        "Quantity": 0
                    },
                    "S3OriginConfig": {
                        "OriginAccessIdentity": ""
                    }
                }
            ]
        },
        "OriginGroups": {
            "Quantity": 0
        },
        "DefaultCacheBehavior": {
            "TargetOriginId": "amzn-s3-demo-bucket.s3.amazonaws.com-cli-example",
            "ForwardedValues": {
                "QueryString": false,
                "Cookies": {
                    "Forward": "none"
                },
```

```
                "Headers": {
                    "Quantity": 0
                },

- For API details, see CreateDistributionWithTags in *Amazon CLI Command Reference*.

`create-distribution`

The following code example shows how to use `create-distribution`.

Amazon CLI

Example 1: To create a CloudFront distribution

The following example creates a distribution for an S3 bucket named `amzn-s3-demo-bucket`, and also specifies `index.html` as the default root object, using command line arguments.

```
aws cloudfront create-distribution \
    --origin-domain-name amzn-s3-demo-bucket.s3.amazonaws.com \
    --default-root-object index.html
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/distribution/
EMLARXS9EXAMPLE",
    "ETag": "E9LHASXEXAMPLE",
    "Distribution": {
        "Id": "EMLARXS9EXAMPLE",
        "ARN": "arn:aws:cloudfront::123456789012:distribution/EMLARXS9EXAMPLE",
        "Status": "InProgress",
        "LastModifiedTime": "2019-11-22T00:55:15.705Z",
        "InProgressInvalidationBatches": 0,
        "DomainName": "d111111abcdef8.cloudfront.net",
```

```

            "IsIPV6Enabled": true
        }
    }
}
```

Example 2: To create a CloudFront distribution using a JSON file

The following example creates a distribution for an S3 bucket named `amzn-s3-demo-bucket`, and also specifies `index.html` as the default root object, using a JSON file.

```
aws cloudfront create-distribution \
    --distribution-config file://dist-config.json
```

Contents of `dist-config.json`:

```
{
    "CallerReference": "cli-example",
    "Aliases": {
        "Quantity": 0
    },
    "DefaultRootObject": "index.html",
    "Origins": {
        "Quantity": 1,
        "Items": [
            {
                "Id": "amzn-s3-demo-bucket.s3.amazonaws.com-cli-example",
                "DomainName": "amzn-s3-demo-bucket.s3.amazonaws.com",
                "OriginPath": "",
                "CustomHeaders": {
                    "Quantity": 0
```

```
                },
                "S3OriginConfig": {
                    "OriginAccessIdentity": ""
                }
            }
        ]
    },

See Example 1 for sample output.

- For API details, see CreateDistribution in *Amazon CLI Command Reference*.

create-field-level-encryption-config

The following code example shows how to use `create-field-level-encryption-config`.

Amazon CLI

To create a CloudFront field-level encryption configuration

The following example creates a field-level encryption configuration by providing the configuration parameters in a JSON file named `fle-config.json`. Before you can create a field-level encryption configuration, you must have a field-level encryption profile. To create a profile, see the create-field-level-encryption-profile command.

For more information about CloudFront field-level encryption, see Using Field-Level Encryption to Help Protect Sensitive Data in the *Amazon CloudFront Developer Guide*.

```
aws cloudfront create-field-level-encryption-config \
    --field-level-encryption-config file://fle-config.json
```

The file `fle-config.json` is a JSON document in the current folder that contains the following:

```
{
    "CallerReference": "cli-example",
    "Comment": "Example FLE configuration",
    "QueryArgProfileConfig": {
        "ForwardWhenQueryArgProfileIsUnknown": true,
        "QueryArgProfiles": {
            "Quantity": 0
        }
    },
    "ContentTypeProfileConfig": {
        "ForwardWhenContentTypeIsUnknown": true,
        "ContentTypeProfiles": {
            "Quantity": 1,
            "Items": [
                {
                    "Format": "URLEncoded",
                    "ProfileId": "P280MFCLSYOCVU",
                    "ContentType": "application/x-www-form-urlencoded"
                }
            ]
```

```
        }
    }
}
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/field-level-encryption/
C3KM2WVD605UAY",
    "ETag": "E2P4Z4VU7TY5SG",
    "FieldLevelEncryption": {
        "Id": "C3KM2WVD605UAY",
        "LastModifiedTime": "2019-12-10T21:30:18.974Z",
        "FieldLevelEncryptionConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example FLE configuration",
            "QueryArgProfileConfig": {
                "ForwardWhenQueryArgProfileIsUnknown": true,
                "QueryArgProfiles": {
                    "Quantity": 0,
                    "Items": []
                }
            },
            "ContentTypeProfileConfig": {
                "ForwardWhenContentTypeIsUnknown": true,
                "ContentTypeProfiles": {
                    "Quantity": 1,
                    "Items": [
                        {
                            "Format": "URLEncoded",
                            "ProfileId": "P280MFCLSYOCVU",
                            "ContentType": "application/x-www-form-urlencoded"
                        }
                    ]
                }
            }
        }
    }
}
```

- For API details, see CreateFieldLevelEncryptionConfig in *Amazon CLI Command Reference*.

`create-field-level-encryption-profile`

The following code example shows how to use `create-field-level-encryption-profile`.

Amazon CLI

To create a CloudFront field-level encryption profile

The following example creates a field-level encryption profile by providing the parameters in a JSON file named `fle-profile-config.json`. Before you can create a field-level encryption profile, you must have a CloudFront public key. To create a CloudFront public key, see the create-public-key command.

For more information about CloudFront field-level encryption, see Using Field-Level Encryption to Help Protect Sensitive Data in the *Amazon CloudFront Developer Guide*.

```
aws cloudfront create-field-level-encryption-profile \
    --field-level-encryption-profile-config file://fle-profile-config.json
```

The file `fle-profile-config.json` is a JSON document in the current folder that contains the following:

```
{
    "Name": "ExampleFLEProfile",
    "CallerReference": "cli-example",
    "Comment": "FLE profile for AWS CLI example",
    "EncryptionEntities": {
        "Quantity": 1,
        "Items": [
            {
                "PublicKeyId": "K2K8NC4HVFE3M0",
                "ProviderId": "ExampleFLEProvider",
                "FieldPatterns": {
                    "Quantity": 1,
                    "Items": [
                        "ExampleSensitiveField"
                    ]
                }
            }
        ]
    }
}
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/field-level-encryption-
profile/PPK0UOSIF5WSV",
    "ETag": "E2QWRUHEXAMPLE",
    "FieldLevelEncryptionProfile": {
        "Id": "PPK0UOSIF5WSV",

        "FieldLevelEncryptionProfileConfig": {
            "Name": "ExampleFLEProfile",
            "CallerReference": "cli-example",
            "Comment": "FLE profile for AWS CLI example",
            "EncryptionEntities": {
                "Quantity": 1,
                "Items": [
                    {
                        "PublicKeyId": "K2K8NC4HVFE3M0",
                        "ProviderId": "ExampleFLEProvider",
                        "FieldPatterns": {
                            "Quantity": 1,
                            "Items": [
                                "ExampleSensitiveField"
                            ]
                        }
                    }
                ]
            }
        }
    }
}
```

- For API details, see CreateFieldLevelEncryptionProfile in *Amazon CLI Command Reference*.

`create-invalidation-for-distribution-tenant`

The following code example shows how to use `create-invalidation-for-distribution-tenant`.

Amazon CLI

To create a CloudFront invalidation for a distribution tenant

The following `create-invalidation-for-distribution-tenant` example creates an invalidation for all files in a CloudFront distribution tenant.

```
aws cloudfront create-invalidation-for-distribution-tenant \
    --id dt_2wjDZi3hD1ivOXf6rpZJO1AB \
    --invalidation-batch '{"Paths": {"Quantity": 1, "Items": ["/*"]},
 "CallerReference": "invalidation-$(date +%s)"}'
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2020-05-31/distribution-tenant/
dt_2wjDZi3hD1ivOXf6rpZJO1AB/invalidation/I2JGL2F1ZAA426PGG0YLLKABC",
    "Invalidation": {
        "Id": "I2JGL2F1ZAA426PGG0YLLKABC",
        "Status": "InProgress",
        "CreateTime": "2025-05-07T16:59:25.947000+00:00",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 1,
                "Items": [
                    "/*"
                ]
            },
            "CallerReference": "invalidation-$(date +%s)"
        }
    }
}
```

For more information, see Invalidate files to remove content in the *Amazon CloudFront Developer Guide*.

- For API details, see CreateInvalidationForDistributionTenant in *Amazon CLI Command Reference*.

`create-invalidation`

The following code example shows how to use `create-invalidation`.

Amazon CLI

To create an invalidation for a CloudFront distribution

The following `create-invalidation` example creates an invalidation for the specified files in the specified CloudFront distribution:

```
aws cloudfront create-invalidation \
    --distribution-id EDFDVBD6EXAMPLE \
    --paths "/example-path/example-file.jpg" "/example-path/example-file2.png"
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/distribution/
EDFDVBD6EXAMPLE/invalidation/I1JLWSDAP8FU89",
    "Invalidation": {
        "Id": "I1JLWSDAP8FU89",
        "Status": "InProgress",
        "CreateTime": "2019-12-05T18:24:51.407Z",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 2,
                "Items": [
                    "/example-path/example-file2.png",
                    "/example-path/example-file.jpg"
                ]
            },
            "CallerReference": "cli-1575570291-670203"
        }
    }
}
```

In the previous example, the Amazon CLI automatically generated a random `CallerReference`. To specify your own `CallerReference`, or to avoid passing the invalidation parameters as command line arguments, you can use a JSON file. The following example creates an invalidation for two files, by providing the invalidation parameters in a JSON file named `inv-batch.json`:

```
aws cloudfront create-invalidation \
    --distribution-id EDFDVBD6EXAMPLE \
    --invalidation-batch file://inv-batch.json
```

Contents of `inv-batch.json`:

```
{
    "Paths": {
        "Quantity": 2,
        "Items": [
            "/example-path/example-file.jpg",
            "/example-path/example-file2.png"
        ]
    },
    "CallerReference": "cli-example"
}
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/distribution/
EDFDVBD6EXAMPLE/invalidation/I2J0I21PCUYOIK",
    "Invalidation": {
        "Id": "I2J0I21PCUYOIK",
        "Status": "InProgress",
        "CreateTime": "2019-12-05T18:40:49.413Z",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 2,
                "Items": [
                    "/example-path/example-file.jpg",
                    "/example-path/example-file2.png"
                ]
            },
            "CallerReference": "cli-example"
        }
    }
}
```

- For API details, see CreateInvalidation in *Amazon CLI Command Reference*.

`create-public-key`

The following code example shows how to use `create-public-key`.

Amazon CLI

To create a CloudFront public key

The following example creates a CloudFront public key by providing the parameters in a JSON file named `pub-key-config.json`. Before you can use this command, you must have a PEM-encoded public key. For more information, see Create an RSA Key Pair in the *Amazon CloudFront Developer Guide*.

```
aws cloudfront create-public-key \
    --public-key-config file://pub-key-config.json
```

The file `pub-key-config.json` is a JSON document in the current folder that contains the following. Note that the public key is encoded in PEM format.

```
{
    "CallerReference": "cli-example",
    "Name": "ExampleKey",
    "EncodedKey": "-----BEGIN PUBLIC KEY-----
\nMIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAxPMbCA2Ks0lnd7IR+3pw

 PUBLIC KEY-----\n",
    "Comment": "example public key"
}
```

Output:

```
{
    "Location": "https://cloudfront.amazonaws.com/2019-03-26/public-key/
KDFB19YGCR002",
    "ETag": "E2QWRUHEXAMPLE",
    "PublicKey": {
        "Id": "KDFB19YGCR002",
        "CreatedTime": "2019-12-05T18:51:43.781Z",
        "PublicKeyConfig": {
            "CallerReference": "cli-example",
            "Name": "ExampleKey",
            "EncodedKey": "-----BEGIN PUBLIC KEY-----
\nMIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAxPMbCA2Ks0lnd7IR+3pw
\nwd3H/7jPGwj8bLUmore7bX+oeGpZ6QmLAe/1UOWcmZX2u70dYcSIzB1ofZtcn4cJ

 PUBLIC KEY-----\n",
            "Comment": "example public key"
        }
    }
}
```

- For API details, see CreatePublicKey in *Amazon CLI Command Reference*.

`delete-cloud-front-origin-access-identity`

The following code example shows how to use `delete-cloud-front-origin-access-identity`.

Amazon CLI

To delete a CloudFront origin access identity

The following example deletes the origin access identity (OAI) with the ID `E74FTE3AEXAMPLE`. To delete an OAI, you must have the OAI's ID and `ETag`. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands. To get the `ETag`, use the get-cloud-front-origin-access-identity or get-cloud-front-origin-access-identity-config command. Use the `--if-match` option to provide the OAI's `ETag`.

```
aws cloudfront delete-cloud-front-origin-access-identity \
    --id E74FTE3AEXAMPLE \
    --if-match E2QWRUHEXAMPLE
```

When successful, this command has no output.

- For API details, see DeleteCloudFrontOriginAccessIdentity in *Amazon CLI Command Reference*.

`delete-connection-group`

The following code example shows how to use `delete-connection-group`.

Amazon CLI

To delete a connection group

The following `delete-connection-group` example deletes a connection group. The connection group must be disabled and can't be associated with any CloudFront resources.

```
aws cloudfront delete-connection-group \
    --id cg_2wjLpjbHkLUdhWAjHllcOeABC \
    --if-match ETVPDKIKX0DABC
```

When successful, this command has no output.

For more information about managing connection groups, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see DeleteConnectionGroup in *Amazon CLI Command Reference*.

`delete-distribution-tenant`

The following code example shows how to use `delete-distribution-tenant`.

Amazon CLI

To delete a distribution tenant

The following `delete-distribution-tenant` example deletes a distribution tenant with ETag `ETVPDKIKX0DABC`. The distribution tenant must be disabled and can't be associated with any CloudFront resources.

```
aws cloudfront delete-distribution-tenant \
    --id dt_2wjMUbg3NHZEQ7OfoalP5zi1AB \
    --if-match ETVPDKIKX0DABC
```

When successful, this command has no output.

For more information, see Delete a distribution in the *Amazon CloudFront Developer Guide*.

- For API details, see DeleteDistributionTenant in *Amazon CLI Command Reference*.

`delete-distribution`

The following code example shows how to use `delete-distribution`.

Amazon CLI

To delete a CloudFront distribution

The following example deletes the CloudFront distribution with the ID EDFDVBD6EXAMPLE. Before you can delete a distribution, you must disable it. To disable a distribution, use the update-distribution command. For more information, see the update-distribution examples.

When a distribution is disabled, you can delete it. To delete a distribution, you must use the `--if-match` option to provide the distribution's ETag. To get the ETag, use the get-distribution or get-distribution-config command.

```
aws cloudfront delete-distribution \
    --id EDFDVBD6EXAMPLE \
    --if-match E2QWRUHEXAMPLE
```

When successful, this command has no output.

- For API details, see DeleteDistribution in *Amazon CLI Command Reference*.

`delete-field-level-encryption-config`

The following code example shows how to use `delete-field-level-encryption-config`.

Amazon CLI

To delete a CloudFront field-level encryption configuration

The following example deletes the CloudFront field-level encryption configuration with the ID C3KM2WVD605UAY. To delete a field-level encryption configuration, you must have its ID and ETag. The ID is returned in the output of the create-field-level-encryption-config and list-field-level-encryption-configs commands. To get the ETag, use the get-field-level-encryption or get-field-level-encryption-config command. Use the `--if-match` option to provide the configuration's ETag.

```
aws cloudfront delete-field-level-encryption-config \
    --id C3KM2WVD605UAY \
    --if-match E26M4BIAV81ZF6
```

When successful, this command has no output.

- For API details, see DeleteFieldLevelEncryptionConfig in *Amazon CLI Command Reference*.

`delete-field-level-encryption-profile`

The following code example shows how to use `delete-field-level-encryption-profile`.

Amazon CLI

To delete a CloudFront field-level encryption profile

The following example deletes the CloudFront field-level encryption profile with the ID `PPK0UOSIF5WSV`. To delete a field-level encryption profile, you must have its ID and `ETag`. The ID is returned in the output of the create-field-level-encryption-profile and list-field-level-encryption-profiles commands. To get the `ETag`, use the get-field-level-encryption-profile or get-field-level-encryption-profile-config command. Use the `--if-match` option to provide the profile's `ETag`.

```
aws cloudfront delete-field-level-encryption-profile \
    --id PPK0UOSIF5WSV \
    --if-match EJETYFJ9CL66D
```

When successful, this command has no output.

- For API details, see DeleteFieldLevelEncryptionProfile in *Amazon CLI Command Reference*.

`delete-public-key`

The following code example shows how to use `delete-public-key`.

Amazon CLI

To delete a CloudFront public key

The following example deletes the CloudFront public key with the ID `KDFB19YGCR002`. To delete a public key, you must have its ID and `ETag`. The ID is returned in the output of the create-public-key and list-public-keys commands. To get the `ETag`, use the get-public-key or get-public-key-config command. Use the `--if-match` option to provide the public key's `ETag`.

```
aws cloudfront delete-public-key \
    --id KDFB19YGCR002 \
    --if-match E2QWRUHEXAMPLE
```

When successful, this command has no output.

- For API details, see DeletePublicKey in *Amazon CLI Command Reference*.

`disassociate-distribution-tenant-web-acl`

The following code example shows how to use `disassociate-distribution-tenant-web-acl`.

Amazon CLI

To disassociate a web ACL from a distribution tenant

The following `disassociate-distribution-tenant-web-acl` example disassociates a web ACL from a distribution tenant with ETag E1PA6795UKMABC.

```
aws cloudfront disassociate-distribution-tenant-web-acl \
    --id dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB \
    --if-match E1PA6795UKMABC
```

Output:

```
{
    "ETag": "E13V1IB3VIYABC",
    "Id": "dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB"
}
```

For more information, see Disable Amazon WAF security protections in the *Amazon CloudFront Developer Guide*.

- For API details, see DisassociateDistributionTenantWebAcl in *Amazon CLI Command Reference*.

`disassociate-distribution-web-acl`

The following code example shows how to use `disassociate-distribution-web-acl`.

Amazon CLI

To disassociate a web ACL from a CloudFront distribution

The following `disassociate-distribution-web-acl` example removes the association between a web ACL and a CloudFront distribution with ETag E13V1IB3VIYABC.

```
aws cloudfront disassociate-distribution-web-acl \
    --id E1XNX8R2G0AABC \
    --if-match EEZQ9Z24VM1ABC
```

Output:

```
{
    "ETag": "E2YWS1C2J30ABC",
    "Id": "E1XNX8R2G0AABC"
}
```

For more information, see Disable Amazon WAF security protections in the *Amazon CloudFront Developer Guide*.

- For API details, see DisassociateDistributionWebAcl in *Amazon CLI Command Reference*.

`get-cloud-front-origin-access-identity-config`

The following code example shows how to use `get-cloud-front-origin-access-identity-config`.

Amazon CLI

To get a CloudFront origin access identity configuration

The following example gets metadata about the CloudFront origin access identity (OAI) with the ID E74FTE3AEXAMPLE, including its ETag. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands.

```
aws cloudfront get-cloud-front-origin-access-identity-config --id E74FTE3AEXAMPLE
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "CloudFrontOriginAccessIdentityConfig": {
        "CallerReference": "cli-example",
        "Comment": "Example OAI"
    }
}
```

- For API details, see GetCloudFrontOriginAccessIdentityConfig in *Amazon CLI Command Reference*.

`get-cloud-front-origin-access-identity`

The following code example shows how to use `get-cloud-front-origin-access-identity`.

Amazon CLI

To get a CloudFront origin access identity

The following example gets the CloudFront origin access identity (OAI) with the ID `E74FTE3AEXAMPLE`, including its `ETag` and the associated S3 canonical ID. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands.

```
aws cloudfront get-cloud-front-origin-access-identity --id E74FTE3AEXAMPLE
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "CloudFrontOriginAccessIdentity": {
        "Id": "E74FTE3AEXAMPLE",
        "S3CanonicalUserId":
 "cd13868f797c227fbea2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",
        "CloudFrontOriginAccessIdentityConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example OAI"
        }
    }
}
```

- For API details, see GetCloudFrontOriginAccessIdentity in *Amazon CLI Command Reference*.

`get-connection-group-by-routing-endpoint`

The following code example shows how to use `get-connection-group-by-routing-endpoint`.

Amazon CLI

To get a connection group by routing endpoint

The following `get-connection-group-by-routing-endpoint` example retrieves information about a connection group using its routing endpoint.

```
aws cloudfront get-connection-group-by-routing-endpoint \
    --routing-endpoint dvdg9gprgabc.cloudfront.net
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "ConnectionGroup": {
        "Id": "cg_2wjDWTBKTlRB87cAaUQFaakABC",
        "Name": "connection-group-2",
        "Arn": "arn:aws:cloudfront::123456789012:connection-group/
cg_2wjDWTBKTlRB87cAaUQFaakABC",
        "CreatedTime": "2025-05-06T15:42:00.790000+00:00",
        "LastModifiedTime": "2025-05-06T15:42:00.790000+00:00",
        "Ipv6Enabled": true,
        "RoutingEndpoint": "dvdg9gprgabc.cloudfront.net",
        "Status": "Deployed",
        "Enabled": true,
        "IsDefault": false
    }
}
```

For more information, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see GetConnectionGroupByRoutingEndpoint in *Amazon CLI Command Reference*.

`get-connection-group`

The following code example shows how to use `get-connection-group`.

Amazon CLI

To get a CloudFront connection group

The following `get-connection-group` example retrieves information about a CloudFront connection group.

```
aws cloudfront get-connection-group \
    --identifier cg_2wjDWTBKTlRB87cAaUQFaakABC
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "ConnectionGroup": {
        "Id": "cg_2wjDWTBKTlRB87cAaUQFaakABC",
        "Name": "connection-group-2",
        "Arn": "arn:aws:cloudfront::123456789012:connection-group/
cg_2wjDWTBKTlRB87cAaUQFaakABC",
        "CreatedTime": "2025-05-06T15:42:00.790000+00:00",
        "LastModifiedTime": "2025-05-06T15:42:00.790000+00:00",
        "Ipv6Enabled": true,
        "RoutingEndpoint": "dvdg9gprgabc.cloudfront.net",
        "Status": "Deployed",
        "Enabled": true,
        "IsDefault": false
    }
}
```

For more information, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see GetConnectionGroup in *Amazon CLI Command Reference*.

`get-distribution-config`

The following code example shows how to use `get-distribution-config`.

Amazon CLI

To get a CloudFront distribution configuration

The following example gets metadata about the CloudFront distribution with the ID `EDFDVBD6EXAMPLE`, including its `ETag`. The distribution ID is returned in the create-distribution and list-distributions commands.

```
aws cloudfront get-distribution-config \
    --id EDFDVBD6EXAMPLE
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "DistributionConfig": {
        "CallerReference": "cli-example",
        "Aliases": {
            "Quantity": 0
        },
        "DefaultRootObject": "index.html",
        "Origins": {
            "Quantity": 1,
            "Items": [
                {
                    "Id": "amzn-s3-demo-bucket.s3.amazonaws.com-cli-example",
                    "DomainName": "amzn-s3-demo-bucket.s3.amazonaws.com",
                    "OriginPath": "",
                    "CustomHeaders": {
                        "Quantity": 0
                    },
                    "S3OriginConfig": {
                        "OriginAccessIdentity": ""
                    }
                }
            ]
        },
        "OriginGroups": {
            "Quantity": 0
        },
        "DefaultCacheBehavior": {
            "TargetOriginId": "amzn-s3-demo-bucket.s3.amazonaws.com-cli-example",
            "ForwardedValues": {
                "QueryString": false,
                "Cookies": {
                    "Forward": "none"
                },
                "Headers": {
                    "Quantity": 0
                },
                "QueryStringCacheKeys": {
```

```
                    "Quantity": 0
                }
            },
            "TrustedSigners": {
                "Enabled": false,
                "Quantity": 0
            },
            "ViewerProtocolPolicy": "allow-all",
            "MinTTL": 0,
            "AllowedMethods": {
                "Quantity": 2,
                "Items": [
                    "HEAD",
                    "GET"
                ],
                "CachedMethods": {
                    "Quantity": 2,
                    "Items": [
                        "HEAD",
                        "GET"
                    ]
                }
            },
            "SmoothStreaming": false,
            "DefaultTTL": 86400,

`get-distribution-tenant-by-domain`

The following code example shows how to use `get-distribution-tenant-by-domain`.

Amazon CLI

To get distribution tenant information by domain

The following `get-distribution-tenant-by-domain` example retrieves information about a distribution tenant using the specified domain.

```
aws cloudfront get-distribution-tenant-by-domain \
    --domain example.com
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "DistributionTenant": {
```

```
        "Id": "dt_2xVInRKCfUzQHgxosDs9hiLk1AB",
        "DistributionId": "E1XNX8R2GOAABC",
        "Name": "example-tenant-4",
        "Arn": "arn:aws:cloudfront::123456789012:distribution-tenant/
dt_2xVInRKCfUzQHgxosDs9hiLk1AB",
        "Domains": [
            {
                "Domain": "example.com",
                "Status": "active"
            }
        ],
        "Parameters": [
            {
                "Name": "testParam",
                "Value": "defaultValue"
            }
        ],
        "ConnectionGroupId": "cg_2whCJoXMYCjHcxaLGrkllvyABC",

        "Enabled": false,
        "Status": "Deployed"
    }
}
```

For more information, see Understand how multi-tenant distributions work in the *Amazon CloudFront Developer Guide*.

- For API details, see GetDistributionTenantByDomain in *Amazon CLI Command Reference*.

`get-distribution-tenant`

The following code example shows how to use `get-distribution-tenant`.

Amazon CLI

To get details about a CloudFront distribution tenant

The following `get-distribution-tenant` example retrieves information about a CloudFront distribution tenant.

```
aws cloudfront get-distribution-tenant \
```

```
    --id dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB
```

Output:

```
{
    "ETag": "E23ZP02F085ABC",
    "DistributionTenant": {
        "Id": "dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB",

        "Status": "InProgress"
    }
}
```

For more information, see Understand how multi-tenant distributions work in the *Amazon CloudFront Developer Guide*.

- For API details, see GetDistributionTenant in *Amazon CLI Command Reference*.

`get-distribution`

The following code example shows how to use `get-distribution`.

Amazon CLI

To get a CloudFront distribution

The following `get-distribution` example gets the CloudFront distribution with the ID `EDFDVBD6EXAMPLE`, including its `ETag`. The distribution ID is returned in the create-distribution and list-distributions commands.

```
aws cloudfront get-distribution \
    --id EDFDVBD6EXAMPLE
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "Distribution": {
        "Id": "EDFDVBD6EXAMPLE",
        "ARN": "arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE",

```

- For API details, see GetDistribution in *Amazon CLI Command Reference*.

`get-field-level-encryption-config`

The following code example shows how to use `get-field-level-encryption-config`.

Amazon CLI

To get metadata about a CloudFront field-level encryption configuration

The following example gets metadata about the CloudFront field-level encryption configuration with the ID C3KM2WVD605UAY, including its ETag:

```
aws cloudfront get-field-level-encryption-config --id C3KM2WVD605UAY
```

Output:

```
{
    "ETag": "E2P4Z4VU7TY5SG",
    "FieldLevelEncryptionConfig": {
        "CallerReference": "cli-example",
        "Comment": "Example FLE configuration",
        "QueryArgProfileConfig": {
            "ForwardWhenQueryArgProfileIsUnknown": true,
            "QueryArgProfiles": {
                "Quantity": 0,
                "Items": []
            }
        },
        "ContentTypeProfileConfig": {
            "ForwardWhenContentTypeIsUnknown": true,
            "ContentTypeProfiles": {
                "Quantity": 1,
                "Items": [
                    {
                        "Format": "URLEncoded",
                        "ProfileId": "P280MFCLSYOCVU",
                        "ContentType": "application/x-www-form-urlencoded"
                    }
                ]
            }
        }
    }
}
```

- For API details, see GetFieldLevelEncryptionConfig in *Amazon CLI Command Reference*.

get-field-level-encryption-profile-config

The following code example shows how to use get-field-level-encryption-profile-config.

Amazon CLI

To get a CloudFront field-level encryption profile configuration

The following example gets metadata about the CloudFront field-level encryption profile with ID PPK0UOSIF5WSV , including its ETag:

```
aws cloudfront get-field-level-encryption-profile-config --id PPK0UOSIF5WSV
```

Output:

```
{
    "ETag": "E1QQG65FS2L2GC",
    "FieldLevelEncryptionProfileConfig": {
        "Name": "ExampleFLEProfile",
        "CallerReference": "cli-example",
        "Comment": "FLE profile for AWS CLI example",
        "EncryptionEntities": {
            "Quantity": 1,
            "Items": [
                {
                    "PublicKeyId": "K2K8NC4HVFE3M0",
                    "ProviderId": "ExampleFLEProvider",
                    "FieldPatterns": {
                        "Quantity": 1,
                        "Items": [
                            "ExampleSensitiveField"
                        ]
                    }
                }
            ]
        }
    }
}
```

- For API details, see GetFieldLevelEncryptionProfileConfig in *Amazon CLI Command Reference*.

`get-field-level-encryption-profile`

The following code example shows how to use `get-field-level-encryption-profile`.

Amazon CLI

To get a CloudFront field-level encryption profile

The following example gets the CloudFront field-level encryption profile with ID PPK0UOSIF5WSV , including its ETag:

```
aws cloudfront get-field-level-encryption-profile --id PPK0UOSIF5WSV
```

Output:

```
{
    "ETag": "E1QQG65FS2L2GC",
    "FieldLevelEncryptionProfile": {
        "Id": "PPK0UOSIF5WSV",
        "LastModifiedTime": "2019-12-10T01:03:16.537Z",

            "Name": "ExampleFLEProfile",
            "CallerReference": "cli-example",
            "Comment": "FLE profile for AWS CLI example",
            "EncryptionEntities": {
                "Quantity": 1,
                "Items": [
                    {
                        "PublicKeyId": "K2K8NC4HVFE3M0",
                        "ProviderId": "ExampleFLEProvider",
                        "FieldPatterns": {
                            "Quantity": 1,
                            "Items": [
                                "ExampleSensitiveField"
                            ]
                        }
                    }
                ]
            }
        }
    }
}
```

- For API details, see GetFieldLevelEncryptionProfile in *Amazon CLI Command Reference*.

`get-field-level-encryption`

The following code example shows how to use `get-field-level-encryption`.

Amazon CLI

To get a CloudFront field-level encryption configuration

The following example gets the CloudFront field-level encryption configuration with the ID `C3KM2WVD605UAY`, including its `ETag`:

```
aws cloudfront get-field-level-encryption --id C3KM2WVD605UAY
```

Output:

```
{
    "ETag": "E2P4Z4VU7TY5SG",
    "FieldLevelEncryption": {
        "Id": "C3KM2WVD605UAY",
        "LastModifiedTime": "2019-12-10T21:30:18.974Z",
        "FieldLevelEncryptionConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example FLE configuration",
            "QueryArgProfileConfig": {
                "ForwardWhenQueryArgProfileIsUnknown": true,
                "QueryArgProfiles": {
                    "Quantity": 0,
                    "Items": []
                }
            },
            "ContentTypeProfileConfig": {
                "ForwardWhenContentTypeIsUnknown": true,
                "ContentTypeProfiles": {
                    "Quantity": 1,
                    "Items": [
                        {
                            "Format": "URLEncoded",
                            "ProfileId": "P280MFCLSYOCVU",
                            "ContentType": "application/x-www-form-urlencoded"
                        }
                    ]
                }
            }
```

```
        }
    }
}
```

- For API details, see GetFieldLevelEncryption in *Amazon CLI Command Reference*.

`get-invalidation-for-distribution-tenant`

The following code example shows how to use `get-invalidation-for-distribution-tenant`.

Amazon CLI

To get an invalidation for a distribution tenant

The following `get-invalidation-for-distribution-tenant` example gets information about an invalidation for a distribution tenant.

```
aws cloudfront get-invalidation-for-distribution-tenant \
    --distribution-tenant-id dt_2wjDZi3hD1iv0Xf6rpZJ0SNE1AB \
    --id I4CU23QAPKMUDUU06F90FGFABC
```

Output:

```
{
    "Invalidation": {
        "Id": "I4CU23QAPKMUDUU06F90FGFABC",
        "Status": "Completed",
        "CreateTime": "2025-05-06T15:46:12.824000+00:00",
        "InvalidationBatch": {
            "Paths": {
                "Quantity": 2,
                "Items": [
                    "/example/invalidation",
                    "/more/invalidations"
                ]
            },
            "CallerReference": "007ee5a6-d0a0-42be-bb61-e7b915969b48"
        }
    }
}
```

For more information, see Invalidate files to remove content in the *Amazon CloudFront Developer Guide*.

- For API details, see GetInvalidationForDistributionTenant in *Amazon CLI Command Reference*.

`get-invalidation`

The following code example shows how to use `get-invalidation`.

Amazon CLI

To get a CloudFront invalidation

The following example gets the invalidation with the ID `I2J0I21PCUYOIK` for the CloudFront distribution with the ID `EDFDVBD6EXAMPLE`:

```
aws cloudfront get-invalidation --id I2J0I21PCUYOIK --distribution-
id EDFDVBD6EXAMPLE
```

Output:

```
{
    "Invalidation": {
        "Status": "Completed",
        "InvalidationBatch": {

`get-managed-certificate-details`

The following code example shows how to use `get-managed-certificate-details`.

Amazon CLI

To get managed certificate details

The following `get-managed-certificate-details` example retrieves the details of a CloudFront managed ACM certificate.

```
aws cloudfront get-managed-certificate-details \
    --identifier dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB
```

Output:

```
{
    "ManagedCertificateDetails": {
        "CertificateArn": "arn:aws:acm:us-
east-1:123456789012:certificate/655dc1fe-6d37-451d-a013-c2db3a034abc",
        "CertificateStatus": "pending-validation",
        "ValidationTokenHost": "self-hosted",
        "ValidationTokenDetails": [
            {
                "Domain": "example.com",
                "RedirectTo": "validation.us-east-1.acm-
validations.aws/123456789012/.well-known/pki-validation/
b315c9ae21284e7918bb9f3f422ab1c7.txt",
                "RedirectFrom": "example.com/.well-known/pki-validation/
b315c9ae21284e7918bb9f3f422ac3c7.txt"
            }
        ]
    }
}
```

For more information, see Request certificates for your CloudFront distribution tenant in the *Amazon CloudFront Developer Guide*.

- For API details, see GetManagedCertificateDetails in *Amazon CLI Command Reference*.

`get-public-key-config`

The following code example shows how to use `get-public-key-config`.

Amazon CLI

To get a CloudFront public key configuration

The following example gets metadata about the CloudFront public key with the ID KDFB19YGCR002, including its ETag. The public key ID is returned in the create-public-key and list-public-keys commands.

```
aws cloudfront get-public-key-config --id KDFB19YGCR002
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "PublicKeyConfig": {
        "CallerReference": "cli-example",
        "Name": "ExampleKey",
        "EncodedKey": "-----BEGIN PUBLIC KEY-----

        "Comment": "example public key"
    }
}
```

- For API details, see GetPublicKeyConfig in *Amazon CLI Command Reference*.

`get-public-key`

The following code example shows how to use `get-public-key`.

Amazon CLI

To get a CloudFront public key

The following example gets the CloudFront public key with the ID KDFB19YGCR002, including its ETag. The public key ID is returned in the create-public-key and list-public-keys commands.

```
aws cloudfront get-public-key --id KDFB19YGCR002
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "PublicKey": {
        "Id": "KDFB19YGCR002",
        "CreatedTime": "2019-12-05T18:51:43.781Z",
        "PublicKeyConfig": {
            "CallerReference": "cli-example",

            "Comment": "example public key"
        }
    }
}
```

- For API details, see GetPublicKey in *Amazon CLI Command Reference*.

`list-cloud-front-origin-access-identities`

The following code example shows how to use `list-cloud-front-origin-access-identities`.

Amazon CLI

To list CloudFront origin access identities

The following example gets a list of the CloudFront origin access identities (OAIs) in your Amazon account:

```
aws cloudfront list-cloud-front-origin-access-identities
```

Output:

```
{
    "CloudFrontOriginAccessIdentityList": {
        "Items": [
            {
                "Id": "E74FTE3AEXAMPLE",
                "S3CanonicalUserId":
 "cd13868f797c227fbea2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",
                "Comment": "Example OAI"
            },
            {
                "Id": "EH1HDMBEXAMPLE",
                "S3CanonicalUserId":
 "1489f6f2e6faacaae7ff64c4c3e6956c24f78788abfc1718c3527c263bf7a17EXAMPLE",
                "Comment": "Test OAI"
            },
            {
                "Id": "E2X2C9TEXAMPLE",
                "S3CanonicalUserId":
 "cbfeebb915a64749f9be546a45b3fcfd3a31c779673c13c4dd460911ae402c2EXAMPLE",
                "Comment": "Example OAI #2"
            }
        ]
    }
}
```

- For API details, see ListCloudFrontOriginAccessIdentities in *Amazon CLI Command Reference*.

`list-connection-groups`

The following code example shows how to use `list-connection-groups`.

Amazon CLI

To list connection groups

The following `list-connection-groups` example lists the available connection groups in your Amazon account.

```
aws cloudfront list-connection-groups
```

Output:

```
{
    "ConnectionGroups": [
        {
            "Id": "cg_2whCJoXMYCjHcxaLGrkllvyABC",
            "Name": "CreatedByCloudFront-cg_2whCJoXMYCjHcxaLGrkllvyABC",
            "Arn": "arn:aws:cloudfront::123456789012:connection-group/

            "LastModifiedTime": "2025-05-05T22:32:29.630000+00:00",
            "ETag": "E23ZP02F085ABC",
            "Enabled": true,
            "Status": "Deployed",
            "IsDefault": true
        },
        {
            "Id": "cg_2wjDWTBKTlRB87cAaUQFaakABC",
            "Name": "connection-group-2",
            "Arn": "arn:aws:cloudfront::123456789012:connection-group/
cg_2wjDWTBKTlRB87cAaUQFaakABC",
            "RoutingEndpoint": "dvdg9gprgabc.cloudfront.net",
            "CreatedTime": "2025-05-06T15:42:00.790000+00:00",
            "LastModifiedTime": "2025-05-06T15:42:00.790000+00:00",
            "ETag": "E23ZP02F085ABC",
            "Enabled": true,
            "Status": "Deployed",
            "IsDefault": false
        }
    ]
}
```

For more information, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see ListConnectionGroups in *Amazon CLI Command Reference*.

`list-distribution-tenants-by-customization`

The following code example shows how to use `list-distribution-tenants-by-customization`.

Amazon CLI

To list distribution tenants by customization

The following `list-distribution-tenants-by-customization` example lists distribution tenants that use the specified web ACL.

```
aws cloudfront list-distribution-tenants-by-customization \
    --web-acl-arn arn:aws:wafv2:us-east-1:123456789012:global/webacl/
CreatedByCloudFront-0273cd2f/a3c19bce-42b5-48a1-a8d4-b2bb2f28eabc
```

Output:

```
{
    "DistributionTenantList": [
        {
            "Id": "dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB",
            "DistributionId": "E1XNX8R2GOAABC",
            "Name": "example-tenant-2",
            "Arn": "arn:aws:cloudfront::123456789012:distribution-tenant/

- For API details, see ListDistributionsByConnectionMode in *Amazon CLI Command Reference*.

`list-distributions`

The following code example shows how to use `list-distributions`.

Amazon CLI

To list CloudFront distributions

The following example gets a list of the CloudFront distributions in your Amazon account.

```
aws cloudfront list-distributions
```

Output:

```
{
```

```
    "DistributionList": {
        "Items": [
            {
                "Id": "E23YS8OEXAMPLE",
                "ARN": "arn:aws:cloudfront::123456789012:distribution/
E23YS8OEXAMPLE",
                "Status": "Deployed",
                "LastModifiedTime": "2024-08-05T18:23:40.375000+00:00",
                "DomainName": "abcdefgh12ijk.cloudfront.net",
                "Aliases": {
                    "Quantity": 0
                },
                "Origins": {
                    "Quantity": 1,
                    "Items": [
                        {
                            "Id": "amzn-s3-demo-bucket.s3.us-east-1.amazonaws.com",
                            "DomainName": "amzn-s3-demo-bucket.s3.us-
east-1.amazonaws.com",
                            "OriginPath": "",
                            "CustomHeaders": {
                                "Quantity": 0
                            },
                            "S3OriginConfig": {
                                "OriginAccessIdentity": ""

                        "Quantity": 0
                    }
                },
                "WebACLId": "",
                "HttpVersion": "HTTP2",
                "IsIPV6Enabled": true,
                "Staging": false
            }
        ]
    }
}
```

- For API details, see ListDistributions in *Amazon CLI Command Reference*.

`list-domain-conflicts`

The following code example shows how to use `list-domain-conflicts`.

Amazon CLI

To list domain conflicts for a CloudFront distribution

The following `list-domain-conflicts` example lists domain conflicts for a CloudFront distribution.

```
aws cloudfront list-domain-conflicts \
    --domain example.com \
    --domain-control-validation-
resource "DistributionTenantId=dt_2x9GhoK0TZRsohWzv1b9It8J1AB"
```

Output:

```
{
    "DomainConflicts": [
        {
            "Domain": "example.com",
            "ResourceType": "distribution-tenant",
```

```
            "ResourceId": "***************ohWzv1b9It8J1AB",
            "AccountId": "123456789012"
        }
    ]
}
```

For more information, see Move an alternate domain name to a different distribution in the *Amazon CloudFront Developer Guide*.

- For API details, see ListDomainConflicts in *Amazon CLI Command Reference*.

`list-field-level-encryption-configs`

The following code example shows how to use `list-field-level-encryption-configs`.

Amazon CLI

To list CloudFront field-level encryption configurations

The following example gets a list of the CloudFront field-level encryption configurations in your Amazon account:

```
aws cloudfront list-field-level-encryption-configs
```

Output:

```
{
    "FieldLevelEncryptionList": {
        "MaxItems": 100,
        "Quantity": 1,
        "Items": [
            {
                "Id": "C3KM2WVD605UAY",
                "LastModifiedTime": "2019-12-10T21:30:18.974Z",
                "Comment": "Example FLE configuration",
                "QueryArgProfileConfig": {
                    "ForwardWhenQueryArgProfileIsUnknown": true,
                    "QueryArgProfiles": {
                        "Quantity": 0,
                        "Items": []
                    }
                },
                "ContentTypeProfileConfig": {
```

```
                    "ForwardWhenContentTypeIsUnknown": true,
                    "ContentTypeProfiles": {
                        "Quantity": 1,
                        "Items": [
                            {
                                "Format": "URLEncoded",
                                "ProfileId": "P280MFCLSYOCVU",
                                "ContentType": "application/x-www-form-urlencoded"
                            }
                        ]
                    }
                }
            }
        ]
    }
}
```

- For API details, see ListFieldLevelEncryptionConfigs in *Amazon CLI Command Reference*.

`list-field-level-encryption-profiles`

The following code example shows how to use `list-field-level-encryption-profiles`.

Amazon CLI

To list CloudFront field-level encryption profiles

The following example gets a list of the CloudFront field-level encryption profiles in your Amazon account:

```
aws cloudfront list-field-level-encryption-profiles
```

Output:

```
{
    "FieldLevelEncryptionProfileList": {
        "MaxItems": 100,
        "Quantity": 2,
        "Items": [
            {
                "Id": "P280MFCLSYOCVU",
                "LastModifiedTime": "2019-12-05T01:05:39.896Z",
```

```

                    "Items": [
                        {
                            "PublicKeyId": "K2ABC10EXAMPLE",
                            "ProviderId": "ExampleFLEProvider2",
                            "FieldPatterns": {
                                "Quantity": 1,
                                "Items": [
                                    "ExampleSensitiveField2"
                                ]
                            }
                        }
                    ]
                },
                "Comment": "FLE profile #2 for AWS CLI example"
            }
        ]
    }
}
```

- For API details, see [ListFieldLevelEncryptionProfiles](#) in *Amazon CLI Command Reference*.

`list-invalidations-for-distribution-tenant`

The following code example shows how to use `list-invalidations-for-distribution-tenant`.

Amazon CLI

To list invalidations for a CloudFront distribution tenant

The following `list-invalidations-for-distribution-tenant` example lists the invalidations for a CloudFront distribution tenant.

```
aws cloudfront list-invalidations-for-distribution-tenant \
    --id dt_2wjDZi3hD1ivOXf6rpZJOSNE1AB
```

Output:

```
{
    "InvalidationList": {
        "Items": [
            {
                "Id": "I4CU23QAPKMUDUU06F9OFGFABC",
                "CreateTime": "2025-05-06T15:46:12.824000+00:00",
                "Status": "Completed"
            }
        ]
    }
}
```

For more information, see Invalidate files to remove content in the *Amazon CloudFront Developer Guide*.

- For API details, see ListInvalidationsForDistributionTenant in *Amazon CLI Command Reference*.

`list-invalidations`

The following code example shows how to use `list-invalidations`.

Amazon CLI

To list CloudFront invalidations

The following example gets a list of the invalidations for the CloudFront distribution with the ID EDFDVBD6EXAMPLE:

```
aws cloudfront list-invalidations --distribution-id EDFDVBD6EXAMPLE
```

Output:

```
{
    "InvalidationList": {
        "Marker": "",
        "Items": [
            {
                "Status": "Completed",
                "Id": "YNY2LI2BVJ4NJU",
                "CreateTime": "2019-08-31T21:15:52.042Z"
            }
        ],
        "IsTruncated": false,
        "MaxItems": 100,
        "Quantity": 1
    }
}
```

- For API details, see ListInvalidations in *Amazon CLI Command Reference*.

`list-public-keys`

The following code example shows how to use `list-public-keys`.

Amazon CLI

To list CloudFront public keys

The following example gets a list of the CloudFront public keys in your Amazon account:

```
aws cloudfront list-public-keys
```

Output:

```
{
    "PublicKeyList": {
        "MaxItems": 100,
```

```
        "Quantity": 2,
        "Items": [
            {
                "Id": "K2K8NC4HVFE3M0",
                "Name": "ExampleKey",
                "CreatedTime": "2019-12-05T01:04:28.818Z",
                "EncodedKey": "-----BEGIN PUBLIC KEY-----

                "Comment": "example public key #2"
            }
        ]
    }
}
```

- For API details, see ListPublicKeys in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags for a CloudFront distribution

The following example gets a list of the tags for a CloudFront distribution:

```
aws cloudfront list-tags-for-resource \
    --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE
```

Output:

```
{
    "Tags": {
        "Items": [
            {
                "Key": "DateCreated",
                "Value": "2019-12-04"
            },
            {
                "Key": "Name",
                "Value": "Example name"
            },
            {
                "Key": "Project",
                "Value": "Example project"
            }
        ]
    }
}
```

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`sign`

The following code example shows how to use `sign`.

Amazon CLI

To sign a CloudFront URL

The following example signs a CloudFront URL. To sign a URL, you need the key pair ID (called the **Access Key ID** in the Amazon Management Console) and the private key of the trusted signer's CloudFront key pair. For more information about signed URLs, see Serving Private Content with Signed URLs and Signed Cookies in the *Amazon CloudFront Developer Guide*.

```
aws cloudfront sign \
```

```
    --url https://d111111abcdef8.cloudfront.net/private-content/private-file.html \
    --key-pair-id APKAEIBAERJR2EXAMPLE \
    --private-key file://cf-signer-priv-key.pem \
    --date-less-than 2020-01-01
```

Output:

```
https://d111111abcdef8.cloudfront.net/private-content/private-
file.html?Expires=1577836800&Signature=nEXK7Kby47XKeZQKVc6pwkif6oZc-
JWSpDkH0UH7EBGGqvgurkecCbgL5VfUAXyLQuJxFwRQWscz-

GGl6l2kgCpXUB6Jx6K~Y3kpVOdzUPOIqFLHAnJojbhxqrVejomZZ2XrquDvNUCCIbePGnR3d24UPaLXG4FKOqNEaWDIB
GNvjRJxqWf93uMobeMOiVYahb-e0KItiQewGcm0eLZQ__&Key-Pair-Id=APKAEIBAERJR2EXAMPLE
```

- For API details, see Sign in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a CloudFront distribution

The following `tag-resource` example adds two tags to the specified CloudFront distribution.

```
aws cloudfront tag-resource \
    --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
    --tags 'Items=[{Key=Name,Value="Example name"},{Key=Project,Value="Example
 project"}]'
```

Instead of using command line arguments, you can provide the tags in a JSON file, as shown in the following example:

```
aws cloudfront tag-resource \
    --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
    --tags file://tags.json
```

Contents of `tags.json`:

```
{
    "Items": [
        {
            "Key": "Name",
            "Value": "Example name"
        },
        {
            "Key": "Project",
            "Value": "Example project"
        }
    ]
}
```

This command produces no output.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from a CloudFront distribution

The following example removes two tags from a CloudFront distribution by using command line arguments:

```
aws cloudfront untag-resource \
    --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
    --tag-keys Items=Name,Project
```

Instead of using command line arguments, you can provide the tag keys in a JSON file, as shown in the following example:

```
aws cloudfront untag-resource \
    --resource arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE \
    --tag-keys file://tag-keys.json
```

The file `tag-keys.json` is a JSON document in the current folder that contains the following:

```
{
    "Items": [
        "Name",
        "Project"
    ]
}
```

When successful, this command has no output.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

update-cloud-front-origin-access-identity

The following code example shows how to use `update-cloud-front-origin-access-identity`.

Amazon CLI

To update a CloudFront origin access identity

The following example updates the origin access identity (OAI) with the ID `E74FTE3AEXAMPLE`. The only field that you can update is the OAI's `Comment`.

To update an OAI, you must have the OAI's ID and `ETag`. The OAI ID is returned in the output of the create-cloud-front-origin-access-identity and list-cloud-front-origin-access-identities commands. To get the `ETag`, use the get-cloud-front-origin-access-identity or get-cloud-front-origin-access-identity-config command. Use the `--if-match` option to provide the OAI's `ETag`.

```
aws cloudfront update-cloud-front-origin-access-identity \
    --id E74FTE3AEXAMPLE \
    --if-match E2QWRUHEXAMPLE \
    --cloud-front-origin-access-identity-config \
        CallerReference=cli-example,Comment="Example OAI Updated"
```

You can accomplish the same thing by providing the OAI configuration in a JSON file, as shown in the following example:

```
aws cloudfront update-cloud-front-origin-access-identity \
    --id E74FTE3AEXAMPLE \
    --if-match E2QWRUHEXAMPLE \
    --cloud-front-origin-access-identity-config file://OAI-config.json
```

The file `OAI-config.json` is a JSON document in the current directory that contains the following:

```
{
    "CallerReference": "cli-example",
    "Comment": "Example OAI Updated"
}
```

Whether you provide the OAI configuration with a command line argument or a JSON file, the output is the same:

```
{
    "ETag": "E9LHASXEXAMPLE",
    "CloudFrontOriginAccessIdentity": {
        "Id": "E74FTE3AEXAMPLE",
        "S3CanonicalUserId":
 "cd13868f797c227fbea2830611a26fe0a21ba1b826ab4bed9b7771c9aEXAMPLE",
        "CloudFrontOriginAccessIdentityConfig": {
            "CallerReference": "cli-example",
            "Comment": "Example OAI Updated"
        }
    }
}
```

- For API details, see [UpdateCloudFrontOriginAccessIdentity](#) in *Amazon CLI Command Reference*.

`update-connection-group`

The following code example shows how to use `update-connection-group`.

Amazon CLI

To update a CloudFront connection group

The following `update-connection-group` example disables a CloudFront connection group and disables IPv6.

```
aws cloudfront update-connection-group \
    --id cg_2yHsDkcPKeUlVkk3aEgLKcjABC \
    --no-ipv6-enabled \
```

```
    --no-enabled \
    --if-match E3UN6WX5RRO2ABC
```

Output:

```
{
    "ETag": "E1F83G8C2ARABC",
    "ConnectionGroup": {
        "Id": "cg_2yHsDkcPKeUlVkk3aEgLKcjABC",
        "Name": "cg-example",
        "Arn": "arn:aws:cloudfront::123456789012:connection-group/
cg_2yHsDkcPKeUlVkk3aEgLKcjABC",
        "CreatedTime": "2025-06-09T20:58:35.481000+00:00",
        "LastModifiedTime": "2025-06-11T16:25:54.280000+00:00",
        "Ipv6Enabled": false,
        "RoutingEndpoint": "du9xp1elo1abc.cloudfront.net",
        "Status": "InProgress",
        "Enabled": false,
        "IsDefault": false
    }
}
```

For more information, see Create custom connection group (optional) in the *Amazon CloudFront Developer Guide*.

- For API details, see UpdateConnectionGroup in *Amazon CLI Command Reference*.

update-distribution-tenant

The following code example shows how to use `update-distribution-tenant`.

Amazon CLI

To update a CloudFront distribution tenant

The following `update-distribution-tenant` example updates a CloudFront distribution tenant with a new parameter value and adds a country to the geo-restrictions.

```
aws cloudfront update-distribution-tenant \
    --cli-input-json file://update-tenant.json
```

Contents of `update-tenant.json`:

```
{
    "Id": "dt_2yMvQgam3QkJo2z54FDl91dk1AB",
    "IfMatch": "E1F83G8C2ARABC",
    "Parameters": [
        {
            "Name": "testParam",
            "Value": "newParameterValue"
        }
    ],
    "Customizations": {
        "WebAcl": {
            "Action": "disable"
        },
        "GeoRestrictions": {
            "RestrictionType": "whitelist",
            "Locations": [
                "DE",
                "GB",
                "ES"
            ]
        }
    }
}
```

Output:

```
{
    "ETag": "E1PA6795UKMABC",
    "DistributionTenant": {
        "Id": "dt_2yMvQgam3QkJo2z54FDl91dk1AB",
        "DistributionId": "E1XNX8R2GOAABC",
        "Name": "new-tenant-customizations",
        "Arn": "arn:aws:cloudfront::123456789012:distribution-tenant/
dt_2yMvQgam3QkJo2z54FDl91dk1AB",
        "Domains": [
            {
                "Domain": "example.com",
                "Status": "active"
            }
        ],
        "Customizations": {
            "WebAcl": {
                "Action": "disable"
```

```
            },
            "GeoRestrictions": {
                "RestrictionType": "whitelist",
                "Locations": [
                    "DE",
                    "ES",
                    "GB"
                ]
            }
        },
        "Parameters": [
            {
                "Name": "testParam",
                "Value": "newParameterValue"
            }
        ],
        "ConnectionGroupId": "cg_2whCJoXMYCjHcxaLGrkllvyABC",
        "CreatedTime": "2025-06-11T15:54:02.142000+00:00",
        "LastModifiedTime": "2025-06-11T16:42:45.531000+00:00",
        "Enabled": false,
        "Status": "InProgress"
    }
}
```

For more information, see Distribution tenant customizations in the *Amazon CloudFront Developer Guide*.

- For API details, see UpdateDistributionTenant in *Amazon CLI Command Reference*.

`update-distribution`

The following code example shows how to use `update-distribution`.

Amazon CLI

Example 1: To update a CloudFront distribution's default root object

The following example updates the default root object to `index.html` for the CloudFront distribution with the ID `EDFDVBD6EXAMPLE`.

```
aws cloudfront update-distribution \
    --id EDFDVBD6EXAMPLE \
    --default-root-object index.html
```

Output:

```
{
    "ETag": "E2QWRUHEXAMPLE",
    "Distribution": {
        "Id": "EDFDVBD6EXAMPLE",
        "ARN": "arn:aws:cloudfront::123456789012:distribution/EDFDVBD6EXAMPLE",
        "Status": "InProgress",
        "LastModifiedTime": "2019-12-06T18:55:39.870Z",
        "InProgressInvalidationBatches": 0,

        }
    }
}
```

Example 2: To update a CloudFront distribution

The following example disables the CloudFront distribution with the ID `EMLARXS9EXAMPLE` by providing the distribution configuration in a JSON file named `dist-config-disable.json`. To update a distribution, you must use the `--if-match` option to provide the distribution's `ETag`. To get the `ETag`, use the get-distribution or get-distribution-config command. Note that the `Enabled` field is set to `false` in the JSON file.

After you use the following example to disable a distribution, you can use the delete-distribution command to delete it.

```
aws cloudfront update-distribution \
    --id EMLARXS9EXAMPLE \
    --if-match E2QWRUHEXAMPLE \
    --distribution-config file://dist-config-disable.json
```

Contents of `dist-config-disable.json`:

        }
    }
}
```

- For API details, see UpdateDistribution in *Amazon CLI Command Reference*.

`update-domain-association`

The following code example shows how to use `update-domain-association`.

Amazon CLI

To update a domain association

The following `update-domain-association` example updates a domain association for a distribution tenant with ETag `E23ZP02F085ABC`.

```
aws cloudfront update-domain-association \
    --domain example.com \
    --target-resource DistributionTenantId=dt_2x9GhoK0TZRsohWzv1b9It8J1AB \
    --if-match E23ZP02F085ABC
```

Output:

```
{
    "ETag": "ETVPDKIKX0ABC",
    "Domain": "example.com",
    "ResourceId": "dt_2x9GhoK0TZRsohWzv1b9It8J1AB"
}
```

For more information, see Move an alternate domain name to a different distribution in the *Amazon CloudFront Developer Guide*.

- For API details, see UpdateDomainAssociation in *Amazon CLI Command Reference*.

`update-field-level-encryption-config`

The following code example shows how to use `update-field-level-encryption-config`.

Amazon CLI

To update a CloudFront field-level encryption configuration

The following example updates the `Comment` field of the field-level encryption configuration with the ID `C3KM2WVD605UAY` by providing the parameters in a JSON file.

To update a field-level encryption configuration, you must have the configuration's ID and `ETag`. The ID is returned in the output of the create-field-level-encryption-config and list-field-level-encryption-configs commands. To get the `ETag`, use the get-field-level-encryption or get-field-level-encryption-config command. Use the `--if-match` option to provide the configuration's `ETag`.

```
aws cloudfront update-field-level-encryption-config \
    --id C3KM2WVD605UAY \
    --if-match E2P4Z4VU7TY5SG \
    --field-level-encryption-config file://fle-config.json
```

The file `fle-config.json` is a JSON document in the current directory that contains the following:

```
{
    "CallerReference": "cli-example",
    "Comment": "Updated example FLE configuration",
    "QueryArgProfileConfig": {
        "ForwardWhenQueryArgProfileIsUnknown": true,
        "QueryArgProfiles": {
            "Quantity": 0
        }
    },
    "ContentTypeProfileConfig": {
        "ForwardWhenContentTypeIsUnknown": true,
```

```
        "ContentTypeProfiles": {
            "Quantity": 1,
            "Items": [
                {
                    "Format": "URLEncoded",
                    "ProfileId": "P280MFCLSYOCVU",
                    "ContentType": "application/x-www-form-urlencoded"
                }
            ]
        }
    }
}
```

Output:

```
{
    "ETag": "E26M4BIAV81ZF6",
    "FieldLevelEncryption": {
        "Id": "C3KM2WVD605UAY",
        "LastModifiedTime": "2019-12-10T22:26:26.170Z",
        "FieldLevelEncryptionConfig": {
            "CallerReference": "cli-example",
            "Comment": "Updated example FLE configuration",
            "QueryArgProfileConfig": {
                "ForwardWhenQueryArgProfileIsUnknown": true,
                "QueryArgProfiles": {
                    "Quantity": 0,
                    "Items": []
                }
            },
            "ContentTypeProfileConfig": {
                "ForwardWhenContentTypeIsUnknown": true,
                "ContentTypeProfiles": {
                    "Quantity": 1,
                    "Items": [
                        {
                            "Format": "URLEncoded",
                            "ProfileId": "P280MFCLSYOCVU",
                            "ContentType": "application/x-www-form-urlencoded"
                        }
                    ]
                }
            }
```

```
        }
    }
}
```

- For API details, see UpdateFieldLevelEncryptionConfig in *Amazon CLI Command Reference*.

`update-field-level-encryption-profile`

The following code example shows how to use `update-field-level-encryption-profile`.

Amazon CLI

To update a CloudFront field-level encryption profile

The following example updates the field-level encryption profile with the ID `PPK0UOSIF5WSV`. This example updates the profile's `Name` and `Comment`, and adds a second `FieldPatterns` item, by providing the parameters in a JSON file.

To update a field-level encryption profile, you must have the profile's ID and `ETag`. The ID is returned in the output of the create-field-level-encryption-profile and list-field-level-encryption-profiles commands. To get the `ETag`, use the get-field-level-encryption-profile or get-field-level-encryption-profile-config command. Use the `--if-match` option to provide the profile's `ETag`.

```
aws cloudfront update-field-level-encryption-profile \
    --id PPK0UOSIF5WSV \
    --if-match E1QQG65FS2L2GC \
    --field-level-encryption-profile-config file://fle-profile-config.json
```

The file `fle-profile-config.json` is a JSON document in the current directory that contains the following:

```
{
    "Name": "ExampleFLEProfileUpdated",
    "CallerReference": "cli-example",
    "Comment": "Updated FLE profile for AWS CLI example",
    "EncryptionEntities": {
        "Quantity": 1,
        "Items": [
            {
                "PublicKeyId": "K2K8NC4HVFE3M0",
```

```
                "ProviderId": "ExampleFLEProvider",
                "FieldPatterns": {
                    "Quantity": 2,
                    "Items": [
                        "ExampleSensitiveField",
                        "SecondExampleSensitiveField"
                    ]
                }
            }
        ]
    }
}
```

Output:

```
{
    "ETag": "EJETYFJ9CL66D",
    "FieldLevelEncryptionProfile": {
        "Id": "PPK0UOSIF5WSV",
        "LastModifiedTime": "2019-12-10T19:05:58.296Z",
        "FieldLevelEncryptionProfileConfig": {
            "Name": "ExampleFLEProfileUpdated",
            "CallerReference": "cli-example",
            "Comment": "Updated FLE profile for AWS CLI example",
            "EncryptionEntities": {
                "Quantity": 1,
                "Items": [
                    {
                        "PublicKeyId": "K2K8NC4HVFE3M0",
                        "ProviderId": "ExampleFLEProvider",
                        "FieldPatterns": {
                            "Quantity": 2,
                            "Items": [
                                "ExampleSensitiveField",
                                "SecondExampleSensitiveField"
                            ]
                        }
                    }
                ]
            }
        }
    }
}
```

- For API details, see UpdateFieldLevelEncryptionProfile in *Amazon CLI Command Reference*.

`verify-dns-configuration`

The following code example shows how to use `verify-dns-configuration`.

Amazon CLI

To verify DNS configuration for a domain

The following `verify-dns-configuration` example verifies the DNS configuration for a domain.

```
aws cloudfront verify-dns-configuration \
    --domain example.com \
    --identifier dt_2x9GhoK0TZRsohWzv1b9It8J1AB
```

Output:

```
{
    "DnsConfigurationList": [
        {
            "Domain": "example.com",
            "Status": "valid-configuration"
        }
    ]
}
```

For more information, see Move an alternate domain name to a different distribution in the *Amazon CloudFront Developer Guide*.

- For API details, see VerifyDnsConfiguration in *Amazon CLI Command Reference*.

Amazon CloudSearch examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon CloudSearch.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Actions

`upload-documents`

The following code example shows how to use `upload-documents`.

Amazon CLI

The following `upload-documents` command uploads a batch of JSON documents to an Amazon CloudSearch domain:

```
aws cloudsearchdomain upload-documents --endpoint-url https://doc-my-domain.us-west-1.cloudsearch.amazonaws.com --content-type application/json --documents document-batch.json
```

Output:

```
{
  "status": "success",
  "adds": 5000,
  "deletes": 0
}
```

- For API details, see UploadDocuments in *Amazon CLI Command Reference*.

CloudTrail examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudTrail.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`add-tags`

The following code example shows how to use `add-tags`.

Amazon CLI

To add tags to trail

The following `add-tags` command adds tags for `Trail1`:

```
aws cloudtrail add-tags --resource-id arn:aws:cloudtrail:us-
east-1:123456789012:trail/Trail1 --tags-
list Key=name,Value=Alice Key=location,Value=us
```

- For API details, see AddTags in *Amazon CLI Command Reference*.

`create-subscription`

The following code example shows how to use `create-subscription`.

Amazon CLI

To create and configure Amazon resources for a trail

The following `create-subscription` command creates a new S3 bucket and SNS topic for `Trail1`.

```
aws cloudtrail create-subscription \
    --name Trail1 \
    --s3-new-bucket amzn-s3-demo-bucket \
    --sns-new-topic my-topic
```

Output:

```
Setting up new S3 bucket amzn-s3-demo-bucket...
Setting up new SNS topic my-topic...
Creating/updating CloudTrail configuration...
CloudTrail configuration:
    {
        "trailList": [
            {
                "IncludeGlobalServiceEvents": true,
                "Name": "Trail1",
                "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/
Trail1",
                "LogFileValidationEnabled": false,
                "IsMultiRegionTrail": false,
                "S3BucketName": "amzn-s3-demo-bucket",
                "SnsTopicName": "my-topic",
                "HomeRegion": "us-east-1"
            }
        ],
        "ResponseMetadata": {
        "HTTPStatusCode": 200,

        }
    }
Starting CloudTrail service...
Logs will be delivered to my-bucket
```

- For API details, see [CreateSubscription](#) in *Amazon CLI Command Reference*.

`create-trail`

The following code example shows how to use `create-trail`.

Amazon CLI

To create a trail

The following `create-trail` example creates a multi-region trail named `Trail1` and specifies an S3 bucket.

```
aws cloudtrail create-trail \
    --name Trail1 \
    --s3-bucket-name amzn-s3-demo-bucket \
```

```
    --is-multi-region-trail
```

Output:

```
{
    "IncludeGlobalServiceEvents": true,
    "Name": "Trail1",
    "TrailARN": "arn:aws:cloudtrail:us-west-2:123456789012:trail/Trail1",
    "LogFileValidationEnabled": false,
    "IsMultiRegionTrail": true,
    "S3BucketName": "amzn-s3-demo-bucket"
}
```

- For API details, see CreateTrail in *Amazon CLI Command Reference*.

`delete-trail`

The following code example shows how to use `delete-trail`.

Amazon CLI

To delete a trail

The following `delete-trail` command deletes a trail named `Trail1`:

```
aws cloudtrail delete-trail --name Trail1
```

- For API details, see DeleteTrail in *Amazon CLI Command Reference*.

`describe-trails`

The following code example shows how to use `describe-trails`.

Amazon CLI

To describe a trail

The following `describe-trails` example returns the settings for `Trail1` and `Trail2`.

```
aws cloudtrail describe-trails \
    --trail-name-list Trail1 Trail2
```

Output:

```
{
    "trailList": [
        {
            "IncludeGlobalServiceEvents": true,
            "Name": "Trail1",
            "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1",
            "LogFileValidationEnabled": false,
            "IsMultiRegionTrail": false,
            "S3BucketName": "amzn-s3-demo-bucket",
            "CloudWatchLogsRoleArn": "arn:aws:iam::123456789012:role/
CloudTrail_CloudWatchLogs_Role",
            "CloudWatchLogsLogGroupArn": "arn:aws:logs:us-east-1:123456789012:log-
group:CloudTrail:*",
            "SnsTopicName": "my-topic",
            "HomeRegion": "us-east-1"
        },
        {
            "IncludeGlobalServiceEvents": true,
            "Name": "Trail2",
            "S3KeyPrefix": "my-prefix",
            "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail2",
            "LogFileValidationEnabled": false,
            "IsMultiRegionTrail": false,
            "S3BucketName": "amzn-s3-demo-bucket2",
            "KmsKeyId": "arn:aws:kms:us-
east-1:123456789012:key/4c5ae5ac-3c13-421e-8335-c7868ef6a769",
            "HomeRegion": "us-east-1"
        }
    ]
}
```

- For API details, see DescribeTrails in *Amazon CLI Command Reference*.

`get-event-selectors`

The following code example shows how to use `get-event-selectors`.

Amazon CLI

To view the event selector settings for a trail

The following `get-event-selectors` command returns the settings for `Trail1`:

```
aws cloudtrail get-event-selectors --trail-name Trail1
```

Output:

```
{
  "EventSelectors": [
      {
          "IncludeManagementEvents": true,
          "DataResources": [],
          "ReadWriteType": "All"
      }
  ],
  "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1"
}
```

- For API details, see GetEventSelectors in *Amazon CLI Command Reference*.

`get-trail-status`

The following code example shows how to use `get-trail-status`.

Amazon CLI

To get the status of a trail

The following `get-trail-status` command returns the delivery and logging details for `Trail1`:

```
aws cloudtrail get-trail-status --name Trail1
```

Output:

```
{
  "LatestNotificationTime": 1454022144.869,
  "LatestNotificationAttemptSucceeded": "2016-01-28T23:02:24Z",
  "LatestDeliveryAttemptTime": "2016-01-28T23:02:24Z",
  "LatestDeliveryTime": 1454022144.869,
  "TimeLoggingStarted": "2015-11-06T18:36:38Z",
  "LatestDeliveryAttemptSucceeded": "2016-01-28T23:02:24Z",
```

```
  "IsLogging": true,
  "LatestCloudWatchLogsDeliveryTime": 1454022144.918,
  "StartLoggingTime": 1446834998.695,
  "StopLoggingTime": 1446834996.933,
  "LatestNotificationAttemptTime": "2016-01-28T23:02:24Z",
  "TimeLoggingStopped": "2015-11-06T18:36:36Z"
}
```

- For API details, see GetTrailStatus in *Amazon CLI Command Reference*.

`list-public-keys`

The following code example shows how to use `list-public-keys`.

Amazon CLI

To list all public keys for a trail

The following `list-public-keys` command returns all public keys whose private keys were used to sign the digest files within the specified time range:

```
aws cloudtrail list-public-keys --start-time 2016-01-01T20:30:00.000Z
```

Output:

```
{
  "PublicKeyList": [
      {
         "ValidityStartTime": 1453076702.0,
         "ValidityEndTime": 1455668702.0,
         "Value": "MIIBCgKCAQEAlSS3cl92HDycr/MTj0moOhas8habjrraXw+KzlWF0axSI2tcF

         "Fingerprint": "7f3f401420072e50a65a141430817ab3"
      }
  ]
}
```

- For API details, see ListPublicKeys in *Amazon CLI Command Reference*.

`list-tags`

The following code example shows how to use `list-tags`.

Amazon CLI

To list the tags for a trail

The following `list-tags` command lists the tags for `Trail1` and `Trail2`:

```
aws cloudtrail list-tags --resource-id-list arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1 arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail2
```

Output:

```
{
 "ResourceTagList": [
     {
         "ResourceId": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1",
         "TagsList": [
             {
                 "Value": "Alice",
                 "Key": "name"
             },
             {
                 "Value": "us",
                 "Key": "location"
             }
         ]
     },
     {
         "ResourceId": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail2",
         "TagsList": [
             {
                 "Value": "Bob",
                 "Key": "name"
             }
         ]
     }
  ]
}
```

- For API details, see ListTags in *Amazon CLI Command Reference*.

`lookup-events`

The following code example shows how to use `lookup-events`.

Amazon CLI

To look up events for a trail

The following `lookup-events` command looks up API activity events by the attribute `EventName`:

```
aws cloudtrail lookup-events --lookup-
attributes AttributeKey=EventName,AttributeValue=ConsoleLogin
```

Output:

```
{
  "Events": [
     {
         "EventId": "654ccbc0-ba0d-486a-9076-dbf7274677a7",
         "Username": "my-session-name",
         "EventTime": "2021-11-18T09:41:02-08:00",
         "CloudTrailEvent": "{\"eventVersion\":\"1.02\",\"userIdentity\":{\"type\":

         "EventName": "ConsoleLogin",
         "Resources": []
     }
```

```
  ]
}
```

- For API details, see LookupEvents in *Amazon CLI Command Reference*.

`put-event-selectors`

The following code example shows how to use `put-event-selectors`.

Amazon CLI

Example 1: Configure a trail to log management events and data events by using advanced event selectors

You can add advanced event selectors, and conditions for your advanced event selectors, up to a maximum of 500 values for all conditions and selectors on a trail. You can use advanced event selectors to log all available data event types. You can use either advanced event selectors or basic event selectors, but not both. If you apply advanced event selectors to a trail, any existing basic event selectors are overwritten.

The following `put-event-selectors` example creates an advanced event selector for a trail named `myTrail` to log all management events, log S3 PutObject and DeleteObject API calls for all but one S3 bucket, log data API calls for a Lambda function named `myFunction`, and log Publish API calls on an SNS topic named `myTopic`.

```
aws cloudtrail put-event-selectors \
    --trail-name myTrail \
    --advanced-event-selectors '[{"Name": "Log all management events",
 "FieldSelectors": [{ "Field": "eventCategory", "Equals": ["Management"] }] },
{"Name": "Log PutObject and DeleteObject events for all but one
 bucket","FieldSelectors": [{ "Field": "eventCategory", "Equals": ["Data"] },
{ "Field": "resources.type", "Equals": ["AWS::S3::Object"] },{ "Field":
 "eventName", "Equals": ["PutObject","DeleteObject"] },{ "Field": "resources.ARN",
 "NotStartsWith": ["arn:aws:s3:::amzn-s3-demo-bucket/"] }]},{"Name": "Log
 data events for a specific Lambda function","FieldSelectors": [{ "Field":
 "eventCategory", "Equals": ["Data"] },{ "Field": "resources.type",
 "Equals": ["AWS::Lambda::Function"] },{ "Field": "resources.ARN", "Equals":
 ["arn:aws:lambda:us-east-1:123456789012:function:myFunction"] }]},{"Name":
 "Log all Publish API calls on a specific SNS topic","FieldSelectors":
 [{ "Field": "eventCategory", "Equals": ["Data"] },{ "Field": "resources.type",
 "Equals": ["AWS::SNS::Topic"] },{ "Field": "eventName", "Equals":
```

```
 ["Publish"] },{ "Field": "resources.ARN", "Equals": ["arn:aws:sns:us-
east-1:123456789012:myTopic.fifo"] }]}]'
```

Output:

```
{
    "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/myTrail",
    "AdvancedEventSelectors": [
        {
            "Name": "Log all management events",
            "FieldSelectors": [
                {
                    "Field": "eventCategory",
                    "Equals": [
                        "Management"
                    ]
                }
            ]
        },
        {
            "Name": "Log PutObject and DeleteObject events for all but one bucket",
            "FieldSelectors": [
                {
                    "Field": "eventCategory",
                    "Equals": [
                        "Data"
                    ]
                },
                {
                    "Field": "resources.type",
                    "Equals": [
                        "AWS::S3::Object"
                    ]
                },
                {
                    "Field": "eventName",
                    "Equals": [
                        "PutObject",
                        "DeleteObject"
                    ]
                },
                {
                    "Field": "resources.ARN",
```

```
                "NotStartsWith": [
                    "arn:aws:s3:::amzn-s3-demo-bucket/"
                ]
            }
        ]
    },
    {
        "Name": "Log data events for a specific Lambda function",
        "FieldSelectors": [
            {
                "Field": "eventCategory",
                "Equals": [
                    "Data"
                ]
            },
            {
                "Field": "resources.type",
                "Equals": [
                    "AWS::Lambda::Function"
                ]
            },
            {
                "Field": "resources.ARN",
                "Equals": [
                    "arn:aws:lambda:us-east-1:123456789012:function:myFunction"
                ]
            }
        ]
    },
    {
        "Name": "Log all Publish API calls on a specific SNS topic",
        "FieldSelectors": [
            {
                "Field": "eventCategory",
                "Equals": [
                    "Data"
                ]
            },
            {
                "Field": "resources.type",
                "Equals": [
                    "AWS::SNS::Topic"
                ]
            },
```

```
                {
                    "Field": "eventName",
                    "Equals": [
                        "Publish"
                    ]
                },
                {
                    "Field": "resources.ARN",
                    "Equals": [
                        "arn:aws:sns:us-east-1:123456789012:myTopic.fifo"
                    ]
                }
            ]
        }
    ]
}
```

For more information, see Log events by using advanced event selectors in the *Amazon CloudTrail User Guide*.

Example 2: Configure event selectors for a trail to log all management events and data events

You can configure up to 5 event selectors for a trail and up to 250 data resources for a trail. Event selectors are also referred to as basic event selectors. You can use event selectors to log management events and data events for S3 objects, Lambda functions, and DynnamoDB tables. To log data events for other resource types, you must use advanced event selectors.

The following `put-event-selectors` example creates an event selector for a trail named `TrailName` to include all management events, data events for two Amazon S3 bucket/prefix combinations, and data events for a single Amazon Lambda function named `hello-world-python-function`.

```
aws cloudtrail put-event-selectors \
    --trail-name TrailName \
    --event-selectors '[{"ReadWriteType": "All","IncludeManagementEvents":
 true,"DataResources": [{"Type":"AWS::S3::Object", "Values": ["arn:aws:s3:::amzn-
s3-demo-bucket/prefix","arn:aws:s3:::amzn-s3-demo-bucket2/prefix2"]},
{"Type": "AWS::Lambda::Function","Values": ["arn:aws:lambda:us-
west-2:999999999999:function:hello-world-python-function"]}]}]'
```

Output:

```
{
    "EventSelectors": [
        {
            "IncludeManagementEvents": true,
            "DataResources": [
                {
                    "Values": [
                        "arn:aws:s3:::amzn-s3-demo-bucket/prefix",
                        "arn:aws:s3:::amzn-s3-demo-bucket2/prefix2"
                    ],
                    "Type": "AWS::S3::Object"
                },
                {
                    "Values": [
                        "arn:aws:lambda:us-west-2:123456789012:function:hello-world-
python-function"
                    ],
                    "Type": "AWS::Lambda::Function"
                },
            ],
            "ReadWriteType": "All"
        }
    ],
    "TrailARN": "arn:aws:cloudtrail:us-east-2:123456789012:trail/TrailName"
}
```

For more information, see Log events by using basic event selectors in the *Amazon CloudTrail User Guide*.

Example 3: Configure event selectors for a trail to log management events, all S3 data events on S3 objects, and all Lambda data events on functions in your account

The following `put-event-selectors` example creates an event selector for a trail named `TrailName2` that includes all management events, and all data events for all Amazon S3 buckets and Amazon Lambda functions in the Amazon account.

```
aws cloudtrail put-event-selectors \
    --trail-name TrailName2 \
    --event-selectors '[{"ReadWriteType": "All","IncludeManagementEvents":
 true,"DataResources": [{"Type":"AWS::S3::Object", "Values": ["arn:aws:s3"]},
{"Type": "AWS::Lambda::Function","Values": ["arn:aws:lambda"]}]}]'
```

Output:

```
{
    "EventSelectors": [
        {
            "IncludeManagementEvents": true,
            "DataResources": [
                {
                    "Values": [
                        "arn:aws:s3"
                    ],
                    "Type": "AWS::S3::Object"
                },
                {
                    "Values": [
                        "arn:aws:lambda"
                    ],
                    "Type": "AWS::Lambda::Function"
                },
            ],
            "ReadWriteType": "All"
        }
    ],
    "TrailARN": "arn:aws:cloudtrail:us-east-2:123456789012:trail/TrailName2"
}
```

For more information, see Log events by using basic event selectors in the *Amazon CloudTrail User Guide*.

- For API details, see PutEventSelectors in *Amazon CLI Command Reference*.

`remove-tags`

The following code example shows how to use `remove-tags`.

Amazon CLI

To remove tags for a trail

The following `remove-tags` command removes the specified tags for `Trail1`:

```
aws cloudtrail remove-tags --resource-id arn:aws:cloudtrail:us-
east-1:123456789012:trail/Trail1 --tags-list Key=name Key=location
```

- For API details, see RemoveTags in *Amazon CLI Command Reference*.

`start-logging`

The following code example shows how to use `start-logging`.

Amazon CLI

To start logging for a trail

The following `start-logging` command turns on logging for `Trail1`:

```
aws cloudtrail start-logging --name Trail1
```

- For API details, see StartLogging in *Amazon CLI Command Reference*.

`stop-logging`

The following code example shows how to use `stop-logging`.

Amazon CLI

To stop logging a trail

The following `stop-logging` command turns off logging for `Trail1`:

```
aws cloudtrail stop-logging --name Trail1
```

- For API details, see StopLogging in *Amazon CLI Command Reference*.

`update-subscription`

The following code example shows how to use `update-subscription`.

Amazon CLI

To update the configuration settings for a trail

The following `update-subscription` example updates the trail to specify a new S3 bucket and SNS topic.

```
aws cloudtrail update-subscription \
    --name Trail1 \
    --s3-new-bucket amzn-s3-demo-bucket \
    --sns-new-topic my-topic-new
```

Output:

```
Setting up new S3 bucket amzn-s3-demo-bucket...
Setting up new SNS topic my-topic-new...
Creating/updating CloudTrail configuration...
CloudTrail configuration:
{
    "trailList": [
        {
            "IncludeGlobalServiceEvents": true,
            "Name": "Trail1",
            "TrailARN": "arn:aws:cloudtrail:us-east-1:123456789012:trail/Trail1",
            "LogFileValidationEnabled": false,
            "IsMultiRegionTrail": false,
            "S3BucketName": "amzn-s3-demo-bucket",
            "SnsTopicName": "my-topic-new",
            "HomeRegion": "us-east-1"
        }
    ],
    "ResponseMetadata": {
        "HTTPStatusCode": 200,
        "RequestId": "31126f8a-c616-11e5-9cc6-2fd637936879"
    }
}
```

- For API details, see UpdateSubscription in *Amazon CLI Command Reference*.

`update-trail`

The following code example shows how to use `update-trail`.

Amazon CLI

To update a trail

The following `update-trail` example updates a trail to use an existing bucket for log delivery.

```
aws cloudtrail update-trail \
    --name Trail1 \
    --s3-bucket-name amzn-s3-demo-bucket
```

Output:

```
{
    "IncludeGlobalServiceEvents": true,
    "Name": "Trail1",
    "TrailARN": "arn:aws:cloudtrail:us-west-2:123456789012:trail/Trail1",
    "LogFileValidationEnabled": false,
    "IsMultiRegionTrail": true,
    "S3BucketName": "amzn-s3-demo-bucket"
}
```

- For API details, see UpdateTrail in *Amazon CLI Command Reference*.

`validate-logs`

The following code example shows how to use `validate-logs`.

Amazon CLI

To validate a log file

The following `validate-logs` command validates the logs for `Trail1`:

```
aws cloudtrail validate-logs --trail-arn arn:aws:cloudtrail:us-
east-1:123456789012:trail/Trail1 --start-time 20160129T19:00:00Z
```

Output:

```
Validating log files for trail arn:aws:cloudtrail:us-east-1:123456789012:trail/
Trail1 between 2016-01-29T19:00:00Z and 2016-01-29T22:15:43Z
Results requested for 2016-01-29T19:00:00Z to 2016-01-29T22:15:43Z
Results found for 2016-01-29T19:24:57Z to 2016-01-29T21:24:57Z:
3/3 digest files valid
15/15 log files valid
```

- For API details, see ValidateLogs in *Amazon CLI Command Reference*.

CloudWatch examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`delete-alarms`

The following code example shows how to use `delete-alarms`.

Amazon CLI

To delete an alarm

The following example uses the `delete-alarms` command to delete the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch delete-alarms --alarm-names myalarm
```

Output:

```
This command returns to the prompt if successful.
```

- For API details, see DeleteAlarms in *Amazon CLI Command Reference*.

`delete-anomaly-detector`

The following code example shows how to use `delete-anomaly-detector`.

Amazon CLI

To delete a specified anomaly detection model

The following `delete-anomaly-detector` example deletes an anomaly detector model in the specified account.

```
aws cloudwatch delete-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Deleting an anomaly detection model in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteAnomalyDetector in *Amazon CLI Command Reference*.

`delete-dashboards`

The following code example shows how to use `delete-dashboards`.

Amazon CLI

To delete specified dashboards

The following `delete-dashboards` example deletes two dashboards named `Dashboard-A` and `Dashboard-B` in the specified account.

```
aws cloudwatch delete-dashboards \
    --dashboard-names Dashboard-A Dashboard-B
```

This command produces no output.

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteDashboards in *Amazon CLI Command Reference*.

`delete-insight-rules`

The following code example shows how to use `delete-insight-rules`.

Amazon CLI

To delete specified contributor insights rules

The following `delete-insight-rules` example deletes two contributor insights rules named `Rule-A` and `Rule-B` in the specified account.

```
aws cloudwatch delete-insight-rules \
    --rule-names Rule-A Rule-B
```

Output:

```
{
    "Failures": []
}
```

For more information, see Use Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteInsightRules in *Amazon CLI Command Reference*.

`delete-metric-stream`

The following code example shows how to use `delete-metric-stream`.

Amazon CLI

To delete a specified metric stream

The following `delete-metric-stream` example deletes the metric stream named `QuickPartial-gSCKv0` in the specified account.

```
aws cloudwatch delete-metric-stream \
    --name QuickPartial-gSCKv0
```

This command produces no output.

For more information, see Use metric streams in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteMetricStream in *Amazon CLI Command Reference*.

describe-alarm-history

The following code example shows how to use `describe-alarm-history`.

Amazon CLI

To retrieve history for an alarm

The following example uses the `describe-alarm-history` command to retrieve history for the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch describe-alarm-history --alarm-name "myalarm" --history-item-
type StateUpdate
```

Output:

```
{
    "AlarmHistoryItems": [
        {
            "Timestamp": "2014-04-09T18:59:06.442Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue\":
\"ALARM\",\"stateReason\":\"testing purposes\"},\"newState\":{\"stateValue\":\"OK
\",\"stateReason\":\"Threshold Crossed: 2 datapoints were not greater than the
 threshold (70.0). The most recent datapoints: [38.958, 40.292].\",\"stateReasonData
\":{\"version\":\"1.0\",\"queryDate\":\"2014-04-09T18:59:06.419+0000\",\"startDate
\":\"2014-04-09T18:44:00.000+0000\",\"statistic\":\"Average\",\"period\":300,
\"recentDatapoints\":[38.958,40.292],\"threshold\":70.0}}}",
            "HistorySummary": "Alarm updated from ALARM to OK"
        },
        {
            "Timestamp": "2014-04-09T18:59:05.805Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue
\":\"OK\",\"stateReason\":\"Threshold Crossed: 2 datapoints were
 not greater than the threshold (70.0). The most recent datapoints:
 [38.839999999999996, 39.714].\",\"stateReasonData\":{\"version\":
\"1.0\",\"queryDate\":\"2014-03-11T22:45:41.569+0000\",\"startDate\":
\"2014-03-11T22:30:00.000+0000\",\"statistic\":\"Average\",\"period\":300,
\"recentDatapoints\":[38.839999999999996,39.714],\"threshold\":70.0}},\"newState\":
{\"stateValue\":\"ALARM\",\"stateReason\":\"testing purposes\"}}",
```

```
            "HistorySummary": "Alarm updated from OK to ALARM"
        }
    ]
}
```

- For API details, see DescribeAlarmHistory in *Amazon CLI Command Reference*.

`describe-alarms-for-metric`

The following code example shows how to use `describe-alarms-for-metric`.

Amazon CLI

To display information about alarms associated with a metric

The following example uses the `describe-alarms-for-metric` command to display information about any alarms associated with the Amazon EC2 CPUUtilization metric and the instance with the ID i-0c986c72.:

```
aws cloudwatch describe-alarms-for-metric --metric-name CPUUtilization --
namespace AWS/EC2 --dimensions Name=InstanceId,Value=i-0c986c72
```

Output:

```
{
    "MetricAlarms": [
        {
            "EvaluationPeriods": 10,
            "AlarmArn": "arn:aws:cloudwatch:us-

            "InsufficientDataActions": [],
            "OKActions": [],
            "ActionsEnabled": false,
            "MetricName": "CPUUtilization"
        }
    ]
}
```

- For API details, see DescribeAlarmsForMetric in *Amazon CLI Command Reference*.

`describe-alarms`

The following code example shows how to use `describe-alarms`.

Amazon CLI

To list information about an alarm

The following example uses the `describe-alarms` command to provide information about the alarm named "myalarm":

```
aws cloudwatch describe-alarms --alarm-names "myalarm"
```

Output:

```
{
    "MetricAlarms": [
        {
            "EvaluationPeriods": 2,
            "AlarmArn": "arn:aws:cloudwatch:us-east-1:123456789012:alarm:myalarm",
            "StateUpdatedTimestamp": "2014-04-09T18:59:06.442Z",
            "AlarmConfigurationUpdatedTimestamp": "2012-12-27T00:49:54.032Z",
            "ComparisonOperator": "GreaterThanThreshold",
            "AlarmActions": [
                "arn:aws:sns:us-east-1:123456789012:myHighCpuAlarm"
            ],
```

```
            "Namespace": "AWS/EC2",
            "AlarmDescription": "CPU usage exceeds 70 percent",
            "StateReasonData": "{\"version\":\"1.0\",\"queryDate\":
\"2014-04-09T18:59:06.419+0000\",\"startDate\":\"2014-04-09T18:44:00.000+0000\",
\"statistic\":\"Average\",\"period\":300,\"recentDatapoints\":[38.958,40.292],
\"threshold\":70.0}",
            "Period": 300,
            "StateValue": "OK",
            "Threshold": 70.0,
            "AlarmName": "myalarm",
            "Dimensions": [
                {
                    "Name": "InstanceId",
                    "Value": "i-0c986c72"
                }
            ],
            "Statistic": "Average",
            "StateReason": "Threshold Crossed: 2 datapoints were not greater than
 the threshold (70.0). The most recent datapoints: [38.958, 40.292].",
            "InsufficientDataActions": [],
            "OKActions": [],
            "ActionsEnabled": true,
            "MetricName": "CPUUtilization"
        }
    ]
}
```

- For API details, see DescribeAlarms in *Amazon CLI Command Reference*.

`describe-anomaly-detectors`

The following code example shows how to use `describe-anomaly-detectors`.

Amazon CLI

To retrieve a list of anomaly detection models

The following `describe-anomaly-detectors` example displays information about anomaly detector models that are associated with the `AWS/Logs` namespace in the specified account.

```
aws cloudwatch describe-anomaly-detectors \
    --namespace AWS/Logs
```

Output:

```
{
    "AnomalyDetectors": [
        {
            "Namespace": "AWS/Logs",
            "MetricName": "IncomingBytes",
            "Dimensions": [],
            "Stat": "SampleCount",
            "Configuration": {
                "ExcludedTimeRanges": []
            },
            "StateValue": "TRAINED",
            "SingleMetricAnomalyDetector": {
                "AccountId": "123456789012",
                "Namespace": "AWS/Logs",
                "MetricName": "IncomingBytes",
                "Dimensions": [],
                "Stat": "SampleCount"
            }
        },
        {
            "Namespace": "AWS/Logs",
            "MetricName": "IncomingBytes",
            "Dimensions": [
                {
                    "Name": "LogGroupName",
                    "Value": "demo"
                }
            ],
            "Stat": "Average",
            "Configuration": {
                "ExcludedTimeRanges": []
            },
            "StateValue": "PENDING_TRAINING",
            "SingleMetricAnomalyDetector": {
                "AccountId": "123456789012",
                "Namespace": "AWS/Logs",
                "MetricName": "IncomingBytes",
                "Dimensions": [
                    {
                        "Name": "LogGroupName",
                        "Value": "demo"
                    }
```

```
                ],
                "Stat": "Average"
            }
        }
    ]
}
```

For more information, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

- For API details, see DescribeAnomalyDetectors in *Amazon CLI Command Reference*.

`describe-insight-rules`

The following code example shows how to use `describe-insight-rules`.

Amazon CLI

To retrieve a list of Contributor Insights rules

The following `describe-insight-rules` example shows all the Contributor Insight rules in the specified account.

```
aws cloudwatch describe-insight-rules
```

Output:

```
{
    "InsightRules": [
        {
            "Name": "Rule-A",
            "State": "ENABLED",
            "Schema": "CloudWatchLogRule/1",
            "Definition": "{\n\t\"AggregateOn\": \"Count\",\n\t\"Contribution\":
 {\n\t\t\"Filters\": [],\n\t\t\"Keys\": [\n\t\t\t\"$.requestId\"\n\t\t]\n\t},\n
\t\"LogFormat\": \"JSON\",\n\t\"Schema\": {\n\t\t\"Name\": \"CloudWatchLogRule
\",\n\t\t\"Version\": 1\n\t},\n\t\"LogGroupARNs\": [\n\t\t\"arn:aws:logs:us-
east-1:123456789012:log-group:demo\"\n\t]\n}",
            "ManagedRule": false
        },
        {
            "Name": "Rule-B",
```

```
            "State": "ENABLED",
            "Schema": "CloudWatchLogRule/1",
            "Definition": "{\n\t\"AggregateOn\": \"Count\",\n\t\"Contribution\":
 {\n\t\t\"Filters\": [],\n\t\t\"Keys\": [\n\t\t\t\"$.requestId\"\n\t\t]\n\t},\n
\t\"LogFormat\": \"JSON\",\n\t\"Schema\": {\n\t\t\"Name\": \"CloudWatchLogRule
\",\n\t\t\"Version\": 1\n\t},\n\t\"LogGroupARNs\": [\n\t\t\"arn:aws:logs:us-
east-1:123456789012:log-group:demo-1\"\n\t]\n}",
            "ManagedRule": false
        }
    ]
}
```

For more information, see Use Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

- For API details, see DescribeInsightRules in *Amazon CLI Command Reference*.

`disable-alarm-actions`

The following code example shows how to use `disable-alarm-actions`.

Amazon CLI

To disable actions for an alarm

The following example uses the `disable-alarm-actions` command to disable all actions for the alarm named myalarm.:

```
aws cloudwatch disable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see DisableAlarmActions in *Amazon CLI Command Reference*.

`disable-insight-rules`

The following code example shows how to use `disable-insight-rules`.

Amazon CLI

To disable specified contributor insight rules

The following `disable-insight-rules` example disables two contributor insights rules named `Rule-A` and `Rule-B` in the specified account.

```
aws cloudwatch disable-insight-rules \
    --rule-names Rule-A Rule-B
```

Output:

```
{
    "Failures": []
}
```

For more information, see Use Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

- For API details, see DisableInsightRules in *Amazon CLI Command Reference*.

`enable-alarm-actions`

The following code example shows how to use `enable-alarm-actions`.

Amazon CLI

To enable all actions for an alarm

The following example uses the `enable-alarm-actions` command to enable all actions for the alarm named myalarm.:

```
aws cloudwatch enable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see EnableAlarmActions in *Amazon CLI Command Reference*.

`enable-insight-rules`

The following code example shows how to use `enable-insight-rules`.

Amazon CLI

To enable specified contributor insight rules

The following `enable-insight-rules` example enables two contributor insights rules named `Rule-A` and `Rule-B` in the specified account.

```
aws cloudwatch enable-insight-rules \
    --rule-names Rule-A Rule-B
```

Output:

```
{
    "Failures": []
}
```

For more information, see Use Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

- For API details, see EnableInsightRules in *Amazon CLI Command Reference*.

`get-dashboard`

The following code example shows how to use `get-dashboard`.

Amazon CLI

To retrieve information about a Dashboard

The following `get-dashboard` example displays information about the dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch get-dashboard \
    --dashboard-name Dashboard-A
```

Output:

```
{
    "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-A",
    "DashboardBody": "{\"widgets\":[{\"type\":\"metric\",\"x\":0,\"y\":0,\"width
\":6,\"height\":6,\"properties\":{\"view\":\"timeSeries\",\"stacked\":false,
\"metrics\":[[\"AWS/EC2\",\"NetworkIn\",\"InstanceId\",\"i-0131f062232ade043\"],[\".
\",\"NetworkOut\",\".\",\".\"]],\"region\":\"us-east-1\"}}]}",
    "DashboardName": "Dashboard-A"
```

```
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see GetDashboard in *Amazon CLI Command Reference*.

`get-insight-rule-report`

The following code example shows how to use `get-insight-rule-report`.

Amazon CLI

To retrieve the time series data collected by a Contributor Insights rule

The following `get-insight-rule-report` example returns the time series data collected by a Contributor Insights rule.

```
aws cloudwatch get-insight-rule-report \
    --rule-name Rule-A \
    --start-time 2024-10-13T20:15:00Z \
    --end-time 2024-10-13T20:30:00Z \
    --period 300
```

Output:

```
{
    "KeyLabels": [
        "PartitionKey"
    ],
    "AggregationStatistic": "Sum",
    "AggregateValue": 0.5,
    "ApproximateUniqueCount": 1,
    "Contributors": [
        {
            "Keys": [
                "RequestID"
            ],
            "ApproximateAggregateValue": 0.5,
            "Datapoints": [
                {
                    "Timestamp": "2024-10-13T21:00:00+00:00",
```

```
                    "ApproximateValue": 0.5
                }
            ]
        }
    ],
    "RuleAttributes": []
}
```

For more information, see Use Contributor Insights to analyze high-cardinality data in the *Amazon CloudWatch User Guide*.

- For API details, see GetInsightRuleReport in *Amazon CLI Command Reference*.

`get-metric-data`

The following code example shows how to use `get-metric-data`.

Amazon CLI

Example 1: To get the Average Total IOPS for the specified EC2 using math expression

The following `get-metric-data` example retrieves CloudWatch metric values for the EC2 instance with InstanceID `i-abcdef` using metric math exprssion that combines EBSReadOps and EBSWriteOps metrics.

```
aws cloudwatch get-metric-data \
    --metric-data-queries file://file.json \
    --start-time 2024-09-29T22:10:00Z \
    --end-time 2024-09-29T22:15:00Z
```

Contents of `file.json`:

```
[
    {
        "Id": "m3",
        "Expression": "(m1+m2)/300",
        "Label": "Avg Total IOPS"
    },
    {
        "Id": "m1",
        "MetricStat": {
            "Metric": {
```

```
                "Namespace": "AWS/EC2",
                "MetricName": "EBSReadOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    },
    {
        "Id": "m2",
        "MetricStat": {
            "Metric": {
                "Namespace": "AWS/EC2",
                "MetricName": "EBSWriteOps",
                "Dimensions": [
                    {
                        "Name": "InstanceId",
                        "Value": "i-abcdef"
                    }
                ]
            },
            "Period": 300,
            "Stat": "Sum",
            "Unit": "Count"
        },
        "ReturnData": false
    }
]
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m3",
            "Label": "Avg Total IOPS",
```

```
            "Timestamps": [
                "2024-09-29T22:10:00+00:00"
            ],
            "Values": [
                96.85
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

Example 2: To monitor the estimated Amazon charges using CloudWatch billing metrics

The following `get-metric-data` example retrieves `EstimatedCharges` CloudWatch metric from Amazon/Billing namespace.

```
aws cloudwatch get-metric-data \
    --metric-data-queries '[{"Id":"m1","MetricStat":{"Metric":
{"Namespace":"AWS/Billing","MetricName":"EstimatedCharges","Dimensions":
[{"Name":"Currency","Value":"USD"}]},"Period":21600,"Stat":"Maximum"}}]' \
    --start-time 2024-09-26T12:00:00Z \
    --end-time 2024-09-26T18:00:00Z \
    --region us-east-1
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m1",
            "Label": "EstimatedCharges",
            "Timestamps": [
                "2024-09-26T12:00:00+00:00"
            ],
            "Values": [
                542.38
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
```

```
}
```

For more information, see Using math expressions with CloudWatch metrics in the *Amazon CloudWatch User Guide*.

- For API details, see GetMetricData in *Amazon CLI Command Reference*.

`get-metric-statistics`

The following code example shows how to use `get-metric-statistics`.

Amazon CLI

To get the CPU utilization per EC2 instance

The following example uses the `get-metric-statistics` command to get the CPU utilization for an EC2 instance with the ID i-abcdef.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-
time 2014-04-08T23:18:00Z --end-time 2014-04-09T23:18:00Z --period 3600 --
namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=i-abcdef
```

Output:

```
{
    "Datapoints": [
        {
            "Timestamp": "2014-04-09T11:18:00Z",
            "Maximum": 44.79,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T20:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T19:18:00Z",
            "Maximum": 50.85,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T09:18:00Z",
```

```
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T03:18:00Z",
            "Maximum": 76.84,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T21:18:00Z",
            "Maximum": 48.96,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T14:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T08:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T16:18:00Z",
            "Maximum": 45.55,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T06:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T13:18:00Z",
            "Maximum": 45.08,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T05:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
```

```
            "Timestamp": "2014-04-09T18:18:00Z",
            "Maximum": 46.88,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T17:18:00Z",
            "Maximum": 52.08,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T07:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T02:18:00Z",
            "Maximum": 51.23,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T12:18:00Z",
            "Maximum": 47.67,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-08T23:18:00Z",
            "Maximum": 46.88,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T10:18:00Z",
            "Maximum": 51.91,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T04:18:00Z",
            "Maximum": 47.13,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T15:18:00Z",
            "Maximum": 48.96,
            "Unit": "Percent"
        },
```

```
        {
            "Timestamp": "2014-04-09T00:18:00Z",
            "Maximum": 48.16,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T01:18:00Z",
            "Maximum": 49.18,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Specifying multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space. If a single metric includes multiple dimensions, you must specify a value for every defined dimension.

For more examples using the `get-metric-statistics` command, see Get Statistics for a Metric in the *Amazon CloudWatch Developer Guide*.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --namespace MyNameSpace
 --dimensions Name=InstanceID,Value=i-abcdef Name=InstanceType,Value=m1.small --
start-time 2016-10-15T04:00:00Z --end-time 2016-10-19T07:00:00Z --statistics Average
 --period 60
```

- For API details, see GetMetricStatistics in *Amazon CLI Command Reference*.

`get-metric-stream`

The following code example shows how to use `get-metric-stream`.

Amazon CLI

To retrieve information about a metric stream

The following `get-metric-stream` example displays information about the metric stream named `QuickFull-GuaFbs` in the specified account.

```
aws cloudwatch get-metric-stream \
    --name QuickFull-GuaFbs
```

Output:

```
{
    "Arn": "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/QuickFull-
GuaFbs",
    "Name": "QuickFull-GuaFbs",
    "FirehoseArn": "arn:aws:firehose:us-east-1:123456789012:deliverystream/
MetricStreams-QuickFull-GuaFbs-WnySbECG",
    "RoleArn": "arn:aws:iam::123456789012:role/service-role/MetricStreams-
FirehosePutRecords-JN10W9B3",
    "State": "running",
    "CreationDate": "2024-10-11T18:48:59.187000+00:00",
    "LastUpdateDate": "2024-10-11T18:48:59.187000+00:00",
    "OutputFormat": "json",
    "IncludeLinkedAccountsMetrics": false
}
```

For more information, see Use metric streams in the *Amazon CloudWatch User Guide*.

- For API details, see GetMetricStream in *Amazon CLI Command Reference*.

`get-metric-widget-image`

The following code example shows how to use `get-metric-widget-image`.

Amazon CLI

To retrieve a snapshot graph of CPUUtilization

The following `get-metric-widget-image` example retrieves snapshot graph for the metric `CPUUtilization` of the EC2 instance with the ID `i-abcde` and saves the retrieved image as a file named "image.png" on your local machine.

```
aws cloudwatch get-metric-widget-image \
    --metric-widget '{"metrics":[["AWS/EC2","CPUUtilization","InstanceId","i-
abcde"]]}' \
    --output-format png \
    --output text | base64 --decode > image.png
```

This command produces no output.

- For API details, see GetMetricWidgetImage in *Amazon CLI Command Reference*.

`list-dashboards`

The following code example shows how to use `list-dashboards`.

Amazon CLI

To retrieve a list of Dashboards

The following `list-dashboards` example lists all the Dashboards in the specified account.

```
aws cloudwatch list-dashboards
```

Output:

```
{
    "DashboardEntries": [
        {
            "DashboardName": "Dashboard-A",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-
A",
            "LastModified": "2024-10-11T18:40:11+00:00",
            "Size": 271
        },
        {
            "DashboardName": "Dashboard-B",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-
B",
            "LastModified": "2024-10-11T18:44:41+00:00",
            "Size": 522
        }
    ]
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see ListDashboards in *Amazon CLI Command Reference*.

`list-metric-streams`

The following code example shows how to use `list-metric-streams`.

Amazon CLI

To retrieve a list of metric streams

The following `list-metric-streams` example lists all the metric streams in the specified account.

```
aws cloudwatch list-metric-streams
```

Output:

```
{
    "Entries": [
        {
            "Arn": "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/
QuickFull-GuaFbs",
            "CreationDate": "2024-10-11T18:48:59.187000+00:00",
            "LastUpdateDate": "2024-10-11T18:48:59.187000+00:00",
            "Name": "QuickFull-GuaFbs",

MetricStreams-QuickFull-GuaFbs-WnySbECG",
            "State": "running",
            "OutputFormat": "json"
        }
    ]
}
```

For more information, see Use metric streams in the *Amazon CloudWatch User Guide*.

- For API details, see ListMetricStreams in *Amazon CLI Command Reference*.

`list-metrics`

The following code example shows how to use `list-metrics`.

Amazon CLI

To list the metrics for Amazon SNS

The following `list-metrics` example displays the metrics for Amazon SNS.

```
aws cloudwatch list-metrics \
    --namespace "AWS/SNS"
```

Output:

```
{
    "Metrics": [
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "NotifyMe"
                }
            ],
            "MetricName": "PublishSize"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "CFO"
                }
            ],
            "MetricName": "PublishSize"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "NotifyMe"
                }
            ],
            "MetricName": "NumberOfNotificationsFailed"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
```

```
                    "Name": "TopicName",
                    "Value": "NotifyMe"
                }
            ],
            "MetricName": "NumberOfNotificationsDelivered"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "NotifyMe"
                }
            ],
            "MetricName": "NumberOfMessagesPublished"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "CFO"
                }
            ],
            "MetricName": "NumberOfMessagesPublished"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "CFO"
                }
            ],
            "MetricName": "NumberOfNotificationsDelivered"
        },
        {
            "Namespace": "AWS/SNS",
            "Dimensions": [
                {
                    "Name": "TopicName",
                    "Value": "CFO"
                }
            ],
```

```
            "MetricName": "NumberOfNotificationsFailed"
        }
    ]
}
```

- For API details, see ListMetrics in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list the tags associated with an existing alarm*

The following `list-tags-for-resource` example lists all the tags associated with an alarm named demo in the specified account.

```
aws cloudwatch list-tags-for-resource \
    --resource-arn arn:aws:cloudwatch:us-east-1:123456789012:alarm:demo
```

Output:

```
{
    "Tags": [
        {
            "Key": "stack",
            "Value": "Production"
        },
        {
            "Key": "team",
            "Value": "Devops"
        }
    ]
}
```

For more information, see Alarms and tagging in the *Amazon CloudWatch User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`put-anomaly-detector`

The following code example shows how to use `put-anomaly-detector`.

Amazon CLI

To create an anomaly detection model

The following `put-anomaly-detector` example creates an anomaly detection model for a CloudWatch metric.

```
aws cloudwatch put-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

- For API details, see PutAnomalyDetector in *Amazon CLI Command Reference*.

`put-composite-alarm`

The following code example shows how to use `put-composite-alarm`.

Amazon CLI

To create a composite cloudwatch alarm

The following `put-composite-alarm` example creates a composite alarm named `ProdAlarm` in the specified account.

```
aws cloudwatch put-composite-alarm \
    --alarm-name ProdAlarm \
    --alarm-rule "ALARM(CPUUtilizationTooHigh) AND ALARM(MemUsageTooHigh)" \
    --alarm-actions arn:aws:sns:us-east-1:123456789012:demo \
    --actions-enabled
```

This command produces no output.

For more information, see Create a composite alarm in the *Amazon CloudWatch User Guide*.

- For API details, see PutCompositeAlarm in *Amazon CLI Command Reference*.

`put-dashboard`

The following code example shows how to use `put-dashboard`.

Amazon CLI

To create a dashboard

The following `put-dashboard` example creates a dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch put-dashboard \
    --dashboard-name Dashboard-A \
    --dashboard-body '{"widgets":
[{"height":6,"width":6,"y":0,"x":0,"type":"metric","properties":
{"view":"timeSeries","stacked":false,"metrics":
[["Namespace","CPUUtilization","Environment","Prod","Type","App"]],"region":"us-
east-1"}}]}'
```

Output:

```
{
    "DashboardValidationMessages": []
}
```

For more information, see Creating a CloudWatch dashboard in the *Amazon CloudWatch User Guide*.

- For API details, see PutDashboard in *Amazon CLI Command Reference*.

`put-insight-rule`

The following code example shows how to use `put-insight-rule`.

Amazon CLI

To create a contributor insights rule

The following `put-insight-rule` example creates a Contributor Insights rule named `VPCFlowLogsContributorInsights` in the specified account.

```
aws cloudwatch put-insight-rule \
    --rule-name VPCFlowLogsContributorInsights \
    --rule-definition file://insight-rule.json \
    --rule-state ENABLED
```

Contents of `insight-rule.json`:

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Count",
    "Contribution": {
        "Filters": [],
        "Keys": [
            "tcp-flag"
        ]
    },
    "LogFormat": "CLF",
    "LogGroupNames": [
        "/vpc/flowlogs/*"
    ],
    "Fields": {
        "23": "tcp-flag"
    }
}
```

This command produces no output.

For more information, see Create a Contributor Insights rule in CloudWatch in the *Amazon CloudWatch User Guide*.

- For API details, see PutInsightRule in *Amazon CLI Command Reference*.

`put-metric-alarm`

The following code example shows how to use `put-metric-alarm`.

Amazon CLI

To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent

The following example uses the `put-metric-alarm` command to send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent:

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70 percent" --metric-name CPUUtilization --namespace AWS/
EC2 --statistic Average --period 300 --threshold 70 --comparison-
operator GreaterThanThreshold  --dimensions "Name=InstanceId,Value=i-12345678" --
evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:111122223333:MyTopic --
unit Percent
```

This command returns to the prompt if successful. If an alarm with the same name already exists, it will be overwritten by the new alarm.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space:

```
aws cloudwatch put-metric-alarm --alarm-name "Default_Test_Alarm3" --alarm-
description "The default example alarm" --namespace "CW EXAMPLE METRICS"
 --metric-name Default_Test --statistic Average --period 60 --evaluation-
periods 3 --threshold 50 --comparison-operator GreaterThanOrEqualToThreshold --
dimensions Name=key1,Value=value1 Name=key2,Value=value2
```

- For API details, see PutMetricAlarm in *Amazon CLI Command Reference*.

`put-metric-data`

The following code example shows how to use `put-metric-data`.

Amazon CLI

To publish a custom metric to Amazon CloudWatch

The following example uses the `put-metric-data` command to publish a custom metric to Amazon CloudWatch:

```
aws cloudwatch put-metric-data --namespace "Usage Metrics" --metric-data file://
metric.json
```

The values for the metric itself are stored in the JSON file, `metric.json`.

Here are the contents of that file:

```
[
  {
    "MetricName": "New Posts",
    "Timestamp": "Wednesday, June 12, 2013 8:28:20 PM",
    "Value": 0.50,
    "Unit": "Count"
  }
]
```

For more information, see Publishing Custom Metrics in the *Amazon CloudWatch Developer Guide*.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name=Value pair. Multiple dimensions are separated by a comma.:

```
aws cloudwatch put-metric-data --metric-name Buffers --
namespace MyNameSpace --unit Bytes --value 231434333 --
dimensions InstanceID=1-23456789,InstanceType=m1.small
```

- For API details, see PutMetricData in *Amazon CLI Command Reference*.

`put-metric-stream`

The following code example shows how to use `put-metric-stream`.

Amazon CLI

To create a metric stream

The following `put-metric-stream` example creates a metric stream named `QuickFull-GuaFb` in the specified account.

```
aws cloudwatch put-metric-stream \
    --name QuickFull-GuaFbs \
    --firehose-arn arn:aws:firehose:us-east-1:123456789012:deliverystream/
MetricStreams-QuickFull-GuaFbs-WnySbECG \
    --role-arn arn:aws:iam::123456789012:role/service-role/MetricStreams-
FirehosePutRecords-JN10W9B3 \
    --output-format json \
    --no-include-linked-accounts-metrics
```

Output:

```
{
    "Arn": "arn:aws:cloudwatch:us-east-1:123456789012:metric-stream/QuickFull-
GuaFbs"
}
```

For more information, see Set up a metric stream in the *Amazon CloudWatch User Guide*.

- For API details, see PutMetricStream in *Amazon CLI Command Reference*.

`set-alarm-state`

The following code example shows how to use `set-alarm-state`.

Amazon CLI

To temporarily change the state of an alarm

The following example uses the `set-alarm-state` command to temporarily change the state of an Amazon CloudWatch alarm named "myalarm" and set it to the ALARM state for testing purposes:

```
aws cloudwatch set-alarm-state --alarm-name "myalarm" --state-value ALARM --state-
reason "testing purposes"
```

This command returns to the prompt if successful.

- For API details, see SetAlarmState in *Amazon CLI Command Reference*.

`start-metric-streams`

The following code example shows how to use `start-metric-streams`.

Amazon CLI

To start a specified metric stream

The following `start-metric-streams` example starts the metric stream named `QuickFull-GuaFbs` in the specified account.

```
aws cloudwatch start-metric-streams \
    --names QuickFull-GuaFbs
```

This command produces no output.

For more information, see Use metric streams in the *Amazon CloudWatch User Guide*.

- For API details, see StartMetricStreams in *Amazon CLI Command Reference*.

`stop-metric-streams`

The following code example shows how to use `stop-metric-streams`.

Amazon CLI

To stop a specified metric stream

The following `stop-metric-streams` example stops the metric stream named `QuickFull-GuaFbs` in the specified account.

```
aws cloudwatch stop-metric-streams \
    --names QuickFull-GuaFbs
```

This command produces no output.

For more information, see Use metric streams in the *Amazon CloudWatch User Guide*.

- For API details, see StopMetricStreams in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add one or more tags to the specified resource

The following `tag-resource` example adds 2 tags to the cloudwatch alarm named demo in the specified account.

```
aws cloudwatch tag-resource \
    --resource-arn arn:aws:cloudwatch:us-east-1:123456789012:alarm:demo \
    --tags Key=stack,Value=Production Key=team,Value=Devops
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources in the *Amazon CloudWatch User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove one or more tags from the specified resource

The following `untag-resource` example removes 2 tags from the cloudwatch alarm named demo in the specified account.

```
aws cloudwatch untag-resource \
    --resource-arn arn:aws:cloudwatch:us-east-1:123456789012:alarm:demo \
    --tag-keys stack team
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources in the *Amazon CloudWatch User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

CloudWatch Logs examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch Logs.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-log-group`

The following code example shows how to use `create-log-group`.

Amazon CLI

The following command creates a log group named `my-logs`:

```
aws logs create-log-group --log-group-name my-logs
```

- For API details, see CreateLogGroup in *Amazon CLI Command Reference*.

`create-log-stream`

The following code example shows how to use `create-log-stream`.

Amazon CLI

The following command creates a log stream named `20150601` in the log group `my-logs`:

```
aws logs create-log-stream --log-group-name my-logs --log-stream-name 20150601
```

- For API details, see CreateLogStream in *Amazon CLI Command Reference*.

`delete-log-group`

The following code example shows how to use `delete-log-group`.

Amazon CLI

The following command deletes a log group named `my-logs`:

```
aws logs delete-log-group --log-group-name my-logs
```

- For API details, see DeleteLogGroup in *Amazon CLI Command Reference*.

`delete-log-stream`

The following code example shows how to use `delete-log-stream`.

Amazon CLI

The following command deletes a log stream named `20150531` from a log group named `my-logs`:

```
aws logs delete-log-stream --log-group-name my-logs --log-stream-name 20150531
```

- For API details, see DeleteLogStream in *Amazon CLI Command Reference*.

`delete-retention-policy`

The following code example shows how to use `delete-retention-policy`.

Amazon CLI

The following command removes the retention policy that has previously been applied to a log group named `my-logs`:

```
aws logs delete-retention-policy --log-group-name my-logs
```

- For API details, see DeleteRetentionPolicy in *Amazon CLI Command Reference*.

`describe-log-groups`

The following code example shows how to use `describe-log-groups`.

Amazon CLI

The following command describes a log group named `my-logs`:

```
aws logs describe-log-groups --log-group-name-prefix my-logs
```

Output:

```
{
    "logGroups": [
        {
            "storedBytes": 0,
            "metricFilterCount": 0,
            "creationTime": 1433189500783,
            "logGroupName": "my-logs",
            "retentionInDays": 5,
            "arn": "arn:aws:logs:us-west-2:0123456789012:log-group:my-logs:*"
        }
    ]
}
```

- For API details, see DescribeLogGroups in *Amazon CLI Command Reference*.

`describe-log-streams`

The following code example shows how to use `describe-log-streams`.

Amazon CLI

The following command shows all log streams starting with the prefix `2015` in the log group `my-logs`:

```
aws logs describe-log-streams --log-group-name my-logs --log-stream-name-prefix 2015
```

Output:

```
{
    "logStreams": [
        {
            "creationTime": 1433189871774,
            "arn": "arn:aws:logs:us-west-2:0123456789012:log-group:my-logs:log-
stream:20150531",
            "logStreamName": "20150531",
            "storedBytes": 0
        },
```

```
        {
            "creationTime": 1433189873898,
            "arn": "arn:aws:logs:us-west-2:0123456789012:log-group:my-logs:log-
stream:20150601",
            "logStreamName": "20150601",
            "storedBytes": 0
        }
    ]
}
```

- For API details, see DescribeLogStreams in *Amazon CLI Command Reference*.

`get-log-events`

The following code example shows how to use `get-log-events`.

Amazon CLI

The following command retrieves log events from a log stream named `20150601` in the log group `my-logs`:

```
aws logs get-log-events --log-group-name my-logs --log-stream-name 20150601
```

Output:

```
{
    "nextForwardToken":
 "f/31961209122447488583055879464742346735121166569214640130",
    "events": [
        {
            "ingestionTime": 1433190494190,
            "timestamp": 1433190184356,
            "message": "Example Event 1"
        },
        {
            "ingestionTime": 1433190516679,
            "timestamp": 1433190184356,
            "message": "Example Event 1"
        },
        {
            "ingestionTime": 1433190494190,
            "timestamp": 1433190184358,
```

```
            "message": "Example Event 2"
        }
    ],
    "nextBackwardToken":
 "b/31961209122358285602261756944988674324553373268216709120"
}
```

- For API details, see GetLogEvents in *Amazon CLI Command Reference*.

put-log-events

The following code example shows how to use `put-log-events`.

Amazon CLI

The following command puts log events to a log stream named `20150601` in the log group `my-logs`:

```
aws logs put-log-events --log-group-name my-logs --log-stream-name 20150601 --log-events file://events
```

Output:

```
{
    "nextSequenceToken": "49542672486831074009579604567656788214806863282469607346"
}
```

The above example reads a JSON array of events from a file named `events` in the current directory:

```
[
  {
    "timestamp": 1433190184356,
    "message": "Example Event 1"
  },
  {
    "timestamp": 1433190184358,
    "message": "Example Event 2"
  },
  {
    "timestamp": 1433190184360,
    "message": "Example Event 3"
```

```
  }
]
```

Each subsequent call requires the next sequence token provided by the previous call to be specified with the sequence token option:

```
aws logs put-log-events --log-group-name my-logs --log-
stream-name 20150601 --log-events file://events2 --sequence-
token "49542672486831074009579604567656788214806863282469607346"
```

Output:

```
{
    "nextSequenceToken": "49542672486831074009579604567900991230369019956308219826"
}
```

- For API details, see PutLogEvents in *Amazon CLI Command Reference*.

`put-retention-policy`

The following code example shows how to use `put-retention-policy`.

Amazon CLI

The following command adds a 5 day retention policy to a log group named `my-logs`:

```
aws logs put-retention-policy --log-group-name my-logs --retention-in-days 5
```

- For API details, see PutRetentionPolicy in *Amazon CLI Command Reference*.

CloudWatch Network Monitoring examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch Network Monitoring.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-monitor`

The following code example shows how to use `create-monitor`.

Amazon CLI

Example 1: To create a network monitor with an aggregation period

The following `create-monitor` example creates a monitor named `Example_NetworkMonitor` with an `aggregationPeriod` set to `30` seconds. The initial `state` of the monitor will be `INACTIVE` because there are no probes associated with it. The state changes to `ACTIVE` only when probes are added. You can use the update-monitor or create-probe commands to add probes to this monitor.

```
aws networkmonitor create-monitor \
     --monitor-name Example_NetworkMonitor \
     --aggregation-period 30
```

Output:

```
{
    "monitorArn": "arn:aws:networkmonitor:region:111122223333:monitor/
Example_NetworkMonitor",
    "monitorName": "Example_NetworkMonitor",
    "state": "INACTIVE",
    "aggregationPeriod": 30,
    "tags": {}
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

Example 2: To create a network monitor with a probe using TCP and also includes tags

The following `create-monitor` example creates a monitor named `Example_NetworkMonitor`. The command also creates one probe that uses the `ICMP` protocol

and includes tags. Since no `aggregationPeriod` is passed in the request, `60` seconds is set as the default. The `state` of the monitor with the probe will be `PENDING` until the monitor is `ACTIVE`. This might take several minutes, at which point the `state` will change to `ACTIVE`, and you can start viewing CloudWatch metrics.

```
aws networkmonitor create-monitor \
    --monitor-name Example_NetworkMonitor \
    --probes sourceArn=arn:aws:ec2:region:111122223333:subnet/subnet-
id,destination=10.0.0.100,destinationPort=80,protocol=TCP,packetSize=56,probeTags={Name=Prob
 \
    --tags Monitor=Monitor1
```

Output:

```
{
    "monitorArn": "arn:aws:networkmonitor:region111122223333:monitor/
Example_NetworkMonitor",
    "monitorName": "Example_NetworkMonitor",
    "state": "PENDING",
    "aggregationPeriod": 60,
    "tags": {
        "Monitor": "Monitor1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

Example 3: To create a network monitor with a probe using ICMP and also includes tags

The following `create-monitor` example creates a monitor named `Example_NetworkMonitor` with an `aggregationPeriod` of `30` seconds. The command also creates one probe that uses the `ICMP` protocol and includes tags. Since no `aggregationPeriod` is passed in the request, `60` seconds is set as the default. The `state` of the monitor with the probe will be `PENDING` until the monitor is `ACTIVE`. This might take several minutes, at which point the `state` will change to `ACTIVE`, and you can start viewing CloudWatch metrics.

```
aws networkmonitor create-monitor \
     --monitor-name Example_NetworkMonitor \
```

```
    --aggregation-period 30 \
    --probes sourceArn=arn:aws:ec2:region111122223333:subnet/subnet-
id,destination=10.0.0.100,protocol=ICMP,packetSize=56,probeTags={Name=Probe1} \
    --tags Monitor=Monitor1
```

Output:

```
{
    "monitorArn": "arn:aws:networkmonitor:region:111122223333:monitor/
Example_NetworkMonitor",
    "monitorName": "Example_NetworkMonitor",
    "state": "PENDING",
    "aggregationPeriod": 30,
    "tags": {
        "Monitor": "Monitor1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see CreateMonitor in *Amazon CLI Command Reference*.

`create-probe`

The following code example shows how to use `create-probe`.

Amazon CLI

Example 1: To create a probe that uses TCP and add it to a network monitor

The following `create-probe` example creates a probe that uses the `TCP` `protocol` and adds the probe to a monitor named `Example_NetworkMonitor`. Once created, the `state` of the monitor with the probe will be `PENDING` until the monitor is `ACTIVE`. This might take several minutes, at which point the state will change to `ACTIVE`, and you can start viewing CloudWatch metrics.

```
aws networkmonitor create-probe \
    --monitor-name Example_NetworkMonitor \
    --probe sourceArn=arn:aws:ec2:region:111122223333:subnet/subnet-
id,destination=10.0.0.100,destinationPort=80,protocol=TCP,packetSize=56,tags={Name=Probe1}
```

Output:

```
{
    "probeId": "probe-12345",
    "probeArn": "arn:aws:networkmonitor:region:111122223333:probe/probe-12345",
    "destination": "10.0.0.100",
    "destinationPort": 80,
    "packetSize": 56,
    "addressFamily": "IPV4",
    "vpcId": "vpc-12345",
    "state": "PENDING",
    "createdAt": "2024-03-29T12:41:57.314000-04:00",
    "modifiedAt": "2024-03-29T12:41:57.314000-04:00",
    "tags": {
        "Name": "Probe1"
    }
}
```

Example 2: To create a probe that uses probe using ICMP and add it to a network monitor

The following `create-probe` example creates a probe that uses the `ICMP` `protocol` and adds the probe to a monitor named `Example_NetworkMonitor`. Once created, the `state` of the monitor with the probe will be `PENDING` until the monitor is `ACTIVE`. This might take several minutes, at which point the state will change to `ACTIVE`, and you can start viewing CloudWatch metrics.

```
aws networkmonitor create-probe \
    --monitor-name Example_NetworkMonitor \
    --probe sourceArn=arn:aws:ec2:region:012345678910:subnet/subnet-
id,destination=10.0.0.100,protocol=ICMP,packetSize=56,tags={Name=Probe1}
```

Output:

```
{
    "probeId": "probe-12345",
    "probeArn": "arn:aws:networkmonitor:region:111122223333:probe/probe-12345",
    "destination": "10.0.0.100",
    "packetSize": 56,
    "addressFamily": "IPV4",
    "vpcId": "vpc-12345",
    "state": "PENDING",
    "createdAt": "2024-03-29T12:44:02.452000-04:00",
```

```
    "modifiedAt": "2024-03-29T12:44:02.452000-04:00",
    "tags": {
        "Name": "Probe1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see CreateProbe in *Amazon CLI Command Reference*.

`delete-monitor`

The following code example shows how to use `delete-monitor`.

Amazon CLI

To delete a monitor

The following `delete-monitor` example deletes a monitor named `Example_NetworkMonitor`.

```
aws networkmonitor delete-monitor \
    --monitor-name Example_NetworkMonitor
```

This command produces no output.

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteMonitor in *Amazon CLI Command Reference*.

`delete-probe`

The following code example shows how to use `delete-probe`.

Amazon CLI

To delete a probe

The following `delete-probe` example deletes a probe with the ID `probe-12345` from a network monitor named `Example_NetworkMonitor`.

```
aws networkmonitor delete-probe \
    --monitor-name Example_NetworkMonitor \
    --probe-id probe-12345
```

This command produces no output.

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteProbe in *Amazon CLI Command Reference*.

`get-monitor`

The following code example shows how to use `get-monitor`.

Amazon CLI

To get monitor information

The following `get-monitor` example gets information about a monitor named `Example_NetworkMonitor`.

```
aws networkmonitor get-monitor \
    --monitor-name Example_NetworkMonitor
```

Output:

```
{
    "monitorArn": "arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor",
    "monitorName": "Example_NetworkMonitor",
    "state": "ACTIVE",
    "aggregationPeriod": 60,
    "tags": {},
    "probes": [],
    "createdAt": "2024-04-01T17:58:07.211000-04:00",
    "modifiedAt": "2024-04-01T17:58:07.211000-04:00"
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see GetMonitor in *Amazon CLI Command Reference*.

`get-probe`

The following code example shows how to use `get-probe`.

Amazon CLI

To view probe details

The following `get-probe` example returns details about a probe with the `probeID` `probe-12345` that's associated with a monitor named `Example_NetworkMonitor`.

```
aws networkmonitor get-probe \
    --monitor-name Example_NetworkMonitor \
    --probe-id probe-12345
```

Output:

```
{
    "probeId": "probe-12345",
    "probeArn": "arn:aws:networkmonitor:region:012345678910:probe/probe-12345",
    "sourceArn": "arn:aws:ec2:region:012345678910:subnet/subnet-12345",
    "destination": "10.0.0.100",
    "destinationPort": 80,
    "protocol": "TCP",
    "packetSize": 56,
    "addressFamily": "IPV4",
    "vpcId": "vpc-12345",
    "state": "ACTIVE",
    "createdAt": "2024-03-29T12:41:57.314000-04:00",
    "modifiedAt": "2024-03-29T12:42:28.610000-04:00",
    "tags": {
        "Name": "Probe1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see GetProbe in *Amazon CLI Command Reference*.

`list-monitors`

The following code example shows how to use `list-monitors`.

Amazon CLI

Example 1: To list all monitors (single monitor)

The following `list-monitors` example returns a list of only a single monitor. The monitor's `state` is `ACTIVE` and it has an `aggregationPeriod` of 60 seconds.

```
aws networkmonitor list-monitors
```

Output:

```
{
    "monitors": [{
            "monitorArn": "arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor",
            "monitorName": "Example_NetworkMonitor",
            "state": "ACTIVE",
            "aggregationPeriod": 60,
            "tags": {
                "Monitor": "Monitor1"
            }
        }
    ]
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

Example 2: To list all monitors (multiple monitors)

The following `list-monitors` example returns a list of three monitors. The `state` of one monitor is `ACTIVE` and generating CloudWatch metrics. The states of the other two monitors are `INACTIVE` and not generating CloudWatch metrics. All three monitors use an `aggregationPeriod` of 60 seconds.

```
aws networkmonitor list-monitors
```

Output:

```
{
    "monitors": [
        {
            "monitorArn": "arn:aws:networkmonitor:us-east-1:111122223333:monitor/
Example_NetworkMonitor",
            "monitorName": "Example_NetworkMonitor",
            "state": "INACTIVE",
            "aggregationPeriod": 60,
            "tags": {}
        },
        {
            "monitorArn": "arn:aws:networkmonitor:us-east-1:111122223333:monitor/
Example_NetworkMonitor2",
            "monitorName": "Example_NetworkMonitor2",
            "state": "ACTIVE",
            "aggregationPeriod": 60,
            "tags": {
                "Monitor": "Monitor1"
            }
        },
        {
            "monitorArn": "arn:aws:networkmonitor:us-east-1:111122223333:monitor/
TestNetworkMonitor_CLI",
            "monitorName": "TestNetworkMonitor_CLI",
            "state": "INACTIVE",
            "aggregationPeriod": 60,
            "tags": {}
        }
    ]
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see ListMonitors in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags for a resource

The following `list-tags-for-resource` example returns a list of the tags for a monitor named `Example_NetworkMonitor`.

```
aws networkmonitor list-tags-for-resource \
    --resource-arn arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor
```

Output:

```
{
    "tags": {
        "Environment": "Dev",
        "Application": "PetStore"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resource

The following `tag-resource` example tags a monitor named `Example_NetworkMonitor` with `Environment=Dev` and `Application=PetStore` tags.

```
aws networkmonitor tag-resource \
    --resource-arn arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor \
    --tags Environment=Dev,Application=PetStore
```

This command produces no output.

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To untag a resource

The following `untag-resource` example removes a `tag-keys` parameter with the key-value pair of `Environment Application` from its association with a monitor named `Example_NetworkMonitor`.

```
aws networkmonitor untag-resource \
    --resource-arn arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor \
    --tag-keys Environment Application
```

This command produces no output.

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-monitor`

The following code example shows how to use `update-monitor`.

Amazon CLI

To update a monitor

The following `update-monitor` example changes a monitor's `aggregationPeriod` from `60` seconds to `30` seconds.

```
aws networkmonitor update-monitor \
    --monitor-name Example_NetworkMonitor \
    --aggregation-period 30
```

Output:

```
{
    "monitorArn": "arn:aws:networkmonitor:region:012345678910:monitor/
Example_NetworkMonitor",
    "monitorName": "Example_NetworkMonitor",
    "state": "PENDING",
    "aggregationPeriod": 30,
    "tags": {
        "Monitor": "Monitor1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see UpdateMonitor in *Amazon CLI Command Reference*.

`update-probe`

The following code example shows how to use `update-probe`.

Amazon CLI

To update a probe

The following `update-probe` example updates a probe's original `destination` IP address and also updates the `packetSize` to `60`.

```
aws networkmonitor update-probe \
    --monitor-name Example_NetworkMonitor \
    --probe-id probe-12345 \
    --destination 10.0.0.150 \
    --packet-size 60
```

Output:

```
{
    "probeId": "probe-12345",
    "probeArn": "arn:aws:networkmonitor:region:012345678910:probe/probe-12345",
    "sourceArn": "arn:aws:ec2:region:012345678910:subnet/subnet-12345",
    "destination": "10.0.0.150",
```

```
    "destinationPort": 80,
    "protocol": "TCP",
    "packetSize": 60,
    "addressFamily": "IPV4",
    "vpcId": "vpc-12345",
    "state": "PENDING",
    "createdAt": "2024-03-29T12:41:57.314000-04:00",
    "modifiedAt": "2024-03-29T13:52:23.115000-04:00",
    "tags": {
        "Name": "Probe1"
    }
}
```

For more information, see How Amazon CloudWatch Network Monitor Works in the *Amazon CloudWatch User Guide*.

- For API details, see UpdateProbe in *Amazon CLI Command Reference*.

CloudWatch Observability Access Monitor examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch Observability Access Monitor.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-link`

The following code example shows how to use `create-link`.

Amazon CLI

To create a link

The following `create-link` example creates a link between a source account and a sink that you have created in a monitoring account.

```
aws oam create-link \
    --label-template sourceAccount \
    --resource-types AWS::CloudWatch::Metric \
    --sink-identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345
```

Output:

```
{
    "Arn": "arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-example11111",
    "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
    "Label": "sourceAccount",
    "LabelTemplate": "sourceAccount",
    "ResourceTypes": [
        "AWS::CloudWatch::Metric"
    ],
    "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345",
    "Tags": {}
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see CreateLink in *Amazon CLI Command Reference*.

`create-sink`

The following code example shows how to use `create-sink`.

Amazon CLI

To create a sink

The following `create-sink` example creates a sink in the current account, so that it can be used as a monitoring account in CloudWatch cross-account observability.

```
aws oam create-sink \
```

```
    --name DemoSink
```

Output:

```
{
    "Arn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345",
    "Id": "a1b2c3d4-5678-90ab-cdef-example12345",
    "Name": "DemoSink",
    "Tags": {}
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see CreateSink in *Amazon CLI Command Reference*.

`delete-link`

The following code example shows how to use `delete-link`.

Amazon CLI

To delete a link

The following `delete-link` example deletes a link between a monitoring account sink and a source account.

```
aws oam delete-link \
    --identifier arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-
example11111
```

This command produces no output.

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteLink in *Amazon CLI Command Reference*.

`delete-sink`

The following code example shows how to use `delete-sink`.

Amazon CLI

To delete a sink

The following `delete-sink` example deletes a sink. You must delete all links to a sink before you can delete that sink.

```
aws oam delete-sink \
    --identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345
```

This command produces no output.

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteSink in *Amazon CLI Command Reference*.

`get-link`

The following code example shows how to use `get-link`.

Amazon CLI

To return complete information about one link

The following `get-link` example returns complete information about a link.

```
aws oam get-link \
    --identifier arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-example11111
```

Output:

```
{
    "Arn": "arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-example11111",
    "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
    "Label": "sourceAccount",
    "LabelTemplate": "sourceAccount",
    "ResourceTypes": [
        "AWS::CloudWatch::Metric"
```

```
    ],
    "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345",
    "Tags": {}
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see GetLink in *Amazon CLI Command Reference*.

`get-sink-policy`

The following code example shows how to use `get-sink-policy`.

Amazon CLI

To return the current sink policy attached to the sink

The following `get-sink-policy` example returns the current sink policy attached to the sink.

```
aws oam get-sink-policy \
    --sink-identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-
cdef-example12345
```

Output:

```
{
    "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345",
    "SinkId": "a1b2c3d4-5678-90ab-cdef-example12345",
    "Policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":{\"AWS\":\"arn:aws:iam::123456789111:root\"},
\"Action\":[\"oam:CreateLink\",\"oam:UpdateLink\"],\"Resource\":\"*\",
\"Condition\":{\"ForAllValues:StringEquals\":{\"oam:ResourceTypes\":
[\"AWS::Logs::LogGroup\",\"AWS::CloudWatch::Metric\",\"AWS::XRay::Trace\",
\"AWS::ApplicationInsights::Application\"]}}}]}"
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see GetSinkPolicy in *Amazon CLI Command Reference*.

`get-sink`

The following code example shows how to use `get-sink`.

Amazon CLI

To return complete information about one monitoring account sink

The following `get-sink` example returns complete information about a monitoring account sink.

```
aws oam get-sink \
    --identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345
```

Output:

```
{
    "Arn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345",
    "Id": "a1b2c3d4-5678-90ab-cdef-example12345",
    "Name": "DemoSink",
    "Tags": {}
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see GetSink in *Amazon CLI Command Reference*.

`list-attached-links`

The following code example shows how to use `list-attached-links`.

Amazon CLI

To return a list of source account links that are linked to this monitoring account sink

The following `list-attached-links` example returns a list of source account links that are linked to this monitoring account sink.

```
aws oam list-attached-links \
```

```
    --sink-identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-
cdef-example12345
```

Output:

```
{
    "Items": [{
        "Label": "Monitoring account",

            "AWS::CloudWatch::Metric",
            "AWS::XRay::Trace"
        ]
    }]
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see ListAttachedLinks in *Amazon CLI Command Reference*.

`list-links`

The following code example shows how to use `list-links`.

Amazon CLI

To return a list of links for one monitoring account sink

The following `list-links` example returns a list of links for one monitoring account sink. Run this operation in a source account to return a list of links to monitoring account sinks that this source account has.

```
aws oam list-links
```

Output:

```
{
    "Items": [{
```

```
        "Arn": "arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-
example11111",
        "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
        "Label": "sourceAccount",
        "ResourceTypes": [
            "AWS::CloudWatch::Metric"
        ],
        "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345"
    }]
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see ListLinks in *Amazon CLI Command Reference*.

`list-sinks`

The following code example shows how to use `list-sinks`.

Amazon CLI

To return the list of sinks created in the monitoring account

The following `list-sinks` example returns a list of sinks created in the monitoring account. Run this operation in a monitoring account.

```
aws oam list-sinks
```

Output:

```
{
    "Items": [
        {
            "Arn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345",
            "Id": "a1b2c3d4-5678-90ab-cdef-example12345",
            "Name": "DemoSink"
        }
    ]
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see ListSinks in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To display the tags associated with a resource

The following `list-tags-for-resource` example displays the tags associated with a sink.

```
aws oam list-tags-for-resource \
    --resource-arn arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345
```

Output:

```
{
    "Tags": {
        "Team": "Devops"
    }
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`put-sink-policy`

The following code example shows how to use `put-sink-policy`.

Amazon CLI

To create or update the resource policy

The following `put-sink-policy` example creates the resource policy that grants permissions to source accounts to link to the monitoring account sink.

```
aws oam put-sink-policy \
    --policy '{"Version":"2012-10-17","Statement":[{"Effect":"Allow","Principal":
{"AWS":"arn:aws:iam::123456789111:root"},"Action":
["oam:CreateLink","oam:UpdateLink"],"Resource":"*","Condition":
{"ForAllValues:StringEquals":{"oam:ResourceTypes":
["AWS::Logs::LogGroup","AWS::CloudWatch::Metric","AWS::XRay::Trace","AWS::ApplicationInsight
 \
    --sink-identifier arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-
cdef-example12345
```

Output:

```
{
    "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345",
    "SinkId": "a1b2c3d4-5678-90ab-cdef-example12345",
    "Policy": "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":
\"Allow\",\"Principal\":{\"AWS\":\"arn:aws:iam::123456789111:root\"},
\"Action\":[\"oam:CreateLink\",\"oam:UpdateLink\"],\"Resource\":\"*\",
\"Condition\":{\"ForAllValues:StringEquals\":{\"oam:ResourceTypes\":
[\"AWS::Logs::LogGroup\",\"AWS::CloudWatch::Metric\",\"AWS::XRay::Trace\",
\"AWS::ApplicationInsights::Application\"]}}}]}"
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see PutSinkPolicy in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To assign one or more tags to the specified resource

The following `tag-resource` example tags a sink `arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345`.

```
aws oam tag-resource \
```

```
    --resource-arn arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-
example12345 \
    --tags team=Devops
```

This command produces no output.

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove one or more tags from the specified resource.

The following `untag-resource` example removes a tag with the key `team` from sink `arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345`.

```
aws oam untag-resource \
    --resource-arn arn:aws:oam:us-east-2:123456789012:sink/f3f42f60-
f0f2-425c-1234-12347bdd821f \
    --tag-keys team
```

This command produces no output.

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-link`

The following code example shows how to use `update-link`.

Amazon CLI

To change what types of data are shared from a source account to its linked monitoring account sink

The following `update-link` example updates the link `arn:aws:oam:us-east-2:123456789111:link/0123e691-e7ef-43fa-1234-c57c837fced0` with resource types `AWS::CloudWatch::Metric` and `AWS::Logs::LogGroup`.

```
aws oam update-link \
    --identifier arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-example11111 \
    --resource-types "AWS::CloudWatch::Metric" "AWS::Logs::LogGroup"
```

Output:

```
{
    "Arn": "arn:aws:oam:us-east-2:123456789111:link/a1b2c3d4-5678-90ab-cdef-example11111",
    "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
    "Label": "sourceAccount",
    "LabelTemplate": "sourceAccount",
    "ResourceTypes": [
        "AWS::CloudWatch::Metric",
        "AWS::Logs::LogGroup"
    ],
    "SinkArn": "arn:aws:oam:us-east-2:123456789012:sink/a1b2c3d4-5678-90ab-cdef-example12345",
    "Tags": {}
}
```

For more information, see CloudWatch cross-account observability in the *Amazon CloudWatch User Guide*.

- For API details, see UpdateLink in *Amazon CLI Command Reference*.

CloudWatch Observability Admin examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch Observability Admin.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`get-telemetry-evaluation-status-for-organization`

The following code example shows how to use `get-telemetry-evaluation-status-for-organization`.

Amazon CLI

To get telemetry onboarding status for the organization

The following `get-telemetry-evaluation-status-for-organization` example returns the current onboarding status of the telemetry config feature for the organization.

```
aws observabilityadmin get-telemetry-evaluation-status-for-organization
```

Output:

```
{
    "Status": "RUNNING"
}
```

For more information, see Auditing CloudWatch telemetry configurations in the *Amazon CloudWatch User Guide*.

- For API details, see GetTelemetryEvaluationStatusForOrganization in *Amazon CLI Command Reference*.

`get-telemetry-evaluation-status`

The following code example shows how to use `get-telemetry-evaluation-status`.

Amazon CLI

To get telemetry onboarding status for the account

The following `get-telemetry-evaluation-status` example returns the current onboarding status of the telemetry config feature in the specified account.

```
aws observabilityadmin get-telemetry-evaluation-status
```

Output:

```
{
    "Status": "RUNNING"
}
```

For more information, see Auditing CloudWatch telemetry configurations in the *Amazon CloudWatch User Guide*.

- For API details, see GetTelemetryEvaluationStatus in *Amazon CLI Command Reference*.

`list-resource-telemetry-for-organization`

The following code example shows how to use `list-resource-telemetry-for-organization`.

Amazon CLI

To retrieve the telemetry configurations for the organization

The following `list-resource-telemetry-for-organization` example returns a list of telemetry configurations in the organization for Amazon resources supported by telemetry config.

```
aws observabilityadmin list-resource-telemetry-for-organization \
    --resource-types  AWS::EC2::Instance
```

Output:

```
{
    "TelemetryConfigurations": [
        {
            "AccountIdentifier": "111111111111",
            "TelemetryConfigurationState": {
                "Logs": "NotApplicable",
                "Metrics": "Disabled",
                "Traces": "NotApplicable"
            },
```

```
            "ResourceType": "AWS::EC2::Instance",
            "ResourceIdentifier": "i-a166400b",
            "ResourceTags": {
                "Name": "dev"
            },
            "LastUpdateTimeStamp": 1733168548521
        },
        {
            "AccountIdentifier": "222222222222",
            "TelemetryConfigurationState": {
                "Logs": "NotApplicable",
                "Metrics": "Disabled",
                "Traces": "NotApplicable"
            },
            "ResourceType": "AWS::EC2::Instance",
            "ResourceIdentifier": "i-b188560f",
            "ResourceTags": {
                "Name": "apache"
            },
            "LastUpdateTimeStamp": 1732744260182
        }
    ]
}
```

For more information, see Auditing CloudWatch telemetry configurations in the *Amazon CloudWatch User Guide*.

- For API details, see ListResourceTelemetryForOrganization in *Amazon CLI Command Reference*.

`list-resource-telemetry`

The following code example shows how to use `list-resource-telemetry`.

Amazon CLI

To retrieve the telemetry configurations for the account

The following `list-resource-telemetry` example returns a list of telemetry configurations for Amazon resources supported by telemetry config in the specified account.

```
aws observabilityadmin list-resource-telemetry \
```

```
    --resource-types  AWS::EC2::Instance
```

Output:

```
{
    "TelemetryConfigurations": [
        {
            "AccountIdentifier": "111111111111",
            "TelemetryConfigurationState": {
                "Logs": "NotApplicable",
                "Metrics": "Disabled",
                "Traces": "NotApplicable"
            },
            "ResourceType": "AWS::EC2::Instance",
            "ResourceIdentifier": "i-0e979d278b040f856",
            "ResourceTags": {
                "Name": "apache"
            },
            "LastUpdateTimeStamp": 1732744260182
        }
    ]
}
```

For more information, see Auditing CloudWatch telemetry configurations in the *Amazon CloudWatch User Guide*.

- For API details, see ListResourceTelemetry in *Amazon CLI Command Reference*.

`start-telemetry-evaluation-for-organization`

The following code example shows how to use `start-telemetry-evaluation-for-organization`.

Amazon CLI

To enable the telemetry config feature

The following `start-telemetry-evaluation-for-organization` example enables the telemetry config feature for the organization.

```
aws observabilityadmin start-telemetry-evaluation-for-organization
```

This command produces no output.

For more information, see Turning on CloudWatch telemetry auditing in the *Amazon CloudWatch User Guide*.

- For API details, see StartTelemetryEvaluationForOrganization in *Amazon CLI Command Reference*.

`start-telemetry-evaluation`

The following code example shows how to use `start-telemetry-evaluation`.

Amazon CLI

To enable the telemetry config feature

The following `start-telemetry-evaluation` example enables the telemetry config feature in the specified account.

```
aws observabilityadmin start-telemetry-evaluation
```

This command produces no output.

For more information, see Turning on CloudWatch telemetry auditing in the *Amazon CloudWatch User Guide*.

- For API details, see StartTelemetryEvaluation in *Amazon CLI Command Reference*.

`stop-telemetry-evaluation-for-organization`

The following code example shows how to use `stop-telemetry-evaluation-for-organization`.

Amazon CLI

To disable the telemetry config feature

The following `stop-telemetry-evaluation-for-organization` example disables the telemetry config feature for the organization.

```
aws observabilityadmin stop-telemetry-evaluation-for-organization
```

This command produces no output.

For more information, see Turning off CloudWatch telemetry auditing in the *Amazon CloudWatch User Guide*.

- For API details, see StopTelemetryEvaluationForOrganization in *Amazon CLI Command Reference*.

`stop-telemetry-evaluation`

The following code example shows how to use `stop-telemetry-evaluation`.

Amazon CLI

To disable the telemetry config feature

The following `stop-telemetry-evaluation` example disables the telemetry config feature in the specified account.

```
aws observabilityadmin stop-telemetry-evaluation
```

This command produces no output.

For more information, see Turning off CloudWatch telemetry auditing in the *Amazon CloudWatch User Guide*.

- For API details, see StopTelemetryEvaluation in *Amazon CLI Command Reference*.

CloudWatch Synthetics examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CloudWatch Synthetics.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-resource`

The following code example shows how to use `associate-resource`.

Amazon CLI

To associate a canary with a group

The following `associate-resource` example associates a canary with a group named demo_group.

```
aws synthetics associate-resource \
    --group-identifier demo_group \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see AssociateResource in *Amazon CLI Command Reference*.

`create-canary`

The following code example shows how to use `create-canary`.

Amazon CLI

To create a canary

The following `create-canary` example creates a canary named demo_canary.

```
aws synthetics create-canary \
    --name demo_canary \
    --code '{"S3Bucket": "artifacts3bucket", "S3Key":"demo_canary.zip", "Handler":
 "index.lambda_handler"}' \
    --artifact-s3-location s3://amzn-s3-demo-bucket/demo_canary.zip \
    --execution-role-arn arn:aws:iam::123456789012:role/demo_canary_role \
    --schedule Expression="rate(10 minutes)" \
    --runtime-version syn-nodejs-puppeteer-9.1
```

Output:

```
{
    "Canary": {
        "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
        "Name": "demo_canary",
        "Code": {
            "Handler": "index.lambda_handler"
        },
        "ExecutionRoleArn": "arn:aws:iam::123456789012:role/demo_canary_role",
        "Schedule": {
            "Expression": "rate(10 minutes)",
            "DurationInSeconds": 0
        },
        "RunConfig": {
            "TimeoutInSeconds": 600,
            "MemoryInMB": 1000,
            "ActiveTracing": false
        },
        "SuccessRetentionPeriodInDays": 31,
        "FailureRetentionPeriodInDays": 31,
        "Status": {
            "State": "CREATING",
            "StateReasonCode": "CREATE_PENDING"
        },
        "Timeline": {
            "Created": "2024-10-15T19:03:08.826000+05:30",
            "LastModified": "2024-10-15T19:03:08.826000+05:30"
        },
        "ArtifactS3Location": "amzn-s3-demo-bucket/demo_canary.zip",
        "RuntimeVersion": "syn-nodejs-puppeteer-9.1",
        "Tags": {}
    }
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see CreateCanary in *Amazon CLI Command Reference*.

`create-group`

The following code example shows how to use `create-group`.

Amazon CLI

To create a group

The following `create-group` example creates a group named `demo_group`.

```
aws synthetics create-group \
    --name demo_group
```

Output:

```
{
    "Group": {
        "Id": "example123",
        "Name": "demo_group",
        "Arn": "arn:aws:synthetics:us-east-1:123456789012:group:example123",
        "Tags": {},
        "CreatedTime": "2024-10-15T14:47:23.811000+05:30",
        "LastModifiedTime": "2024-10-15T14:47:23.811000+05:30"
    }
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see CreateGroup in *Amazon CLI Command Reference*.

`delete-canary`

The following code example shows how to use `delete-canary`.

Amazon CLI

To permanently delete a canary

The following `delete-canary` example deletes a canary named `demo_canary`.

```
aws synthetics delete-canary \
    --name demo_canary
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteCanary in *Amazon CLI Command Reference*.

`delete-group`

The following code example shows how to use `delete-group`.

Amazon CLI

To delete a group

The following `delete-group` example deletes a group named `demo_group`.

```
aws synthetics delete-group \
    --group-identifier demo_group
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteGroup in *Amazon CLI Command Reference*.

`describe-canaries-last-run`

The following code example shows how to use `describe-canaries-last-run`.

Amazon CLI

To see information from the most recent run of each canary

The following `describe-canaries-last-run` example returns the most recent run of each canary that you have created.

```
aws synthetics describe-canaries-last-run
```

Output:

```
{
    "CanariesLastRun": [
        {
```

```
            "CanaryName": "demo_canary",
            "LastRun": {
                "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
                "Name": "demo_canary",
                "Status": {
                    "State": "PASSED",
                    "StateReason": "",
                    "StateReasonCode": ""
                },
                "Timeline": {
                    "Started": "2024-10-15T19:20:39.691000+05:30",
                    "Completed": "2024-10-15T19:20:58.211000+05:30"
                },
                "ArtifactS3Location": "cw-syn-results-123456789012-us-east-1/canary/
us-east-1/demo_canary-abc-example1234/2024/10/15/13/50-39-690"
            }
        }
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DescribeCanariesLastRun in *Amazon CLI Command Reference*.

`describe-canaries`

The following code example shows how to use `describe-canaries`.

Amazon CLI

To list canaries in your account

The following `describe-canaries` example lists the details of canaries in your account.

```
aws synthetics describe-canaries
```

Output:

```
{
    "Canaries": [
        {
            "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
```

```
            "Name": "demo_canary",
            "Code": {
                "SourceLocationArn": "arn:aws:lambda:us-
east-1:123456789012:layer:cwsyn-demo_canary-a1b2c3d4-5678-90ab-cdef-
example11111b8:1",

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DescribeCanaries in *Amazon CLI Command Reference*.

describe-runtime-versions

The following code example shows how to use `describe-runtime-versions`.

Amazon CLI

To return a list of synthetics canary runtime versions

The following `describe-runtime-versions` example returns the list of synthetics canary runtime versions.

```
aws synthetics describe-runtime-versions
```

Output:

```
{
    "RuntimeVersions": [
        {
            "VersionName": "syn-nodejs-puppeteer-9.1",
            "Description": "Security fixes and bug fix for date range error in har.
 Dependencies: Node JS 20.x, Puppeteer-core 22.12.1, Chromium 126.0.6478.126",
            "ReleaseDate": "2024-10-02T05:30:00+05:30"
        },
        {
            "VersionName": "syn-nodejs-puppeteer-9.0",
            "Description": "Upgraded Chromium and Puppeteer. Dependencies: Node JS
 20.x, Puppeteer-core 22.12.1, Chromium 126.0.6478.126",
            "ReleaseDate": "2024-07-22T05:30:00+05:30"
        },
        {
            "VersionName": "syn-nodejs-puppeteer-8.0",
            "Description": "Upgraded Chromium and Puppeteer. Dependencies: Node JS

            "Description": "Upgraded to NodeJS 16.x. Dependencies: Node JS 16.x,
Puppeteer-core 5.5.0, Chromium 92.0.4512.0",
```

```
            "ReleaseDate": "2023-05-01T05:30:00+05:30",
            "DeprecationDate": "2024-03-08T13:30:00+05:30"
        }
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DescribeRuntimeVersions in *Amazon CLI Command Reference*.

`disassociate-resource`

The following code example shows how to use `disassociate-resource`.

Amazon CLI

To remove a canary from a group

The following `disassociate-resource` example removes a canary from the group named `demo_group`.

```
aws synthetics disassociate-resource \
    --group-identifier demo_group \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see DisassociateResource in *Amazon CLI Command Reference*.

`get-canary-runs`

The following code example shows how to use `get-canary-runs`.

Amazon CLI

To retrieve a list of runs for a specified canary

The following `get-canary-runs` example retrieves a list of runs for the canary named `demo_canary`.

```
aws synthetics get-canary-runs \
    --name demo_canary
```

Output:

```
{
    "CanaryRuns": [
        {
            "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
            "Name": "demo_canary",
            "Status": {
                "State": "PASSED",
                "StateReason": "",
                "StateReasonCode": ""
            },
            "Timeline": {
                "Started": "2024-10-16T10:38:57.013000+05:30",
                "Completed": "2024-10-16T10:39:25.793000+05:30"
            },
            "ArtifactS3Location": "cw-syn-results-123456789012-us-east-1/canary/us-
east-1/demo_canary-abc-example1234/2024/10/15/13/50-39-690"
        }
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see GetCanaryRuns in *Amazon CLI Command Reference*.

`get-canary`

The following code example shows how to use `get-canary`.

Amazon CLI

To retrieve complete information about one canary

The following `get-canary` example retrieves complete information about the canary named `demo_canary`.

```
aws synthetics get-canary \
```

```
    --name demo_canary
```

Output:

```
{
    "Canary": {
        "Id": "a1b2c3d4-5678-90ab-cdef-example11111",
        "Name": "demo_canary",
        "Code": {

        }
    }
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see GetCanary in *Amazon CLI Command Reference*.

`get-group`

The following code example shows how to use `get-group`.

Amazon CLI

To return information about one group

The following `get-group` example returns information about the group named `demo_group`.

```
aws synthetics get-group \
    --group-identifier demo_group
```

Output:

```
{
    "Group": {
        "Id": "example123",
        "Name": "demo_group",
        "Arn": "arn:aws:synthetics:us-east-1:123456789012:group:example123",
        "Tags": {},
        "CreatedTime": "2024-10-15T14:47:23.811000+05:30",
        "LastModifiedTime": "2024-10-15T14:47:23.811000+05:30"
    }
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see GetGroup in *Amazon CLI Command Reference*.

`list-associated-groups`

The following code example shows how to use `list-associated-groups`.

Amazon CLI

To return a list of the groups

The following `list-associated-groups` example returns a list of the groups associated with the canary named `demo_canary`.

```
aws synthetics list-associated-groups \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary
```

Output:

```
{
    "Groups": [
        {
            "Id": "example123",
            "Name": "demo_group",
            "Arn": "arn:aws:synthetics:us-east-1:123456789012:group:example123"
        }
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see ListAssociatedGroups in *Amazon CLI Command Reference*.

`list-group-resources`

The following code example shows how to use `list-group-resources`.

Amazon CLI

To return a list of the ARNs of the canaries that are associated with the specified group

The following `list-group-resources` example returns a list of the ARNs of the canaries that are associated with the group named `demo_group`.

```
aws synthetics list-group-resources \
    --group-identifier demo_group
```

Output:

```
{
    "Resources": [
```

```
        "arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary"
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see ListGroupResources in *Amazon CLI Command Reference*.

`list-groups`

The following code example shows how to use `list-groups`.

Amazon CLI

To return a list of all groups in the account

The following `list-groups` example returns a list of all groups in the account.

```
aws synthetics list-groups
```

Output:

```
{
    "Groups": [
        {
            "Id": "example123",
            "Name": "demo_group",
            "Arn": "arn:aws:synthetics:us-east-1:123456789012:group:example123"
        }
    ]
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see ListGroups in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

Example 1: To display the tags associated with a canary

The following `list-tags-for-resource` example returns the tags associated with a canary named `demo_canary`.

```
aws synthetics list-tags-for-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary
```

Output:

```
{
    "Tags": {
        "blueprint": "heartbeat"
    }
}
```

Example 2: To display the tags associated with a group

The following `list-tags-for-resource` example returns the tags associated with a group named `demo_group`.

```
aws  synthetics list-tags-for-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:group:example123
```

Output:

```
{
    "Tags": {
        "team": "Devops"
    }
}
```

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`start-canary`

The following code example shows how to use `start-canary`.

Amazon CLI

To run a canary

The following `start-canary` example runs a canary named `demo_canary`.

```
aws synthetics start-canary \
    --name demo_canary
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see StartCanary in *Amazon CLI Command Reference*.

`stop-canary`

The following code example shows how to use `stop-canary`.

Amazon CLI

To stop a canary

The following `stop-canary` example stops the canary named `demo_canary`.

```
aws synthetics stop-canary \
    --name demo_canary
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see StopCanary in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

Example 1: To assign a tag to the canary

The following `tag-resource` example assigns a tag to the canary named `demo_canary`.

```
aws synthetics tag-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary \
    --tags blueprint=heartbeat
```

This command produces no output.

Example 2: To assign a tag to the group

The following `tag-resource` example assigns a tag to the group named `demo_group`.

```
aws synthetics tag-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:group:example123 \
    --tags team=Devops
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

Example 1: To remove a tag from the canary

The following `untag-resource` example removes a tag from the canary named `demo_canary`.

```
aws synthetics untag-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:canary:demo_canary \
```

```
    --tag-keys blueprint
```

This command produces no output.

Example 2: To remove a tag from the group

The following `untag-resource` example assigns a removes a tag from the group named `demo_group`.

```
aws synthetics untag-resource \
    --resource-arn arn:aws:synthetics:us-east-1:123456789012:group:example123 \
    --tag-keys team
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-canary`

The following code example shows how to use `update-canary`.

Amazon CLI

To update a canary

The following `update-canary` example updates the configuration of a canary named `demo_canary`.

```
aws synthetics update-canary \
    --name demo_canary \
    --schedule Expression="rate(15 minutes)"
```

This command produces no output.

For more information, see Synthetic monitoring (canaries) in the *Amazon CloudWatch User Guide*.

- For API details, see UpdateCanary in *Amazon CLI Command Reference*.

CodeArtifact examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeArtifact.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-external-connection`

The following code example shows how to use `associate-external-connection`.

Amazon CLI

To add an external connection to a repository

The following `associate-external-connection` example adds an external connection to npmjs.com to a repository named test-repo.

```
aws codeartifact associate-external-connection \
    --repository test-repo \
    --domain test-domain \
    --external-connection public:npmjs
```

Output:

```
{
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
```

```
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "upstreams": [],
        "externalConnections": [
            {
                "externalConnectionName": "public:npmjs",
                "packageFormat": "npm",
                "status": "AVAILABLE"
            }
        ]
    }
}
```

For more information, see Add an external connection in the *Amazon CodeArtifact User Guide*.

- For API details, see AssociateExternalConnection in *Amazon CLI Command Reference*.

`copy-package-versions`

The following code example shows how to use `copy-package-versions`.

Amazon CLI

To copy package versions from one repository to another

The following `copy-package-versions` moves versions 4.0.0 and 5.0.0 of a package named test-package from my-repo to test-repo.

```
aws codeartifact copy-package-versions \
    --domain test-domain \
    --source-repository my-repo \
    --destination-repository test-repo \
    --format npm \
    --package test-package \
    --versions '["4.0.0", "5.0.0"]'
```

Output:

```
{
    "format": "npm",
    "package": "test-package",
    "versions": [
        {
```

```
        "version": "5.0.0",
        "revision": "REVISION-1-SAMPLE-6C81EFF7DA55CC",
        "status": "Published"
        },
        {
        "version": "4.0.0",
        "revision": "REVISION-2-SAMPLE-55C752BEE772FC",
        "status": "Published"
        }
    ]
}
```

For more information, see Copy packages between repositories in the *Amazon CodeArtifact User Guide*.

- For API details, see CopyPackageVersions in *Amazon CLI Command Reference*.

`create-domain`

The following code example shows how to use `create-domain`.

Amazon CLI

To create a domain

The following `create-domain` example creates a domain named test-domain.

```
aws codeartifact create-domain \
    --domain test-domain
```

Output:

```
{
    "domain": {
        "name": "test-domain",
        "owner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:domain/test-domain",
        "status": "Active",
        "createdTime": "2020-10-20T13:16:48.559000-04:00",
        "encryptionKey": "arn:aws:kms:us-west-2:111122223333:key/a1b2c3d4-5678-90ab-
cdef-EXAMPLE11111",
        "repositoryCount": 0,
        "assetSizeBytes": 0
```

```
    }
}
```

For more information, see Create a domain in the *Amazon CodeArtifact User Guide*.

- For API details, see CreateDomain in *Amazon CLI Command Reference*.

`create-repository`

The following code example shows how to use `create-repository`.

Amazon CLI

To create a repository

The following `create-repository` example creates a repository named test-repo inside a domain named test-domain.

```
aws codeartifact create-repository \
    --domain test-domain \
    --domain-owner 111122223333 \
    --repository test-repo \
    --description "This is a test repository."
```

Output:

```
{
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "description": "This is a test repository.",
        "upstreams": [],
        "externalConnections": []
    }
}
```

For more information, see Create a domain in the *Amazon CodeArtifact User Guide*.

- For API details, see CreateRepository in *Amazon CLI Command Reference*.

`delete-domain-permissions-policy`

The following code example shows how to use `delete-domain-permissions-policy`.

Amazon CLI

To delete the permissions policy document from a domain

The following `delete-domain-permissions-policy` example deletes the permission policy from a domain named test-domain.

```
aws codeartifact delete-domain-permissions-policy \
    --domain test-domain
```

Output:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "BasicDomainPolicy",
            "Action": [
                "codeartifact:GetDomainPermissionsPolicy",
                "codeartifact:ListRepositoriesInDomain",
                "codeartifact:GetAuthorizationToken",
                "codeartifact:CreateRepository"
            ],
            "Effect": "Allow",
            "Resource": "*",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            }
        }
    ]
}
```

For more information, see Delete a domain policy in the *Amazon CodeArtifact User Guide*.

- For API details, see DeleteDomainPermissionsPolicy in *Amazon CLI Command Reference*.

`delete-domain`

The following code example shows how to use `delete-domain`.

Amazon CLI

To delete a domain

The following `delete-domain` example deletes a domain named `test-domain`.

```
aws codeartifact delete-domain \
    --domain test-domain
```

Output:

```
{
    "domain": {
        "name": "test-domain",
        "owner": "417498243647",
        "arn": "arn:aws:codeartifact:us-west-2:417498243647:domain/test-domain",
        "status": "Deleted",
        "createdTime": "2020-10-20T13:16:48.559000-04:00",
        "encryptionKey": "arn:aws:kms:us-west-2:417498243647:key/c9fe2447-0795-4fda-
afbe-8464574ae162",
        "repositoryCount": 0,
        "assetSizeBytes": 0
    }
}
```

For more information, see Delete a domain in the *Amazon CodeArtifact User Guide*.

- For API details, see DeleteDomain in *Amazon CLI Command Reference*.

`delete-package-versions`

The following code example shows how to use `delete-package-versions`.

Amazon CLI

To delete package versions

The following `delete-package-versions` example deletes version 4.0.0 of a package named test-package.

```
aws codeartifact delete-package-versions \
    --domain test-domain \
```

```
    --repo test-repo \
    --format npm \
    --package test-package \
    --versions 4.0.0
```

Output:

```
{
    "successfulVersions": {
        "4.0.0": {
            "revision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
            "status": "Deleted"
        }
    },
    "failedVersions": {}
}
```

For more information, see Delete a package version in the *Amazon CodeArtifact User Guide*.

- For API details, see DeletePackageVersions in *Amazon CLI Command Reference*.

`delete-repository-permissions-policy`

The following code example shows how to use `delete-repository-permissions-policy`.

Amazon CLI

To delete a permissions policy from a repository

The following `delete-repository-permissions-policy` example deletes the permission policy from a repository named test-repo.

```
aws codeartifact delete-repository-permissions-policy \
    --domain test-domain \
    --repository test-repo
```

Output:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": [
                "codeartifact:DescribePackageVersion",
                "codeartifact:DescribeRepository",
                "codeartifact:GetPackageVersionReadme",
                "codeartifact:GetRepositoryEndpoint",
                "codeartifact:ListPackages",
                "codeartifact:ListPackageVersions",
                "codeartifact:ListPackageVersionAssets",
                "codeartifact:ListPackageVersionDependencies",
                "codeartifact:ReadFromRepository"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information, see Delete a policy in the *Amazon CodeArtifact User Guide*.

- For API details, see DeleteRepositoryPermissionsPolicy in *Amazon CLI Command Reference*.

`delete-repository`

The following code example shows how to use `delete-repository`.

Amazon CLI

To delete a repository

The following `delete-repository` example deletes a repository named `test-repo` in a domain named `test-domain`.

```
aws codeartifact delete-repository \
    --domain test-domain \
    --repository test-repo
```

Output:

```
{
```

```
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "description": "This is a test repository",
        "upstreams": [],
        "externalConnections": []
    }
}
```

For more information, see Delete a repository in the *Amazon CodeArtifact User Guide*.

- For API details, see DeleteRepository in *Amazon CLI Command Reference*.

`describe-domain`

The following code example shows how to use `describe-domain`.

Amazon CLI

To get information about a domain

The following `describe-domain` example returns a DomainDescription object for a domain named test-domain.

```
aws codeartifact describe-domain \
    --domain test-domain
```

Output:

```
{
    "domain": {
        "name": "test-domain",
        "owner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:domain/test-domain",
        "status": "Active",
        "createdTime": "2020-10-20T13:16:48.559000-04:00",
        "encryptionKey": "arn:aws:kms:us-west-2:111122223333:key/a1b2c3d4-5678-90ab-
cdef-EXAMPLE11111",
        "repositoryCount": 2,
```

```
        "assetSizeBytes": 0,
        "s3BucketArn": "arn:aws:s3:::assets-111122223333-us-west-2"
    }
}
```

For more information, see Domain overview in the *Amazon CodeArtifact User Guide*.

- For API details, see DescribeDomain in *Amazon CLI Command Reference*.

`describe-repository`

The following code example shows how to use `describe-repository`.

Amazon CLI

To get information about a repository

The following `describe-repository` example returns a RepositoryDescription object for a repository named test-repo.

```
aws codeartifact describe-repository \
    --domain test-domain \
    --repository test-repo
```

Output:

```
{
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "description": "This is a test repository.",
        "upstreams": [],
        "externalConnections": []
    }
}
```

For more information, see Create a domain in the *Amazon CodeArtifact User Guide*.

- For API details, see DescribeRepository in *Amazon CLI Command Reference*.

`disassociate-external-connection`

The following code example shows how to use `disassociate-external-connection`.

Amazon CLI

To remove an external connection from a repository

The following `disassociate-external-connection` example removes an external connection to npmjs.com from a repository named test-repo.

```
aws codeartifact disassociate-external-connection \
    --repository test-repo \
    --domain test-domain \
    --external-connection public:npmjs
```

Output:

```
{
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "upstreams": [],
        "externalConnections": []
    }
}
```

For more information, see Remove an external connection in the *Amazon CodeArtifact User Guide*.

- For API details, see DisassociateExternalConnection in *Amazon CLI Command Reference*.

`dispose-package-versions`

The following code example shows how to use `dispose-package-versions`.

Amazon CLI

To delete a package version's assets and set its status to Disposed

The following `dispose-package-versions` example deletes the assets of test-package version 4.0.0 and sets its status to Disposed.

```
aws codeartifact dispose-package-versions \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --versions 4.0.0
```

Output:

```
{
    "successfulVersions": {
        "4.0.0": {
            "revision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
            "status": "Disposed"
        }
    },
    "failedVersions": {}
}
```

For more information, see Working with packages in CodeArtifact in the *Amazon CodeArtifact User Guide*.

- For API details, see DisposePackageVersions in *Amazon CLI Command Reference*.

`get-authorization-token`

The following code example shows how to use `get-authorization-token`.

Amazon CLI

To get an authorization token

The following `get-authorization-token` example retrieves a CodeArtifact authorization token.

```
aws codeartifact get-authorization-token \
    --domain test-domain \
    --query authorizationToken \
    --output text
```

Output:

```
This command will return the authorization token. You can store the output in an
 environment variable when calling the command.
```

For more information, see Configure pip without the login command in the *Amazon CodeArtifact User Guide*.

- For API details, see GetAuthorizationToken in *Amazon CLI Command Reference*.

`get-domain-permissions-policy`

The following code example shows how to use `get-domain-permissions-policy`.

Amazon CLI

To get the permissions policy document for a domain

The following `get-domain-permissions-policy` example gets the permission policy attached to a domain named test-domain.

```
aws codeartifact get-domain-permissions-policy \
    --domain test-domain
```

Output:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "BasicDomainPolicy",
            "Action": [
                "codeartifact:GetDomainPermissionsPolicy",
                "codeartifact:ListRepositoriesInDomain",
                "codeartifact:GetAuthorizationToken",
                "codeartifact:CreateRepository"
            ],
            "Effect": "Allow",
            "Resource": "*",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:root"
            }
```

```
        }
    ]
}
```

For more information, see Read a domain policy in the *Amazon CodeArtifact User Guide*.

- For API details, see GetDomainPermissionsPolicy in *Amazon CLI Command Reference*.

`get-package-version-asset`

The following code example shows how to use `get-package-version-asset`.

Amazon CLI

To get an asset from a package version

The following `get-package-version-asset` example retrieves the `package.tgz` asset for version 4.0.0 of an npm package named test-package.

```
aws codeartifact get-package-version-asset \
    --domain test-domain \
    --repository test-repo \
    --format npm \
    --package test-package \
    --package-version 4.0.0 \
    --asset 'package.tgz' \
    outfileName
```

Output:

```
The output for this command will also store the raw asset in the file provided in
 place of outfileName.

{
    "assetName": "package.tgz",
    "packageVersion": "4.0.0",
    "packageVersionRevision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs="
}
```

For more information, see List package version assets in the *Amazon CodeArtifact User Guide*.

- For API details, see GetPackageVersionAsset in *Amazon CLI Command Reference*.

`get-package-version-readme`

The following code example shows how to use `get-package-version-readme`.

Amazon CLI

To get a package version's readme file

The following `get-package-version-readme` example retrieves the readme file for version 4.0.0 of an npm package named test-package.

```
aws codeartifact get-package-version-readme \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --package-version 4.0.0
```

Output:

```
{
    "format": "npm",
    "package": "test-package",
    "version": "4.0.0",
    "readme": "<div align=\"center\">\n   <a href=\https://github.com/test-package/
testpack\"> ... more content ... \n",
    "versionRevision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs="
}
```

For more information, see View package version readme file in the *Amazon CodeArtifact User Guide*.

- For API details, see GetPackageVersionReadme in *Amazon CLI Command Reference*.

`get-repository-endpoint`

The following code example shows how to use `get-repository-endpoint`.

Amazon CLI

To get a repository's URL endpoint

The following `get-repository-endpoint` example returns the npm endpoint for the test-repo repository.

```
aws codeartifact get-repository-endpoint \
    --domain test-domain \
    --repository test-repo \
    --format npm
```

Output:

```
{
    "repositoryEndpoint": "https://test-domain-111122223333.d.codeartifact.us-
west-2.amazonaws.com/npm/test-repo/"
}
```

For more information, see Connect to a repository in the *Amazon CodeArtifact User Guide*.

- For API details, see GetRepositoryEndpoint in *Amazon CLI Command Reference*.

`get-repository-permissions-policy`

The following code example shows how to use `get-repository-permissions-policy`.

Amazon CLI

To get the permissions policy document for a repository

The following `get-repository-permissions-policy` example gets the permission policy attached to a repository named test-repo.

```
aws codeartifact get-repository-permissions-policy \
    --domain test-domain \
    --repository test-repo
```

Output:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
```

```
                "AWS": "arn:aws:iam::111122223333:root"
            },
            "Action": [
                "codeartifact:DescribePackageVersion",
                "codeartifact:DescribeRepository",
                "codeartifact:GetPackageVersionReadme",
                "codeartifact:GetRepositoryEndpoint",
                "codeartifact:ListPackages",
                "codeartifact:ListPackageVersions",
                "codeartifact:ListPackageVersionAssets",
                "codeartifact:ListPackageVersionDependencies",
                "codeartifact:ReadFromRepository"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information, see Read a policy in the *Amazon CodeArtifact User Guide*.

- For API details, see GetRepositoryPermissionsPolicy in *Amazon CLI Command Reference*.

`list-domains`

The following code example shows how to use `list-domains`.

Amazon CLI

To list domains

The following `list-domains` example returns a summary of all domains owned by the Amazon account that makes the call.

```
aws codeartifact list-domains
```

Output:

```
{
    "domains": [
        {
            "name": "my-domain",
            "owner": "111122223333",
            "status": "Active",
```

```
            "encryptionKey": "arn:aws:kms:us-west-2:111122223333:key/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        {
            "name": "test-domain",
            "owner": "111122223333",
            "status": "Active",
            "encryptionKey": "arn:aws:kms:us-west-2:111122223333:key/
a1b2c3d4-5678-90ab-cdef-EXAMPLE22222"
        }
    ]
}
```

For more information, see Working with domains in CodeArtifact in the *Amazon CodeArtifact User Guide*.

- For API details, see ListDomains in *Amazon CLI Command Reference*.

`list-package-version-assets`

The following code example shows how to use `list-package-version-assets`.

Amazon CLI

To view a package version's assets

The following `list-package-version-assets` example retrieves the assets for version 4.0.0 of an npm package named test-package.

```
aws codeartifact list-package-version-assets \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --package-version 4.0.0
```

Output:

```
{
    "format": "npm",
    "package": "test-package",
    "version": "4.0.0",
    "versionRevision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
```

```
    "assets": [
        {
            "name": "package.tgz",
            "size": 316680,
            "hashes": {
                "MD5": "60078ec6d9e76b89fb55c860832742b2",
                "SHA-1": "b44a9b6297bcb698f1c51a3545a2b3b368d59c52",
                "SHA-256":
 "d2aa8c6afc3c8591765785a37d1c5acae482a8eb3ab9729ed28922692454f2e2",
                "SHA-512":
 "3e585d15c8a594e20d7de57b362ea81754c011acb2641a19f1b72c8531ea39825896bab344ae616a0a5a824cb9
            }
        }
    ]
}
```

For more information, see List package version assets in the *Amazon CodeArtifact User Guide*.

- For API details, see ListPackageVersionAssets in *Amazon CLI Command Reference*.

`list-package-version-dependencies`

The following code example shows how to use `list-package-version-dependencies`.

Amazon CLI

To view a package version's dependencies

The following `list-package-version-dependencies` example retrieves the dependencies for version 4.0.0 of an npm package named test-package.

```
aws codeartifact list-package-version-dependencies \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --package-version 4.0.0
```

Output:

```
{
    "format": "npm",
    "package": "test-package",
```

```
    "version": "4.0.0",
    "versionRevision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
    "dependencies": [
        {
            "namespace": "testns",
            "package": "testdep1",
            "dependencyType": "regular",
            "versionRequirement": "1.8.5"
        },
        {
            "namespace": "testns",
            "package": "testdep2",
            "dependencyType": "regular",
            "versionRequirement": "1.8.5"
        }
    ]
}
```

For more information, see View and update package version details and dependencies in the *Amazon CodeArtifact User Guide*.

- For API details, see ListPackageVersionDependencies in *Amazon CLI Command Reference*.

`list-package-versions`

The following code example shows how to use `list-package-versions`.

Amazon CLI

To list package versions for a package

The following `list-package-versions` example returns a list of package versions for a package named `kind-of`.

```
aws codeartifact list-package-versions \
    --package kind-of \
    --domain test-domain \
    --repository test-repo \
    --format npm
```

Output:

```
{
```

```
    "defaultDisplayVersion": "1.0.1",
    "format": "npm",
    "package": "kind-of",
    "versions": [
        {
            "version": "1.0.1",
            "revision": "REVISION-SAMPLE-1-C7F4S5E9B772FC",
            "status": "Published"
        },
        {
            "version": "1.0.0",
            "revision": "REVISION-SAMPLE-2-C752BEEF6D2CFC",
            "status": "Published"
        },
        {
            "version": "0.1.2",
            "revision": "REVISION-SAMPLE-3-654S65A5C5E1FC",
            "status": "Published"
        },
        {
            "version": "0.1.1",
            "revision": "REVISION-SAMPLE-1-C7F4S5E9B772FC"",
            "status": "Published"
        },
        {
            "version": "0.1.0",
            "revision": "REVISION-SAMPLE-4-AF669139B772FC",
            "status": "Published"
        }
    ]
}
```

For more information, see List package versions in the *Amazon CodeArtifact User Guide*.

- For API details, see ListPackageVersions in *Amazon CLI Command Reference*.

`list-packages`

The following code example shows how to use `list-packages`.

Amazon CLI

To list packages in a repository

The following `list-packages` example list packages in a repository named `test-repo` in a domain named `test-domain`.

```
aws codeartifact list-packages \
    --domain test-domain \
    --repository test-repo
```

Output:

```
{
    "packages": [
        {
            "format": "npm",
            "package": "lodash"
        }
        {
            "format": "python",
            "package": "test-package"
        }
    ]
}
```

For more information, see List package names in the *Amazon CodeArtifact User Guide*.

- For API details, see ListPackages in *Amazon CLI Command Reference*.

`list-repositories-in-domain`

The following code example shows how to use `list-repositories-in-domain`.

Amazon CLI

To list repositories in a domain

The following `list-repositories-in-domain` example returns a summary of all repositories in the test-domain domain.

```
aws codeartifact list-repositories-in-domain \
    --domain test-domain
```

Output:

```
{
    "repositories": [
        {
            "name": "test-repo",
            "administratorAccount": "111122223333",
            "domainName": "test-domain",
            "domainOwner": "111122223333",
            "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-
domain/test-repo",
            "description": "This is a test repository."
        },
        {
            "name": "test-repo2",
            "administratorAccount": "111122223333",
            "domainName": "test-domain",
            "domainOwner": "111122223333",
            "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-
domain/test-repo2",
            "description": "This is a test repository."
        }
    ]
}
```

For more information, see List repositories in the *Amazon CodeArtifact User Guide*.

- For API details, see ListRepositoriesInDomain in *Amazon CLI Command Reference*.

`list-repositories`

The following code example shows how to use `list-repositories`.

Amazon CLI

To list repositories

The following `list-repositories` example returns a summary of all repositories in domain owned by the Amazon account that makes the call.

```
aws codeartifact list-repositories
```

Output:

```
{
    "repositories": [
        {
            "name": "npm-store",
            "administratorAccount": "111122223333",
            "domainName": "my-domain",
            "domainOwner": "111122223333",
            "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/my-
domain/npm-store",
            "description": "Provides npm artifacts from npm, Inc."
        },
        {
            "name": "target-repo",
            "administratorAccount": "111122223333",
            "domainName": "my-domain",
            "domainOwner": "111122223333",
            "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/my-
domain/target-repo",
            "description": "test target repo"
        },
        {
            "name": "test-repo2",
            "administratorAccount": "111122223333",
            "domainName": "test-domain",
            "domainOwner": "111122223333",
            "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-
domain/test-repo2",
            "description": "This is a test repository."
        }
    ]
}
```

For more information, see List repositories in the *Amazon CodeArtifact User Guide*.

- For API details, see ListRepositories in *Amazon CLI Command Reference*.

`login`

The following code example shows how to use `login`.

Amazon CLI

To configure authentication to your repository with the login command

The following `login` example configures the npm package manager with a repository named test-repo in a domain named test-domain.

```
aws codeartifact login \
    --domain test-domain \
    --repository test-repo \
    --tool npm
```

Output:

```
Successfully configured npm to use AWS CodeArtifact repository https://test-
domain-111122223333.d.codeartifact.us-west-2.amazonaws.com/npm/test-repo/
Login expires in 12 hours at 2020-11-12 01:53:16-05:00
```

For more information, see Getting started with the Amazon CLI in the *Amazon CodeArtifact User Guide*.

- For API details, see Login in *Amazon CLI Command Reference*.

`put-domain-permissions-policy`

The following code example shows how to use `put-domain-permissions-policy`.

Amazon CLI

To attach a permissions policy to a domain

The following `put-domain-permissions-policy` example attaches a permission policy that is defined in the policy.json file to a domain named test-domain.

```
aws codeartifact put-domain-permissions-policy \
    --domain test-domain \
    --policy-document file://PATH/TO/policy.json
```

Output:

```
{
    "policy": {
        "resourceArn": "arn:aws:codeartifact:region-id:111122223333:domain/test-
domain",
        "document": "{ ...policy document content...}",
```

```
        "revision": "MQlyyTQRASRU3HB58gBtSDHXG7Q3hvxxxxxxx="
    }
}
```

For more information, see Set a domain policy in the *Amazon CodeArtifact User Guide*.

- For API details, see PutDomainPermissionsPolicy in *Amazon CLI Command Reference*.

`put-repository-permissions-policy`

The following code example shows how to use `put-repository-permissions-policy`.

Amazon CLI

To attach a permissions policy to a repository

The following `put-repository-permissions-policy` example attaches a permission policy that is defined in the policy.json file to a repository named test-repo.

```
aws codeartifact put-repository-permissions-policy \
    --domain test-domain \
    --repository test-repo \
    --policy-document file://PATH/TO/policy.json
```

Output:

```
{
    "policy": {
        "resourceArn": "arn:aws:codeartifact:region-id:111122223333:repository/test-
domain/test-repo",
        "document": "{ ...policy document content...}",
        "revision": "MQlyyTQRASRU3HB58gBtSDHXG7Q3hvxxxxxxx="
    }
}
```

For more information, see Set a policy in the *Amazon CodeArtifact User Guide*.

- For API details, see PutRepositoryPermissionsPolicy in *Amazon CLI Command Reference*.

`update-package-versions-status`

The following code example shows how to use `update-package-versions-status`.

Amazon CLI

To update package version status

The following `update-package-versions-status` example updates the status of version 4.0.0 of the test-package package to Archived.

```
aws codeartifact update-package-versions-status \
    --domain test-domain \
    --repo test-repo \
    --format npm \
    --package test-package \
    --versions 4.0.0 \
    --target-status Archived
```

Output:

```
{
    "successfulVersions": {
        "4.0.0": {
            "revision": "Ciqe5/9yicvkJT13b5/LdLpCyE6fqA7poa9qp+FilPs=",
            "status": "Archived"
        }
    },
    "failedVersions": {}
}
```

For more information, see Update package version status in the *Amazon CodeArtifact User Guide*.

- For API details, see UpdatePackageVersionsStatus in *Amazon CLI Command Reference*.

`update-repository`

The following code example shows how to use `update-repository`.

Amazon CLI

To update a repository

The following `update-repository` example updates the description of a repo named test-repo in a domain named test-domain to "this is an updated description".

```
aws codeartifact update-repository \
    --domain test-domain \
    --repository test-repo \
    --description "this is an updated description"
```

Output:

```
{
    "repository": {
        "name": "test-repo",
        "administratorAccount": "111122223333",
        "domainName": "test-domain",
        "domainOwner": "111122223333",
        "arn": "arn:aws:codeartifact:us-west-2:111122223333:repository/test-domain/
test-repo",
        "description": "this is an updated description",
        "upstreams": [],
        "externalConnections": []
    }
}
```

For more information, see View or modify a repository configuration in the *Amazon CodeArtifact User Guide*.

- For API details, see UpdateRepository in *Amazon CLI Command Reference*.

CodeBuild examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeBuild.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`batch-delete-builds`

The following code example shows how to use `batch-delete-builds`.

Amazon CLI

To delete builds in Amazon CodeBuild.

The following `batch-delete-builds` example deletes builds in CodeBuild with the specified IDs.

```
aws codebuild batch-delete-builds --ids my-build-project-one:a1b2c3d4-5678-9012-abcd-11111EXAMPLE my-build-project-two:a1b2c3d4-5678-9012-abcd-22222EXAMPLE
```

Output:

```
{
    "buildsNotDeleted": [
        {
            "id": "arn:aws:codebuild:us-west-2:123456789012:build/my-build-project-one:a1b2c3d4-5678-9012-abcd-11111EXAMPLE",
            "statusCode": "BUILD_IN_PROGRESS"
        }
    ],
    "buildsDeleted": [
        "arn:aws:codebuild:us-west-2:123456789012:build/my-build-project-two:a1b2c3d4-5678-9012-abcd-22222EXAMPLE"
    ]
}
```

For more information, see Delete Builds (Amazon CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see BatchDeleteBuilds in *Amazon CLI Command Reference*.

`batch-get-build-batches`

The following code example shows how to use `batch-get-build-batches`.

Amazon CLI

To view details of builds in Amazon CodeBuild.

The following `batch-get-build-batches` example gets information about build batches in CodeBuild with the specified IDs.

```
aws codebuild batch-get-build-batches \
    --ids codebuild-demo-project:e9c4f4df-3f43-41d2-ab3a-60fe2EXAMPLE
```

Output:

```
{
    "buildBatches": [
        {
            "id": "codebuild-demo-project:e9c4f4df-3f43-41d2-ab3a-60fe2EXAMPLE",

For more information, see Batch builds in Amazon CodeBuild <https://docs.aws.amazon.com/codebuild/latest/userguide/batch-build.html>)__ in the *Amazon CodeBuild User Guide*.

- For API details, see BatchGetBuildBatches in *Amazon CLI Command Reference*.

`batch-get-builds`

The following code example shows how to use `batch-get-builds`.

Amazon CLI

To view details of builds in Amazon CodeBuild.

The following `batch-get-builds` example gets information about builds in CodeBuild with the specified IDs.

```
aws codebuild batch-get-builds --ids codebuild-demo-project:e9c4f4df-3f43-41d2-ab3a-60fe2EXAMPLE codebuild-demo-project:815e755f-bade-4a7e-80f0-efe51EXAMPLE
```

Output:

```

`batch-get-projects`

The following code example shows how to use `batch-get-projects`.

Amazon CLI

To get a list of Amazon CodeBuild build project names.

The following `batch-get-projects` example gets a list of CodeBuild build projects specified by name.

```
aws codebuild batch-get-projects --names codebuild-demo-project codebuild-demo-project2 my-other-demo-project
```

In the following output, the `projectsNotFound` array lists any build project names that were specified, but not found. The `projects` array lists details for each build project where information was found.

```
{
    "projectsNotFound": [],
    "projects": [
        {
            "encryptionKey": "arn:aws:kms:us-west-2:123456789012:alias/aws/s3",
            "name": "codebuild-demo-project2",
            "queuedTimeoutInMinutes": 480,
            "timeoutInMinutes": 60,
            "source": {

`batch-get-report-groups`

The following code example shows how to use `batch-get-report-groups`.

Amazon CLI

To get information about one or more report groups in Amazon CodeBuild.

The following `batch-get-report-groups` example retrieves information about the report group with the specified ARN.

```
aws codebuild batch-get-report-groups \
    --report-group-arns arn:aws:codebuild:<region-ID>:<user-ID>:report-group/
<report-group-name>
```

Output:

```
{
    "reportGroups": [
        {
            "arn": "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/<report-
group-name>",
            "name": "report-group-name",
            "type": "TEST",
            "exportConfig": {
                "exportConfigType": "NO_EXPORT"
            },

`create-project`

The following code example shows how to use `create-project`.

Amazon CLI

Example 1: To create an Amazon CodeBuild build project

The following `create-project` example creates a CodeBuild build project using source files from an S3 bucket

```
aws codebuild create-project \
    --name "my-demo-project" \
    --source "{\"type\": \"S3\",\"location\": \"codebuild-us-west-2-123456789012-
input-bucket/my-source.zip\"}" \
    --artifacts {"\"type\": \"S3\",\"location\": \"codebuild-us-west-2-123456789012-
output-bucket\""} \
    --environment "{\"type\": \"LINUX_CONTAINER\",\"image\": \"aws/codebuild/
standard:1.0\",\"computeType\": \"BUILD_GENERAL1_SMALL\"}" \
    --service-role "arn:aws:iam::123456789012:role/service-role/my-codebuild-
service-role"
```

Output:

```
{
    "project": {
        "arn": "arn:aws:codebuild:us-west-2:123456789012:project/my-demo-project",
        "name": "my-cli-demo-project",
        "encryptionKey": "arn:aws:kms:us-west-2:123456789012:alias/aws/s3",
        "serviceRole": "arn:aws:iam::123456789012:role/service-role/my-codebuild-
service-role",
        "lastModified": 1556839783.274,
        "badge": {
            "badgeEnabled": false
        },

}
```

Example 2: To create an Amazon CodeBuild build project using a JSON input file for the parameters

The following `create-project` example creates a CodeBuild build project by passing all of the required parameters in a JSON input file. Create the input file template by running the command with only the `--generate-cli-skeleton parameter`.

```
aws codebuild create-project --cli-input-json file://create-project.json
```

The input JSON file `create-project.json` contains the following content:

```
{
    "name": "codebuild-demo-project",
    "source": {
        "type": "S3",
        "location": "codebuild-region-ID-account-ID-input-bucket/MessageUtil.zip"
    },
    "artifacts": {
        "type": "S3",
        "location": "codebuild-region-ID-account-ID-output-bucket"
    },
    "environment": {
        "type": "LINUX_CONTAINER",
        "image": "aws/codebuild/standard:1.0",
        "computeType": "BUILD_GENERAL1_SMALL"
    },
    "serviceRole": "serviceIAMRole"
}
```

Output:

```
{
    "project": {
        "name": "codebuild-demo-project",
        "serviceRole": "serviceIAMRole",
        "tags": [],
        "artifacts": {
            "packaging": "NONE",
            "type": "S3",
            "location": "codebuild-region-ID-account-ID-output-bucket",
            "name": "message-util.zip"
```

```
        },
        "lastModified": 1472661575.244,
        "timeoutInMinutes": 60,
        "created": 1472661575.244,
        "environment": {
            "computeType": "BUILD_GENERAL1_SMALL",
            "image": "aws/codebuild/standard:1.0",
            "type": "LINUX_CONTAINER",
            "environmentVariables": []
        },
        "source": {
            "type": "S3",
            "location": "codebuild-region-ID-account-ID-input-bucket/
MessageUtil.zip"
        },
        "encryptionKey": "arn:aws:kms:region-ID:account-ID:alias/aws/s3",
        "arn": "arn:aws:codebuild:region-ID:account-ID:project/codebuild-demo-
project"
    }
}
```

For more information, see Create a Build Project (Amazon CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see CreateProject in *Amazon CLI Command Reference*.

`create-report-group`

The following code example shows how to use `create-report-group`.

Amazon CLI

To create a report group in Amazon CodeBuild.

The following `create-report-group` example creates a new report group.

```
aws codebuild create-report-group \
    --cli-input-json file://create-report-group-source.json
```

Contents of create-report-group-source.json:

```
{
```

```
    "name": "cli-created-report-group",
    "type": "TEST",
    "exportConfig": {
        "exportConfigType": "S3",
        "s3Destination": {
            "bucket": "amzn-s3-demo-bucket",
            "path": "",
            "packaging": "ZIP",
            "encryptionDisabled": true
        }
    }
}
```

Output:

```
{
    "reportGroup": {
        "arn": "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/cli-created-
report-group",
        "name": "cli-created-report-group",
        "type": "TEST",
        "exportConfig": {
            "exportConfigType": "S3",
            "s3Destination": {
                "bucket": "amzn-s3-demo-bucket",
                "path": "",
                "packaging": "ZIP",
                "encryptionDisabled": true
            }
        },
        "created": 1602020026.775,
        "lastModified": 1602020026.775
    }
}
```

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see CreateReportGroup in *Amazon CLI Command Reference*.

`create-webhook`

The following code example shows how to use `create-webhook`.

Amazon CLI

To create webhook filters for an Amazon CodeBuild project

The following `create-webhook` example creates a webhook for a CodeBuild project named `my-project` that has two filter groups. The first filter group specifies pull requests that are created, updated, or reopened on branches with Git reference names that match the regular expression `^refs/heads/master$` and head references that match `^refs/heads/myBranch$`. The second filter group specifies push requests on branches with Git reference names that do not match the regular expression `^refs/heads/myBranch$`.

```
aws codebuild create-webhook \
    --project-name my-project \
    --filter-groups "[[{\"type\":\"EVENT\",\"pattern\":\"PULL_REQUEST_CREATED,
 PULL_REQUEST_UPDATED, PULL_REQUEST_REOPENED\"},{\"type\":\"HEAD_REF\",\"pattern
\":\"^refs/heads/myBranch$\",\"excludeMatchedPattern\":true},{\"type\":\"BASE_REF
\",\"pattern\":\"^refs/heads/master$\",\"excludeMatchedPattern\":true}],[{\"type\":
\"EVENT\",\"pattern\":\"PUSH\"},{\"type\":\"HEAD_REF\",\"pattern\":\"^refs/heads/
myBranch$\",\"excludeMatchedPattern\":true}]]"
```

Output:

```
{
    "webhook": {
        "payloadUrl": "https://codebuild.us-west-2.amazonaws.com/webhooks?
t=eyJlbmNyeXB0ZWREYXRhIjoiVVl5MGtoeGRwSzZFRXl2Wnh4bld1Z0tKZ291TVpQNEtFamQ3RDlDYWpRaGIreVFrdm
        "url": "https://api.github.com/repos/iversonic/codedeploy-sample/
hooks/105190656",
        "lastModifiedSecret": 1556311319.069,
        "filterGroups": [
            [
                {
                    "type": "EVENT",
                    "pattern": "PULL_REQUEST_CREATED, PULL_REQUEST_UPDATED,
 PULL_REQUEST_REOPENED",
                    "excludeMatchedPattern": false
                },
                {
                    "type": "HEAD_REF",
                    "pattern": "refs/heads/myBranch$",
                    "excludeMatchedPattern": true
                },
```

```
                {
                    "type": "BASE_REF",
                    "pattern": "refs/heads/master$",
                    "excludeMatchedPattern": true
                }
            ],
            [
                {
                    "type": "EVENT",
                    "pattern": "PUSH",
                    "excludeMatchedPattern": false
                },
                {
                    "type": "HEAD_REF",
                    "pattern": "refs/heads/myBranch$",
                    "excludeMatchedPattern": true
                }
            ]
        ]
    }
}
```

For more information, see Filter GitHub Webhook Events (SDK) in the *Amazon CodeBuild User Guide*.

- For API details, see CreateWebhook in *Amazon CLI Command Reference*.

`delete-build-batch`

The following code example shows how to use `delete-build-batch`.

Amazon CLI

To delete a batch build in Amazon CodeBuild.

The following `delete-build-batch` example deletes the specified batch build.

```
aws codebuild delete-build-batch \
    --id <project-name>:<batch-ID>
```

Output:

```
{
```

```
    "statusCode": "BATCH_DELETED",
    "buildsDeleted": [
        "arn:aws:codebuild:<region-ID>:<account-ID>:build/<project-name>:<build-
ID>",
        "arn:aws:codebuild:<region-ID>:<account-ID>:build/<project-name>:<build-
ID>",
        "arn:aws:codebuild:<region-ID>:<account-ID>:build/<project-name>:<build-
ID>",
        "arn:aws:codebuild:<region-ID>:<account-ID>:build/<project-name>:<build-ID>"
    ],
    "buildsNotDeleted": []
}
```

For more information, see Batch builds in Amazon CodeBuild in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteBuildBatch in *Amazon CLI Command Reference*.

`delete-project`

The following code example shows how to use `delete-project`.

Amazon CLI

To delete an Amazon CodeBuild build project

The following `delete-project` example deletes the specified CodeBuild build project.

```
aws codebuild delete-project --name my-project
```

This command produces no output.

For more information, see Delete a Build Project (Amazon CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteProject in *Amazon CLI Command Reference*.

`delete-report-group`

The following code example shows how to use `delete-report-group`.

Amazon CLI

To delete a report groups in Amazon CodeBuild.

The following `delete-report-group` example deletes the report group with the specified ARN.

```
aws codebuild delete-report-group \
    --arn arn:aws:codebuild:<region-ID>:<user-ID>:report-group/<report-group-name>
```

This command produces no output.

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteReportGroup in *Amazon CLI Command Reference*.

`delete-report`

The following code example shows how to use `delete-report`.

Amazon CLI

To delete a report in Amazon CodeBuild.

The following `delete-report` example deletes the specified report.

```
aws codebuild delete-report \
    --arn arn:aws:codebuild:<region-ID>:<account-ID>:report/<report-group-
name>:<report-ID>
```

This command produces no output.

For more information, see Working with reports in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteReport in *Amazon CLI Command Reference*.

`delete-source-credentials`

The following code example shows how to use `delete-source-credentials`.

Amazon CLI

To disconnect from a source provider and remove its access tokens.

The following `delete-source-credentials` example disconnects from a source provider and removes its tokens. The ARN of source credentials used to connect to the source provider determines which source credentials.

```
aws codebuild delete-source-credentials --arn arn-of-your-credentials
```

Output:

```
{
    "arn": "arn:aws:codebuild:your-region:your-account-id:token/your-server-type"
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteSourceCredentials in *Amazon CLI Command Reference*.

`delete-webhook`

The following code example shows how to use `delete-webhook`.

Amazon CLI

To delete a webhook filter from an Amazon CodeBuild project

The following `delete-webhook` example deletes a webhook from the specified CodeBuild project.

```
aws codebuild delete-webhook --project-name my-project
```

This command produces no output.

For more information, see Stop Running Builds Automatically (Amazon CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see DeleteWebhook in *Amazon CLI Command Reference*.

`describe-code-coverages`

The following code example shows how to use `describe-code-coverages`.

Amazon CLI

To get detailed information about code coverage test results in Amazon CodeBuild.

The following `describe-code-coverages` example gets information about the code coverage test results in the specified report.

```
aws codebuild describe-code-coverages \
    --report-arn arn:aws:codebuild:<region-ID>:<account-ID>:report/<report-group-name>:<report-ID>
```

Output:

```
{
    "codeCoverages": [
        {
            "id": "20a0adcc-db13-4b66-804b-ecaf9f852855",
            "reportARN": "arn:aws:codebuild:<region-ID>:972506530580:report/<report-group-name>:<report-ID>",
            "filePath": "<source-file-1-path>",
            "lineCoveragePercentage": 83.33,
            "linesCovered": 5,
            "linesMissed": 1,
            "branchCoveragePercentage": 50.0,
            "branchesCovered": 1,
            "branchesMissed": 1,
            "expired": "2020-11-20T21:22:45+00:00"
        },
        {
            "id": "0887162d-bf57-4cf1-a164-e432373d1a83",
            "reportARN": "arn:aws:codebuild:<region-ID>:972506530580:report/<report-group-name>:<report-ID>",
            "filePath": "<source-file-2-path>",
            "lineCoveragePercentage": 90.9,
            "linesCovered": 10,
            "linesMissed": 1,
            "branchCoveragePercentage": 50.0,
            "branchesCovered": 1,
            "branchesMissed": 1,
            "expired": "2020-11-20T21:22:45+00:00"
        }
    ]
}
```

For more information, see Code coverage reports in the *Amazon CodeBuild User Guide*.

- For API details, see DescribeCodeCoverages in *Amazon CLI Command Reference*.

`describe-test-cases`

The following code example shows how to use `describe-test-cases`.

Amazon CLI

To get detailed information about test cases in Amazon CodeBuild.

The following `describe-test-cases` example gets information about the test cases in the specified report.

```
aws codebuild describe-test-cases \
    --report-arn arn:aws:codebuild:<region-ID>:<account-ID>:report/<report-group-name>:<report-ID>
```

Output:

```
{
    "testCases": [
        {
            "reportArn": "arn:aws:codebuild:<region-ID>:<account-ID>:report/<report-group-name>:<report-ID>",
            "testRawDataPath": "<test-report-path>",
            "prefix": "NUnit.Tests.Assemblies.MockTestFixture",
            "name": "NUnit.Tests.Assemblies.MockTestFixture.NotRunnableTest",
            "status": "ERROR",
            "durationInNanoSeconds": 0,
            "message": "No arguments were provided\n",
            "expired": "2020-11-20T17:52:10+00:00"
        },
        {
            "reportArn": "arn:aws:codebuild:<region-ID>:<account-ID>:report/<report-group-name>:<report-ID>",
            "testRawDataPath": "<test-report-path>",
            "prefix": "NUnit.Tests.Assemblies.MockTestFixture",
            "name": "NUnit.Tests.Assemblies.MockTestFixture.TestWithException",
            "status": "ERROR",
            "durationInNanoSeconds": 0,
```

```
            "message": "System.ApplicationException : Intentional Exception
\nat NUnit.Tests.Assemblies.MockTestFixture.MethodThrowsException()\nat
 NUnit.Tests.Assemblies.MockTestFixture.TestWithException()\n\n",
            "expired": "2020-11-20T17:52:10+00:00"
        }
    ]
}
```

For more information, see Working with test reporting in Amazon CodeBuild in the *Amazon CodeBuild User Guide*.

- For API details, see DescribeTestCases in *Amazon CLI Command Reference*.

`import-source-credentials`

The following code example shows how to use `import-source-credentials`.

Amazon CLI

Connect an Amazon CodeBuild user to a source provider by importing credentials for the source provider.

The following `import-source-credentials` example imports a token for a Bitbucket repository that uses BASIC_AUTH for its authentication type.

```
aws codebuild import-source-credentials --server-type BITBUCKET --auth-
type BASIC_AUTH --token my-Bitbucket-password --username my-Bitbucket-username
```

Output:

```
{
    "arn": "arn:aws:codebuild:us-west-2:123456789012:token/bitbucket"
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see ImportSourceCredentials in *Amazon CLI Command Reference*.

`invalidate-project-cache`

The following code example shows how to use `invalidate-project-cache`.

Amazon CLI

To reset the cache for an Amazon CodeBuild build project.

The following `invalidate-project-cache` example resets the cache for the specified CodeBuild project.

```
aws codebuild invalidate-project-cache --project-name my-project
```

This command produces no output.

For more information, see Build Caching in CodeBuild in the *Amazon CodeBuild User Guide*.

- For API details, see InvalidateProjectCache in *Amazon CLI Command Reference*.

`list-build-batches-for-project`

The following code example shows how to use `list-build-batches-for-project`.

Amazon CLI

To list batch builds for a specific build project in Amazon CodeBuild.

The following `list-build-batches-for-project` example lists the CodeBuild batch builds for the specified project.

```
aws codebuild list-build-batches-for-project \
    --project-name "<project-name>"
```

Output:

```
{
    "ids": [
        "<project-name>:<batch-ID>",
        "<project-name>:<batch-ID>"
    ]
}
```

For more information, see Batch builds in Amazon CodeBuild in the *Amazon CodeBuild User Guide*.

- For API details, see ListBuildBatchesForProject in *Amazon CLI Command Reference*.

`list-build-batches`

The following code example shows how to use `list-build-batches`.

Amazon CLI

To list batch builds in Amazon CodeBuild.

The following `list-build-batches` example lists the CodeBuild batch builds for the current account.

```
aws codebuild list-build-batches
```

Output:

```
{
    "ids": [
        "<project-name>:<batch-ID>",
        "<project-name>:<batch-ID>"
    ]
}
```

For more information, see Batch builds in Amazon CodeBuild <https://docs.aws.amazon.com/codebuild/latest/userguide/batch-build.html>)__ in the *Amazon CodeBuild User Guide*.

- For API details, see ListBuildBatches in *Amazon CLI Command Reference*.

`list-builds-for-project`

The following code example shows how to use `list-builds-for-project`.

Amazon CLI

To view a list of builds for an Amazon CodeBuild build project.

The following `list-builds-for-project` example lists the build IDs in descending order for the specified CodeBuild build project.

```
aws codebuild list-builds-for-project --project-name codebuild-demo-project --sort-order DESCENDING
```

Output:

```
{
    "ids": [
        "codebuild-demo-project:1a2b3c4d-5678-90ab-cdef-11111example",
        "codebuild-demo-project:1a2b3c4d-5678-90ab-cdef-22222example",
        "codebuild-demo-project:1a2b3c4d-5678-90ab-cdef-33333example",
        "codebuild-demo-project:1a2b3c4d-5678-90ab-cdef-44444example",
        "codebuild-demo-project:1a2b3c4d-5678-90ab-cdef-55555example"
    ]
}
```

For more information, see View a List of Build IDs for a Build Project (Amazon CLI) in the *Amazon CodeBuild User Guide*

- For API details, see ListBuildsForProject in *Amazon CLI Command Reference*.

`list-builds`

The following code example shows how to use `list-builds`.

Amazon CLI

To get a list of Amazon CodeBuild builds IDs.

The following `list-builds` example gets a list of CodeBuild IDs sorted in ascending order.

```
aws codebuild list-builds --sort-order ASCENDING
```

The output includes a `nextToken` value which indicates that there is more output available.

```
{
    "nextToken": "4AEA6u7J...The full token has been omitted for
 brevity...MzY2OA==",
    "ids": [
        "codebuild-demo-project:815e755f-bade-4a7e-80f0-efe51EXAMPLE"
        "codebuild-demo-project:84a7f3d1-d40e-4956-b4cf-7a9d4EXAMPLE"
            ... The full list of build IDs has been omitted for brevity ...
        "codebuild-demo-project:931d0b72-bf6f-4040-a472-5c707EXAMPLE"
    ]
}
```

Run this command again and provide the `nextToken` value in the previous response as a parameter to get the next part of the output. Repeat until you don't receive a `nextToken` value in the response.

```
aws codebuild list-builds --sort-order ASCENDING --next-
token 4AEA6u7J...The full token has been omitted for brevity...MzY2OA==
```

Next part of the output:

```
{
    "ids": [
        "codebuild-demo-project:49015049-21cf-4b50-9708-df115EXAMPLE",
        "codebuild-demo-project:543e7206-68a3-46d6-a4da-759abEXAMPLE",
            ... The full list of build IDs has been omitted for brevity ...
        "codebuild-demo-project:c282f198-4582-4b38-bdc0-26f96EXAMPLE"
    ]
}
```

For more information, see View a List of Build IDs (Amazon CLI) in the *Amazon CodeBuild User Guide*

- For API details, see ListBuilds in *Amazon CLI Command Reference*.

`list-curated-environment-images`

The following code example shows how to use `list-curated-environment-images`.

Amazon CLI

To get a list of Docker images managed by Amazon CodeBuild that you can use for your builds.

The following `list-curated-environment-images` example lists the Docker images managed by CodeBuild that can be used for builds.:

```
aws codebuild list-curated-environment-images
```

Output:

```
{
```

```
    "platforms": [
        {
            "platform": "AMAZON_LINUX",

            ]
        }
    ]
}
```

For more information, see Docker Images Provided by CodeBuild in the *Amazon CodeBuild User Guide*

- For API details, see ListCuratedEnvironmentImages in *Amazon CLI Command Reference*.

`list-projects`

The following code example shows how to use `list-projects`.

Amazon CLI

To get a list of Amazon CodeBuild build project names.

The following `list-projects` example gets a list of CodeBuild build projects sorted by name in ascending order.

```
aws codebuild list-projects --sort-by NAME --sort-order ASCENDING
```

The output includes a `nextToken` value which indicates that there is more output available.

```
{
    "nextToken": "Ci33ACF6...The full token has been omitted for brevity...U
+AkMx8=",
    "projects": [
        "codebuild-demo-project",
        "codebuild-demo-project2",
            ... The full list of build project names has been omitted for
 brevity ...
        "codebuild-demo-project99"
    ]
}
```

Run this command again and provide the `nextToken` value from the previous response as a parameter to get the next part of the output. Repeat until you don't receive a `nextToken` value in the response.

```
aws codebuild list-projects  --sort-by NAME --sort-order ASCENDING --next-
token Ci33ACF6...The full token has been omitted for brevity...U+AkMx8=

{
    "projects": [
        "codebuild-demo-project100",
        "codebuild-demo-project101",

  ... The full list of build project names has been omitted for brevity ...
        "codebuild-demo-project122"

  ]
}
```

For more information, see View a List of Build Project Names (Amazon CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see ListProjects in *Amazon CLI Command Reference*.

`list-report-groups`

The following code example shows how to use `list-report-groups`.

Amazon CLI

To get a list of the report group ARNs in Amazon CodeBuild.

The following `list-report-groups` example retrieves the report group ARNs for the account in the region.

```
aws codebuild list-report-groups
```

Output:

```
{
    "reportGroups": [
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-1",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-2",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-3"
    ]
}
```

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see ListReportGroups in *Amazon CLI Command Reference*.

`list-reports-for-report-group`

The following code example shows how to use `list-reports-for-report-group`.

Amazon CLI

To get a list of the reports in a report group in Amazon CodeBuild.

The following `list-report-for-report-groups` example retrieves the reports in the specified report group for the account in the region.

```
aws codebuild list-reports-for-report-group \
    --report-group-arn arn:aws:codebuild:<region-ID>:<user-ID>:report-group/<report-group-name>
```

Output:

```
{
    "reports": [
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/report-1",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/report-2",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/report-3"
    ]
}
```

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see ListReportsForReportGroup in *Amazon CLI Command Reference*.

`list-reports`

The following code example shows how to use `list-reports`.

Amazon CLI

To get a list of the reports for the current account in Amazon CodeBuild.

The following `list-reports` example retrieves the ARNs of the reports for the current account.

```
aws codebuild list-reports
```

Output:

```
{
    "reports": [
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/<report-group-name>:<report
 ID>",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/<report-group-name>:<report
 ID>",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report/<report-group-name>:<report
 ID>"
    ]
}
```

For more information, see Working with reports in the *Amazon CodeBuild User Guide*.

- For API details, see ListReports in *Amazon CLI Command Reference*.

`list-shared-projects`

The following code example shows how to use `list-shared-projects`.

Amazon CLI

To list the shared project in Amazon CodeBuild.

The following `list-shared-projects` example lists the CodeBuild shared projects that are available to the current account.

```
aws codebuild list-shared-projects
```

Output:

```
{
    "projects": [
        "arn:aws:codebuild:<region-ID>:<account-ID>:project/<shared-project-
name-1>",
        "arn:aws:codebuild:<region-ID>:<account-ID>:project/<shared-project-name-2>"
    ]
}
```

For more information, see Working with shared projects in the *Amazon CodeBuild User Guide*.

- For API details, see ListSharedProjects in *Amazon CLI Command Reference*.

`list-shared-report-groups`

The following code example shows how to use `list-shared-report-groups`.

Amazon CLI

To get a list of the shared report group ARNs in Amazon CodeBuild.

The following `list-shared-report-groups` example retrieves the report group ARNs for the account in the region.

```
aws codebuild list-shared-report-groups
```

Output:

```
{
    "reportGroups": [
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-1",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-2",
        "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/report-group-3"
    ]
}
```

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see ListSharedReportGroups in *Amazon CLI Command Reference*.

`list-source-credentials`

The following code example shows how to use `list-source-credentials`.

Amazon CLI

To view a list of sourceCredentialsObjects

The following `list-source-credentials` example lists tokens for an Amazon account connected to one Bitbucket account and one GitHub account. Each `sourceCredentialsInfos` object in the response contains connected source credentials information.

```
aws codebuild list-source-credentials
```

Output:

```
{
    "sourceCredentialsInfos": [
        {
            "serverType": "BITBUCKET",
            "arn": "arn:aws:codebuild:us-west-2:123456789012:token/bitbucket",
            "authType": "BASIC_AUTH"
        },
        {
            "serverType": "GITHUB",
            "arn": "arn:aws:codebuild:us-west-2:123456789012:token/github",
            "authType": "OAUTH"
        }
    ]
```

```
}
```

For more information, see Connect Source Providers with Access Tokens (CLI) in the *Amazon CodeBuild User Guide*.

- For API details, see ListSourceCredentials in *Amazon CLI Command Reference*.

`retry-build-batch`

The following code example shows how to use `retry-build-batch`.

Amazon CLI

To retry a failed batch build in Amazon CodeBuild.

The following `retry-build-batch` example restarts the specified batch build.

```
aws codebuild retry-build-batch \
    --id <project-name>:<batch-ID>
```

Output:

```
{
    "buildBatch": {
        "id": "<project-name>:<batch-ID>",
        "arn": "arn:aws:codebuild:<region-ID>:<account-ID>:build-batch/<project-
name>:<batch-ID>",

`start-build-batch`

The following code example shows how to use `start-build-batch`.

Amazon CLI

To start a batch build in Amazon CodeBuild.

The following `start-build-batch` example starts a batch build of the specified project.

```
aws codebuild start-build-batch \
    --project-name <project-name>
```

Output:

```
{
    "buildBatch": {
        "id": "<project-name>:<batch-ID>",
        "arn": "arn:aws:codebuild:<region-ID>:<account-ID>:build-batch/<project-
name>:<batch-ID>",
        "startTime": "2020-10-21T16:54:24.740000+00:00",
        "currentPhase": "SUBMITTED",

`start-build`

The following code example shows how to use `start-build`.

Amazon CLI

To start running a build of an Amazon CodeBuild build project.

The following `start-build` example starts a build for the specified CodeBuild project. The build overrides both the project's setting for the number of minutes the build is allowed to be queued before it times out and the project's artifact settings.

```
aws codebuild start-build \
    --project-name "my-demo-project" \
    --queued-timeout-in-minutes-override 5 \
    --artifacts-override {"\"type\": \"S3\",\"location\": \"arn:aws:s3:::artifacts-
override\",\"overrideArtifactName\":true"}
```

Output:

```
{
    "build": {
        "serviceRole": "arn:aws:iam::123456789012:role/service-role/my-codebuild-
service-role",
        "buildStatus": "IN_PROGRESS",
        "buildComplete": false,
        "projectName": "my-demo-project",
        "timeoutInMinutes": 60,
        "source": {
            "insecureSsl": false,
            "type": "S3",
            "location": "codebuild-us-west-2-123456789012-input-bucket/my-
source.zip"
        },
```

```

`update-project`

The following code example shows how to use `update-project`.

Amazon CLI

To change an Amazon CodeBuild build project's settings.

The following `update-project` example changes the settings of the specified CodeBuild build project named my-demo-project.

```
aws codebuild update-project --name "my-demo-project" \
    --description "This project is updated" \
    --source "{\"type\": \"S3\",\"location\": \"codebuild-us-west-2-123456789012-
input-bucket/my-source-2.zip\"}" \
    --artifacts {"\"type\": \"S3\",\"location\": \"codebuild-us-west-2-123456789012-
output-bucket-2\""} \
    --environment "{\"type\": \"LINUX_CONTAINER\",\"image\": \"aws/codebuild/
standard:1.0\",\"computeType\": \"BUILD_GENERAL1_MEDIUM\"}" \
    --service-role "arn:aws:iam::123456789012:role/service-role/my-codebuild-
service-role"
```

The output displays the updated settings.

```
{
    "project": {
        "arn": "arn:aws:codebuild:us-west-2:123456789012:project/my-demo-project",
        "environment": {
            "privilegedMode": false,
            "environmentVariables": [],
            "type": "LINUX_CONTAINER",
```

```
            "image": "aws/codebuild/standard:1.0",
            "computeType": "BUILD_GENERAL1_MEDIUM",
            "imagePullCredentialsType": "CODEBUILD"
        },
        "queuedTimeoutInMinutes": 480,
        "description": "This project is updated",
        "artifacts": {
            "packaging": "NONE",
            "name": "my-demo-project",
            "type": "S3",
            "namespaceType": "NONE",
            "encryptionDisabled": false,
            "location": "codebuild-us-west-2-123456789012-output-bucket-2"
        },
        "encryptionKey": "arn:aws:kms:us-west-2:123456789012:alias/aws/s3",

source-2.zip"
        }
    }
}
```

For more information, see Change a Build Project's Settings (Amazon CLI) in the *Amazon CodeBuild User Guide*

- For API details, see UpdateProject in *Amazon CLI Command Reference*.

update-report-group

The following code example shows how to use update-report-group.

Amazon CLI

To update a report group in Amazon CodeBuild.

The following update-report-group example changes the export type of the report group to "NO_EXPORT".

```
aws codebuild update-report-group \
    --arn arn:aws:codebuild:<region-ID>:<user-ID>:report-group/cli-created-report-group \
    --export-config="exportConfigType=NO_EXPORT"
```

Output:

```
{
    "reportGroup": {
        "arn": "arn:aws:codebuild:<region-ID>:<user-ID>:report-group/cli-created-report-group",
        "name": "cli-created-report-group",
        "type": "TEST",
        "exportConfig": {
            "exportConfigType": "NO_EXPORT"
        },
        "created": 1602020686.009,
        "lastModified": 1602021033.454,
        "tags": []
    }
}
```

For more information, see Working with report groups in the *Amazon CodeBuild User Guide*.

- For API details, see UpdateReportGroup in *Amazon CLI Command Reference*.

update-webhook

The following code example shows how to use update-webhook.

Amazon CLI

To update the webhook for an Amazon CodeBuild project

The following `update-webhook` example updates a webhook for the specified CodeBuild project with two filter groups. The `--rotate-secret` parameter specifies that GitHub rotate the project's secret key every time a code change triggers a build. The first filter group specifies pull requests that are created, updated, or reopened on branches with Git reference names that match the regular expression `^refs/heads/master$` and head references that match `^refs/heads/myBranch$`. The second filter group specifies push requests on branches with Git reference names that do not match the regular expression `^refs/heads/myBranch$`.

```
aws codebuild update-webhook \
    --project-name Project2 \
    --rotate-secret \
    --filter-groups "[[{\"type\":\"EVENT\",\"pattern\":\"PULL_REQUEST_CREATED,
 PULL_REQUEST_UPDATED, PULL_REQUEST_REOPENED\"},{\"type\":\"HEAD_REF\",\"pattern
\":\"^refs/heads/myBranch$\",\"excludeMatchedPattern\":true},{\"type\":\"BASE_REF
\",\"pattern\":\"^refs/heads/master$\",\"excludeMatchedPattern\":true}],[{\"type\":
\"EVENT\",\"pattern\":\"PUSH\"},{\"type\":\"HEAD_REF\",\"pattern\":\"^refs/heads/
myBranch$\",\"excludeMatchedPattern\":true}]]"
```

Output:

```
{
    "webhook": {
        "filterGroups": [
            [
                {
                    "pattern": "PULL_REQUEST_CREATED, PULL_REQUEST_UPDATED,
 PULL_REQUEST_REOPENED",
                    "type": "EVENT"
                },
                {
                    "excludeMatchedPattern": true,
                    "pattern": "refs/heads/myBranch$",
                    "type": "HEAD_REF"
                },
                {
                    "excludeMatchedPattern": true,
                    "pattern": "refs/heads/master$",
                    "type": "BASE_REF"
```

```
                }
            ],
            [
                {
                    "pattern": "PUSH",
                    "type": "EVENT"
                },
                {
                    "excludeMatchedPattern": true,
                    "pattern": "refs/heads/myBranch$",
                    "type": "HEAD_REF"
                }
            ]
        ],
        "lastModifiedSecret": 1556312220.133
    }
}
```

For more information, see Change a Build Project's Settings (Amazon CLI) in the *Amazon CodeBuild User Guide*

- For API details, see UpdateWebhook in *Amazon CLI Command Reference*.

CodeCommit examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeCommit.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-approval-rule-template-with-repository`

The following code example shows how to use `associate-approval-rule-template-with-repository`.

Amazon CLI

To associate an approval rule template with a repository

The following `associate-approval-rule-template-with-repository` example associates the specified approval rule template with a repository named `MyDemoRepo`.

```
aws codecommit associate-approval-rule-template-with-repository \
    --repository-name MyDemoRepo  \
    --approval-rule-template-name 2-approver-rule-for-main
```

This command produces no output.

For more information, see Associate an Approval Rule Template with a Repository in the *Amazon CodeCommit User Guide*.

- For API details, see AssociateApprovalRuleTemplateWithRepository in *Amazon CLI Command Reference*.

`batch-associate-approval-rule-template-with-repositories`

The following code example shows how to use `batch-associate-approval-rule-template-with-repositories`.

Amazon CLI

To associate an approval rule template with multiple repositories in a single operation

The following `batch-associate-approval-rule-template-with-repositories` example associates the specified approval rule template with repositories named `MyDemoRepo` and `MyOtherDemoRepo`.

Note: Approval rule templates are specific to the Amazon Region where they are created. They can only be associated with repositories in that Amazon Region.

```
aws codecommit batch-associate-approval-rule-template-with-repositories \
    --repository-names MyDemoRepo, MyOtherDemoRepo  \
    --approval-rule-template-name 2-approver-rule-for-main
```

Output:

```
{
    "associatedRepositoryNames": [
        "MyDemoRepo",
        "MyOtherDemoRepo"
    ],
    "errors": []
}
```

For more information, see Associate an Approval Rule Template with a Repository in the *Amazon CodeCommit User Guide*.

- For API details, see BatchAssociateApprovalRuleTemplateWithRepositories in *Amazon CLI Command Reference*.

`batch-describe-merge-conflicts`

The following code example shows how to use `batch-describe-merge-conflicts`.

Amazon CLI

To get information about merge conflicts in all files or a subset of files in a merge between two commit specifiers

The following `batch-describe-merge-conflicts` example determines the merge conflicts for merging a source branch named `feature-randomizationfeature` with a destination branch named `main` using the `THREE_WAY_MERGE` strategy in a repository named `MyDemoRepo`.

```
aws codecommit batch-describe-merge-conflicts \
    --source-commit-specifier feature-randomizationfeature \
    --destination-commit-specifier main \
    --merge-option THREE_WAY_MERGE \
    --repository-name MyDemoRepo
```

Output:

```
{
    "conflicts": [
        {
            "conflictMetadata": {
                "filePath": "readme.md",
                "fileSizes": {
                    "source": 139,
                    "destination": 230,
                    "base": 85
                },
                "fileModes": {
                    "source": "NORMAL",
                    "destination": "NORMAL",
                    "base": "NORMAL"
                },
                "objectTypes": {
                    "source": "FILE",
                    "destination": "FILE",
                    "base": "FILE"
                },
                "numberOfConflicts": 1,
                "isBinaryFile": {
                    "source": false,
                    "destination": false,
                    "base": false
                },
                "contentConflict": true,
                "fileModeConflict": false,
                "objectTypeConflict": false,

                    "source": "M",
                    "destination": "M"
                }
            },
            "mergeHunks": [
                {
                    "isConflict": true,
                    "source": {
                        "startLine": 0,
                        "endLine": 3,
                        "hunkContent": "VGhpcyBpEXAMPLE=="
                    },
```

```
                    "destination": {
                        "startLine": 0,
                        "endLine": 1,
                        "hunkContent": "VXNlIHRoEXAMPLE="
                    }
                }
            ]
        }
    ],
    "errors": [],
    "destinationCommitId": "86958e0aEXAMPLE",
    "sourceCommitId": "6ccd57fdEXAMPLE",
    "baseCommitId": "767b6958EXAMPLE"
}
```

For more information, see Resolve Conflicts in a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see BatchDescribeMergeConflicts in *Amazon CLI Command Reference*.

`batch-disassociate-approval-rule-template-from-repositories`

The following code example shows how to use `batch-disassociate-approval-rule-template-from-repositories`.

Amazon CLI

To disassociate an approval rule template from multiple repositories in a single operation

The following `batch-disassociate-approval-rule-template-from-repositories` example disassociates the specified approval rule template from repositories named `MyDemoRepo` and `MyOtherDemoRepo`.

```
aws codecommit batch-disassociate-approval-rule-template-from-repositories \
    --repository-names MyDemoRepo, MyOtherDemoRepo  \
    --approval-rule-template-name 1-approval-rule-for-all pull requests
```

Output:

```
{
    "disassociatedRepositoryNames": [
        "MyDemoRepo",
```

```
        "MyOtherDemoRepo"
    ],
    "errors": []
}
```

For more information, see Disassociate an Approval Rule Template in the *Amazon CodeCommit User Guide*.

- For API details, see BatchDisassociateApprovalRuleTemplateFromRepositories in *Amazon CLI Command Reference*.

`batch-get-commits`

The following code example shows how to use `batch-get-commits`.

Amazon CLI

To view information about multiple commits

The following `batch-get-commits` example displays details about the specified commits.

```
aws codecommit batch-get-commits  \
    --repository-name MyDemoRepo  \
    --commit-ids 317f8570EXAMPLE 4c925148EXAMPLE
```

Output:

```
{
    "commits": [
      {
        "additionalData": "",
        "committer": {
            "date": "1508280564 -0800",
            "name": "Mary Major",
            "email": "mary_major@example.com"
        },
        "author": {
            "date": "1508280564 -0800",
            "name": "Mary Major",
            "email": "mary_major@example.com"
        },
        "commitId": "317f8570EXAMPLE",
```

```
        "treeId": "1f330709EXAMPLE",
        "parents": [
            "6e147360EXAMPLE"
        ],
        "message": "Change variable name and add new response element"
    },
    {
        "additionalData": "",
        "committer": {
            "date": "1508280542 -0800",

        },
        "author": {
            "date": "1508280542 -0800",
            "name": "Li Juan",
            "email": "li_juan@example.com"
        },
        "commitId": "4c925148EXAMPLE",
        "treeId": "1f330709EXAMPLE",
        "parents": [
            "317f8570EXAMPLE"
        ],
        "message": "Added new class"
    }
}
```

For more information, see View Commit Details in the *Amazon CodeCommit User Guide*.

- For API details, see BatchGetCommits in *Amazon CLI Command Reference*.

`batch-get-repositories`

The following code example shows how to use `batch-get-repositories`.

Amazon CLI

To view details about multiple repositories

This example shows details about multiple Amazon CodeCommit repositories.

```
aws codecommit batch-get-repositories \
    --repository-names MyDemoRepo MyOtherDemoRepo
```

Output:

```
{
    "repositoriesNotFound": [],
    "repositories": [
         {
            "creationDate": 1429203623.625,
            "defaultBranch": "main",
            "repositoryName": "MyDemoRepo",
            "cloneUrlSsh": "ssh://git-codecommit.us-east-2.amazonaws.com/v1/repos/
MyDemoRepo",

            "Arn": "arn:aws:codecommit:us-east-2:111111111111:MyOtherDemoRepo"
            "accountId": "111111111111"
        }
    ],
    "repositoriesNotFound": []
}
```

- For API details, see BatchGetRepositories in *Amazon CLI Command Reference*.

`create-approval-rule-template`

The following code example shows how to use `create-approval-rule-template`.

Amazon CLI

To create an approval rule template

The following `create-approval-rule-template` example creates an approval rule template named `2-approver-rule-for-main ``. The template requires two users who assume the role of ``CodeCommitReview` to approve any pull request before it can be merged to the `main` branch.

```
aws codecommit create-approval-rule-template \
    --approval-rule-template-name 2-approver-rule-for-main \
    --approval-rule-template-description  "Requires two developers from the team to
 approve the pull request if the destination branch is main" \
    --approval-rule-template-content "{\"Version\": \"2018-11-08\",
\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type
\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}"
```

Output:

```
{
    "approvalRuleTemplate": {
        "approvalRuleTemplateName": "2-approver-rule-for-main",
        "creationDate": 1571356106.936,
        "approvalRuleTemplateId": "dd8b17fe-EXAMPLE",
        "approvalRuleTemplateContent": "{\"Version\": \"2018-11-08\",
\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type
\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
        "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
        "approvalRuleTemplateDescription": "Requires two developers from the team to
 approve the pull request if the destination branch is main",
        "lastModifiedDate": 1571356106.936,
        "ruleContentSha256": "4711b576EXAMPLE"
    }
}
```

For more information, see Create an Approval Rule Template in the *Amazon CodeCommit User Guide*.

- For API details, see CreateApprovalRuleTemplate in *Amazon CLI Command Reference*.

`create-branch`

The following code example shows how to use `create-branch`.

Amazon CLI

To create a branch

This example creates a branch in an Amazon CodeCommit repository. This command produces output only if there are errors.

Command:

```
aws codecommit create-branch --repository-name MyDemoRepo --branch-name MyNewBranch
 --commit-id 317f8570EXAMPLE
```

Output:

```
None.
```

- For API details, see CreateBranch in *Amazon CLI Command Reference*.

`create-commit`

The following code example shows how to use `create-commit`.

Amazon CLI

To create a commit

The following `create-commit` example demonstrates how to create an initial commit for a repository that adds a `readme.md` file to a repository named MyDemoRepo in the `main` branch.

```
aws codecommit create-commit \
    --repository-name MyDemoRepo \
    --branch-name main \
    --put-files "filePath=readme.md,fileContent='Welcome to our team repository.'"
```

Output:

```
{
```

```
    "filesAdded": [
        {
            "blobId": "5e1c309d-EXAMPLE",
            "absolutePath": "readme.md",
            "fileMode": "NORMAL"
        }
    ],
    "commitId": "4df8b524-EXAMPLE",
    "treeId": "55b57003-EXAMPLE",
    "filesDeleted": [],
    "filesUpdated": []
}
```

For more information, see Create a Commit in Amazon CodeCommit in the *Amazon CodeCommit User Guide*.

- For API details, see CreateCommit in *Amazon CLI Command Reference*.

`create-pull-request-approval-rule`

The following code example shows how to use `create-pull-request-approval-rule`.

Amazon CLI

To create an approval rule for a pull request

The following `create-pull-request-approval-rule` example creates an approval rule named `Require two approved approvers` for the specified pull request. The rule specifies that two approvals are required from an approval pool. The pool includes all users who access CodeCommit by assuming the role of `CodeCommitReview` in the `123456789012` Amazon account. It also includes either an IAM user or federated user named `Nikhil_Jayashankar` from the same Amazon account.

```
aws codecommit create-pull-request-approval-rule  \
    --approval-rule-name "Require two approved approvers"  \
    --approval-rule-content "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers
\": [\"CodeCommitApprovers:123456789012:Nikhil_Jayashankar\",
 \"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}"
```

Output:

```
{
    "approvalRule": {
        "approvalRuleName": "Require two approved approvers",
        "lastModifiedDate": 1570752871.932,
        "ruleContentSha256": "7c44e6ebEXAMPLE",
        "creationDate": 1570752871.932,
        "approvalRuleId": "aac33506-EXAMPLE",
        "approvalRuleContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers
\": [\"CodeCommitApprovers:123456789012:Nikhil_Jayashankar\",
 \"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
        "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major"
    }
}
```

For more information, see Create an Approval Rule in the *Amazon CodeCommit User Guide*.

- For API details, see CreatePullRequestApprovalRule in *Amazon CLI Command Reference*.

`create-pull-request`

The following code example shows how to use `create-pull-request`.

Amazon CLI

To create a pull request

The following `create-pull-request` example creates a pull request named 'Pronunciation difficulty analyzer' with a description of 'Please review these changes by Tuesday' that targets the 'jane-branch' source branch and is to be merged to the default branch 'main' in an Amazon CodeCommit repository named 'MyDemoRepo'.

```
aws codecommit create-pull-request \
    --title "My Pull Request" \
    --description "Please review these changes by Tuesday" \
    --client-request-token 123Example \
    --targets repositoryName=MyDemoRepo,sourceReference=MyNewBranch
```

Output:

```
{
```

```
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",
\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type
\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approver-rule-for-main",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "originApprovalRuleTemplate": {
                    "approvalRuleTemplateId": "dd3d22fe-EXAMPLE",
                    "approvalRuleTemplateName": "2-approver-rule-for-main"
                },
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
        "authorArn": "arn:aws:iam::111111111111:user/Jane_Doe",
        "description": "Please review these changes by Tuesday",
        "title": "Pronunciation difficulty analyzer",
        "pullRequestTargets": [
            {
                "destinationCommit": "5d036259EXAMPLE",
                "destinationReference": "refs/heads/main",
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "317f8570EXAMPLE",
                "sourceReference": "refs/heads/jane-branch",
                "mergeMetadata": {
                    "isMerged": false
                }
            }
        ],
        "lastActivityDate": 1508962823.285,
        "pullRequestId": "42",
        "clientRequestToken": "123Example",
        "pullRequestStatus": "OPEN",
        "creationDate": 1508962823.285
    }
}
```

- For API details, see CreatePullRequest in *Amazon CLI Command Reference*.

`create-repository`

The following code example shows how to use `create-repository`.

Amazon CLI

To create a repository

This example creates a repository and associates it with the user's Amazon account.

Command:

```
aws codecommit create-repository --repository-name MyDemoRepo --repository-
description "My demonstration repository"
```

Output:

```
{
    "repositoryMetadata": {
        "repositoryName": "MyDemoRepo",
                "cloneUrlSsh": "ssh://git-codecommit.us-east-1.amazonaws.com/v1/
repos/MyDemoRepo",
                "lastModifiedDate": 1444766838.027,
        "repositoryDescription": "My demonstration repository",
                "cloneUrlHttp": "https://git-codecommit.us-east-1.amazonaws.com/v1/
repos/MyDemoRepo",
        "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE",
                "Arn": "arn:aws:codecommit:us-
east-1:111111111111EXAMPLE:MyDemoRepo",
        "accountId": "111111111111"
    }
}
```

- For API details, see CreateRepository in *Amazon CLI Command Reference*.

`create-unreferenced-merge-commit`

The following code example shows how to use `create-unreferenced-merge-commit`.

Amazon CLI

To create an unreferenced commit that represents the result of merging two commit specifiers

The following `create-unreferenced-merge-commit` example creates a commit that represents the results of a merge between a source branch named `bugfix-1234` with a destination branch named `main` using the THREE_WAY_MERGE strategy in a repository named `MyDemoRepo`.

```
aws codecommit create-unreferenced-merge-commit \
    --source-commit-specifier bugfix-1234 \
    --destination-commit-specifier main \
    --merge-option THREE_WAY_MERGE \
    --repository-name MyDemoRepo \
    --name "Maria Garcia" \
    --email "maria_garcia@example.com" \
    --commit-message "Testing the results of this merge."
```

Output:

```
{
    "commitId": "4f178133EXAMPLE",
    "treeId": "389765daEXAMPLE"
}
```

For more information, see Resolve Conflicts in a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see CreateUnreferencedMergeCommit in *Amazon CLI Command Reference*.

`credential-helper`

The following code example shows how to use `credential-helper`.

Amazon CLI

To set up the credential helper included in the Amazon CLI with Amazon CodeCommit

The `credential-helper` utility is not designed to be called directly from the Amazon CLI. Instead it is intended to be used as a parameter with the `git config` command to set up your local computer. It enables Git to use HTTPS and a cryptographically signed version of your IAM user credentials or Amazon EC2 instance role whenever Git needs to authenticate with Amazon to interact with CodeCommit repositories.

```
git config --global credential.helper '!aws codecommit credential-helper $@'
```

```
git config --global credential.UseHttpPath true
```

Output:

```
[credential]
    helper = !aws codecommit credential-helper $@
    UseHttpPath = true
```

For more information, see Setting up for Amazon CodeCommit Using Other Methods in the *Amazon CodeCommit User Guide*. Review the content carefully, and then follow the procedures in one of the following topics: For HTTPS Connections on Linux, macOS, or Unix or For HTTPS Connections on Windows in the *Amazon CodeCommit User Guide*.

- For API details, see CredentialHelper in *Amazon CLI Command Reference*.

`delete-approval-rule-template`

The following code example shows how to use `delete-approval-rule-template`.

Amazon CLI

To delete an approval rule template

The following `delete-approval-rule-template` example deletes the specified approval rule template.

```
aws codecommit delete-approval-rule-template  \
    --approval-rule-template-name 1-approver-for-all-pull-requests
```

Output:

```
{
    "approvalRuleTemplateId": "41de97b7-EXAMPLE"
}
```

For more information, see Delete an Approval Rule Template in the *Amazon CodeCommit User Guide*.

- For API details, see DeleteApprovalRuleTemplate in *Amazon CLI Command Reference*.

`delete-branch`

The following code example shows how to use `delete-branch`.

Amazon CLI

To delete a branch

This example shows how to delete a branch in an Amazon CodeCommit repository.

Command:

```
aws codecommit delete-branch --repository-name MyDemoRepo --branch-name MyNewBranch
```

Output:

```
{
  "branch": {
      "commitId": "317f8570EXAMPLE",
      "branchName": "MyNewBranch"
  }
}
```

- For API details, see DeleteBranch in *Amazon CLI Command Reference*.

`delete-comment-content`

The following code example shows how to use `delete-comment-content`.

Amazon CLI

To delete the content of a comment

You can only delete the content of a comment if you created the comment. This example demonstrates how to delete the content of a comment with the system-generated ID of `ff30b348EXAMPLEb9aa670f`.

```
aws codecommit delete-comment-content \
    --comment-id ff30b348EXAMPLEb9aa670f
```

Output:

```
{
    "comment": {
        "creationDate": 1508369768.142,
        "deleted": true,
        "lastModifiedDate": 1508369842.278,
        "clientRequestToken": "123Example",
        "commentId": "ff30b348EXAMPLEb9aa670f",
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "callerReactions": [],
        "reactionCounts":
        {
            "CLAP" : 1
        }
    }
}
```

- For API details, see DeleteCommentContent in *Amazon CLI Command Reference*.

`delete-file`

The following code example shows how to use `delete-file`.

Amazon CLI

To delete a file

The following `delete-file` example demonstrates how to delete a file named `README.md` from a branch named `main` with a most recent commit ID of `c5709475EXAMPLE` in a repository named `MyDemoRepo`.

```
aws codecommit delete-file \
    --repository-name MyDemoRepo \
    --branch-name main \
    --file-path README.md \
    --parent-commit-id c5709475EXAMPLE
```

Output:

```
{
    "blobId":"559b44fEXAMPLE",
    "commitId":"353cf655EXAMPLE",
```

```
    "filePath":"README.md",
    "treeId":"6bc824cEXAMPLE"
}
```

For more information, see Edit or Delete a File in Amazon CodeCommit in the *Amazon CodeCommit API Reference* guide.

- For API details, see DeleteFile in *Amazon CLI Command Reference*.

`delete-pull-request-approval-rule`

The following code example shows how to use `delete-pull-request-approval-rule`.

Amazon CLI

To delete an approval rule for a pull request

The following `delete-pull-request-approval-rule` example deletes the approval rule named `My Approval Rule` for the specified pull request.

```
aws codecommit delete-pull-request-approval-rule  \
    --approval-rule-name "My Approval Rule"  \
    --pull-request-id 15
```

Output:

```
{
    "approvalRuleId": "077d8e8a8-EXAMPLE"
}
```

For more information, see Edit or Delete an Approval Rule in the *Amazon CodeCommit User Guide*.

- For API details, see DeletePullRequestApprovalRule in *Amazon CLI Command Reference*.

`delete-repository`

The following code example shows how to use `delete-repository`.

Amazon CLI

To delete a repository

This example shows how to delete an Amazon CodeCommit repository.

Command:

```
aws codecommit delete-repository --repository-name MyDemoRepo
```

Output:

```
{
  "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE"
}
```

- For API details, see DeleteRepository in *Amazon CLI Command Reference*.

`describe-merge-conflicts`

The following code example shows how to use `describe-merge-conflicts`.

Amazon CLI

To get detailed information about merge conflicts

The following `describe-merge-conflicts` example determines the merge conflicts for a file named `readme.md` in the specified source branch and destination branch using the THREE_WAY_MERGE strategy.

```
aws codecommit describe-merge-conflicts \
    --source-commit-specifier feature-randomizationfeature \
    --destination-commit-specifier main \
    --merge-option THREE_WAY_MERGE \
    --file-path readme.md \
    --repository-name MyDemoRepo
```

Output:

```
{
    "conflictMetadata": {
        "filePath": "readme.md",
        "fileSizes": {
            "source": 139,
            "destination": 230,
            "base": 85
```

```
        },
        "fileModes": {
            "source": "NORMAL",
            "destination": "NORMAL",
            "base": "NORMAL"
        },
        "objectTypes": {
            "source": "FILE",
            "destination": "FILE",
            "base": "FILE"
        },
        "numberOfConflicts": 1,
        "isBinaryFile": {
            "source": false,
            "destination": false,
            "base": false
        },
        "contentConflict": true,
        "fileModeConflict": false,
        "objectTypeConflict": false,
        "mergeOperations": {
            "source": "M",
            "destination": "M"
        }
    },
    "mergeHunks": [
        {
            "isConflict": true,
            "source": {
                "startLine": 0,
                "endLine": 3,
                "hunkContent": "VGhpcyBpEXAMPLE="
            },
            "destination": {
                "startLine": 0,
                "endLine": 1,
                "hunkContent": "VXNlIHRoEXAMPLE="
            }
        }
    ],
    "destinationCommitId": "86958e0aEXAMPLE",
    "sourceCommitId": "6ccd57fdEXAMPLE",
    "baseCommitId": "767b69580EXAMPLE"
```

```
}
```

For more information, see Resolve Conflicts in a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see DescribeMergeConflicts in *Amazon CLI Command Reference*.

`describe-pull-request-events`

The following code example shows how to use `describe-pull-request-events`.

Amazon CLI

To view events in a pull request

The following `describe-pull-request-events` example retrieves the events for a pull request with the ID of '8'.

```
aws codecommit describe-pull-request-events --pull-request-id 8
```

Output:

```
{
    "pullRequestEvents": [
        {
            "pullRequestId": "8",
            "pullRequestEventType": "PULL_REQUEST_CREATED",
            "eventDate": 1510341779.53,
            "actor": "arn:aws:iam::111111111111:user/Zhang_Wei"
        },
        {
            "pullRequestStatusChangedEventMetadata": {
                "pullRequestStatus": "CLOSED"
            },
            "pullRequestId": "8",
            "pullRequestEventType": "PULL_REQUEST_STATUS_CHANGED",
            "eventDate": 1510341930.72,
            "actor": "arn:aws:iam::111111111111:user/Jane_Doe"
        }
    ]
}
```

- For API details, see DescribePullRequestEvents in *Amazon CLI Command Reference*.

`disassociate-approval-rule-template-from-repository`

The following code example shows how to use `disassociate-approval-rule-template-from-repository`.

Amazon CLI

To disassociate an approval rule template from a repository

The following `disassociate-approval-rule-template-from-repository` example disassociates the specified approval rule template from a repository named `MyDemoRepo`.

```
aws codecommit disassociate-approval-rule-template-from-repository \
    --repository-name MyDemoRepo  \
    --approval-rule-template-name 1-approver-rule-for-all-pull-requests
```

This command produces no output.

For more information, see Disassociate an Approval Rule Template in the *Amazon CodeCommit User Guide*.

- For API details, see DisassociateApprovalRuleTemplateFromRepository in *Amazon CLI Command Reference*.

`evaluate-pull-request-approval-rules`

The following code example shows how to use `evaluate-pull-request-approval-rules`.

Amazon CLI

To evaluate whether a pull request has all of its approval rules satisfied

The following `evaluate-pull-request-approval-rules` example evaluates the state of approval rules on the specified pull request. In this example, an approval rule has not been satisfied for the pull request, so the output of the command shows an `approved` value of `false`.

```
aws codecommit evaluate-pull-request-approval-rules \
```

```
    --pull-request-id 27  \
    --revision-id 9f29d167EXAMPLE
```

Output:

```
{
    "evaluation": {
        "approved": false,
        "approvalRulesNotSatisfied": [
            "Require two approved approvers"
        ],
        "overridden": false,
        "approvalRulesSatisfied": []
    }
}
```

For more information, see Merge a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see EvaluatePullRequestApprovalRules in *Amazon CLI Command Reference*.

`get-approval-rule-template`

The following code example shows how to use `get-approval-rule-template`.

Amazon CLI

To get the content of an approval rule template

The following `get-approval-rule-template` example gets the content of an approval rule template named `1-approver-rule-for-all-pull-requests`.

```
aws codecommit get-approval-rule-template \
    --approval-rule-template-name 1-approver-rule-for-all-pull-requests
```

Output:

```
{
    "approvalRuleTemplate": {
        "approvalRuleTemplateContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 1,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
```

```
        "ruleContentSha256": "621181bbEXAMPLE",
        "lastModifiedDate": 1571356106.936,
        "creationDate": 1571356106.936,
        "approvalRuleTemplateName": "1-approver-rule-for-all-pull-requests",
        "lastModifiedUser": "arn:aws:iam::123456789012:user/Li_Juan",
        "approvalRuleTemplateId": "a29abb15-EXAMPLE",
        "approvalRuleTemplateDescription": "All pull requests must be approved by
 one developer on the team."
    }
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see GetApprovalRuleTemplate in *Amazon CLI Command Reference*.

`get-blob`

The following code example shows how to use `get-blob`.

Amazon CLI

To view information about a Git blob object

The following `get-blob` example retrieves information about a Git blob with the ID of '2eb4af3bEXAMPLE' in an Amazon CodeCommit repository named 'MyDemoRepo'.

```
aws codecommit get-blob  --repository-name MyDemoRepo  --blob-id 2eb4af3bEXAMPLE
```

Output:

```
{
    "content": "QSBCaW5hcnkgTGFyToEXAMPLE="
}
```

- For API details, see GetBlob in *Amazon CLI Command Reference*.

`get-branch`

The following code example shows how to use `get-branch`.

Amazon CLI

To get information about a branch

This example gets information about a branch in an Amazon CodeCommit repository.

Command:

```
aws codecommit get-branch --repository-name MyDemoRepo --branch-name MyNewBranch
```

Output:

```
{
  "BranchInfo": {
        "commitID": "317f8570EXAMPLE",
                "branchName": "MyNewBranch"
  }
}
```

- For API details, see GetBranch in *Amazon CLI Command Reference*.

`get-comment-reactions`

The following code example shows how to use `get-comment-reactions`.

Amazon CLI

To view emoji reactions to a comment

The following `get-comment-reactions` example lists all emoji reactions to a comment with the ID of `abcd1234EXAMPLEb5678efgh`. If the font for your shell supports displaying Emoji Version 1.0, then in the output for `emoji` the emoji is displayed.

```
aws codecommit get-comment-reactions \
    --comment-id abcd1234EXAMPLEb5678efgh
```

Output:

```
{
    "reactionsForComment": {
        [
           {
```

```
                "reaction": {
                    "emoji:"??",
                    "shortCode": "thumbsup",
                    "unicode": "U+1F44D"
                },
                "users": [
                    "arn:aws:iam::123456789012:user/Li_Juan",
                    "arn:aws:iam::123456789012:user/Mary_Major",
                    "arn:aws:iam::123456789012:user/Jorge_Souza"
                ]
            },
            {
                "reaction": {
                    "emoji": "??",
                    "shortCode": "thumbsdown",
                    "unicode": "U+1F44E"
                },
                "users": [
                    "arn:aws:iam::123456789012:user/Nikhil_Jayashankar"
                ]
            },
            {
                "reaction": {
                    "emoji": "??",
                    "shortCode": "confused",
                    "unicode": "U+1F615"
                },
                "users": [
                    "arn:aws:iam::123456789012:user/Saanvi_Sarkar"
                ]
            }
        ]
    }
}
```

For more information, see Comment on a commit in Amazon CodeCommit in the *Amazon CodeCommit User Guide*.

- For API details, see GetCommentReactions in *Amazon CLI Command Reference*.

`get-comment`

The following code example shows how to use `get-comment`.

Amazon CLI

To view details of a comment

This example demonstrates how to view details of a comment with the system-generated comment ID of `ff30b348EXAMPLEb9aa670f`.

```
aws codecommit get-comment \
    --comment-id ff30b348EXAMPLEb9aa670f
```

Output:

```
{
    "comment": {
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "clientRequestToken": "123Example",
        "commentId": "ff30b348EXAMPLEb9aa670f",
        "content": "Whoops - I meant to add this comment to the line, but I don't
 see how to delete it.",
        "creationDate": 1508369768.142,
        "deleted": false,
        "commentId": "",
        "lastModifiedDate": 1508369842.278,
        "callerReactions": [],
        "reactionCounts":
        {
            "SMILE" : 6,
            "THUMBSUP" : 1
        }
    }
}
```

- For API details, see GetComment in *Amazon CLI Command Reference*.

`get-comments-for-compared-commit`

The following code example shows how to use `get-comments-for-compared-commit`.

Amazon CLI

To view comments on a commit

This example demonstrates how to view view comments made on the comparison between two commits in a repository named MyDemoRepo.

```
aws codecommit get-comments-for-compared-commit \
    --repository-name MyDemoRepo \
    --before-commit-ID 6e147360EXAMPLE \
    --after-commit-id 317f8570EXAMPLE
```

Output:

```
{
    "commentsForComparedCommitData": [
        {
            "afterBlobId": "1f330709EXAMPLE",
            "afterCommitId": "317f8570EXAMPLE",
            "beforeBlobId": "80906a4cEXAMPLE",
            "beforeCommitId": "6e147360EXAMPLE",
            "comments": [
                {
                    "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
                    "clientRequestToken": "123Example",
                    "commentId": "ff30b348EXAMPLEb9aa670f",
                    "content": "Whoops - I meant to add this comment to the line,
 not the file, but I don't see how to delete it.",
                    "creationDate": 1508369768.142,
                    "deleted": false,
                    "CommentId": "123abc-EXAMPLE",
                    "lastModifiedDate": 1508369842.278,
                    "callerReactions": [],
                    "reactionCounts":
                    {
                        "SMILE" : 6,
                        "THUMBSUP" : 1
                    }
                },
                {
                    "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
                    "clientRequestToken": "123Example",
                    "commentId": "553b509bEXAMPLE56198325",
                    "content": "Can you add a test case for this?",
                    "creationDate": 1508369612.240,
                    "deleted": false,
                    "commentId": "456def-EXAMPLE",
```

```
                    "lastModifiedDate": 1508369612.240,

                    "reactionCounts":
                    {
                        "THUMBSUP" : 2
                    }
                }
            ],
            "location": {
                "filePath": "cl_sample.js",
                "filePosition": 1232,
                "relativeFileVersion": "after"
            },
            "repositoryName": "MyDemoRepo"
        }
    ],
    "nextToken": "exampleToken"
}
```

- For API details, see GetCommentsForComparedCommit in *Amazon CLI Command Reference*.

`get-comments-for-pull-request`

The following code example shows how to use `get-comments-for-pull-request`.

Amazon CLI

To view comments for a pull request

This example demonstrates how to view comments for a pull request in a repository named MyDemoRepo.

```
aws codecommit get-comments-for-pull-request \
    --repository-name MyDemoRepo \
    --before-commit-ID 317f8570EXAMPLE \
    --after-commit-id 5d036259EXAMPLE
```

Output:

```
{
    "commentsForPullRequestData": [
        {
```

```
            "afterBlobId": "1f330709EXAMPLE",
            "afterCommitId": "5d036259EXAMPLE",
            "beforeBlobId": "80906a4cEXAMPLE",
            "beforeCommitId": "317f8570EXAMPLE",
            "comments": [
                {
                    "authorArn": "arn:aws:iam::111111111111:user/Saanvi_Sarkar",
                    "clientRequestToken": "",
                    "commentId": "abcd1234EXAMPLEb5678efgh",
                    "content": "These don't appear to be used anywhere. Can we
remove them?",
                    "creationDate": 1508369622.123,
                    "deleted": false,
                    "lastModifiedDate": 1508369622.123,
                    "callerReactions": [],
                    "reactionCounts":
                    {
                        "THUMBSUP" : 6,
                        "CONFUSED" : 1
                    }
                },
                {
                    "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
                    "clientRequestToken": "",
                    "commentId": "442b498bEXAMPLE5756813",
                    "content": "Good catch. I'll remove them.",

                    {
                        "THUMBSUP" : 14
                    }
                }
            ],
            "location": {
                "filePath": "ahs_count.py",
                "filePosition": 367,
                "relativeFileVersion": "AFTER"
            },
            "repositoryName": "MyDemoRepo",
            "pullRequestId": "42"
        }
```

```
    ],
    "nextToken": "exampleToken"
}
```

- For API details, see GetCommentsForPullRequest in *Amazon CLI Command Reference*.

`get-commit`

The following code example shows how to use `get-commit`.

Amazon CLI

To view information about a commit in a repository

This example shows details about a commit with the system-generated ID of '7e9fd3091thisisanexamplethisisanexample1' in an Amazon CodeCommit repository named 'MyDemoRepo'.

Command:

```
aws codecommit get-commit --repository-name MyDemoRepo --commit-
id 7e9fd3091thisisanexamplethisisanexample1
```

Output:

```
{
  "commit": {
      "additionalData": "",
      "committer": {
          "date": "1484167798 -0800",
          "name": "Mary Major",
          "email": "mary_major@example.com"
      },
      "author": {
          "date": "1484167798 -0800",
          "name": "Mary Major",
          "email": "mary_major@example.com"
      },
      "treeId": "347a3408thisisanexampletreeidexample",
      "parents": [
          "7aa87a031thisisanexamplethisisanexample1"
      ],
```

```
        "message": "Fix incorrect variable name"
    }
}
```

- For API details, see GetCommit in *Amazon CLI Command Reference*.

`get-differences`

The following code example shows how to use `get-differences`.

Amazon CLI

To get information about differences for a commit specifier in a repository

This example shows view metadata information about changes between two commit specifiers (branch, tag, HEAD, or other fully qualified references, such as commit IDs) in a renamed folder in Amazon CodeCommit repository named MyDemoRepo. The example includes several options that are not required, including --before-commit-specifier, --before-path, and --after-path, in order to more fully illustrate how you can use these options to limit the results. The response includes file mode permissions.

Command:

```
aws codecommit get-differences --repository-name MyDemoRepo --before-
commit-specifier 955bba12thisisanexamplethisisanexample --after-commit-
specifier 14a95463thisisanexamplethisisanexample --before-path tmp/example-folder --
after-path tmp/renamed-folder
```

Output:

```
{
  "differences": [
      {
          "afterBlob": {
              "path": "blob.txt",
              "blobId": "2eb4af3b1thisisanexamplethisisanexample1",
              "mode": "100644"
          },
          "changeType": "M",
          "beforeBlob": {
              "path": "blob.txt",
              "blobId": "bf7fcf281thisisanexamplethisisanexample1",
```

```
            "mode": "100644"
        }
    }
  ]
}
```

- For API details, see GetDifferences in *Amazon CLI Command Reference*.

`get-file`

The following code example shows how to use `get-file`.

Amazon CLI

To get the base-64 encoded contents of a file in an Amazon CodeCommit repository

The following `get-file` example demonstrates how to get the base-64 encoded contents of a file named `README.md` from a branch named `main` in a repository named `MyDemoRepo`.

```
aws codecommit get-file \
    --repository-name MyDemoRepo \
    --commit-specifier main \
    --file-path README.md
```

Output:

```
{
    "blobId":"559b44fEXAMPLE",
    "commitId":"c5709475EXAMPLE",
    "fileContent":"IyBQaHVzEXAMPLE",
    "filePath":"README.md",
    "fileMode":"NORMAL",
    "fileSize":1563
}
```

For more information, see GetFile in the *Amazon CodeCommit API Reference* guide.

- For API details, see GetFile in *Amazon CLI Command Reference*.

`get-folder`

The following code example shows how to use `get-folder`.

Amazon CLI

To get the contents of a folder in an Amazon CodeCommit repository

The following `get-folder` example demonstrates how to get the contents of a top-level folder from a repository named `MyDemoRepo`.

```
aws codecommit get-folder --repository-name MyDemoRepo --folder-path ""
```

Output:

```
{
    "commitId":"c5709475EXAMPLE",
    "files":[
        {
            "absolutePath":".gitignore",
            "blobId":"74094e8bEXAMPLE",
            "fileMode":"NORMAL",
            "relativePath":".gitignore"
        },
        {
            "absolutePath":"Gemfile",
            "blobId":"9ceb72f6EXAMPLE",
            "fileMode":"NORMAL",
            "relativePath":"Gemfile"
        },
        {
            "absolutePath":"Gemfile.lock",
            "blobId":"795c4a2aEXAMPLE",
            "fileMode":"NORMAL",
            "relativePath":"Gemfile.lock"
        },
        {
            "absolutePath":"LICENSE.txt",
            "blobId":"0c7932c8EXAMPLE",
            "fileMode":"NORMAL",
            "relativePath":"LICENSE.txt"
        },
        {
            "absolutePath":"README.md",
            "blobId":"559b44feEXAMPLE",
            "fileMode":"NORMAL",
            "relativePath":"README.md"
```

```
        }
    ],
    "folderPath":"",
    "subFolders":[
        {
            "absolutePath":"public",
            "relativePath":"public",
            "treeId":"d5e92ae3aEXAMPLE"
        },
        {
            "absolutePath":"tmp",
            "relativePath":"tmp",
            "treeId":"d564d0bcEXAMPLE"
        }
    ],
    "subModules":[],
    "symbolicLinks":[],
    "treeId":"7b3c4dadEXAMPLE"
}
```

For more information, see GetFolder in the *Amazon CodeCommit API Reference* guide.

- For API details, see GetFolder in *Amazon CLI Command Reference*.

`get-merge-commit`

The following code example shows how to use `get-merge-commit`.

Amazon CLI

To get detailed information about a merge commit

The following `get-merge-commit` example displays details about a merge commit for the source branch named `bugfix-bug1234` with a destination branch named `main` in a repository named `MyDemoRepo`.

```
aws codecommit get-merge-commit \
    --source-commit-specifier bugfix-bug1234 \
    --destination-commit-specifier main \
    --repository-name MyDemoRepo
```

Output:

```
{
    "sourceCommitId": "c5709475EXAMPLE",
    "destinationCommitId": "317f8570EXAMPLE",
    "baseCommitId": "fb12a539EXAMPLE",
    "mergeCommitId": "ffc4d608eEXAMPLE"
}
```

For more information, see View Commit Details in the *Amazon CodeCommit User Guide*.

- For API details, see GetMergeCommit in *Amazon CLI Command Reference*.

`get-merge-conflicts`

The following code example shows how to use `get-merge-conflicts`.

Amazon CLI

To view whether there are any merge conflicts for a pull request

The following `get-merge-conflicts` example displays whether there are any merge conflicts between the tip of a source branch named `feature-randomizationfeature` and a destination branch named 'main' in a repository named `MyDemoRepo`.

```
aws codecommit get-merge-conflicts \
    --repository-name MyDemoRepo \
    --source-commit-specifier feature-randomizationfeature \
    --destination-commit-specifier main \
    --merge-option THREE_WAY_MERGE
```

Output:

```
{
    "mergeable": false,
    "destinationCommitId": "86958e0aEXAMPLE",
    "sourceCommitId": "6ccd57fdEXAMPLE",
    "baseCommitId": "767b6958EXAMPLE",
    "conflictMetadataList": [
        {
            "filePath": "readme.md",
            "fileSizes": {
                "source": 139,
```

```
                "destination": 230,
                "base": 85
            },
            "fileModes": {
                "source": "NORMAL",
                "destination": "NORMAL",
                "base": "NORMAL"
            },
            "objectTypes": {
                "source": "FILE",
                "destination": "FILE",
                "base": "FILE"
            },
            "numberOfConflicts": 1,
            "isBinaryFile": {
                "source": false,
                "destination": false,
                "base": false
            },
            "contentConflict": true,
            "fileModeConflict": false,
            "objectTypeConflict": false,
            "mergeOperations": {
                "source": "M",
                "destination": "M"
            }
        }
    ]
}
```

- For API details, see GetMergeConflicts in *Amazon CLI Command Reference*.

`get-merge-options`

The following code example shows how to use `get-merge-options`.

Amazon CLI

To get information about the merge options available for merging two specified branches

The following `get-merge-options` example determines the merge options available for merging a source branch named `bugfix-bug1234` with a destination branch named `main` in a repository named `MyDemoRepo`.

```
aws codecommit get-merge-options \
    --source-commit-specifier bugfix-bug1234 \
    --destination-commit-specifier main \
    --repository-name MyDemoRepo
```

Output:

```
{
    "mergeOptions": [
        "FAST_FORWARD_MERGE",
        "SQUASH_MERGE",
        "THREE_WAY_MERGE"
    ],
    "sourceCommitId": "18059494EXAMPLE",
    "destinationCommitId": "ffd3311dEXAMPLE",
    "baseCommitId": "ffd3311dEXAMPLE"
}
```

For more information, see Resolve Conflicts in a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see GetMergeOptions in *Amazon CLI Command Reference*.

`get-pull-request-approval-states`

The following code example shows how to use `get-pull-request-approval-states`.

Amazon CLI

To view approvals on a pull request

The following `get-pull-request-approval-states` example returns approvals for the specified pull request.

```
aws codecommit get-pull-request-approval-states \
    --pull-request-id 8 \
    --revision-id 9f29d167EXAMPLE
```

Output:

```
{
    "approvals": [
```

```
        {
            "userArn": "arn:aws:iam::123456789012:user/Mary_Major",
            "approvalState": "APPROVE"
        }
    ]
}
```

For more information, see View Pull Requests in the *Amazon CodeCommit User Guide*.

- For API details, see GetPullRequestApprovalStates in *Amazon CLI Command Reference*.

`get-pull-request-override-state`

The following code example shows how to use `get-pull-request-override-state`.

Amazon CLI

To get information about the override status of a pull request

The following `get-pull-request-override-state` example returns the override state for the specified pull request. In this example, the approval rules for the pull request were overridden by a user named Mary Major, so the output returns a value of `true`.:

```
aws codecommit get-pull-request-override-state \
    --pull-request-id 34  \
    --revision-id 9f29d167EXAMPLE
```

Output:

```
{
    "overridden": true,
    "overrider": "arn:aws:iam::123456789012:user/Mary_Major"
}
```

For more information, see Override Approval Rules on a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see GetPullRequestOverrideState in *Amazon CLI Command Reference*.

`get-pull-request`

The following code example shows how to use `get-pull-request`.

Amazon CLI

To view details of a pull request

This example demonstrates how to view information about a pull request with the ID of 27.

```
aws codecommit get-pull-request \
    --pull-request-id 27
```

Output:

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approver-rule-for-main",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
        "lastActivityDate": 1562619583.565,
        "pullRequestTargets": [
            {
                "sourceCommit": "ca45e279EXAMPLE",
                "sourceReference": "refs/heads/bugfix-1234",
                "mergeBase": "a99f5ddbEXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": false
                },
                "destinationCommit": "2abfc6beEXAMPLE",
                "repositoryName": "MyDemoRepo"
            }
        ],
        "revisionId": "e47def21EXAMPLE",
        "title": "Quick fix for bug 1234",
        "authorArn": "arn:aws:iam::123456789012:user/Nikhil_Jayashankar",
```

```
        "clientRequestToken": "d8d7612e-EXAMPLE",
        "creationDate": 1562619583.565,
        "pullRequestId": "27",
        "pullRequestStatus": "OPEN"
    }
}
```

- For API details, see GetPullRequest in *Amazon CLI Command Reference*.

`get-repository-triggers`

The following code example shows how to use `get-repository-triggers`.

Amazon CLI

To get information about triggers in a repository

This example shows details about triggers configured for an Amazon CodeCommit repository named MyDemoRepo.

```
aws codecommit get-repository-triggers \
    --repository-name MyDemoRepo
```

Output:

```
{
    "configurationId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE",
    "triggers": [
        {
            "destinationArn": "arn:aws:sns:us-
east-1:111111111111:MyCodeCommitTopic",
            "branches": [
                "main",
                "preprod"
            ],
            "name": "MyFirstTrigger",
            "customData": "",
            "events": [
                "all"
            ]
        },
        {
```

```
            "destinationArn": "arn:aws:lambda:us-
east-1:111111111111:function:MyCodeCommitPythonFunction",
            "branches": [],
            "name": "MySecondTrigger",
            "customData": "EXAMPLE",
            "events": [
                "all"
            ]
        }
    ]
}
```

- For API details, see GetRepositoryTriggers in *Amazon CLI Command Reference*.

`get-repository`

The following code example shows how to use `get-repository`.

Amazon CLI

To get information about a repository

This example shows details about an Amazon CodeCommit repository.

```
aws codecommit get-repository \
    --repository-name MyDemoRepo
```

Output:

```
{
    "repositoryMetadata": {
        "creationDate": 1429203623.625,
        "defaultBranch": "main",
        "repositoryName": "MyDemoRepo",
        "cloneUrlSsh": "ssh://git-codecommit.us-east-1.amazonaws.com/v1/repos/v1/
repos/MyDemoRepo",
        "lastModifiedDate": 1430783812.0869999,
        "repositoryDescription": "My demonstration repository",
        "cloneUrlHttp": "https://codecommit.us-east-1.amazonaws.com/v1/repos/
MyDemoRepo",
        "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE",
        "Arn": "arn:aws:codecommit:us-east-1:80398EXAMPLE:MyDemoRepo
```

```
        "accountId": "111111111111"
    }
}
```

- For API details, see GetRepository in *Amazon CLI Command Reference*.

`list-approval-rule-templates`

The following code example shows how to use `list-approval-rule-templates`.

Amazon CLI

To list all approval rule templates in an Amazon Region

The following `list-approval-rule-templates` example lists all approval rule templates in the specified Region. If no Amazon Region is specified as a parameter, the command returns approval rule templates for the region specified in the Amazon CLI profile used to run the command.

```
aws codecommit list-approval-rule-templates \
    --region us-east-2
```

Output:

```
{
    "approvalRuleTemplateNames": [
        "2-approver-rule-for-main",
        "1-approver-rule-for-all-pull-requests"
    ]
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see ListApprovalRuleTemplates in *Amazon CLI Command Reference*.

`list-associated-approval-rule-templates-for-repository`

The following code example shows how to use `list-associated-approval-rule-templates-for-repository`.

Amazon CLI

To list all templates associated with a repository

The following `list-associated-approval-rule-templates-for-repository` example lists all approval rule templates associated with a repository named MyDemoRepo.

```
aws codecommit list-associated-approval-rule-templates-for-repository \
    --repository-name MyDemoRepo
```

Output:

```
{
  "approvalRuleTemplateNames": [
    "2-approver-rule-for-main",
    "1-approver-rule-for-all-pull-requests"
  ]
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see ListAssociatedApprovalRuleTemplatesForRepository in *Amazon CLI Command Reference*.

`list-branches`

The following code example shows how to use `list-branches`.

Amazon CLI

To view a list of branch names

This example lists all branch names in an Amazon CodeCommit repository.

```
aws codecommit list-branches \
    --repository-name MyDemoRepo
```

Output:

```
{
```

```
    "branches": [
        "MyNewBranch",
        "main"
    ]
}
```

- For API details, see ListBranches in *Amazon CLI Command Reference*.

`list-pull-requests`

The following code example shows how to use `list-pull-requests`.

Amazon CLI

To view a list of pull requests in a repository

This example demonstrates how to list pull requests created by an IAM user with the ARN 'arn:aws:iam::111111111111:user/Li_Juan' and the status of 'CLOSED' in an Amazon CodeCommit repository named 'MyDemoRepo':

```
aws codecommit list-pull-requests --author-arn arn:aws:iam::111111111111:user/
Li_Juan --pull-request-status CLOSED --repository-name MyDemoRepo
```

Output:

```
{
 "nextToken": "",
 "pullRequestIds": ["2","12","16","22","23","35","30","39","47"]
}
```

- For API details, see ListPullRequests in *Amazon CLI Command Reference*.

`list-repositories-for-approval-rule-template`

The following code example shows how to use `list-repositories-for-approval-rule-template`.

Amazon CLI

To list all repositories associated with a template

The following `list-repositories-for-approval-rule-template` example lists all repositories associated with the specified approval rule template.

```
aws codecommit list-repositories-for-approval-rule-template \
    --approval-rule-template-name 2-approver-rule-for-main
```

Output:

```
{
    "repositoryNames": [
        "MyDemoRepo",
        "MyClonedRepo"
    ]
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see ListRepositoriesForApprovalRuleTemplate in *Amazon CLI Command Reference*.

`list-repositories`

The following code example shows how to use `list-repositories`.

Amazon CLI

To view a list of repositories

This example lists all Amazon CodeCommit repositories associated with the user's Amazon account.

Command:

```
aws codecommit list-repositories
```

Output:

```
{
  "repositories": [
      {
```

```
            "repositoryName": "MyDemoRepo"
            "repositoryId": "f7579e13-b83e-4027-aaef-650c0EXAMPLE",
        },
        {
            "repositoryName": "MyOtherDemoRepo"
            "repositoryId": "cfc29ac4-b0cb-44dc-9990-f6f51EXAMPLE"
        }
    ]
}
```

- For API details, see ListRepositories in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To view the Amazon tags for a repository

The following `list-tags-for-resource` example lists tag keys and tag values for the specified repository.

```
aws codecommit list-tags-for-resource \
    --resource-arn arn:aws:codecommit:us-west-2:111111111111:MyDemoRepo
```

Output:

```
{
    "tags": {
        "Status": "Secret",
        "Team": "Saanvi"
    }
}
```

For more information, see View Tags for a Repository in the *Amazon CodeCommit User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`merge-branches-by-fast-forward`

The following code example shows how to use `merge-branches-by-fast-forward`.

Amazon CLI

To merge two branches using the fast-forward merge strategy

The following `merge-branches-by-fast-forward` example merges the specified source branch with the specified destination branch in a repository named `MyDemoRepo`.

```
aws codecommit merge-branches-by-fast-forward \
    --source-commit-specifier bugfix-bug1234 \
    --destination-commit-specifier bugfix-bug1233 \
    --repository-name MyDemoRepo
```

Output:

```
{
    "commitId": "4f178133EXAMPLE",
    "treeId": "389765daEXAMPLE"
}
```

For more information, see Compare and Merge Branches in the *Amazon CodeCommit User Guide*.

- For API details, see MergeBranchesByFastForward in *Amazon CLI Command Reference*.

`merge-branches-by-squash`

The following code example shows how to use `merge-branches-by-squash`.

Amazon CLI

To merge two branches using the squash merge strategy

The following `merge-branches-by-squash` example merges the specified source branch with the specified destination branch in a repository named `MyDemoRepo`.

```
aws codecommit merge-branches-by-squash \
    --source-commit-specifier bugfix-bug1234 \
    --destination-commit-specifier bugfix-bug1233 \
    --author-name "Maria Garcia" \
    --email "maria_garcia@example.com" \
    --commit-message "Merging two fix branches to prepare for a general patch." \
    --repository-name MyDemoRepo
```

Output:

```
{
    "commitId": "4f178133EXAMPLE",
    "treeId": "389765daEXAMPLE"
}
```

For more information, see Compare and Merge Branches in the *Amazon CodeCommit User Guide*.

- For API details, see MergeBranchesBySquash in *Amazon CLI Command Reference*.

`merge-branches-by-three-way`

The following code example shows how to use `merge-branches-by-three-way`.

Amazon CLI

To merge two branches using the three-way merge strategy

The following `merge-branches-by-three-way` example merges the specified source branch with the specified destination branch in a repository named `MyDemoRepo`.

```
aws codecommit merge-branches-by-three-way \
    --source-commit-specifier main \
    --destination-commit-specifier bugfix-bug1234 \
    --author-name "Jorge Souza" --email "jorge_souza@example.com" \
    --commit-message "Merging changes from main to bugfix branch before additional
 testing." \
    --repository-name MyDemoRepo
```

Output:

```
{
    "commitId": "4f178133EXAMPLE",
    "treeId": "389765daEXAMPLE"
}
```

For more information, see Compare and Merge Branches in the *Amazon CodeCommit User Guide*.

- For API details, see MergeBranchesByThreeWay in *Amazon CLI Command Reference*.

`merge-pull-request-by-fast-forward`

The following code example shows how to use `merge-pull-request-by-fast-forward`.

Amazon CLI

To merge and close a pull request

This example demonstrates how to merge and close a pull request with the ID of '47' and a source commit ID of '99132ab0EXAMPLE' in a repository named MyDemoRepo.

```
aws codecommit merge-pull-request-by-fast-forward \
    --pull-request-id 47 \
    --source-commit-id 99132ab0EXAMPLE \
    --repository-name MyDemoRepo
```

Output:

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 1,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "I want one approver for this pull request",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
        "authorArn": "arn:aws:iam::123456789012:user/Li_Juan",
        "clientRequestToken": "",
        "creationDate": 1508530823.142,
        "description": "Review the latest changes and updates to the global
 variables",
        "lastActivityDate": 1508887223.155,
        "pullRequestId": "47",
```

```
        "pullRequestStatus": "CLOSED",
        "pullRequestTargets": [
            {
                "destinationCommit": "9f31c968EXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": true,
                    "mergedBy": "arn:aws:iam::123456789012:user/Mary_Major"
                },
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "99132ab0EXAMPLE",
                "sourceReference": "refs/heads/variables-branch"
            }
        ],
        "title": "Consolidation of global variables"
    }
}
```

For more information, see Merge a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see MergePullRequestByFastForward in *Amazon CLI Command Reference*.

`merge-pull-request-by-squash`

The following code example shows how to use `merge-pull-request-by-squash`.

Amazon CLI

To merge a pull request using the squash merge strategy

The following `merge-pull-request-by-squash` example merges and closes the specified pull request using the conflict resolution strategy of ACCEPT_SOURCE in a repository named MyDemoRepo.

```
aws codecommit merge-pull-request-by-squash \
    --pull-request-id 47 \
    --source-commit-id 99132ab0EXAMPLE \
    --repository-name MyDemoRepo \
    --conflict-detail-level LINE_LEVEL \
    --conflict-resolution-strategy ACCEPT_SOURCE \
    --name "Jorge Souza" --email "jorge_souza@example.com" \
    --commit-message "Merging pull request 47 by squash and accepting source in
 merge conflicts"
```

Output:

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",
\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type
\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approver-rule-for-main",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "originApprovalRuleTemplate": {
                    "approvalRuleTemplateId": "dd8b17fe-EXAMPLE",
                    "approvalRuleTemplateName": "2-approver-rule-for-main"
                },
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
        "authorArn": "arn:aws:iam::123456789012:user/Li_Juan",
        "clientRequestToken": "",
        "creationDate": 1508530823.142,
        "description": "Review the latest changes and updates to the global
 variables",
        "lastActivityDate": 1508887223.155,
        "pullRequestId": "47",
        "pullRequestStatus": "CLOSED",
        "pullRequestTargets": [
            {
                "destinationCommit": "9f31c968EXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": true,
                    "mergedBy": "arn:aws:iam::123456789012:user/Mary_Major"
                },
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "99132ab0EXAMPLE",
                "sourceReference": "refs/heads/variables-branch"
            }
        ],
        "title": "Consolidation of global variables"
```

```
    }
}
```

For more information, see Merge a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see MergePullRequestBySquash in *Amazon CLI Command Reference*.

`merge-pull-request-by-three-way`

The following code example shows how to use `merge-pull-request-by-three-way`.

Amazon CLI

To merge a pull request using the three-way merge strategy

The following `merge-pull-request-by-three-way` example merges and closes the specified pull request using the default options for conflict detail and conflict resolution strategy in a repository named MyDemoRepo.

```
aws codecommit merge-pull-request-by-three-way \
    --pull-request-id 47 \
    --source-commit-id 99132ab0EXAMPLE \
    --repository-name MyDemoRepo \
    --name "Maria Garcia" \
    --email "maria_garcia@example.com" \

```

For more information, see Merge a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see MergePullRequestByThreeWay in *Amazon CLI Command Reference*.

`override-pull-request-approval-rules`

The following code example shows how to use `override-pull-request-approval-rules`.

Amazon CLI

To override approval rule requirements on a pull request

The following `override-pull-request-approval-rules` example overrides approval rules on the specified pull request. To revoke an override instead, set the `--override-status` parameter value to `REVOKE`.

```
aws codecommit override-pull-request-approval-rules \
    --pull-request-id 34  \
    --revision-id 927df8d8EXAMPLE \
    --override-status OVERRIDE
```

This command produces no output.

For more information, see Override Approval Rules on a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see OverridePullRequestApprovalRules in *Amazon CLI Command Reference*.

`post-comment-for-compared-commit`

The following code example shows how to use `post-comment-for-compared-commit`.

Amazon CLI

To create a comment on a commit

This example demonstrates how to add the comment `"Can you add a test case for this?"` on the change to the `cl_sample.js` file in the comparison between two commits in a repository named `MyDemoRepo`.

```
aws codecommit post-comment-for-compared-commit \
    --repository-name MyDemoRepo \
    --before-commit-id 317f8570EXAMPLE \
    --after-commit-id 5d036259EXAMPLE \
    --client-request-token 123Example \
    --content "Can you add a test case for this?" \
    --location filePath=cl_sample.js,filePosition=1232,relativeFileVersion=AFTER
```

Output:

```
{
    "afterBlobId": "1f330709EXAMPLE",
    "afterCommitId": "317f8570EXAMPLE",
```

```
    "beforeBlobId": "80906a4cEXAMPLE",
    "beforeCommitId": "6e147360EXAMPLE",
    "comment": {
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "clientRequestToken": "",
        "commentId": "553b509bEXAMPLE56198325",
        "content": "Can you add a test case for this?",
        "creationDate": 1508369612.203,
        "deleted": false,
        "commentId": "abc123-EXAMPLE",
        "lastModifiedDate": 1508369612.203,
        "callerReactions": [],
        "reactionCounts": []
    },
    "location": {
        "filePath": "cl_sample.js",
        "filePosition": 1232,
        "relativeFileVersion": "AFTER"
    ,
    "repositoryName": "MyDemoRepo"
    }
}
```

- For API details, see PostCommentForComparedCommit in *Amazon CLI Command Reference*.

`post-comment-for-pull-request`

The following code example shows how to use `post-comment-for-pull-request`.

Amazon CLI

To add a comment to a pull request

The following `post-comment-for-pull-request` example adds the comment "These don't appear to be used anywhere. Can we remove them?" on the change to the `ahs_count.py` file in a pull request with the ID of 47 in a repository named `MyDemoRepo`.

```
aws codecommit post-comment-for-pull-request \
    --pull-request-id "47" \
    --repository-name MyDemoRepo \
    --before-commit-id 317f8570EXAMPLE \
    --after-commit-id 5d036259EXAMPLE \
```

```
    --client-request-token 123Example \
    --content "These don't appear to be used anywhere. Can we remove them?" \
    --location filePath=ahs_count.py,filePosition=367,relativeFileVersion=AFTER
```

Output:

```
{
     "afterBlobId": "1f330709EXAMPLE",
     "afterCommitId": "5d036259EXAMPLE",
     "beforeBlobId": "80906a4cEXAMPLE",
     "beforeCommitId": "317f8570EXAMPLE",
     "comment": {
            "authorArn": "arn:aws:iam::111111111111:user/Saanvi_Sarkar",
            "clientRequestToken": "123Example",
            "commentId": "abcd1234EXAMPLEb5678efgh",
            "content": "These don't appear to be used anywhere. Can we remove
 them?",
            "creationDate": 1508369622.123,
            "deleted": false,
            "CommentId": "",
            "lastModifiedDate": 1508369622.123,
            "callerReactions": [],
            "reactionCounts": []
        },
        "location": {
            "filePath": "ahs_count.py",
            "filePosition": 367,
            "relativeFileVersion": "AFTER"
         },
     "repositoryName": "MyDemoRepo",
     "pullRequestId": "47"
}
```

- For API details, see PostCommentForPullRequest in *Amazon CLI Command Reference*.

`post-comment-reply`

The following code example shows how to use `post-comment-reply`.

Amazon CLI

To reply to a comment on a commit or in a pull request

This example demonstrates how to add the reply "Good catch. I'll remove them." to the comment with the system-generated ID of abcd1234EXAMPLEb5678efgh.

```
aws codecommit post-comment-reply \
    --in-reply-to abcd1234EXAMPLEb5678efgh \
    --content "Good catch. I'll remove them." \
    --client-request-token 123Example
```

Output:

```
{
    "comment": {
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "clientRequestToken": "123Example",
        "commentId": "442b498bEXAMPLE5756813",
        "content": "Good catch. I'll remove them.",
        "creationDate": 1508369829.136,
        "deleted": false,
        "CommentId": "abcd1234EXAMPLEb5678efgh",
        "lastModifiedDate": 150836912.221,
        "callerReactions": [],
        "reactionCounts": []
    }
}
```

- For API details, see PostCommentReply in *Amazon CLI Command Reference*.

put-comment-reaction

The following code example shows how to use put-comment-reaction.

Amazon CLI

To reply to a comment on a commit with an emoji

The following put-comment-reaction example replies to a comment with the ID of abcd1234EXAMPLEb5678efgh with an emoji reaction value of :thumbsup:.

```
aws codecommit put-comment-reaction \
    --comment-id abcd1234EXAMPLEb5678efgh \
    --reaction-value :thumbsup:
```

This command produces no output.

For more information, see Comment on a commit in Amazon CodeCommit in the *Amazon CodeCommit User Guide*.

- For API details, see PutCommentReaction in *Amazon CLI Command Reference*.

`put-file`

The following code example shows how to use `put-file`.

Amazon CLI

To add a file to a repository

The following `put-file` example adds a file named 'ExampleSolution.py' to a repository named 'MyDemoRepo' to a branch named 'feature-randomizationfeature' whose most recent commit has an ID of '4c925148EXAMPLE'.

```
aws codecommit put-file \
    --repository-name MyDemoRepo \
    --branch-name feature-randomizationfeature \
    --file-content file://MyDirectory/ExampleSolution.py \
    --file-path /solutions/ExampleSolution.py \
    --parent-commit-id 4c925148EXAMPLE \
    --name "Maria Garcia" \
    --email "maria_garcia@example.com" \
    --commit-message "I added a third randomization routine."
```

Output:

```
{
    "blobId": "2eb4af3bEXAMPLE",
    "commitId": "317f8570EXAMPLE",
    "treeId": "347a3408EXAMPLE"
}
```

- For API details, see PutFile in *Amazon CLI Command Reference*.

`put-repository-triggers`

The following code example shows how to use `put-repository-triggers`.

Amazon CLI

To add or update a trigger in a repository

This example demonstrates how to update triggers named 'MyFirstTrigger' and 'MySecondTrigger' using an already-created JSON file (here named MyTriggers.json) that contains the structure of all the triggers for a repository named MyDemoRepo. To learn how to get the JSON for existing triggers, see the get-repository-triggers command.

```
aws codecommit put-repository-triggers \
    --repository-name MyDemoRepo file://MyTriggers.json
```

Contents of `MyTriggers.json`:

```
{
    "repositoryName": "MyDemoRepo",
    "triggers": [
        {
            "destinationArn": "arn:aws:sns:us-
east-1:80398EXAMPLE:MyCodeCommitTopic",
            "branches": [
                "main",
                "preprod"
            ],
            "name": "MyFirstTrigger",
            "customData": "",
            "events": [
                "all"
            ]
        },
        {
            "destinationArn": "arn:aws:lambda:us-
east-1:111111111111:function:MyCodeCommitPythonFunction",
            "branches": [],
            "name": "MySecondTrigger",
            "customData": "EXAMPLE",
            "events": [
                "all"
            ]
        }
    ]
}
```

Output:

```
{
    "configurationId": "6fa51cd8-35c1-EXAMPLE"
}
```

- For API details, see PutRepositoryTriggers in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add Amazon tags to an existing repository

The following `tag-resource` example tags the specified repository with two tags.

```
aws codecommit tag-resource \
    --resource-arn arn:aws:codecommit:us-west-2:111111111111:MyDemoRepo \
    --tags Status=Secret,Team=Saanvi
```

This command produces no output.

For more information, see Add a Tag to a Repository in the *Amazon CodeCommit User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`test-repository-triggers`

The following code example shows how to use `test-repository-triggers`.

Amazon CLI

To test triggers in a repository

This example demonstrates how to test a trigger named 'MyFirstTrigger' in an Amazon CodeCommit repository named MyDemoRepo. In this example, events in the repository trigger notifications from an Amazon Simple Notification Service (Amazon SNS) topic.

Command:

```
aws codecommit test-repository-triggers --repository-name MyDemoRepo
 --triggers name=MyFirstTrigger,destinationArn=arn:aws:sns:us-
east-1:111111111111:MyCodeCommitTopic,branches=mainline,preprod,events=all
```

Output:

```
{
  "successfulExecutions": [
      "MyFirstTrigger"
  ],
  "failedExecutions": []
}
```

- For API details, see TestRepositoryTriggers in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove Amazon tags from a repository

The following `untag-resource` example removes the tag with the specified key from the repository named `MyDemoRepo`.

```
aws codecommit untag-resource \
    --resource-arn arn:aws:codecommit:us-west-2:111111111111:MyDemoRepo \
    --tag-keys Status
```

This command produces no output.

For more information, see Remove a Tag from a Repository in the *Amazon CodeCommit User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-approval-rule-template-content`

The following code example shows how to use `update-approval-rule-template-content`.

Amazon CLI

To update the content of an approval rule template

The following `update-approval-rule-template-content` example changes the content of the specified approval rule template to redefine the approval pool to users who assume the role of `CodeCommitReview`.

```
aws codecommit update-approval-rule-template-content \
    --approval-rule-template-name 1-approver-rule  \
    --new-rule-content "{\"Version\": \"2018-11-08\",\"DestinationReferences
\": [\"refs/heads/main\"],\"Statements\": [{\"Type\": \"Approvers
\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}"
```

Output:

```
{
    "approvalRuleTemplate": {
        "creationDate": 1571352720.773,
        "approvalRuleTemplateDescription": "Requires 1 approval for all pull
 requests from the CodeCommitReview pool",
        "lastModifiedDate": 1571358728.41,
        "approvalRuleTemplateId": "41de97b7-EXAMPLE",
        "approvalRuleTemplateContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 1,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
        "approvalRuleTemplateName": "1-approver-rule-for-all-pull-requests",
        "ruleContentSha256": "2f6c21a5EXAMPLE",
        "lastModifiedUser": "arn:aws:iam::123456789012:user/Li_Juan"
    }
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see UpdateApprovalRuleTemplateContent in *Amazon CLI Command Reference*.

`update-approval-rule-template-description`

The following code example shows how to use `update-approval-rule-template-description`.

Amazon CLI

To update the description of an approval rule template

The following `update-approval-rule-template-description` example changes the description of the specified approval rule template to `Requires 1 approval for all pull requests from the CodeCommitReview pool.`:

```
aws codecommit update-approval-rule-template-description \
    --approval-rule-template-name 1-approver-rule-for-all-pull-requests  \
    --approval-rule-template-description "Requires 1 approval for all pull requests
 from the CodeCommitReview pool"
```

Output:

```
{
  "approvalRuleTemplate": {
    "creationDate": 1571352720.773,
    "approvalRuleTemplateDescription": "Requires 1 approval for all pull requests
 from the CodeCommitReview pool",
    "lastModifiedDate": 1571358728.41,
    "approvalRuleTemplateId": "41de97b7-EXAMPLE",
    "approvalRuleTemplateContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 1,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
    "approvalRuleTemplateName": "1-approver-rule-for-all-pull-requests",
    "ruleContentSha256": "2f6c21a5EXAMPLE",
    "lastModifiedUser": "arn:aws:iam::123456789012:user/Li_Juan"
  }
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see UpdateApprovalRuleTemplateDescription in *Amazon CLI Command Reference*.

`update-approval-rule-template-name`

The following code example shows how to use `update-approval-rule-template-name`.

Amazon CLI

To update the name of an approval rule template

The following `update-approval-rule-template-name` example changes the name of an approval rule template from `1-approver-rule` to 1-approver-rule-for-all-pull-requests`.

```
aws codecommit update-approval-rule-template-name \
    --old-approval-rule-template-name 1-approver-rule  \
    --new-approval-rule-template-name 1-approver-rule-for-all-pull-requests
```

Output:

```
{
  "approvalRuleTemplate": {
    "approvalRuleTemplateName": "1-approver-rule-for-all-pull-requests",
    "lastModifiedDate": 1571358241.619,
    "approvalRuleTemplateId": "41de97b7-EXAMPLE",
    "approvalRuleTemplateContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 1,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
    "creationDate": 1571352720.773,
    "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
    "approvalRuleTemplateDescription": "All pull requests must be approved by one
 developer on the team.",
    "ruleContentSha256": "2f6c21a5cEXAMPLE"
  }
}
```

For more information, see Manage Approval Rule Templates in the *Amazon CodeCommit User Guide*.

- For API details, see UpdateApprovalRuleTemplateName in *Amazon CLI Command Reference*.

`update-comment`

The following code example shows how to use `update-comment`.

Amazon CLI

To update a comment on a commit

This example demonstrates how to add the content "Fixed as requested. I'll update the pull request." to a comment with an ID of 442b498bEXAMPLE5756813.

```
aws codecommit update-comment \
    --comment-id 442b498bEXAMPLE5756813 \
    --content "Fixed as requested. I'll update the pull request."
```

Output:

```
{
    "comment": {
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "clientRequestToken": "",
        "commentId": "442b498bEXAMPLE5756813",
        "content": "Fixed as requested. I'll update the pull request.",
        "creationDate": 1508369929.783,
        "deleted": false,
        "lastModifiedDate": 1508369929.287,
        "callerReactions": [],
        "reactionCounts":
            {
                "THUMBSUP" : 2
            }
    }
}
```

- For API details, see UpdateComment in *Amazon CLI Command Reference*.

update-default-branch

The following code example shows how to use update-default-branch.

Amazon CLI

To change the default branch for a repository

This example changes the default branch for an Amazon CodeCommit repository. This command produces output only if there are errors.

Command:

```
aws codecommit update-default-branch --repository-name MyDemoRepo --default-branch-
name MyNewBranch
```

Output:

```
None.
```

- For API details, see UpdateDefaultBranch in *Amazon CLI Command Reference*.

update-pull-request-approval-rule-content

The following code example shows how to use update-pull-request-approval-rule-content.

Amazon CLI

To edit an approval rule for a pull request

The following update-pull-request-approval-rule-content example updates she specified approval rule to require one user approval from an approval pool that includes any IAM user in the 123456789012 Amazon account.

```
aws codecommit update-pull-request-approval-rule-content \
    --pull-request-id 27  \
    --approval-rule-name "Require two approved approvers" \
    --approval-rule-content "{Version: 2018-11-08, Statements: [{Type:
 \"Approvers\", NumberOfApprovalsNeeded: 1, ApprovalPoolMembers:
[\"CodeCommitApprovers:123456789012:user/*\"]}]}"
```

Output:

```
{
    "approvalRule": {
        "approvalRuleContent": "{Version: 2018-11-08, Statements:
 [{Type: \"Approvers\", NumberOfApprovalsNeeded: 1, ApprovalPoolMembers:
[\"CodeCommitApprovers:123456789012:user/*\"]}]}",
        "approvalRuleId": "aac33506-EXAMPLE",
        "originApprovalRuleTemplate": {},
        "creationDate": 1570752871.932,
        "lastModifiedDate": 1570754058.333,
```

```
        "approvalRuleName": Require two approved approvers",
        "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
        "ruleContentSha256": "cd93921cEXAMPLE",
    }
}
```

For more information, see Edit or Delete an Approval Rule in the *Amazon CodeCommit User Guide*.

- For API details, see UpdatePullRequestApprovalRuleContent in *Amazon CLI Command Reference*.

`update-pull-request-approval-state`

The following code example shows how to use `update-pull-request-approval-state`.

Amazon CLI

To approve or revoke approval for a pull request

The following `update-pull-request-approval-state` example approves a pull request with the ID of 27 and a revision ID of `9f29d167EXAMPLE`. If you wanted to revoke approval instead, then set the `--approval-state` parameter value to `REVOKE`.

```
aws codecommit update-pull-request-approval-state \
    --pull-request-id 27  \
    --revision-id 9f29d167EXAMPLE  \
    --approval-state "APPROVE"
```

This command produces no output.

For more information, see Review a Pull Request in the *Amazon CodeCommit User Guide*.

- For API details, see UpdatePullRequestApprovalState in *Amazon CLI Command Reference*.

`update-pull-request-description`

The following code example shows how to use `update-pull-request-description`.

Amazon CLI

To change the description of a pull request

This example demonstrates how to change the description of a pull request with the ID of 47.

```
aws codecommit update-pull-request-description \
    --pull-request-id 47 \
    --description "Updated the pull request to remove unused global variable."
```

Output:

```
{
    "pullRequest": {
        "authorArn": "arn:aws:iam::111111111111:user/Li_Juan",
        "clientRequestToken": "",
        "creationDate": 1508530823.155,
        "description": "Updated the pull request to remove unused global variable.",
        "lastActivityDate": 1508372423.204,
        "pullRequestId": "47",
        "pullRequestStatus": "OPEN",
        "pullRequestTargets": [
            {
                "destinationCommit": "9f31c968EXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": false,
                },
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "99132ab0EXAMPLE",
                "sourceReference": "refs/heads/variables-branch"
            }
        ],
        "title": "Consolidation of global variables"
    }
}
```

- For API details, see UpdatePullRequestDescription in *Amazon CLI Command Reference*.

`update-pull-request-status`

The following code example shows how to use `update-pull-request-status`.

Amazon CLI

To change the status of a pull request

This example demonstrates how to to change the status of a pull request with the ID of 42 to a status of CLOSED in an Amazon CodeCommit repository named MyDemoRepo.

```
aws codecommit update-pull-request-status \
    --pull-request-id 42 \
    --pull-request-status CLOSED
```

Output:

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",\"Statements\":
 [{\"Type\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approvers-needed-for-this-change",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
        "authorArn": "arn:aws:iam::123456789012:user/Li_Juan",
        "clientRequestToken": "",
        "creationDate": 1508530823.165,
        "description": "Updated the pull request to remove unused global variable.",
        "lastActivityDate": 1508372423.12,
        "pullRequestId": "47",
        "pullRequestStatus": "CLOSED",
        "pullRequestTargets": [
            {
                "destinationCommit": "9f31c968EXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": false,
                },
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "99132ab0EXAMPLE",
                "sourceReference": "refs/heads/variables-branch"
            }
        ],
```

```
        "title": "Consolidation of global variables"
    }
}
```

- For API details, see UpdatePullRequestStatus in *Amazon CLI Command Reference*.

update-pull-request-title

The following code example shows how to use `update-pull-request-title`.

Amazon CLI

To change the title of a pull request

This example demonstrates how to change the title of a pull request with the ID of 47.

```
aws codecommit update-pull-request-title \
    --pull-request-id 47 \
    --title "Consolidation of global variables - updated review"
```

Output:

```
{
    "pullRequest": {
        "approvalRules": [
            {
                "approvalRuleContent": "{\"Version\": \"2018-11-08\",
\"DestinationReferences\": [\"refs/heads/main\"],\"Statements\": [{\"Type
\": \"Approvers\",\"NumberOfApprovalsNeeded\": 2,\"ApprovalPoolMembers\":
 [\"arn:aws:sts::123456789012:assumed-role/CodeCommitReview/*\"]}]}",
                "approvalRuleId": "dd8b17fe-EXAMPLE",
                "approvalRuleName": "2-approver-rule-for-main",
                "creationDate": 1571356106.936,
                "lastModifiedDate": 571356106.936,
                "lastModifiedUser": "arn:aws:iam::123456789012:user/Mary_Major",
                "originApprovalRuleTemplate": {
                    "approvalRuleTemplateId": "dd8b26gr-EXAMPLE",
                    "approvalRuleTemplateName": "2-approver-rule-for-main"
                },
                "ruleContentSha256": "4711b576EXAMPLE"
            }
        ],
```

```
        "authorArn": "arn:aws:iam::123456789012:user/Li_Juan",
        "clientRequestToken": "",
        "creationDate": 1508530823.12,
        "description": "Review the latest changes and updates to the global
 variables. I have updated this request with some changes, including removing some
 unused variables.",
        "lastActivityDate": 1508372657.188,
        "pullRequestId": "47",
        "pullRequestStatus": "OPEN",
        "pullRequestTargets": [
            {
                "destinationCommit": "9f31c968EXAMPLE",
                "destinationReference": "refs/heads/main",
                "mergeMetadata": {
                    "isMerged": false,
                },
                "repositoryName": "MyDemoRepo",
                "sourceCommit": "99132ab0EXAMPLE",
                "sourceReference": "refs/heads/variables-branch"
            }
        ],
        "title": "Consolidation of global variables - updated review"
    }
}
```

- For API details, see UpdatePullRequestTitle in *Amazon CLI Command Reference*.

`update-repository-description`

The following code example shows how to use `update-repository-description`.

Amazon CLI

To change the description for a repository

This example changes the description for an Amazon CodeCommit repository. This command produces output only if there are errors.

Command:

```
aws codecommit update-repository-description --repository-name MyDemoRepo --
repository-description "This description was changed"
```

Output:

```
None.
```

- For API details, see UpdateRepositoryDescription in *Amazon CLI Command Reference*.

`update-repository-name`

The following code example shows how to use `update-repository-name`.

Amazon CLI

To change the name of a repository

This example changes the name of an Amazon CodeCommit repository. This command produces output only if there are errors. Changing the name of the Amazon CodeCommit repository will change the SSH and HTTPS URLs that users need to connect to the repository. Users will not be able to connect to this repository until they update their connection settings. Also, because the repository's ARN will change, changing the repository name will invalidate any IAM user policies that rely on this repository's ARN.

Command:

```
aws codecommit update-repository-name --old-name MyDemoRepo --new-
name MyRenamedDemoRepo
```

Output:

```
None.
```

- For API details, see UpdateRepositoryName in *Amazon CLI Command Reference*.

CodeDeploy examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeDeploy.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`add-tags-to-on-premises-instances`

The following code example shows how to use `add-tags-to-on-premises-instances`.

Amazon CLI

To add tags to on-premises instances

The following `add-tags-to-on-premises-instances` example associates in Amazon CodeDeploy the same on-premises instance tag to two on-premises instances. It does not register the on-premises instances with Amazon CodeDeploy.

```
aws deploy add-tags-to-on-premises-instances \
    --instance-names AssetTag12010298EX AssetTag23121309EX \
    --tags Key=Name,Value=CodeDeployDemo-OnPrem
```

This command produces no output.

- For API details, see AddTagsToOnPremisesInstances in *Amazon CLI Command Reference*.

`batch-get-application-revisions`

The following code example shows how to use `batch-get-application-revisions`.

Amazon CLI

To retrieve information about application revisions

The following `batch-get-application-revisions` example retrieves information about the specified revision stored in a GitHub repository.

```
aws deploy batch-get-application-revisions \
```

```
    --application-name my-codedeploy-application \
    --revisions "[{\"gitHubLocation\": {\"commitId\":
 \"fa85936EXAMPLEa31736c051f10d77297EXAMPLE\",\"repository\": \"my-github-token/my-
repository\"},\"revisionType\": \"GitHub\"}]"
```

Output:

```
{
    "revisions": [
        {
            "genericRevisionInfo": {
                "description": "Application revision registered by Deployment ID: d-
A1B2C3111",
                "lastUsedTime": 1556912355.884,
                "registerTime": 1556912355.884,
                "firstUsedTime": 1556912355.884,
                "deploymentGroups": []
            },
            "revisionLocation": {
                "revisionType": "GitHub",
                "gitHubLocation": {
                    "commitId": "fa85936EXAMPLEa31736c051f10d77297EXAMPLE",
                    "repository": "my-github-token/my-repository"
                }
            }
        }
    ],
    "applicationName": "my-codedeploy-application",
    "errorMessage": ""
}
```

For more information, see BatchGetApplicationRevisions in the *Amazon CodeDeploy API Reference*.

- For API details, see BatchGetApplicationRevisions in *Amazon CLI Command Reference*.

`batch-get-applications`

The following code example shows how to use `batch-get-applications`.

Amazon CLI

To get information about multiple applications

The following `batch-get-applications` example displays information about multiple applications that are associated with the user's Amazon account.

```
aws deploy batch-get-applications --application-names WordPress_App MyOther_App
```

Output:

```
{
    "applicationsInfo": [
        {
            "applicationName": "WordPress_App",
            "applicationId": "d9dd6993-f171-44fa-a811-211e4EXAMPLE",
            "createTime": 1407878168.078,
            "linkedToGitHub": false
        },
        {
            "applicationName": "MyOther_App",
            "applicationId": "8ca57519-31da-42b2-9194-8bb16EXAMPLE",
            "createTime": 1407453571.63,
            "linkedToGitHub": false
        }
    ]
}
```

- For API details, see BatchGetApplications in *Amazon CLI Command Reference*.

`batch-get-deployment-groups`

The following code example shows how to use `batch-get-deployment-groups`.

Amazon CLI

To retrieve information about one or more deployment groups

The following `batch-get-deployment-groups` example retrieves information about two of the deployment groups that are associated with the specified CodeDeploy application.

```
aws deploy batch-get-deployment-groups \
    --application-name my-codedeploy-application \
    --deployment-group-names "[\"my-deployment-group-1\",\"my-deployment-group-2\"]"
```

Output:

```
{
    "deploymentGroupsInfo": [
        {
            "deploymentStyle": {
                "deploymentOption": "WITHOUT_TRAFFIC_CONTROL",
                "deploymentType": "IN_PLACE"
            },
            "autoRollbackConfiguration": {
                "enabled": false
            },
            "onPremisesTagSet": {
                "onPremisesTagSetList": []
            },
            "serviceRoleArn": "arn:aws:iam::123456789012:role/
CodeDeployServiceRole",
            "lastAttemptedDeployment": {
                "endTime": 1556912366.415,
                "status": "Failed",
                "createTime": 1556912355.884,
                "deploymentId": "d-A1B2C3111"
            },
            "autoScalingGroups": [],
            "deploymentGroupName": "my-deployment-group-1",
            "ec2TagSet": {
                "ec2TagSetList": [
                    [
                        {
                            "Type": "KEY_AND_VALUE",
                            "Value": "my-EC2-instance",
                            "Key": "Name"
                        }
                    ]
                ]
            },

            "deploymentConfigName": "CodeDeployDefault.AllAtOnce"
        }
    ],
    "errorMessage": ""
}
```

For more information, see BatchGetDeploymentGroups in the *Amazon CodeDeploy API Reference*.

- For API details, see BatchGetDeploymentGroups in *Amazon CLI Command Reference*.

`batch-get-deployment-targets`

The following code example shows how to use `batch-get-deployment-targets`.

Amazon CLI

To retrieve the targets associated with a deployment

The following `batch-get-deployment-targets` example returns information about one of the targets associated with the specified deployment.

```
aws deploy batch-get-deployment-targets \
    --deployment-id "d-1A2B3C4D5" \
    --target-ids "i-01a2b3c4d5e6f1111"
```

Output:

```
{
    "deploymentTargets": [
        {
            "deploymentTargetType": "InstanceTarget",
            "instanceTarget": {
                "lifecycleEvents": [
                    {
                        "startTime": 1556918592.162,
                        "lifecycleEventName": "ApplicationStop",
                        "status": "Succeeded",
                        "endTime": 1556918592.247,
                        "diagnostics": {
                            "scriptName": "",
                            "errorCode": "Success",
                            "logTail": "",
                            "message": "Succeeded"
                        }
                    },
                    {
                        "startTime": 1556918593.193,
                        "lifecycleEventName": "DownloadBundle",
                        "status": "Succeeded",
                        "endTime": 1556918593.981,
                        "diagnostics": {
                            "scriptName": "",
                            "errorCode": "Success",
                            "logTail": "",
                            "message": "Succeeded"
                        }
                    },
```

```
                    {
                        "startTime": 1556918594.805,
                        "lifecycleEventName": "BeforeInstall",
                        "status": "Succeeded",
                        "endTime": 1556918681.807,
                        "diagnostics": {
                            "scriptName": "",
                            "errorCode": "Success",

                            "message": "Succeeded"
                        }
                    }
                ],
                "targetArn": "arn:aws:ec2:us-west-2:123456789012:instance/
i-01a2b3c4d5e6f1111",
                "deploymentId": "d-1A2B3C4D5",
                "lastUpdatedAt": 1556918687.504,
                "targetId": "i-01a2b3c4d5e6f1111",
                "status": "Succeeded"
            }
        }
    ]
}
```

For more information, see BatchGetDeploymentTargets in the *Amazon CodeDeploy API Reference*.

- For API details, see BatchGetDeploymentTargets in *Amazon CLI Command Reference*.

`batch-get-deployments`

The following code example shows how to use `batch-get-deployments`.

Amazon CLI

To get information about multiple deployments

The following `batch-get-deployments` example displays information about multiple deployments that are associated with the user's Amazon account.

```
aws deploy batch-get-deployments --deployment-ids d-A1B2C3111 d-A1B2C3222
```

Output:

```
{
    "deploymentsInfo": [
        {
            "applicationName": "WordPress_App",
            "status": "Failed",
            "deploymentOverview": {
                "Failed": 0,
                "InProgress": 0,
                "Skipped": 0,
                "Succeeded": 1,
                "Pending": 0
            },
            "deploymentConfigName": "CodeDeployDefault.OneAtATime",
            "creator": "user",
            "deploymentGroupName": "WordPress_DG",
            "revision": {
                "revisionType": "S3",
                "s3Location": {
                "bundleType": "zip",
                "version": "uTecLusEXAMPLEFXtfUcyfV8bEXAMPLE",
                "bucket": "amzn-s3-demo-bucket",
                "key": "WordPressApp.zip"
                }
            },
            "deploymentId": "d-A1B2C3111",
            "createTime": 1408480721.9,
            "completeTime": 1408480741.822
        },
        {
            "applicationName": "MyOther_App",
            "status": "Failed",
            "deploymentOverview": {
                "Failed": 1,
                "InProgress": 0,
                "Skipped": 0,
                "Succeeded": 0,
                "Pending": 0
            },
            "deploymentConfigName": "CodeDeployDefault.OneAtATime",
            "creator": "user",
            "errorInformation": {
                "message": "Deployment failed: Constraint default violated: No hosts
 succeeded.",
```

```
                "code": "HEALTH_CONSTRAINTS"
            },
            "deploymentGroupName": "MyOther_DG",
            "revision": {
                "revisionType": "S3",
                "s3Location": {
                "bundleType": "zip",
                "eTag": "\"dd56cfdEXAMPLE8e768f9d77fEXAMPLE\"",
                "bucket": "amzn-s3-demo-bucket",
                "key": "MyOtherApp.zip"
                }
            },
            "deploymentId": "d-A1B2C3222",
            "createTime": 1409764576.589,
            "completeTime": 1409764596.101
        }
    ]
}
```

- For API details, see BatchGetDeployments in *Amazon CLI Command Reference*.

`batch-get-on-premises-instances`

The following code example shows how to use `batch-get-on-premises-instances`.

Amazon CLI

To get information about one or more on-premises instances

The following `batch-get-on-premises-instances` example gets information about two on-premises instances.

```
aws deploy batch-get-on-premises-instances --instance-
names AssetTag12010298EX AssetTag23121309EX
```

Output:

```
{
    "instanceInfos": [
        {
            "iamUserArn": "arn:aws:iam::123456789012:user/AWS/CodeDeploy/
AssetTag12010298EX",
```

```
            "tags": [
                {
                    "Value": "CodeDeployDemo-OnPrem",
                    "Key": "Name"
                }
            ],
            "instanceName": "AssetTag12010298EX",
            "registerTime": 1425579465.228,
            "instanceArn": "arn:aws:codedeploy:us-west-2:123456789012:instance/
AssetTag12010298EX_4IwLNI2Alh"
        },
        {
            "iamUserArn": "arn:aws:iam::123456789012:user/AWS/CodeDeploy/
AssetTag23121309EX",
            "tags": [
                {
                    "Value": "CodeDeployDemo-OnPrem",
                    "Key": "Name"
                }
            ],
            "instanceName": "AssetTag23121309EX",
            "registerTime": 1425595585.988,
            "instanceArn": "arn:aws:codedeploy:us-west-2:80398EXAMPLE:instance/
AssetTag23121309EX_PomUy64Was"
        }
    ]
}
```

- For API details, see [BatchGetOnPremisesInstances](#) in *Amazon CLI Command Reference*.

`continue-deployment`

The following code example shows how to use `continue-deployment`.

Amazon CLI

To start rerouting traffic without waiting for a specified wait time to elapse.

The following `continue-deployment` example starts rerouting traffic from instances in the original environment that are ready to start shifting traffic to instances in the replacement environment.

```
aws deploy continue-deployment \
```

```
    --deployment-id "d-A1B2C3111" \
    --deployment-wait-type "READY_WAIT"
```

This command produces no output.

For more information, see ContinueDeployment in the *Amazon CodeDeploy API Reference*.

- For API details, see ContinueDeployment in *Amazon CLI Command Reference*.

`create-application`

The following code example shows how to use `create-application`.

Amazon CLI

To create an application

The following `create-application` example creates an application and associates it with the user's Amazon account.

```
aws deploy create-application --application-name MyOther_App
```

Output:

```
{
    "applicationId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE"
}
```

- For API details, see CreateApplication in *Amazon CLI Command Reference*.

`create-deployment-config`

The following code example shows how to use `create-deployment-config`.

Amazon CLI

To create a custom deployment configuration

The following `create-deployment-config` example creates a custom deployment configuration and associates it with the user's Amazon account.

```
aws deploy create-deployment-config \
```

```
    --deployment-config-name ThreeQuartersHealthy \
    --minimum-healthy-hosts type=FLEET_PERCENT,value=75
```

Output:

```
{
    "deploymentConfigId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE"
}
```

- For API details, see CreateDeploymentConfig in *Amazon CLI Command Reference*.

`create-deployment-group`

The following code example shows how to use `create-deployment-group`.

Amazon CLI

To create a deployment group

The following `create-deployment-group` example creates a deployment group and associates it with the specified application and the user's Amazon account.

```
aws deploy create-deployment-group \
    --application-name WordPress_App \
    --auto-scaling-groups CodeDeployDemo-ASG \
    --deployment-config-name CodeDeployDefault.OneAtATime \
    --deployment-group-name WordPress_DG \
    --ec2-tag-filters Key=Name,Value=CodeDeployDemo,Type=KEY_AND_VALUE \
    --service-role-arn arn:aws:iam::123456789012:role/CodeDeployDemoRole
```

Output:

```
{
    "deploymentGroupId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE"
}
```

- For API details, see CreateDeploymentGroup in *Amazon CLI Command Reference*.

`create-deployment`

The following code example shows how to use `create-deployment`.

Amazon CLI

Example 1: To create a CodeDeploy deployment using the EC2/On-premises compute platform

The following `create-deployment` example creates a deployment and associates it with the user's Amazon account.

```
aws deploy create-deployment \
    --application-name WordPress_App \
    --deployment-config-name CodeDeployDefault.OneAtATime \
    --deployment-group-name WordPress_DG \
    --description "My demo deployment" \
    --s3-location bucket=amzn-s3-demo-
bucket,bundleType=zip,eTag=dd56cfdEXAMPLE8e768f9d77fEXAMPLE,key=WordPressApp.zip
```

Output:

```
{
    "deploymentId": "d-A1B2C3111"
}
```

Example 2: To create a CodeDeploy deployment using the Amazon ECS compute platform

The following `create-deployment` example uses the following two files to deploy an Amazon ECS service.

Contents of `create-deployment.json` file:

```
{
    "applicationName": "ecs-deployment",
    "deploymentGroupName": "ecs-deployment-dg",
    "revision": {
        "revisionType": "S3",
        "s3Location": {
            "bucket": "ecs-deployment-bucket",
            "key": "appspec.yaml",
            "bundleType": "YAML"
        }
    }
}
```

That file, in turn, retrieves the following file `appspec.yaml` from an S3 bucket called `ecs-deployment-bucket`.

```
version: 0.0
Resources:
  - TargetService:
      Type: AWS::ECS::Service
      Properties:
        TaskDefinition: "arn:aws:ecs:region:123456789012:task-definition/ecs-task-
def:2"
        LoadBalancerInfo:
          ContainerName: "sample-app"
          ContainerPort: 80
        PlatformVersion: "LATEST"
```

Command:

```
aws deploy create-deployment \
    --cli-input-json file://create-deployment.json \
    --region us-east-1
```

Output:

```
{
    "deploymentId": "d-1234ABCDE"
}
```

For more information, see CreateDeployment in the *Amazon CodeDeploy API Reference*.

- For API details, see CreateDeployment in *Amazon CLI Command Reference*.

`delete-application`

The following code example shows how to use `delete-application`.

Amazon CLI

To delete an application

The following `delete-application` example deletes the specified application that is associated with the user's Amazon account.

```
aws deploy delete-application --application-name WordPress_App
```

This command produces no output.

- For API details, see DeleteApplication in *Amazon CLI Command Reference*.

`delete-deployment-config`

The following code example shows how to use `delete-deployment-config`.

Amazon CLI

To delete a deployment configuration

The following `delete-deployment-config` example deletes a custom deployment configuration that is associated with the user's Amazon account.

```
aws deploy delete-deployment-config --deployment-config-name ThreeQuartersHealthy
```

This command produces no output.

- For API details, see DeleteDeploymentConfig in *Amazon CLI Command Reference*.

`delete-deployment-group`

The following code example shows how to use `delete-deployment-group`.

Amazon CLI

To delete a deployment group

The following `delete-deployment-group` example deletes a deployment group that is associated with the specified application.

```
aws deploy delete-deployment-group \
    --application-name WordPress_App \
    --deployment-group-name WordPress_DG
```

Output:

```
{
```

```
    "hooksNotCleanedUp": []
}
```

- For API details, see DeleteDeploymentGroup in *Amazon CLI Command Reference*.

`delete-git-hub-account-token`

The following code example shows how to use `delete-git-hub-account-token`.

Amazon CLI

To deletes a GitHub account connection

The following `delete-git-hub-account-token` example deletes the connection of the specified GitHub account.

```
aws deploy delete-git-hub-account-token --token-name my-github-account
```

Output:

```
{
    "tokenName": "my-github-account"
}
```

For more information, see DeleteGitHubAccountToken in the *Amazon CodeDeploy API Reference*.

- For API details, see DeleteGitHubAccountToken in *Amazon CLI Command Reference*.

`deregister-on-premises-instance`

The following code example shows how to use `deregister-on-premises-instance`.

Amazon CLI

To deregister an on-premises instance

The following `deregister-on-premises-instance` example deregisters an on-premises instance with Amazon CodeDeploy, but it does not delete the IAM user associated with the instance, nor does it disassociate in Amazon CodeDeploy the on-premises instance tags from the instance. It also does not uninstall the Amazon CodeDeploy Agent from the instance nor remove the on-premises configuration file from the instance.

```
aws deploy deregister-on-premises-instance --instance-name AssetTag12010298EX
```

This command produces no output.

- For API details, see DeregisterOnPremisesInstance in *Amazon CLI Command Reference*.

`deregister`

The following code example shows how to use `deregister`.

Amazon CLI

To deregister an on-premises instance

The following `deregister` example deregisters an on-premises instance with Amazon CodeDeploy. It does not delete the IAM user that is associated with the instance. It disassociates in Amazon CodeDeploy the on-premises tags from the instance. It does not uninstall the Amazon CodeDeploy Agent from the instance nor remove the on-premises configuration file from the instance.

```
aws deploy deregister \
    --instance-name AssetTag12010298EX \
    --no-delete-iam-user \
    --region us-west-2
```

Output:

```
Retrieving on-premises instance information... DONE
IamUserArn: arn:aws:iam::80398EXAMPLE:user/AWS/CodeDeploy/AssetTag12010298EX
Tags: Key=Name,Value=CodeDeployDemo-OnPrem
Removing tags from the on-premises instance... DONE
Deregistering the on-premises instance... DONE
Run the following command on the on-premises instance to uninstall the codedeploy-
agent:
aws deploy uninstall
```

- For API details, see Deregister in *Amazon CLI Command Reference*.

`get-application-revision`

The following code example shows how to use `get-application-revision`.

Amazon CLI

To get information about an application revision

The following `get-application-revision` example displays information about an application revision that is associated with the specified application.

```
aws deploy get-application-revision \
    --application-name WordPress_App \
    --s3-location bucket=amzn-s3-demo-
bucket,bundleType=zip,eTag=dd56cfdEXAMPLE8e768f9d77fEXAMPLE,key=WordPressApp.zip
```

Output:

```
{
    "applicationName": "WordPress_App",
    "revisionInfo": {
        "description": "Application revision registered by Deployment ID: d-
A1B2C3111",
        "registerTime": 1411076520.009,
        "deploymentGroups": "WordPress_DG",
        "lastUsedTime": 1411076520.009,
        "firstUsedTime": 1411076520.009
    },
    "revision": {
        "revisionType": "S3",
        "s3Location": {
            "bundleType": "zip",
            "eTag": "dd56cfdEXAMPLE8e768f9d77fEXAMPLE",
            "bucket": "amzn-s3-demo-bucket",
            "key": "WordPressApp.zip"
        }
    }
}
```

- For API details, see GetApplicationRevision in *Amazon CLI Command Reference*.

`get-application`

The following code example shows how to use `get-application`.

Amazon CLI

To get information about an application

The following `get-application` example displays information about an application that is associated with the user's Amazon account.

```
aws deploy get-application --application-name WordPress_App
```

Output:

```
{
    "application": {
        "applicationName": "WordPress_App",
        "applicationId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "createTime": 1407878168.078,
        "linkedToGitHub": false
    }
}
```

- For API details, see GetApplication in *Amazon CLI Command Reference*.

`get-deployment-config`

The following code example shows how to use `get-deployment-config`.

Amazon CLI

To get information about a deployment configuration

The following `get-deployment-config` example displays information about a deployment configuration that is associated with the user's Amazon account.

```
aws deploy get-deployment-config --deployment-config-name ThreeQuartersHealthy
```

Output:

```
{
    "deploymentConfigInfo": {
        "deploymentConfigId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "minimumHealthyHosts": {
            "type": "FLEET_PERCENT",
```

```
            "value": 75
        },
        "createTime": 1411081164.379,
        "deploymentConfigName": "ThreeQuartersHealthy"
    }
}
```

- For API details, see GetDeploymentConfig in *Amazon CLI Command Reference*.

`get-deployment-group`

The following code example shows how to use `get-deployment-group`.

Amazon CLI

To view information about a deployment group

The following `get-deployment-group` example displays information about a deployment group that is associated with the specified application.

```
aws deploy get-deployment-group \
    --application-name WordPress_App \
    --deployment-group-name WordPress_DG
```

Output:

```
{
    "deploymentGroupInfo": {
        "applicationName": "WordPress_App",
        "autoScalingGroups": [
            "CodeDeployDemo-ASG"
        ],
        "deploymentConfigName": "CodeDeployDefault.OneAtATime",
        "ec2TagFilters": [
            {
                "Type": "KEY_AND_VALUE",
                "Value": "CodeDeployDemo",
                "Key": "Name"
            }
        ],
        "deploymentGroupId": "a1b2c3d4-5678-90ab-cdef-11111EXAMPLE",
        "serviceRoleArn": "arn:aws:iam::123456789012:role/CodeDeployDemoRole",
```

```
        "deploymentGroupName": "WordPress_DG"
    }
}
```

- For API details, see GetDeploymentGroup in *Amazon CLI Command Reference*.

`get-deployment-instance`

The following code example shows how to use `get-deployment-instance`.

Amazon CLI

To get information about a deployment instance

The following `get-deployment-instance` example displays information about a deployment instance that is associated with the specified deployment.

```
aws deploy get-deployment-instance --deployment-id d-QA4G4F9EX --instance-
id i-902e9fEX
```

Output:

```
{
    "instanceSummary": {
        "instanceId": "arn:aws:ec2:us-east-1:80398EXAMPLE:instance/i-902e9fEX",
        "lifecycleEvents": [
            {
                "status": "Succeeded",
                "endTime": 1408480726.569,
                "startTime": 1408480726.437,
                "lifecycleEventName": "ApplicationStop"
            },
            {
                "status": "Succeeded",
                "endTime": 1408480728.016,
                "startTime": 1408480727.665,
                "lifecycleEventName": "DownloadBundle"
            },
            {
                "status": "Succeeded",
                "endTime": 1408480729.744,
                "startTime": 1408480729.125,
```

```
                "lifecycleEventName": "BeforeInstall"
            },
            {
                "status": "Succeeded",
                "endTime": 1408480730.979,
                "startTime": 1408480730.844,
                "lifecycleEventName": "Install"
            },
            {
                "status": "Failed",
                "endTime": 1408480732.603,
                "startTime": 1408480732.1,
                "lifecycleEventName": "AfterInstall"
            },
            {
                "status": "Skipped",
                "endTime": 1408480732.606,
                "lifecycleEventName": "ApplicationStart"
            },
            {
                "status": "Skipped",
                "endTime": 1408480732.606,
                "lifecycleEventName": "ValidateService"
            }
        ],
        "deploymentId": "d-QA4G4F9EX",
        "lastUpdatedAt": 1408480733.152,
        "status": "Failed"
    }
}
```

- For API details, see GetDeploymentInstance in *Amazon CLI Command Reference*.

`get-deployment-target`

The following code example shows how to use `get-deployment-target`.

Amazon CLI

To return information about a deployment target

The following `get-deployment-target` example returns information about a deployment target that is associated with the specified deployment.

```
aws deploy get-deployment-target \
    --deployment-id "d-A1B2C3111" \
    --target-id "i-a1b2c3d4e5f611111"
```

Output:

```
{
    "deploymentTarget": {
        "deploymentTargetType": "InstanceTarget",
        "instanceTarget": {
            "lastUpdatedAt": 1556918687.504,
            "targetId": "i-a1b2c3d4e5f611111",
            "targetArn": "arn:aws:ec2:us-west-2:123456789012:instance/i-
a1b2c3d4e5f611111",
            "status": "Succeeded",
            "lifecycleEvents": [
                {
                    "status": "Succeeded",
                    "diagnostics": {
                        "errorCode": "Success",
                        "message": "Succeeded",
                        "logTail": "",
                        "scriptName": ""
                    },
                    "lifecycleEventName": "ApplicationStop",
                    "startTime": 1556918592.162,
                    "endTime": 1556918592.247
                },
                {
                    "status": "Succeeded",
                    "diagnostics": {

                }
            ],
            "deploymentId": "d-A1B2C3111"
        }
    }
}
```

For more information, see GetDeploymentTarget in the *Amazon CodeDeploy API Reference*.

- For API details, see GetDeploymentTarget in *Amazon CLI Command Reference*.

`get-deployment`

The following code example shows how to use `get-deployment`.

Amazon CLI

To get information about a deployment

The following `get-deployment` example displays information about a deployment that is associated with the user's Amazon account.

```
aws deploy get-deployment --deployment-id d-A1B2C3123
```

Output:

```
{
    "deploymentInfo": {
        "applicationName": "WordPress_App",
        "status": "Succeeded",
        "deploymentOverview": {
```

```
            "Failed": 0,
            "InProgress": 0,
            "Skipped": 0,
            "Succeeded": 1,
            "Pending": 0
        },
        "deploymentConfigName": "CodeDeployDefault.OneAtATime",
        "creator": "user",
        "description": "My WordPress app deployment",
        "revision": {
            "revisionType": "S3",
            "s3Location":  {
            "bundleType": "zip",
            "eTag": "\"dd56cfdEXAMPLE8e768f9d77fEXAMPLE\"",
            "bucket": "amzn-s3-demo-bucket",
            "key": "WordPressApp.zip"
            }
        },
        "deploymentId": "d-A1B2C3123",
        "deploymentGroupName": "WordPress_DG",
        "createTime": 1409764576.589,
        "completeTime": 1409764596.101,
        "ignoreApplicationStopFailures": false
    }
}
```

- For API details, see GetDeployment in *Amazon CLI Command Reference*.

`get-on-premises-instance`

The following code example shows how to use `get-on-premises-instance`.

Amazon CLI

To get information about an on-premises instance

The following `get-on-premises-instance` example retrieves information about the specified on-premises instance.

```
aws deploy get-on-premises-instance --instance-name AssetTag12010298EX
```

Output:

```
{
    "instanceInfo": {
    "iamUserArn": "arn:aws:iam::123456789012:user/AWS/CodeDeploy/
AssetTag12010298EX",
        "tags": [
        {
            "Value": "CodeDeployDemo-OnPrem",
            "Key": "Name"
        }
        ],
        "instanceName": "AssetTag12010298EX",
        "registerTime": 1425579465.228,
        "instanceArn": "arn:aws:codedeploy:us-east-1:123456789012:instance/
AssetTag12010298EX_4IwLNI2Alh"
    }
}
```

- For API details, see GetOnPremisesInstance in *Amazon CLI Command Reference*.

`install`

The following code example shows how to use `install`.

Amazon CLI

To install an on-premises instance

The following `install` example copies the on-premises configuration file from the specified location on the instance to the location on the instance that the Amazon CodeDeploy Agent expects to find it. It also installs the Amazon CodeDeploy Agent on the instance. It does not create any IAM user, nor register the on-premises instance with Amazon CodeDeploy, nor associate any on-premises instance tags in Amazon CodeDeploy for the instance.

```
aws deploy install \
    --override-config \
    --config-file C:\temp\codedeploy.onpremises.yml \
    --region us-west-2 \
    --agent-installer s3://aws-codedeploy-us-west-2/latest/codedeploy-agent.msi
```

Output:

```
Creating the on-premises instance configuration file... DONE
Installing the AWS CodeDeploy Agent... DONE
```

- For API details, see Install in *Amazon CLI Command Reference*.

`list-application-revisions`

The following code example shows how to use `list-application-revisions`.

Amazon CLI

To get information about application revisions

The following `list-application-revisions` example displays information about all application revisions that are associated with the specified application.

```
aws deploy list-application-revisions \
    --application-name WordPress_App \
    --s-3-bucket amzn-s3-demo-bucket \
    --deployed exclude \
    --s-3-key-prefix WordPress_ \
    --sort-by lastUsedTime \
    --sort-order descending
```

Output:

```
{
    "revisions": [
        {
            "revisionType": "S3",
            "s3Location": {
                "version": "uTecLusvCB_JqHFXtfUcyfV8bEXAMPLE",
                "bucket": "amzn-s3-demo-bucket",
                "key": "WordPress_App.zip",
                "bundleType": "zip"
            }
        },
        {
            "revisionType": "S3",
            "s3Location": {
                "version": "tMk.UxgDpMEVb7V187ZM6wVAWEXAMPLE",
```

```
                "bucket": "amzn-s3-demo-bucket",
                "key": "WordPress_App_2-0.zip",
                "bundleType": "zip"
            }
        }
    ]
}
```

- For API details, see ListApplicationRevisions in *Amazon CLI Command Reference*.

`list-applications`

The following code example shows how to use `list-applications`.

Amazon CLI

To get information about applications

The following `list-applications` example displays information about all applications that are associated with the user's Amazon account.

```
aws deploy list-applications
```

Output:

```
{
    "applications": [
        "WordPress_App",
        "MyOther_App"
    ]
}
```

- For API details, see ListApplications in *Amazon CLI Command Reference*.

`list-deployment-configs`

The following code example shows how to use `list-deployment-configs`.

Amazon CLI

To get information about deployment configurations

The following `list-deployment-configs` example displays information about all deployment configurations that are associated with the user's Amazon account.

```
aws deploy list-deployment-configs
```

Output:

```
{
    "deploymentConfigsList": [
        "ThreeQuartersHealthy",
        "CodeDeployDefault.AllAtOnce",
        "CodeDeployDefault.HalfAtATime",
        "CodeDeployDefault.OneAtATime"
    ]
}
```

- For API details, see ListDeploymentConfigs in *Amazon CLI Command Reference*.

`list-deployment-groups`

The following code example shows how to use `list-deployment-groups`.

Amazon CLI

To get information about deployment groups

The following `list-deployment-groups` example displays information about all deployment groups that are associated with the specified application.

```
aws deploy list-deployment-groups --application-name WordPress_App
```

Output:

```
{
    "applicationName": "WordPress_App",
    "deploymentGroups": [
        "WordPress_DG",
        "WordPress_Beta_DG"
    ]
}
```

- For API details, see ListDeploymentGroups in *Amazon CLI Command Reference*.

`list-deployment-instances`

The following code example shows how to use `list-deployment-instances`.

Amazon CLI

To get information about deployment instances

The following `list-deployment-instances` example displays information about all deployment instances that are associated with the specified deployment.

```
aws deploy list-deployment-instances \
    --deployment-id d-A1B2C3111 \
    --instance-status-filter Succeeded
```

Output:

```
{
    "instancesList": [
        "i-EXAMPLE11",
        "i-EXAMPLE22"
    ]
}
```

- For API details, see ListDeploymentInstances in *Amazon CLI Command Reference*.

`list-deployment-targets`

The following code example shows how to use `list-deployment-targets`.

Amazon CLI

To retrieve a list of target IDs that are associated with a deployment

The following `list-deployment-targets` example retrieves a list of target IDs associated with deployments that have a status of "Failed" or "InProgress."

```
aws deploy list-deployment-targets \
```

```
    --deployment-id "d-A1B2C3111" \
    --target-filters "{\"TargetStatus\":[\"Failed\",\"InProgress\"]}"
```

Output:

```
{
    "targetIds": [
        "i-0f1558aaf90e5f1f9"
    ]
}
```

For more information, see ListDeploymentTargets in the *Amazon CodeDeploy API Reference*.

- For API details, see ListDeploymentTargets in *Amazon CLI Command Reference*.

`list-deployments`

The following code example shows how to use `list-deployments`.

Amazon CLI

To get information about deployments

The following `list-deployments` example displays information about all deployments that are associated with the specified application and deployment group.

```
aws deploy list-deployments \
    --application-name WordPress_App \
    --create-time-range start=2014-08-19T00:00:00,end=2014-08-20T00:00:00 \
    --deployment-group-name WordPress_DG \
    --include-only-statuses Failed
```

Output:

```
{
    "deployments": [
        "d-EXAMPLE11",
        "d-EXAMPLE22",
        "d-EXAMPLE33"
    ]
}
```

- For API details, see ListDeployments in *Amazon CLI Command Reference*.

`list-git-hub-account-token-names`

The following code example shows how to use `list-git-hub-account-token-names`.

Amazon CLI

To lists the names of stored connections to GitHub accounts

The following `list-git-hub-account-token-names` example lists the names of the stored connections to GitHub accounts for the current Amazon user.

```
aws deploy list-git-hub-account-token-names
```

Output:

```
{
    "tokenNameList": [
        "my-first-token",
        "my-second-token",
        "my-third-token"
    ]
}
```

For more information, see ListGitHubAccountTokenNames in the *Amazon CodeDeploy API Reference*.

- For API details, see ListGitHubAccountTokenNames in *Amazon CLI Command Reference*.

`list-on-premises-instances`

The following code example shows how to use `list-on-premises-instances`.

Amazon CLI

To get information about one or more on-premises instances

The following `list-on-premises-instances` example retrieves a list of available on-premises instance names for instances that are registered in Amazon CodeDeploy and also have the specified on-premises instance tag associated in Amazon CodeDeploy with the instance.

```
aws deploy list-on-premises-instances \
    --registration-status Registered \
    --tag-filters Key=Name,Value=CodeDeployDemo-OnPrem,Type=KEY_AND_VALUE
```

Output:

```
{
    "instanceNames": [
        "AssetTag12010298EX"
    ]
}
```

- For API details, see ListOnPremisesInstances in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags for a resource (application)

The following `list-tags-for-resource` example lists the tags applied to an application named testApp in CodeDeploy.

```
aws deploy list-tags-for-resource \
    --resource-arn arn:aws:codedeploy:us-west-2:111122223333:application:testApp
```

Output:

```
{
    "Tags": [
        {
            "Key": "Type",
            "Value": "testType"
        },
        {
            "Key": "Name",
            "Value": "testName"
        }
```

```
    ]
}
```

For more information, see Tagging instances for deployment groups in CodeDeploy in the *Amazon CodeDeploy User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

push

The following code example shows how to use push.

Amazon CLI

To bundle and deploy an Amazon CodeDeploy compatible application revision to Amazon S3

The following push example bundles and deploys an application revision to Amazon S3 and then associates the application revision with the specified application.

```
aws deploy push \
    --application-name WordPress_App \
    --description "This is my deployment" \
    --ignore-hidden-files \
    --s3-location s3://amzn-s3-demo-bucket/WordPressApp.zip \
    --source /tmp/MyLocalDeploymentFolder/
```

The output describes how to use the create-deployment command to create a deployment that uses the uploaded application revision.

```
To deploy with this revision, run:
aws deploy create-deployment --application-name WordPress_App --
deployment-config-name <deployment-config-name> --deployment-group-
name <deployment-group-name> --s3-location bucket=amzn-s3-demo-
bucket,key=WordPressApp.zip,bundleType=zip,eTag="cecc9b8EXAMPLE50a6e71fdb88EXAMPLE",version=
```

- For API details, see Push in *Amazon CLI Command Reference*.

register-application-revision

The following code example shows how to use register-application-revision.

Amazon CLI

To register information about an already-uploaded application revision

The following `register-application-revision` example registers information about an already-uploaded application revision stored in Amazon S3 with Amazon CodeDeploy.

```
aws deploy register-application-revision \
    --application-name WordPress_App \
    --description "Revised WordPress application" \
    --s3-location bucket=amzn-s3-demo-
bucket,key=RevisedWordPressApp.zip,bundleType=zip,eTag=cecc9b8a08eac650a6e71fdb88EXAMPLE
```

This command produces no output.

- For API details, see RegisterApplicationRevision in *Amazon CLI Command Reference*.

`register-on-premises-instance`

The following code example shows how to use `register-on-premises-instance`.

Amazon CLI

To register an on-premises instance

The following `register-on-premises-instance` example registers an on-premises instance with Amazon CodeDeploy. It does not create the specified IAM user, nor does it associate in Amazon CodeDeploy any on-premises instances tags with the registered instance.

```
aws deploy register-on-premises-instance \
    --instance-name AssetTag12010298EX \
    --iam-user-arn arn:aws:iam::80398EXAMPLE:user/CodeDeployDemoUser-OnPrem
```

This command produces no output.

- For API details, see RegisterOnPremisesInstance in *Amazon CLI Command Reference*.

`register`

The following code example shows how to use `register`.

Amazon CLI

To register an on-premises instance

The following `register` example registers an on-premises instance with Amazon CodeDeploy, associates in Amazon CodeDeploy the specified on-premises instance tag with the registered instance, and creates an on-premises configuration file that can be copied to the instance. It does not create the IAM user, nor does it install the Amazon CodeDeploy Agent on the instance.

```
aws deploy register \
    --instance-name AssetTag12010298EX \
    --iam-user-arn arn:aws:iam::80398EXAMPLE:user/CodeDeployUser-OnPrem \
    --tags Key=Name,Value=CodeDeployDemo-OnPrem \
    --region us-west-2
```

Output:

```
Registering the on-premises instance... DONE
Adding tags to the on-premises instance... DONE
Copy the on-premises configuration file named codedeploy.onpremises.yml to the on-
premises instance, and run the following command on the on-premises instance to
 install and configure the AWS CodeDeploy Agent:
aws deploy install --config-file codedeploy.onpremises.yml
```

- For API details, see Register in *Amazon CLI Command Reference*.

`remove-tags-from-on-premises-instances`

The following code example shows how to use `remove-tags-from-on-premises-instances`.

Amazon CLI

To remove tags from one or more on-premises instances

The following `remove-tags-from-on-premises-instances` example disassociates the specified on-premises tags in Amazon CodeDeploy from on-premises instances. It does not deregister the on-premises instances in Amazon CodeDeploy, nor uninstall the Amazon CodeDeploy Agent from the instance, nor remove the on-premises configuration file from the instances, nor delete the IAM users that are associated with the instances.

```
aws deploy remove-tags-from-on-premises-instances \
```

```
    --instance-names AssetTag12010298EX AssetTag23121309EX \
    --tags Key=Name,Value=CodeDeployDemo-OnPrem
```

This command produces no output.

- For API details, see RemoveTagsFromOnPremisesInstances in *Amazon CLI Command Reference*.

`stop-deployment`

The following code example shows how to use `stop-deployment`.

Amazon CLI

To attempt to stop a deployment

The following `stop-deployment` example attempts to stop an in-progress deployment that is associated with the user's Amazon account.

aws deploy stop-deployment --deployment-id d-A1B2C3111

Output:

```
{
    "status": "Succeeded",
    "statusMessage": "No more commands will be scheduled for execution in the
 deployment instances"
}
```

- For API details, see StopDeployment in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resoure (application)

The following `tag-resource` example adds two tags with keys Name and Type, and values testName and testType to an application named testApp in CodeDeploy.:

```
aws deploy tag-resource \
    --resource-arn  arn:aws:codedeploy:us-west-2:111122223333:application:testApp \
    --tags Key=Name,Value=testName Key=Type,Value=testType
```

If successful, this command produces no output.

For more information, see Tagging instances for deployment groups in CodeDeploy in the *Amazon CodeDeploy User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`uninstall`

The following code example shows how to use `uninstall`.

Amazon CLI

To uninstall an on-premises instance

The following `uninstall` example uninstalls the Amazon CodeDeploy Agent from the on-premises instance and removes the on-premises configuration file from the instance. It doesn't deregister the instance in Amazon CodeDeploy, nor disassociate any on-premises instance tags in Amazon CodeDeploy from the instance, nor delete the IAM user that is associated with the instance.

```
aws deploy uninstall
```

This command produces no output.

- For API details, see Uninstall in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from a resource (application)

The following `untag-resource` example removes two tags with keys Name and Type from an application named testApp in CodeDeploy.

```
aws deploy untag-resource \
    --resource-arn  arn:aws:codedeploy:us-west-2:111122223333:application:testApp \
    --tag-keys Name Type
```

If successful, this command produces no output.

For more information, see Tagging instances for deployment groups in CodeDeploy in the *Amazon CodeDeploy User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-application`

The following code example shows how to use `update-application`.

Amazon CLI

To change details of an application

The following `update-application` example changes the name of an application that is associated with the user's Amazon account.

```
aws deploy update-application \
    --application-name WordPress_App \
    --new-application-name My_WordPress_App
```

This command produces no output.

- For API details, see UpdateApplication in *Amazon CLI Command Reference*.

`update-deployment-group`

The following code example shows how to use `update-deployment-group`.

Amazon CLI

To change information about a deployment group

The following `update-deployment-group` example changes the settings of a deployment group that is associated with the specified application.

```
aws deploy update-deployment-group \
    --application-name WordPress_App \
    --auto-scaling-groups My_CodeDeployDemo_ASG \
    --current-deployment-group-name WordPress_DG \
    --deployment-config-name CodeDeployDefault.AllAtOnce \
    --ec2-tag-filters Key=Name,Type=KEY_AND_VALUE,Value=My_CodeDeployDemo \
    --new-deployment-group-name My_WordPress_DepGroup \
    --service-role-arn arn:aws:iam::80398EXAMPLE:role/CodeDeployDemo-2
```

This command produces no output.

- For API details, see UpdateDeploymentGroup in *Amazon CLI Command Reference*.

CodeGuru Reviewer examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeGuru Reviewer.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`associate-repository`

The following code example shows how to use `associate-repository`.

Amazon CLI

Example 1: To create a Bitbucket repository association

The following `associate-repository` example creates a repository association using an existing Bitbucket repository.

```
aws codeguru-reviewer associate-repository \
    --repository 'Bitbucket={Owner=sample-owner, Name=mySampleRepo,
 ConnectionArn=arn:aws:codestar-connections:us-west-2:123456789012:connection/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 }'
```

Output:

```
{
    "RepositoryAssociation": {
        "ProviderType": "Bitbucket",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1596216896.979,
        "AssociationId": "association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "CreatedTimeStamp": 1596216896.979,
        "ConnectionArn": "arn:aws:codestar-connections:us-
west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "State": "Associating",
        "StateReason": "Pending Repository Association",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "Owner": "sample-owner"
    }
}
```

For more information, see Create a Bitbucket repository association in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

Example 2: To create a GitHub Enterprise repository association

The following `associate-repository` example creates a repository association using an existing GitHub Enterprise repository.

```
aws codeguru-reviewer associate-repository \
    --repository 'GitHubEnterpriseServer={Owner=sample-owner, Name=mySampleRepo,
 ConnectionArn=arn:aws:codestar-connections:us-west-2:123456789012:connection/
a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 }'
```

Output:

```
{
    "RepositoryAssociation": {
```

```
        "ProviderType": "GitHubEnterpriseServer",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1596216896.979,
        "AssociationId": "association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "CreatedTimeStamp": 1596216896.979,
        "ConnectionArn": "arn:aws:codestar-connections:us-
west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "State": "Associating",
        "StateReason": "Pending Repository Association",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "Owner": "sample-owner"
    }
}
```

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the *Amazon Codeguru Reviewer User Guide*.

Example 3: To create an Amazon CodeCommit repository association

The following `associate-repository` example creates a repository association using an existing Amazon CodeCommit repository.

```
aws codeguru-reviewer associate-repository \
    --repository CodeCommit={Name=mySampleRepo}
```

Output:

```
{
    "RepositoryAssociation": {
        "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "Name": "My-ecs-beta-repo",
        "LastUpdatedTimeStamp": 1595634764.029,
        "ProviderType": "CodeCommit",
        "CreatedTimeStamp": 1595634764.029,
        "Owner": "544120495673",
        "State": "Associating",
        "StateReason": "Pending Repository Association",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:544120495673:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
}
```

For more information, see Create an Amazon CodeCommit repository association in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see AssociateRepository in *Amazon CLI Command Reference*.

`create-code-review`

The following code example shows how to use `create-code-review`.

Amazon CLI

To create a code review.

The following `create-code-review` creates a review of code in the `mainline` branch of an Amazon CodeCommit repository that is named `my-repository-name`.

```
aws codeguru-reviewer create-code-review \
    --name my-code-review \
    --repository-association-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
    --type '{"RepositoryAnalysis": {"RepositoryHead": {"BranchName": "mainline"}}}'
```

Output:

```
{
    "CodeReview": {
        "Name": "my-code-review",
        "CodeReviewArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222:code-
review:RepositoryAnalysis-my-code-review",
        "RepositoryName": "my-repository-name",
        "Owner": "123456789012",
        "ProviderType": "CodeCommit",
        "State": "Pending",
        "StateReason": "CodeGuru Reviewer has received the request, and a code
 review is scheduled.",
        "CreatedTimeStamp": 1618873489.195,
        "LastUpdatedTimeStamp": 1618873489.195,
        "Type": "RepositoryAnalysis",
        "SourceCodeType": {
            "RepositoryHead": {
                "BranchName": "mainline"
            }
```

```
        },
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
}
```

For more information, see Create code reviews in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see CreateCodeReview in *Amazon CLI Command Reference*.

`describe-code-review`

The following code example shows how to use `describe-code-review`.

Amazon CLI

List details about a code review.

The following `describe-code-review` lists information about a review of code in the "mainline" branch of an Amazon CodeCommit repository that is named "my-repo-name".

```
aws codeguru-reviewer put-recommendation-feedback \
    --code-review-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111:code-
review:RepositoryAnalysis-my-repository-name-branch-abcdefgh12345678 \
    --recommendation-
id 3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb \
    --reactions ThumbsUp
```

Output

```
{
        "CodeReview": {
            "Name": "My-ecs-beta-repo-master-xs6di4kfd4j269dz",
            "CodeReviewArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222:code-
review:RepositoryAnalysis-my-repo-name",
            "RepositoryName": "My-ecs-beta-repo",
            "Owner": "123456789012",
            "ProviderType": "CodeCommit",
            "State": "Pending",
            "StateReason": "CodeGuru Reviewer is reviewing the source code.",
```

```
            "CreatedTimeStamp": 1618874226.226,
            "LastUpdatedTimeStamp": 1618874233.689,
            "Type": "RepositoryAnalysis",
            "SourceCodeType": {
                "RepositoryHead": {
                    "BranchName": "mainline"
                }
            },
            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        }
    }
```

For more information, see View code review details in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see DescribeCodeReview in *Amazon CLI Command Reference*.

`describe-recommendation-feedback`

The following code example shows how to use `describe-recommendation-feedback`.

Amazon CLI

To view information about feedback on a recommendation

The following `describe-recommendation-feedback` displays information about feedback on a recommendation. This recommendation has one ThumbsUp reaction.

```
aws codeguru-reviewer describe-recommendation-feedback \
    --code-review-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111:code-
review:RepositoryAnalysis-my-repository-name-branch-abcdefgh12345678 \
    --recommendation-
id 3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb
```

Output:

```
{
    "RecommendationFeedback": {
        "CodeReviewArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111:code-
review:RepositoryAnalysis-my-repository-name-branch-abcdefgh12345678",
```

```
        "RecommendationId":
 "3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb",
        "Reactions": [
            "ThumbsUp"
        ],
        "UserId": "aws-user-id",
        "CreatedTimeStamp": 1618877070.313,
        "LastUpdatedTimeStamp": 1618877948.881
    }
}
```

For more information, see View recommendations and provide feedback and Step 4: Provide feedback in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see DescribeRecommendationFeedback in *Amazon CLI Command Reference*.

`describe-repository-association`

The following code example shows how to use `describe-repository-association`.

Amazon CLI

Example 1: To return information about a GitHub repository association

The following `describe-repository-association` example returns information about a repository association that uses a GitHub Enterprise repository and is in the `Associated` state.

```
aws codeguru-reviewer describe-repository-association \
    --association-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "RepositoryAssociation": {
        "AssociationId": "b822717e-0711-4e8a-bada-0e738289c75e",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1588102637.649,
        "ProviderType": "GitHub",
        "CreatedTimeStamp": 1588102615.636,
        "Owner": "sample-owner",
        "State": "Associated",
```

```
        "StateReason": "Pull Request Notification configuration successful",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
}
```

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

Example 2: To return information about a failed repository association

The following `describe-repository-association` example returns information about a repository association that uses a GitHub Enterprise repository and is in the `Failed` state.

```
aws codeguru-reviewer describe-repository-association \
    --association-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "RepositoryAssociation": {
        "ProviderType": "GitHubEnterpriseServer",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1596217036.892,
        "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "CreatedTimeStamp": 1596216896.979,
        "ConnectionArn": "arn:aws:codestar-connections:us-
west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "State": "Failed",
        "StateReason": "Failed, Please retry.",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
        "Owner": "sample-owner"
    }
}
```

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

Example 3: To return information about a disassociating repository association

The following `describe-repository-association` example returns information about a repository association that uses a GitHub Enterprise repository and is in the `Disassociating` state.

```
aws codeguru-reviewer describe-repository-association \
    --association-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "RepositoryAssociation": {
        "ProviderType": "GitHubEnterpriseServer",
        "Name": "mySampleRepo",
        "LastUpdatedTimeStamp": 1596217036.892,
        "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "CreatedTimeStamp": 1596216896.979,
        "ConnectionArn": "arn:aws:codestar-connections:us-
west-2:123456789012:connection/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
        "State": "Disassociating",
        "StateReason": "Source code access removal in progress",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
        "Owner": "sample-owner"
    }
}
```

For more information, see Create a GitHub Enterprise Server repository association in Amazon CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see DescribeRepositoryAssociation in *Amazon CLI Command Reference*.

`disassociate-repository`

The following code example shows how to use `disassociate-repository`.

Amazon CLI

To disassociate a repository association

The following `disassociate-repository` disassociates a repository association that is using an Amazon CodeCommit repository.

```
aws codeguru-reviewer disassociate-repository \
    --association-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "RepositoryAssociation": {
        "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "Name": "my-repository",
        "Owner": "123456789012",
        "ProviderType": "CodeCommit",
        "State": "Disassociating",
        "LastUpdatedTimeStamp": 1618939174.759,
        "CreatedTimeStamp": 1595636947.096
    },
    "Tags": {
        "Status": "Secret",
        "Team": "Saanvi"
    }
}
```

For more information, see Disassociate a repository in CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see DisassociateRepository in *Amazon CLI Command Reference*.

`list-code-reviews`

The following code example shows how to use `list-code-reviews`.

Amazon CLI

To list code reviews created in your Amazon account in the last 90 days.

The following `list-code-reviews` example lists the code reviews created in the last 90 days using pull requests.

```
aws codeguru-reviewer list-code-reviews \
    --type PullRequest
```

Output:

```
{
    "CodeReviewSummaries": [
        {
            "LastUpdatedTimeStamp": 1588897288.054,
            "Name": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "ProviderType": "GitHub",
            "PullRequestId": "5",
            "MetricsSummary": {
                "MeteredLinesOfCodeCount": 24,
                "FindingsCount": 1
            },
            "CreatedTimeStamp": 1588897068.512,
            "State": "Completed",
            "CodeReviewArn": "arn:aws:codeguru-reviewer:us-west-2:123456789012:code-

```

For more information, see View all code reviews in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see ListCodeReviews in *Amazon CLI Command Reference*.

`list-recommendation-feedback`

The following code example shows how to use `list-recommendation-feedback`.

Amazon CLI

To list customer recommendation feedback for a recommendation on an associated repository

The following `list-recommendation-feedback` Lists customer feedback on all recommendations on a code review. This code review has one piece of feedback, a "ThumbsUp", from a customer.

```
aws codeguru-reviewer list-recommendation-feedback \
    --code-review-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111:code-
review:RepositoryAnalysis-my-repository-name-branch-abcdefgh12345678
```

Output:

```
{
    "RecommendationFeedbackSummaries": [
        {
            "RecommendationId":
 "3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb",
            "Reactions": [
                "ThumbsUp"
            ],
            "UserId": "aws-user-id"
        }
    ]
}
```

For more information, see Step 4: Provide feedback in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see ListRecommendationFeedback in *Amazon CLI Command Reference*.

`list-recommendations`

The following code example shows how to use `list-recommendations`.

Amazon CLI

To list the recommendations for a completed code review

The following `list-recommendations` example lists the recommendations for a comleted code review. This code review has one recommendations.

```
aws codeguru-reviewer list-recommendations \
    --code-review-arn arn:aws:codeguru-reviewer:us-west-2:544120495673:code-
review:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "RecommendationSummaries": [
        {
            "Description": "\n\n**Problem**  \n You are using a `ConcurrentHashMap`,
 but your usage of `containsKey()` and `get()` may not be thread-safe at lines: **63
```

```
 and 64**. In between the check and the `get()` another thread can remove the key
 and the `get()` will return `null`. The remove that can remove the key is at line:
 **59**.\n\n**Fix**  \n Consider calling `get()`, checking instead of your current
 check if the returned object is `null`, and then using that object only, without
 calling `get()` again.\n\n**More info**  \n [View an example on GitHub](https://
github.com/apache/hadoop/blob/f16cf877e565084c66bc63605659b157c4394dc8/hadoop-tools/
hadoop-aws/src/main/java/org/apache/hadoop/fs/s3a/s3guard/S3Guard.java#L302-L304)
 (external link).",
            "RecommendationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "StartLine": 63,
            "EndLine": 64,
            "FilePath": "src/main/java/com/company/sample/application/
CreateOrderThread.java"
        }
    ]
}
```

For more information, see Step 4: Provide feedback in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see ListRecommendations in *Amazon CLI Command Reference*.

`list-repository-associations`

The following code example shows how to use `list-repository-associations`.

Amazon CLI

To list the repository associations in your Amazon account

The following `list-repository-associations` example returns a list of repository association summary objects in your account. You can filter the returned list by `ProviderType`, `Name`, `State`, and `Owner`.

```
aws codeguru-reviewer list-repository-associations
```

Output:

```
{
    "RepositoryAssociationSummaries": [
        {
            "LastUpdatedTimeStamp": 1595886609.616,
```

```
            "Name": "test",
            "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "Owner": "sample-owner",
            "State": "Associated",
            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "ProviderType": "Bitbucket"
        },
        {
            "LastUpdatedTimeStamp": 1595636969.035,
            "Name": "CodeDeploy-CodePipeline-ECS-Tutorial",
            "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "Owner": "123456789012",
            "State": "Associated",
            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "ProviderType": "CodeCommit"
        },
        {
            "LastUpdatedTimeStamp": 1595634785.983,
            "Name": "My-ecs-beta-repo",
            "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE33333",
            "Owner": "123456789012",
            "State": "Associated",

            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE44444",
            "ProviderType": "CodeCommit"
        },
        {
            "LastUpdatedTimeStamp": 1588102637.649,
            "Name": "aws-codeguru-profiler-sample-application",
            "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE55555",
            "Owner": "sample-owner",
            "State": "Associated",
```

```
            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE55555",
            "ProviderType": "GitHub"
        },
        {
            "LastUpdatedTimeStamp": 1588028233.995,
            "Name": "codeguru-profiler-demo-app",
            "AssociationId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE66666",
            "Owner": "sample-owner",
            "State": "Associated",
            "AssociationArn": "arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE66666",
            "ProviderType": "GitHub"
        }
    ]
}
```

For more information, see View all repository associations in CodeGuru Reviewer in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see ListRepositoryAssociations in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list the tags on an associated repository

The following `list-tags-for-resource` lists the tags on an associated repository. This associated repository has two tags.

```
aws codeguru-reviewer list-tags-for-resource \
    --resource-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "Tags": {
        "Status": "Secret",
```

```
        "Team": "Saanvi"
    }
}
```

For more information, see View tags for a CodeGuru Reviewer associated repository (Amazon CLI) in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`put-recommendation-feedback`

The following code example shows how to use `put-recommendation-feedback`.

Amazon CLI

To add a recommendation to a code review

The following `put-recommendation-feedback` puts a ThumbsUp recommendation on a code review.

```
aws codeguru-reviewer put-recommendation-feedback \
    --code-review-arn \arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111:code-
review:RepositoryAnalysis-my-repository-name-branch-abcdefgh12345678 \
    --recommendation-
id 3be1b2e5d7ef6e298a06499379ee290c9c596cf688fdcadb08285ddb0dd390eb \
    --reactions ThumbsUp
```

This command produces no output.

For more information, see Step 4: Provide feedback in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see PutRecommendationFeedback in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add a tag to an associated repository

The following `tag-resource` adds two tags to an associated repository

```
aws codeguru-reviewer tag-resource \
    --resource-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
    --tags Status=Secret,Team=Saanvi
```

This command produces no output.

For more information, see Add a tag to a CodeGuru Reviewer associated repository (Amazon CLI) and Add or update tags for a CodeGuru Reviewer associated repository (Amazon CLI) in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To untag an associated repository

The following `untag-resource` removes two tags with keys "Secret" and "Team" from an associated repository.

```
aws codeguru-reviewer untag-resource \
    --resource-arn arn:aws:codeguru-reviewer:us-
west-2:123456789012:association:a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
    --tag-keys Status Team
```

This command produces no output.

For more information, see Remove tags from a CodeGuru Reviewer associated repository (Amazon CLI) in the *Amazon CodeGuru Reviewer User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

CodePipeline examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodePipeline.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`acknowledge-job`

The following code example shows how to use `acknowledge-job`.

Amazon CLI

To retrieve information about a specified job

This example returns information about a specified job, including the status of that job if it exists. This is only used for job workers and custom actions. To determine the value of nonce and the job ID, use aws codepipeline poll-for-jobs.

Command:

```
aws codepipeline acknowledge-job --job-id f4f4ff82-2d11-EXAMPLE --nonce 3
```

Output:

```
{
  "status": "InProgress"
}
```

- For API details, see AcknowledgeJob in *Amazon CLI Command Reference*.

`create-custom-action-type`

The following code example shows how to use `create-custom-action-type`.

Amazon CLI

To create a custom action

This example creates a custom action for Amazon CodePipeline using an already-created JSON file (here named MyCustomAction.json) that contains the structure of the custom action. For more information about the requirements for creating a custom action, including the structure of the file, see the Amazon CodePipeline User Guide.

```
aws codepipeline create-custom-action-type --cli-input-json file://
MyCustomAction.json
```

Contents of JSON file `MyCustomAction.json`:

```
{
    "category": "Build",
    "provider": "MyJenkinsProviderName",
    "version": "1",
    "settings": {
        "entityUrlTemplate": "https://192.0.2.4/job/{Config:ProjectName}/",
        "executionUrlTemplate": "https://192.0.2.4/job/{Config:ProjectName}/
lastSuccessfulBuild/{ExternalExecutionId}/"
    },
    "configurationProperties": [
        {
            "name": "MyJenkinsExampleBuildProject",
            "required": true,
            "key": true,
            "secret": false,
            "queryable": false,
            "description": "The name of the build project must be provided when this
 action is added to the pipeline.",
            "type": "String"
        }
    ],
    "inputArtifactDetails": {
        "maximumCount": 1,
        "minimumCount": 0
    },
    "outputArtifactDetails": {
        "maximumCount": 1,
        "minimumCount": 0
    }
```

```
}
```

This command returns the structure of the custom action.

- For API details, see CreateCustomActionType in *Amazon CLI Command Reference*.

`create-pipeline`

The following code example shows how to use `create-pipeline`.

Amazon CLI

To create a pipeline

This example creates a pipeline in Amazon CodePipeline using an already-created JSON file (here named MySecondPipeline.json) that contains the structure of the pipeline. For more information about the requirements for creating a pipeline, including the structure of the file, see the Amazon CodePipeline User Guide.

Command:

```
aws codepipeline create-pipeline --cli-input-json file://MySecondPipeline.json
```

JSON file sample contents:

```
{
 "pipeline": {
  "roleArn": "arn:aws:iam::111111111111:role/AWS-CodePipeline-Service",
  "stages": [
    {
      "name": "Source",
      "actions": [
        {
          "inputArtifacts": [],
          "name": "Source",
          "actionTypeId": {
            "category": "Source",
            "owner": "AWS",
            "version": "1",
            "provider": "S3"
          },
          "outputArtifacts": [
            {
```

```
              "name": "MyApp"
            }
          ],
          "configuration": {
            "S3Bucket": "awscodepipeline-demo-bucket",
            "S3ObjectKey": "aws-codepipeline-s3-aws-codedeploy_linux.zip"
          },
          "runOrder": 1
        }
      ]
    },
    {
      "name": "Beta",
      "actions": [
        {
          "inputArtifacts": [
            {
              "name": "MyApp"
            }
          ],
          "name": "CodePipelineDemoFleet",
          "actionTypeId": {
            "category": "Deploy",
            "owner": "AWS",
            "version": "1",
            "provider": "CodeDeploy"
          },
          "outputArtifacts": [],
          "configuration": {
            "ApplicationName": "CodePipelineDemoApplication",
            "DeploymentGroupName": "CodePipelineDemoFleet"
          },
          "runOrder": 1
        }
      ]
    }
  ],
  "artifactStore": {
    "type": "S3",
    "location": "codepipeline-us-east-1-11EXAMPLE11"
  },
  "name": "MySecondPipeline",
  "version": 1
}
```

```
}
```

Output:

```
This command returns the structure of the pipeline.
```

- For API details, see CreatePipeline in *Amazon CLI Command Reference*.

`delete-custom-action-type`

The following code example shows how to use `delete-custom-action-type`.

Amazon CLI

To delete a custom action

This example deletes a custom action in Amazon CodePipeline by using an already-created JSON file (here named DeleteMyCustomAction.json) that contains the action type, provider name, and version number of the action to be deleted. Use the list-action-types command to view the correct values for category, version, and provider.

Command:

```
aws codepipeline delete-custom-action-type --cli-input-json file://
DeleteMyCustomAction.json
```

JSON file sample contents:

```
{
  "category": "Build",
  "version": "1",
  "provider": "MyJenkinsProviderName"
}
```

Output:

```
None.
```

- For API details, see DeleteCustomActionType in *Amazon CLI Command Reference*.

`delete-pipeline`

The following code example shows how to use `delete-pipeline`.

Amazon CLI

To delete a pipeline

This example deletes a pipeline named MySecondPipeline from Amazon CodePipeline. Use the list-pipelines command to view a list of pipelines associated with your Amazon account.

Command:

```
aws codepipeline delete-pipeline --name MySecondPipeline
```

Output:

```
None.
```

- For API details, see DeletePipeline in *Amazon CLI Command Reference*.

`delete-webhook`

The following code example shows how to use `delete-webhook`.

Amazon CLI

To delete a webhook

The following `delete-webhook` example deletes a webhook for a GitHub version 1 source action. You must use the `deregister-webhook-with-third-party` command to deregister the webhook before you delete it.

```
aws codepipeline delete-webhook \
    --name my-webhook
```

This command produces no output.

For more information, see Delete the webhook for your GitHub source in the *Amazon CodePipeline User Guide*.

- For API details, see DeleteWebhook in *Amazon CLI Command Reference*.

`deregister-webhook-with-third-party`

The following code example shows how to use `deregister-webhook-with-third-party`.

Amazon CLI

To deregister a webhook

The following `deregister-webhook-with-third-party` example deletes a webhook for a GitHub version 1 source action. You must deregister the webhook before you delete it.

```
aws codepipeline deregister-webhook-with-third-party \
    --webhook-name my-webhook
```

This command produces no output.

For more information, see Delete the webhook for your GitHub source in the *Amazon CodePipeline User Guide*.

- For API details, see DeregisterWebhookWithThirdParty in *Amazon CLI Command Reference*.

`disable-stage-transition`

The following code example shows how to use `disable-stage-transition`.

Amazon CLI

To disable a transition to a stage in a pipeline

This example disables transitions into the Beta stage of the MyFirstPipeline pipeline in Amazon CodePipeline.

Command:

```
aws codepipeline disable-stage-transition --pipeline-name MyFirstPipeline --stage-
name Beta  --transition-type Inbound
```

Output:

```
None.
```

- For API details, see DisableStageTransition in *Amazon CLI Command Reference*.

`enable-stage-transition`

The following code example shows how to use `enable-stage-transition`.

Amazon CLI

To enable a transition to a stage in a pipeline

This example enables transitions into the Beta stage of the MyFirstPipeline pipeline in Amazon CodePipeline.

Command:

```
aws codepipeline enable-stage-transition --pipeline-name MyFirstPipeline --stage-name Beta  --transition-type Inbound
```

Output:

```
None.
```

- For API details, see EnableStageTransition in *Amazon CLI Command Reference*.

`get-job-details`

The following code example shows how to use `get-job-details`.

Amazon CLI

To get details of a job

This example returns details about a job whose ID is represented by f4f4ff82-2d11-EXAMPLE. This command is only used for custom actions. When this command is called, Amazon CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline, if required for the custom action. This command will also return any secret values defined for the action, if any are defined.

Command:

```
aws codepipeline get-job-details --job-id f4f4ff82-2d11-EXAMPLE
```

Output:

```
{
 "jobDetails": {
  "accountId": "111111111111",
  "data": {
    "actionConfiguration": {
      "__type": "ActionConfiguration",
      "configuration": {
        "ProjectName": "MyJenkinsExampleTestProject"
      }
    },
    "actionTypeId": {
      "__type": "ActionTypeId",
      "category": "Test",
      "owner": "Custom",
      "provider": "MyJenkinsProviderName",
      "version": "1"
    },
    "artifactCredentials": {
      "__type": "AWSSessionCredentials",
      "accessKeyId": "AKIAIOSFODNN7EXAMPLE",

`get-pipeline-state`

The following code example shows how to use `get-pipeline-state`.

Amazon CLI

To get information about the state of a pipeline

This example returns the most recent state of a pipeline named MyFirstPipeline.

Command:

```
aws codepipeline get-pipeline-state --name MyFirstPipeline
```

Output:

```
{
 "created": 1446137312.204,
 "pipelineName": "MyFirstPipeline",
 "pipelineVersion": 1,
 "stageStates": [
  {
    "actionStates": [
      {
        "actionName": "Source",
```

```
        "entityUrl": "https://console.aws.amazon.com/s3/home?#",
        "latestExecution": {
          "lastStatusChange": 1446137358.328,
          "status": "Succeeded"
        }
      }
    ],
    "stageName": "Source"
  },
  {
    "actionStates": [
      {
        "actionName": "CodePipelineDemoFleet",
        "entityUrl": "https://console.aws.amazon.com/codedeploy/home?#/applications/
CodePipelineDemoApplication/deployment-groups/CodePipelineDemoFleet",
        "latestExecution": {
          "externalExecutionId": "d-EXAMPLE",
          "externalExecutionUrl": "https://console.aws.amazon.com/codedeploy/home?#/

`list-action-executions`

The following code example shows how to use `list-action-executions`.

Amazon CLI

To list action executions

The following `list-action-executions` example views action execution details for a pipeline, such as action execution ID, input artifacts, output artifacts, execution result, and status.

```
aws codepipeline list-action-executions \
    --pipeline-name myPipeline
```

Output:

```
{
    "actionExecutionDetails": [
        {
            "pipelineExecutionId": "EXAMPLE0-adfc-488e-bf4c-1111111720d3",

- For API details, see ListActionExecutions in *Amazon CLI Command Reference*.

`list-action-types`

The following code example shows how to use `list-action-types`.

Amazon CLI

To view the action types available

Used by itself, the list-action-types command returns the structure of all actions available to your Amazon account. This example uses the --action-owner-filter option to return only custom actions.

Command:

```
aws codepipeline list-action-types --action-owner-filter Custom
```

Output:

```
{
  "actionTypes": [
      {
          "inputArtifactDetails": {
              "maximumCount": 5,
              "minimumCount": 0
          },
          "actionConfigurationProperties": [
              {
                  "secret": false,
                  "required": true,
                  "name": "MyJenkinsExampleBuildProject",
                  "key": true,
                  "queryable": true
              }
          ],
          "outputArtifactDetails": {
              "maximumCount": 5,
              "minimumCount": 0
          },
          "id": {
              "category": "Build",
              "owner": "Custom",
              "version": "1",
              "provider": "MyJenkinsProviderName"
          },
          "settings": {
              "entityUrlTemplate": "http://192.0.2.4/job/{Config:ProjectName}",
              "executionUrlTemplate": "http://192.0.2.4/job/{Config:ProjectName}/
{ExternalExecutionId}"
          }
      },
      {
          "inputArtifactDetails": {
              "maximumCount": 5,
              "minimumCount": 0
          },
          "actionConfigurationProperties": [
              {
                  "secret": false,
                  "required": true,
                  "name": "MyJenkinsExampleTestProject",
```

```
                "key": true,
                "queryable": true
            }
        ],
        "outputArtifactDetails": {
            "maximumCount": 5,
            "minimumCount": 0
        },
        "id": {
            "category": "Test",
            "owner": "Custom",
            "version": "1",
            "provider": "MyJenkinsProviderName"
        },
        "settings": {
            "entityUrlTemplate": "http://192.0.2.4/job/{Config:ProjectName}",
            "executionUrlTemplate": "http://192.0.2.4/job/{Config:ProjectName}/
{ExternalExecutionId}"
        }
    }
  ]
}
```

- For API details, see ListActionTypes in *Amazon CLI Command Reference*.

`list-pipeline-executions`

The following code example shows how to use `list-pipeline-executions`.

Amazon CLI

To view pipeline execution history

The following `list-pipeline-executions` example shows the pipeline execution history for a pipeline in your Amazon account.

```
aws codepipeline list-pipeline-executions \
    --pipeline-name MyPipeline
```

Output:

```
{
```

```
    "pipelineExecutionSummaries": [
        {
            "lastUpdateTime": 1496380678.648,
            "pipelineExecutionId": "7cf7f7cb-3137-539g-j458-d7eu3EXAMPLE",
            "startTime": 1496380258.243,
            "status": "Succeeded"
        },
        {
            "lastUpdateTime": 1496591045.634,
            "pipelineExecutionId": "3137f7cb-8d494hj4-039j-d84l-d7eu3EXAMPLE",
            "startTime": 1496590401.222,
            "status": "Succeeded"
        },
        {
            "lastUpdateTime": 1496946071.6456,
            "pipelineExecutionId": "4992f7jf-7cf7-913k-k334-d7eu3EXAMPLE",
            "startTime": 1496945471.5645,
            "status": "Succeeded"
        }
    ]
}
```

For more information, see View execution history in the *Amazon CodePipeline User Guide*.

- For API details, see ListPipelineExecutions in *Amazon CLI Command Reference*.

`list-pipelines`

The following code example shows how to use `list-pipelines`.

Amazon CLI

To view a list of pipelines

This example lists all Amazon CodePipeline pipelines associated with the user's Amazon account.

Command:

```
aws codepipeline list-pipelines
```

Output:

```
{
  "pipelines": [
      {
          "updated": 1439504274.641,
          "version": 1,
          "name": "MyFirstPipeline",
          "created": 1439504274.641
      },
      {
          "updated": 1436461837.992,
          "version": 2,
          "name": "MySecondPipeline",
          "created": 1436460801.381
      }
      ]
}
```

- For API details, see ListPipelines in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags

The following `list-tags-for-resource` example retrieves a list of all tags attached to the specified pipeline resource.

```
aws codepipeline list-tags-for-resource \
    --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline
```

Output:

```
{
    "tags": {
        "Project": "ProjectA",
        "IscontainerBased": "true"
    }
}
```

For more information, see View tags for a pipeline (CLI) in the *Amazon CodePipeline User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`list-webhooks`

The following code example shows how to use `list-webhooks`.

Amazon CLI

To list webhooks

The following `list-webhooks` example retrieves a list of all tags attached to the specified pipeline resource.

```
aws codepipeline list-webhooks \
    --endpoint-url "https://codepipeline.eu-central-1.amazonaws.com" \
    --region "eu-central-1"
```

Output:

```
{
    "webhooks": [
        {
            "url": "https://webhooks.domain.com/
trigger111111111EXAMPLE1111111111111111": {
                "authenticationConfiguration": {
                    "SecretToken": "Secret"
                },
                "name": "my-webhook",
                "authentication": "GITHUB_HMAC",
                "targetPipeline": "my-Pipeline",
                "targetAction": "Source",
                "filters": [
                    {
                        "jsonPath": "$.ref",
                        "matchEquals": "refs/heads/{Branch}"
                    }
                ]
            },
            "arn": "arn:aws:codepipeline:eu-central-1:123456789012:webhook:my-
webhook"
        }
```

```
    ]
}
```

For more information, see List webhooks in your account in the *Amazon CodePipeline User Guide*.

- For API details, see ListWebhooks in *Amazon CLI Command Reference*.

`poll-for-jobs`

The following code example shows how to use `poll-for-jobs`.

Amazon CLI

To view any available jobs

This example returns information about any jobs for a job worker to act upon. This example uses a pre-defined JSON file (MyActionTypeInfo.json) to supply information about the action type for which the job worker processes jobs. This command is only used for custom actions. When this command is called, Amazon CodePipeline returns temporary credentials for the Amazon S3 bucket used to store artifacts for the pipeline. This command will also return any secret values defined for the action, if any are defined.

Command:

```
aws codepipeline poll-for-jobs --cli-input-json file://MyActionTypeInfo.json
```

JSON file sample contents:

```
{
  "actionTypeId": {
    "category": "Test",
    "owner": "Custom",
    "provider": "MyJenkinsProviderName",
    "version": "1"
  },
  "maxBatchSize": 5,
  "queryParam": {
      "ProjectName": "MyJenkinsTestProject"
  }
}
```

Output:

```
{
 "jobs": [
  {
    "accountId": "111111111111",
    "data": {
      "actionConfiguration": {
        "__type": "ActionConfiguration",
        "configuration": {
          "ProjectName": "MyJenkinsExampleTestProject"
        }
      },
      "actionTypeId": {
        "__type": "ActionTypeId",
        "category": "Test",
        "owner": "Custom",
        "provider": "MyJenkinsProviderName",
        "version": "1"
      },
      "artifactCredentials": {
        "__type": "AWSSessionCredentials",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "secretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY",
        "sessionToken":
 "fICCQD6m7oRw0uXOjANBgkqhkiG9w0BAQUFADCBiDELMAkGA1UEBhMCVVMxCzAJBgNVBAgTAldBMRAwDgYDVQQHEwd

      },
      "inputArtifacts": [
        {
          "__type": "Artifact",
          "location": {
            "s3Location": {
              "bucketName": "codepipeline-us-east-1-11EXAMPLE11",
              "objectKey": "MySecondPipeline/MyAppBuild/EXAMPLE"
            },
            "type": "S3"
          },
          "name": "MyAppBuild"
        }
      ],
```

```
      "outputArtifacts": [],
      "pipelineContext": {
        "__type": "PipelineContext",
        "action": {
          "name": "MyJenkinsTest-Action"
        },
        "pipelineName": "MySecondPipeline",
        "stage": {
          "name": "Testing"
        }
      }
    },
    "id": "ef66c259-64f9-EXAMPLE",
    "nonce": "3"
  }
 ]
}
```

- For API details, see PollForJobs in *Amazon CLI Command Reference*.

`put-webhook`

The following code example shows how to use `put-webhook`.

Amazon CLI

To create a webhook

The following `put-webhook` example creates a webhook for a GitHub version 1 source action. After you create the webhook, you must use the register-webhook-with-third-party command to register it.

```
aws codepipeline put-webhook \
    --cli-input-json file://webhook_json.json \
    --region "eu-central-1"
```

Contents of `webhook_json.json`:

```
{
    "webhook": {
        "name": "my-webhook",
        "targetPipeline": "pipeline_name",
```

```
        "targetAction": "source_action_name",
        "filters": [
            {
                "jsonPath": "$.ref",
                "matchEquals": "refs/heads/{Branch}"
            }
        ],
        "authentication": "GITHUB_HMAC",
        "authenticationConfiguration": {
            "SecretToken": "secret"
        }
    }
}
```

Output:

```
{
    "webhook": {
        "url": "https://webhooks.domain.com/
trigger111111111EXAMPLE11111111111111111",
        "definition": {
            "authenticationConfiguration": {
                "SecretToken": "secret"
            },
            "name": "my-webhook",
            "authentication": "GITHUB_HMAC",
            "targetPipeline": "pipeline_name",
            "targetAction": "Source",
            "filters": [
                {
                    "jsonPath": "$.ref",
                    "matchEquals": "refs/heads/{Branch}"
                }
            ]
        },
        "arn": "arn:aws:codepipeline:eu-central-1:123456789012:webhook:my-webhook"
    },
    "tags": [
        {
            "key": "Project",
            "value": "ProjectA"
        }
    ]
```

```
}
```

For more information, see Create a webhook for a GitHub source in the *Amazon CodePipeline User Guide*.

- For API details, see PutWebhook in *Amazon CLI Command Reference*.

`retry-stage-execution`

The following code example shows how to use `retry-stage-execution`.

Amazon CLI

To retry a failed action

The following `retry-stage-execution` example retries a stage that has a failed action.

```
aws codepipeline retry-stage-execution \
    --pipeline-name MyPipeline \
    --stage-name Deploy \
    --pipeline-execution-id b59babff-5f34-EXAMPLE \
    --retry-mode FAILED_ACTIONS
```

Output:

```
{
    "pipelineExecutionId": "b59babff-5f34-EXAMPLE"
}
```

For more information, see Retry failed actions (CLI) in the *Amazon CodePipeline User Guide*.

- For API details, see RetryStageExecution in *Amazon CLI Command Reference*.

`start-pipeline-execution`

The following code example shows how to use `start-pipeline-execution`.

Amazon CLI

To run the latest revision through a pipeline

This example runs the latest revision present in the source stage of a pipeline through the pipeline named "MyFirstPipeline".

Command:

```
aws codepipeline start-pipeline-execution --name MyFirstPipeline
```

Output:

```
{
  "pipelineExecutionId": "3137f7cb-7cf7-EXAMPLE"
}
```

- For API details, see StartPipelineExecution in *Amazon CLI Command Reference*.

`stop-pipeline-execution`

The following code example shows how to use `stop-pipeline-execution`.

Amazon CLI

To stop a pipeline execution

The following `stop-pipeline-execution` example defaults to waiting until in-progress actions finish, and then stops the pipeline. You cannot choose to stop and wait if the execution is already in a Stopping state. You can choose to stop and abandon an execution that is already in a Stopping state.

```
aws codepipeline stop-pipeline-execution \
    --pipeline-name MyFirstPipeline \
    --pipeline-execution-id d-EXAMPLE \
    --reason "Stopping pipeline after the build action is done"
```

This command returns no output.

For more information, see Stop a pipeline execution (CLI) in the *Amazon CodePipeline User Guide*.

- For API details, see StopPipelineExecution in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resource

The following `tag-resource` example associates a set of provided tags with a pipeline. Use this command to add or edit tags.

```
aws codepipeline tag-resource \
    --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline \
    --tags key=Project,value=ProjectA key=IscontainerBased,value=true
```

This command produces no output.

For more information, see Add tags to a pipeline (CLI) in the *Amazon CodePipeline User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove Amazon tags from a connections resource

The following `untag-resource` example removes a tag from the specified resource.

```
aws codepipeline untag-resource \
    --resource-arn arn:aws:codepipeline:us-east-1:123456789012:MyPipeline \
    --tag-keys Project IscontainerBased
```

This command produces no output.

For more information, see Remove tags from a pipeline (CLI) in the *Amazon CodePipeline User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-pipeline`

The following code example shows how to use `update-pipeline`.

Amazon CLI

To update the structure of a pipeline

This example uses the update-pipeline command with the --cli-input-json argument. This example uses a pre-defined JSON file (MyFirstPipeline.json) to update the structure of a pipeline. Amazon CodePipeline recognizes the pipeline name contained in the JSON file, and then applies any changes from modified fields in the pipeline structure to update the pipeline.

Use the following guidelines when creating the pre-defined JSON file:

If you are working with a pipeline structure retrieved using the get-pipeline command, you must remove the metadata section from the pipeline structure in the JSON file (the "metadata": { } lines and the "created," "pipelineARN," and "updated" fields within).The pipeline name cannot be changed.

Command:

```
aws codepipeline update-pipeline --cli-input-json file://MyFirstPipeline.json
```

Sample JSON file contents:

```
{
 "pipeline": {
  "roleArn": "arn:aws:iam::111111111111:role/AWS-CodePipeline-Service",
  "stages": [
    {
      "name": "Source",
      "actions": [
        {
          "inputArtifacts": [],
          "name": "Source",
          "actionTypeId": {
            "category": "Source",
            "owner": "AWS",
            "version": "1",
            "provider": "S3"
          },
          "outputArtifacts": [
            {
              "name": "MyApp"
            }
          ],
```

```
          "configuration": {
            "S3Bucket": "awscodepipeline-demo-bucket2",
            "S3ObjectKey": "aws-codepipeline-s3-aws-codedeploy_linux.zip"
          },
          "runOrder": 1
        }
      ]
    },
    {
      "name": "Beta",
      "actions": [
        {
          "inputArtifacts": [
            {
              "name": "MyApp"
            }
          ],
          "name": "CodePipelineDemoFleet",
          "actionTypeId": {
            "category": "Deploy",
            "owner": "AWS",
            "version": "1",
            "provider": "CodeDeploy"
          },
          "outputArtifacts": [],
          "configuration": {
            "ApplicationName": "CodePipelineDemoApplication",
            "DeploymentGroupName": "CodePipelineDemoFleet"
          },
          "runOrder": 1
        }
      ]
    }
  ],
  "artifactStore": {
    "type": "S3",
    "location": "codepipeline-us-east-1-11EXAMPLE11"
  },
  "name": "MyFirstPipeline",
  "version": 1
 }
}
```

Output:

```
{
 "pipeline": {
  "artifactStore": {
    "location": "codepipeline-us-east-1-11EXAMPLE11",
    "type": "S3"
  },
  "name": "MyFirstPipeline",
  "roleArn": "arn:aws:iam::111111111111:role/AWS-CodePipeline-Service",
  "stages": [
    {
      "actions": [
        {
          "actionTypeId": {
            "__type": "ActionTypeId",
            "category": "Source",
            "owner": "AWS",
            "provider": "S3",
            "version": "1"
          },
          "configuration": {
            "S3Bucket": "awscodepipeline-demo-bucket2",
            "S3ObjectKey": "aws-codepipeline-s3-aws-codedeploy_linux.zip"
          },
          "inputArtifacts": [],
          "name": "Source",
          "outputArtifacts": [
            {
              "name": "MyApp"
            }
          ],
          "runOrder": 1
        }
      ],
      "name": "Source"
    },
    {
      "actions": [
        {
          "actionTypeId": {
            "__type": "ActionTypeId",
            "category": "Deploy",
            "owner": "AWS",
```

```
            "provider": "CodeDeploy",
            "version": "1"
          },
          "configuration": {
            "ApplicationName": "CodePipelineDemoApplication",
            "DeploymentGroupName": "CodePipelineDemoFleet"
          },
          "inputArtifacts": [
            {
              "name": "MyApp"
            }
          ],
          "name": "CodePipelineDemoFleet",
          "outputArtifacts": [],
          "runOrder": 1
        }
      ],
      "name": "Beta"
    }
  ],
  "version": 3
 }
}
```

- For API details, see [UpdatePipeline](#) in *Amazon CLI Command Reference*.

AWS CodeStar Notifications examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with AWS CodeStar Notifications.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- [Actions](#)

Actions

`create-notification-rule`

The following code example shows how to use `create-notification-rule`.

Amazon CLI

To create a notification rule

The following `create-notification-rule` example uses a JSON file named `rule.json` to create a notification rule named `MyNotificationRule` for a repository named `MyDemoRepo` in the specified Amazon account. Notifications with the `FULL` detail type are sent to the specified target Amazon SNS topic when branches and tags are created.

```
aws codestar-notifications create-notification-rule \
    --cli-input-json file://rule.json
```

Contents of `rule.json`:

```
{
    "Name": "MyNotificationRule",
    "EventTypeIds": [
        "codecommit-repository-branches-and-tags-created"
    ],
    "Resource": "arn:aws:codecommit:us-east-1:123456789012:MyDemoRepo",
    "Targets": [
        {
            "TargetType": "SNS",
            "TargetAddress": "arn:aws:sns:us-
east-1:123456789012:MyNotificationTopic"
        }
    ],
    "Status": "ENABLED",
    "DetailType": "FULL"
}
```

Output:

```
{
    "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE"
```

```
}
```

For more information, see Create a Notification rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see CreateNotificationRule in *Amazon CLI Command Reference*.

`delete-notification-rule`

The following code example shows how to use `delete-notification-rule`.

Amazon CLI

To delete a notification rule

The following `delete-notification-rule` example deletes the specified notification rule.

```
aws codestar-notifications delete-notification-rule \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE
```

Output:

```
{
    "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE"
}
```

For more information, see Delete a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see DeleteNotificationRule in *Amazon CLI Command Reference*.

`delete-target`

The following code example shows how to use `delete-target`.

Amazon CLI

To delete a notification rule target

The following `delete-target` example removes the specified target from all notification rules configured to use it as a target, and then deletes the target.

```
aws codestar-notifications  delete-target \
    --target-address arn:aws:sns:us-east-1:123456789012:MyNotificationTopic \
    --force-unsubscribe-all
```

This command produces no output.

For more information, see Delete a Notification Rule Target in the *Amazon Developer Tools Console User Guide*.

- For API details, see DeleteTarget in *Amazon CLI Command Reference*.

`describe-notification-rule`

The following code example shows how to use `describe-notification-rule`.

Amazon CLI

To retrieve details of a notification rule

The following `describe-notification-rule` example retrieves the details of the specified notification rule.

```
aws codestar-notifications describe-notification-rule \
    --arn arn:aws:codestar-notifications:us-west-2:123456789012:notificationrule/
dc82df7a-EXAMPLE
```

Output:

```
{
    "LastModifiedTimestamp": 1569199844.857,
    "EventTypes": [
        {
            "ServiceName": "CodeCommit",
            "EventTypeName": "Branches and tags: Created",
            "ResourceType": "Repository",
            "EventTypeId": "codecommit-repository-branches-and-tags-created"
        }
    ],
    "Status": "ENABLED",
```

```
    "DetailType": "FULL",
    "Resource": "arn:aws:codecommit:us-west-2:123456789012:MyDemoRepo",
    "Arn": "arn:aws:codestar-notifications:us-west-w:123456789012:notificationrule/
dc82df7a-EXAMPLE",
    "Targets": [
        {
            "TargetStatus": "ACTIVE",
            "TargetAddress": "arn:aws:sns:us-
west-2:123456789012:MyNotificationTopic",
            "TargetType": "SNS"
        }
    ],
    "Name": "MyNotificationRule",
    "CreatedTimestamp": 1569199844.857,
    "CreatedBy": "arn:aws:iam::123456789012:user/Mary_Major"
}
```

For more information, see View Notification Rules in the *Amazon Developer Tools Console User Guide*.

- For API details, see DescribeNotificationRule in *Amazon CLI Command Reference*.

`list-event-types`

The following code example shows how to use `list-event-types`.

Amazon CLI

To get a list of event types for a notification rule

The following `list-event-types` example retrieves a filtered list of all available notification event types for CodeDeploy applications. If instead you use no filter, the command returns all notification event types for all resource types.

```
aws codestar-notifications list-event-types \
    --filters Name=SERVICE_NAME,Value=CodeDeploy
```

Output:

```
{
    "EventTypes": [
        {
            "EventTypeId": "codedeploy-application-deployment-succeeded",
```

```
            "ServiceName": "CodeDeploy",
            "EventTypeName": "Deployment: Succeeded",
            "ResourceType": "Application"
        },
        {
            "EventTypeId": "codedeploy-application-deployment-failed",
            "ServiceName": "CodeDeploy",
            "EventTypeName": "Deployment: Failed",
            "ResourceType": "Application"
        },
        {
            "EventTypeId": "codedeploy-application-deployment-started",
            "ServiceName": "CodeDeploy",
            "EventTypeName": "Deployment: Started",
            "ResourceType": "Application"
        }
    ]
}
```

For more information, see Create a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see ListEventTypes in *Amazon CLI Command Reference*.

`list-notification-rules`

The following code example shows how to use `list-notification-rules`.

Amazon CLI

To retrieve a list of notification rules

The following `list-notification-rules` example retrieves a list of all notification rules in the specified Amazon Region.

```
aws codestar-notifications list-notification-rules --region us-east-1
```

Output:

```
{
    "NotificationRules": [
        {
            "Id": "dc82df7a-EXAMPLE",
```

```
            "Arn": "arn:aws:codestar-notifications:us-
east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
        },
        {
            "Id": "8d1f0983-EXAMPLE",
            "Arn": "arn:aws:codestar-notifications:us-
east-1:123456789012:notificationrule/8d1f0983-EXAMPLE"
        }
    ]
}
```

For more information, see View Notification Rules in the *Amazon Developer Tools Console User Guide*.

- For API details, see ListNotificationRules in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To get a list of tags attached to a notification rule

The following `list-tags-for-resource` example retrieves a list of all tags attached to the specified notification rule. In this example, the notification rule currently has no tags associated with it.

```
aws codestar-notifications list-tags-for-resource \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
fe1efd35-EXAMPLE
```

Output:

```
{
    "Tags": {}
}
```

For more information, see Create a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`list-targets`

The following code example shows how to use `list-targets`.

Amazon CLI

To retrieve a list of notification rule targets

The following `list-targets` example retrieves a list of all notification rule targets in the specified Amazon Region.

```
aws codestar-notifications list-targets \
    --region us-east-1
```

Output:

```
{
    "Targets": [
        {
            "TargetAddress": "arn:aws:sns:us-
east-1:123456789012:MySNSTopicForNotificationRules",
            "TargetType": "SNS",
            "TargetStatus": "ACTIVE"
        },
        {
            "TargetAddress": "arn:aws:sns:us-
east-1:123456789012:MySNSTopicForNotificationsAboutMyDemoRepo",
            "TargetType": "SNS",
            "TargetStatus": "ACTIVE"
        }
    ]
}
```

For more information, see View Notification Rule Targets in the *Amazon Developer Tools Console User Guide*.

- For API details, see ListTargets in *Amazon CLI Command Reference*.

`subscribe`

The following code example shows how to use `subscribe`.

Amazon CLI

To add a target to a notification rule

The following `subscribe` example adds an Amazon SNS topic as a target for the specified notification rule.

```
aws codestar-notifications subscribe \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE \
    --target TargetType=SNS,TargetAddress=arn:aws:sns:us-east-1:123456789012:MyNotificationTopic
```

Output:

```
{
    "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/dc82df7a-EXAMPLE"
}
```

For more information, see Add or Remove an Amazon SNS Topic as a Target for a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see Subscribe in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To add a tag to a notification rule

The following `tag-resource` example adds a tag with the key name of `Team` and the value of `Li_Juan` to the specified notification rule.

```
aws codestar-notifications tag-resource \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/fe1efd35-EXAMPLE \
    --tags Team=Li_Juan
```

Output:

```
{
    "Tags": {
        "Team": "Li_Juan"
    }
}
```

For more information, see Create a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`unsubscribe`

The following code example shows how to use `unsubscribe`.

Amazon CLI

To remove a target from a notification rule

The following `unsubscribe` example removes an Amazon SNS topic as a target from the specified notification rule.

```
aws codestar-notifications unsubscribe \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE \
    --target TargetType=SNS,TargetAddress=arn:aws:sns:us-
east-1:123456789012:MyNotificationTopic
```

Output:

```
{
    "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE"
    "TargetAddress": "arn:aws:sns:us-east-1:123456789012:MyNotificationTopic"
}
```

For more information, see Add or Remove an Amazon SNS Topic as a Target for a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see Unsubscribe in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove a tag from a notification rule

The following `untag-resource` example removes the tag with the key name `Team` from the specified notification rule.

```
aws codestar-notifications untag-resource \
    --arn arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
fe1efd35-EXAMPLE \
    --tag-keys Team
```

This command produces no output.

For more information, see Edit a Notification Rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-notification-rule`

The following code example shows how to use `update-notification-rule`.

Amazon CLI

To update a notification rule

The following `update-notification-rule` example updates a notification rule named `MyNotificationRule` in the Amazon account `123456789012` using a JSON file named `update.json`.

```
aws codestar-notifications update-notification-rule \
    --cli-input-json file://update.json
```

Contents of `update.json`:

```
{
    "Name": "MyUpdatedNotificationRule",
    "EventTypeIds": [
        "codecommit-repository-branches-and-tags-created"
    ],
    "Resource": "arn:aws:codecommit:us-east-1:123456789012:MyDemoRepo",
    "Targets": [
        {
            "TargetType": "SNS",
            "TargetAddress": "arn:aws:sns:us-
east-1:123456789012:MyNotificationTopic"
        }
    ],
    "Status": "ENABLED",
    "DetailType": "FULL"
}
```

Output:

```
{
    "Arn": "arn:aws:codestar-notifications:us-east-1:123456789012:notificationrule/
dc82df7a-EXAMPLE"
}
```

For more information, see Edit a notification rule in the *Amazon Developer Tools Console User Guide*.

- For API details, see UpdateNotificationRule in *Amazon CLI Command Reference*.

CodeConnections examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with CodeConnections.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-connection`

The following code example shows how to use `create-connection`.

Amazon CLI

To create a connection

The following `create-connection` example shows how to create a connection to a third-party repository. This example creates a connection where the third-party provider is Bitbucket.

A connection created through the Amazon CLI or Amazon CloudFormation is in Pending status by default. After you create a connection with the CLI or Amazon CloudFormation, use the console to edit the connection to make its status Available.

```
aws codestar-connections create-connection \
    --provider-type Bitbucket \
    --connection-name MyConnection
```

Output:

```
{
    "ConnectionArn": "arn:aws:codestar-connections:us-
east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f"
}
```

For more information, see Create a connection in the *Developer Tools console User Guide*.

- For API details, see CreateConnection in *Amazon CLI Command Reference*.

`create-host`

The following code example shows how to use `create-host`.

Amazon CLI

To create a host

The following `create-host` example shows how to create a host to represent the endpoint for the infrastructure where your third-party provider is installed. This example creates a host where the third-party installed provider is GitHub Enterprise Server.

A host created through the Amazon CLI is in Pending status by default. After you create a host with the CLI, use the console or the CLI to set up the host to make its status Available.

```
aws codestar-connections create-host \
    --name MyHost \
    --provider-type GitHubEnterpriseServer \
    --provider-endpoint "https://my-instance.dev"
```

Output:

```
{
    "HostArn": "arn:aws:codestar-connections:us-east-1:123456789012:host/My-
Host-28aef605"
}
```

For more information, see Create a host (CLI) in the *Developer Tools console User Guide*.

- For API details, see CreateHost in *Amazon CLI Command Reference*.

`delete-connection`

The following code example shows how to use `delete-connection`.

Amazon CLI

To delete a connection

The following `delete-connection` example shows how to delete a connection.

```
aws codestar-connections delete-connection \
    --connection-arn arn:aws:codestar-connections:us-west-2:123456789012:connection/
aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f
```

This command produces no output.

For more information, see Delete a connection (CLI) in the *Developer Tools console User Guide*.

- For API details, see DeleteConnection in *Amazon CLI Command Reference*.

`delete-host`

The following code example shows how to use `delete-host`.

Amazon CLI

To delete a host

The following `delete-host` example shows how to delete a host. Before you can delete a host, you must delete all connections associated with the host.

```
aws codestar-connections delete-host \
    --host-arn "arn:aws:codestar-connections:us-east-1 :123456789012:host/My-Host-28aef605"
```

This command produces no output.

For more information, see Delete a host (CLI) in the *Developer Tools console User Guide*.

- For API details, see DeleteHost in *Amazon CLI Command Reference*.

`get-connection`

The following code example shows how to use `get-connection`.

Amazon CLI

To get information about a connection

The following `get-connection` example shows details about a connection.

```
aws codestar-connections get-connection \
    --connection-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f
```

Output:

```
{
    "Connection": {
        "ConnectionName": "MyConnection",
```

```
        "ConnectionArn": "arn:aws:codestar-connections:us-
east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
        "ProviderType": "Bitbucket",
        "OwnerAccountId": "123456789012",
        "ConnectionStatus": "AVAILABLE"
    }
}
```

For more information, see View connection details in the *Developer Tools console User Guide*.

- For API details, see GetConnection in *Amazon CLI Command Reference*.

`get-host`

The following code example shows how to use `get-host`.

Amazon CLI

To get information about a host

The following `get-host` example shows details about a host:

```
aws codestar-connections get-host \
    --host-arn arn:aws:codestar-connections:us-east-1:123456789012:host/
MyHost-28aef605
```

Output:

```
{
    "Name": "MyHost",
    "Status": "AVAILABLE",
    "ProviderType": "GitHubEnterpriseServer",
    "ProviderEndpoint": "https://test-instance-1.dev/"
}
```

For more information, see View host details (CLI) in the *Developer Tools console User Guide*.

- For API details, see GetHost in *Amazon CLI Command Reference*.

`list-connections`

The following code example shows how to use `list-connections`.

Amazon CLI

To list connections

The following `list-connections` example retrieves a list of all connections in your account for the Bitbucket provider type.:

```
aws codestar-connections list-connections \
--provider-type Bitbucket \
--max-results 5 \
--next-token: next-token
```

Output:

```
{
    "Connections": [
        {
            "ConnectionName": "my-connection",
            "ProviderType": "Bitbucket",
            "Status": "PENDING",
            "ARN": "arn:aws:codestar-connections:us-east-1:123456789012:connection/
aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
            "OwnerAccountId": "123456789012"
        },
        {
            "ConnectionName": "my-other-connection",
            "ProviderType": "Bitbucket",
            "Status": "AVAILABLE",
            "ARN": "arn:aws:codestar-connections:us-east-1:123456789012:connection/
aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f",
            "OwnerAccountId": "123456789012"
        },
    ],
    "NextToken": "next-token"
}
```

For more information, see List connections (CLI) in the *Developer Tools console User Guide*.

- For API details, see ListConnections in *Amazon CLI Command Reference*.

`list-hosts`

The following code example shows how to use `list-hosts`.

Amazon CLI

To list hosts

The following `list-hosts` example retrieves a list of all hosts in your account.

```
aws codestar-connections list-hosts
```

Output:

```
{
    "Hosts": [
        {
            "Name": "My-Host",
            "HostArn": "arn:aws:codestar-connections:us-east-1:123456789012:host/My-
Host-28aef605",
            "ProviderType": "GitHubEnterpriseServer",
            "ProviderEndpoint": "https://my-instance.test.dev",
            "Status": "AVAILABLE"
        }
    ]
}
```

For more information, see List hosts (CLI) in the *Developer Tools console User Guide*.

- For API details, see ListHosts in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list tags

The following `list-tags-for-resource` example retrieves a list of all tags attached to the specified connections resource.

```
aws codestar-connections list-tags-for-resource \
    --resource-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/
aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f
```

Output:

```
{
    "Tags": [
        {
            "Key": "Project",
            "Value": "ProjectA"
        },
        {
            "Key": "ReadOnly",
            "Value": "true"
        }
    ]
}
```

For more information, see View tags for a connections resource in the *Developer Tools console User Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a resource

The following `tag-resource` example associates a set of provided tags with a connection. Use this command to add or edit tags.

```
aws codestar-connections tag-resource \
    --resource-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f \
    --tags Key=Project,Value=ProjectA Key=IscontainerBased,Value=true
```

This command produces no output.

For more information, see Add tags to a connections resource in the *Developer Tools console User Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove Amazon tags from a connections resource

The following `untag-resource` removes a tag from the specified resource.

```
aws codestar-connections untag-resource \
    --resource-arn arn:aws:codestar-connections:us-east-1:123456789012:connection/aEXAMPLE-8aad-4d5d-8878-dfcab0bc441f \
    --tag-keys Project ReadOnly
```

Output:

```
{
    "Tags": []
}
```

For more information, see Remove tags from a connections resource in the *Developer Tools console User Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

Amazon Cognito Identity examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Cognito Identity.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`create-identity-pool`

The following code example shows how to use `create-identity-pool`.

Amazon CLI

To create an identity pool with Cognito identity pool provider

This example creates an identity pool named MyIdentityPool. It has a Cognito identity pool provider. Unauthenticated identities are not allowed.

Command:

```
aws cognito-identity create-identity-pool --identity-pool-
name MyIdentityPool --no-allow-unauthenticated-identities --cognito-
identity-providers ProviderName="cognito-idp.us-west-2.amazonaws.com/us-
west-2_aaaaaaaaa",ClientId="3n4b5urk1ft4fl3mg5e62d9ado",ServerSideTokenCheck=false
```

Output:

```
{
  "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
  "IdentityPoolName": "MyIdentityPool",
  "AllowUnauthenticatedIdentities": false,
  "CognitoIdentityProviders": [
      {
          "ProviderName": "cognito-idp.us-west-2.amazonaws.com/us-west-2_111111111",
          "ClientId": "3n4b5urk1ft4fl3mg5e62d9ado",
          "ServerSideTokenCheck": false
      }
  ]
}
```

- For API details, see CreateIdentityPool in *Amazon CLI Command Reference*.

`delete-identities`

The following code example shows how to use `delete-identities`.

Amazon CLI

To delete identity pool

This example deletes an identity pool.

Command:

```
aws cognito-identity delete-identity-pool --identity-ids-to-delete "us-west-2:11111111-1111-1111-1111-111111111111"
```

Output:

```
{
  "UnprocessedIdentityIds": []
}
```

- For API details, see DeleteIdentities in *Amazon CLI Command Reference*.

`delete-identity-pool`

The following code example shows how to use `delete-identity-pool`.

Amazon CLI

To delete identity pool

The following `delete-identity-pool` example deletes the specified identity pool.

Command:

```
aws cognito-identity delete-identity-pool \
    --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111"
```

This command produces no output.

- For API details, see DeleteIdentityPool in *Amazon CLI Command Reference*.

`describe-identity-pool`

The following code example shows how to use `describe-identity-pool`.

Amazon CLI

To describe an identity pool

This example describes an identity pool.

Command:

```
aws cognito-identity describe-identity-pool --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111"
```

Output:

```
{
  "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
  "IdentityPoolName": "MyIdentityPool",
  "AllowUnauthenticatedIdentities": false,
  "CognitoIdentityProviders": [
      {
          "ProviderName": "cognito-idp.us-west-2.amazonaws.com/us-west-2_111111111",
          "ClientId": "3n4b5urk1ft4fl3mg5e62d9ado",
          "ServerSideTokenCheck": false
      }
  ]
}
```

- For API details, see DescribeIdentityPool in *Amazon CLI Command Reference*.

`get-identity-pool-roles`

The following code example shows how to use `get-identity-pool-roles`.

Amazon CLI

To get identity pool roles

This example gets identity pool roles.

Command:

```
aws cognito-identity get-identity-pool-roles --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111"
```

Output:

```
{
  "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
  "Roles": {
      "authenticated": "arn:aws:iam::111111111111:role/
Cognito_MyIdentityPoolAuth_Role",
      "unauthenticated": "arn:aws:iam::111111111111:role/
Cognito_MyIdentityPoolUnauth_Role"
  }
}
```

- For API details, see GetIdentityPoolRoles in *Amazon CLI Command Reference*.

`list-identity-pools`

The following code example shows how to use `list-identity-pools`.

Amazon CLI

To list identity pools

This example lists identity pools. There s a maximum of 20 identities listed.

Command:

```
aws cognito-identity list-identity-pools --max-results 20
```

Output:

```
{
  "IdentityPools": [
      {
          "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
          "IdentityPoolName": "MyIdentityPool"
      },
      {
          "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
          "IdentityPoolName": "AnotherIdentityPool"
      },
      {
```

```
            "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
            "IdentityPoolName": "IdentityPoolRegionA"
        }
    ]
}
```

- For API details, see ListIdentityPools in *Amazon CLI Command Reference*.

`set-identity-pool-roles`

The following code example shows how to use `set-identity-pool-roles`.

Amazon CLI

To set identity pool roles

The following `set-identity-pool-roles` example sets an identity pool role.

```
aws cognito-identity set-identity-pool-roles \
    --identity-pool-id "us-west-2:11111111-1111-1111-1111-111111111111" \
    --roles authenticated="arn:aws:iam::111111111111:role/
Cognito_MyIdentityPoolAuth_Role"
```

- For API details, see SetIdentityPoolRoles in *Amazon CLI Command Reference*.

`update-identity-pool`

The following code example shows how to use `update-identity-pool`.

Amazon CLI

To update an identity pool

This example updates an identity pool. It sets the name to MyIdentityPool. It adds Cognito as an identity provider. It disallows unauthenticated identities.

Command:

```
aws cognito-identity update-identity-pool --identity-pool-id "us-
west-2:11111111-1111-1111-1111-111111111111" --identity-pool-
name "MyIdentityPool" --no-allow-unauthenticated-identities --cognito-
```

```
identity-providers ProviderName="cognito-idp.us-west-2.amazonaws.com/us-
west-2_111111111",ClientId="3n4b5urk1ft4fl3mg5e62d9ado",ServerSideTokenCheck=false
```

Output:

```
{
  "IdentityPoolId": "us-west-2:11111111-1111-1111-1111-111111111111",
  "IdentityPoolName": "MyIdentityPool",
  "AllowUnauthenticatedIdentities": false,
  "CognitoIdentityProviders": [
      {
          "ProviderName": "cognito-idp.us-west-2.amazonaws.com/us-west-2_111111111",
          "ClientId": "3n4b5urk1ft4fl3mg5e62d9ado",
          "ServerSideTokenCheck": false
      }
  ]
}
```

- For API details, see UpdateIdentityPool in *Amazon CLI Command Reference*.

Amazon Cognito Identity Provider examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Cognito Identity Provider.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`add-custom-attributes`

The following code example shows how to use `add-custom-attributes`.

Amazon CLI

To add a custom attribute

This example adds a custom attribute CustomAttr1 to a user pool. It is a String type, and requires a minimum of 1 character and a maximum of 15. It is not required.

Command:

```
aws cognito-idp add-custom-attributes --user-pool-id us-west-2_aaaaaaaaa --custom-
attributes
 Name="CustomAttr1",AttributeDataType="String",DeveloperOnlyAttribute=false,Required=false,S
```

- For API details, see AddCustomAttributes in *Amazon CLI Command Reference*.

`admin-add-user-to-group`

The following code example shows how to use `admin-add-user-to-group`.

Amazon CLI

To add a user to a group

This example adds user Jane to group MyGroup.

Command:

```
aws cognito-idp admin-add-user-to-group --user-pool-id us-west-2_aaaaaaaaa --
username Jane --group-name MyGroup
```

- For API details, see AdminAddUserToGroup in *Amazon CLI Command Reference*.

`admin-confirm-sign-up`

The following code example shows how to use `admin-confirm-sign-up`.

Amazon CLI

To confirm user registration

This example confirms user jane@example.com.

Command:

```
aws cognito-idp admin-confirm-sign-up --user-pool-id us-west-2_aaaaaaaaa --
username jane@example.com
```

- For API details, see AdminConfirmSignUp in *Amazon CLI Command Reference*.

`admin-create-user`

The following code example shows how to use `admin-create-user`.

Amazon CLI

To create a user

The following `admin-create-user` example creates a user with the specified settings email address and phone number.

```
aws cognito-idp admin-create-user \
    --user-pool-id us-west-2_aaaaaaaaa \
    --username diego \
    --user-attributes Name=email,Value=diego@example.com
 Name=phone_number,Value="+15555551212" \
    --message-action SUPPRESS
```

Output:

```
{
    "User": {
        "Username": "diego",
        "Attributes": [
            {
                "Name": "sub",
                "Value": "7325c1de-b05b-4f84-b321-9adc6e61f4a2"
            },
            {
                "Name": "phone_number",
                "Value": "+15555551212"
            },
            {
                "Name": "email",
```

```
                "Value": "diego@example.com"
            }
        ],
        "UserCreateDate": 1548099495.428,
        "UserLastModifiedDate": 1548099495.428,
        "Enabled": true,
        "UserStatus": "FORCE_CHANGE_PASSWORD"
    }
}
```

- For API details, see AdminCreateUser in *Amazon CLI Command Reference*.

`admin-delete-user-attributes`

The following code example shows how to use `admin-delete-user-attributes`.

Amazon CLI

To delete a user attribute

This example deletes a custom attribute CustomAttr1 for user diego@example.com.

Command:

```
aws cognito-idp admin-delete-user-attributes --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com --user-attribute-names "custom:CustomAttr1"
```

- For API details, see AdminDeleteUserAttributes in *Amazon CLI Command Reference*.

`admin-delete-user`

The following code example shows how to use `admin-delete-user`.

Amazon CLI

To delete a user

This example deletes a user.

Command:

```
aws cognito-idp admin-delete-user --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com
```

- For API details, see AdminDeleteUser in *Amazon CLI Command Reference*.

admin-disable-provider-for-user

The following code example shows how to use admin-disable-provider-for-user.

Amazon CLI

To unlink a federated user from a local user profile

The following admin-disable-provider-for-user example disconnects a Google user from their linked local profile.

```
aws cognito-idp admin-disable-provider-for-user \
    --user-pool-id us-west-2_EXAMPLE \
    --
user ProviderAttributeName=Cognito_Subject,ProviderAttributeValue=0000000000000000,ProviderN
```

For more information, see Linking federated users to an existing user profile in the *Amazon Cognito Developer Guide*.

- For API details, see AdminDisableProviderForUser in *Amazon CLI Command Reference*.

admin-disable-user

The following code example shows how to use admin-disable-user.

Amazon CLI

To prevent sign-in by a user

The following admin-disable-user example prevents sign-in by the user diego@example.com.

```
aws cognito-idp admin-disable-user \
    --user-pool-id us-west-2_EXAMPLE \
```

```
    --username diego@example.com
```

For more information, see Managing users in the *Amazon Cognito Developer Guide*.

- For API details, see AdminDisableUser in *Amazon CLI Command Reference*.

`admin-enable-user`

The following code example shows how to use `admin-enable-user`.

Amazon CLI

To enable sign-in by a user

The following `admin-enable-user` example enables sign-in by the user diego@example.com.

```
aws cognito-idp admin-enable-user \
    --user-pool-id us-west-2_EXAMPLE \
    --username diego@example.com
```

For more information, see Managing users in the *Amazon Cognito Developer Guide*.

- For API details, see AdminEnableUser in *Amazon CLI Command Reference*.

`admin-forget-device`

The following code example shows how to use `admin-forget-device`.

Amazon CLI

To forget a device

This example forgets device for username jane@example.com

Command:

```
aws cognito-idp admin-forget-device --user-pool-id us-west-2_aaaaaaaaa --
username jane@example.com --device-key us-west-2_abcd_1234-5678
```

- For API details, see AdminForgetDevice in *Amazon CLI Command Reference*.

admin-get-device

The following code example shows how to use admin-get-device.

Amazon CLI

To get a device

The following admin-get-device example displays one device for the user diego.

```
aws cognito-idp admin-get-device \
    --user-pool-id us-west-2_EXAMPLE \
    --username diego \
    --device-key us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "Device": {
        "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "DeviceAttributes": [
            {
                "Name": "device_status",
                "Value": "valid"
            },
            {
                "Name": "device_name",
                "Value": "MyDevice"
            },
            {
                "Name": "dev:device_arn",
                "Value": "arn:aws:cognito-idp:us-west-2:123456789012:owner/diego.us-
west-2_EXAMPLE/device/us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
            },
            {
                "Name": "dev:device_owner",
                "Value": "diego.us-west-2_EXAMPLE"
            },
            {
                "Name": "last_ip_used",
                "Value": "192.0.2.1"
            },
            {
```

```
                "Name": "dev:device_remembered_status",
                "Value": "remembered"
            },
            {
                "Name": "dev:device_sdk",
                "Value": "aws-sdk"
            }
        ],
        "DeviceCreateDate": 1715100742.022,
        "DeviceLastModifiedDate": 1723233651.167,
        "DeviceLastAuthenticatedDate": 1715100742.0
    }
}
```

For more information, see Working with user devices in your user pool in the *Amazon Cognito Developer Guide*.

- For API details, see AdminGetDevice in *Amazon CLI Command Reference*.

`admin-get-user`

The following code example shows how to use `admin-get-user`.

Amazon CLI

To get a user

This example gets information about username jane@example.com.

Command:

```
aws cognito-idp admin-get-user --user-pool-id us-west-2_aaaaaaaaa --
username jane@example.com
```

Output:

```
{
  "Username": "4320de44-2322-4620-999b-5e2e1c8df013",
  "Enabled": true,
  "UserStatus": "FORCE_CHANGE_PASSWORD",
  "UserCreateDate": 1548108509.537,
```

```
  "UserAttributes": [
      {
          "Name": "sub",
          "Value": "4320de44-2322-4620-999b-5e2e1c8df013"
      },
      {
          "Name": "email_verified",
          "Value": "true"
      },
      {
          "Name": "phone_number_verified",
          "Value": "true"
      },
      {
          "Name": "phone_number",
          "Value": "+01115551212"
      },
      {
          "Name": "email",
          "Value": "jane@example.com"
      }
  ],
  "UserLastModifiedDate": 1548108509.537
}
```

- For API details, see AdminGetUser in *Amazon CLI Command Reference*.

`admin-initiate-auth`

The following code example shows how to use `admin-initiate-auth`.

Amazon CLI

To sign in a user as an admin

The following `admin-initiate-auth` example signs in the user diego@example.com. This example also includes metadata for threat protection and ClientMetadata for Lambda triggers. The user is configured for TOTP MFA and receives a challenge to provide a code from their authenticator app before they can complete authentication.

```
aws cognito-idp admin-initiate-auth \
    --user-pool-id us-west-2_EXAMPLE \
```

```
    --client-id 1example23456789 \
    --auth-flow ADMIN_USER_PASSWORD_AUTH \
    --auth-parameters USERNAME=diego@example.com,PASSWORD="My@Example
$Password3!",SECRET_HASH=ExampleEncodedClientIdSecretAndUsername= \
    --context-data="{\"EncodedData\":\"abc123example\",\"HttpHeaders\":
[{\"headerName\":\"UserAgent\",\"headerValue\":\"Mozilla/5.0 (Windows NT 6.1;
 Win64; x64; rv:47.0) Gecko/20100101 Firefox/47.0\"}],\"IpAddress\":\"192.0.2.1\",
\"ServerName\":\"example.com\",\"ServerPath\":\"/login\"}" \
    --client-metadata="{\"MyExampleKey\": \"MyExampleValue\"}"
```

Output:

```
{
    "ChallengeName": "SOFTWARE_TOKEN_MFA",
    "Session": "AYABeExample...",
    "ChallengeParameters": {
        "FRIENDLY_DEVICE_NAME": "MyAuthenticatorApp",
        "USER_ID_FOR_SRP": "diego@example.com"
    }
}
```

For more information, see Admin authentication flow in the *Amazon Cognito Developer Guide*.

- For API details, see AdminInitiateAuth in *Amazon CLI Command Reference*.

admin-link-provider-for-user

The following code example shows how to use `admin-link-provider-for-user`.

Amazon CLI

To link a local user to a federated user

The following `admin-link-provider-for-user` example links the local user diego to a user who will do federated sign-in with Google.

```
aws cognito-idp admin-link-provider-for-user \
    --user-pool-id us-west-2_EXAMPLE \
    --destination-user ProviderName=Cognito,ProviderAttributeValue=diego \
    --source-
user ProviderAttributeName=Cognito_Subject,ProviderAttributeValue=0000000000000000,ProviderN
```

For more information, see Linking federated users to an existing user profile in the *Amazon Cognito Developer Guide*.

- For API details, see AdminLinkProviderForUser in *Amazon CLI Command Reference*.

`admin-list-devices`

The following code example shows how to use `admin-list-devices`.

Amazon CLI

To list devices for a user

The following `admin-list-devices` example lists devices for the user diego.

```
aws cognito-idp admin-list-devices \
    --user-pool-id us-west-2_EXAMPLE \
    --username diego \
    --limit 1
```

Output:

```
{
    "Devices": [
        {
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceAttributes": [
                {
                    "Name": "device_status",
                    "Value": "valid"
                },
                {
                    "Name": "device_name",
                    "Value": "MyDevice"
                },
                {
                    "Name": "dev:device_arn",
                    "Value": "arn:aws:cognito-idp:us-west-2:123456789012:owner/
diego.us-west-2_EXAMPLE/device/us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
                },
                {
                    "Name": "dev:device_owner",
                    "Value": "diego.us-west-2_EXAMPLE"
```

```
                },
                {
                    "Name": "last_ip_used",
                    "Value": "192.0.2.1"
                },
                {
                    "Name": "dev:device_remembered_status",
                    "Value": "remembered"
                },
                {
                    "Name": "dev:device_sdk",
                    "Value": "aws-sdk"
                }
            ],
            "DeviceCreateDate": 1715100742.022,
            "DeviceLastModifiedDate": 1723233651.167,
            "DeviceLastAuthenticatedDate": 1715100742.0
        }
    ]
}
```

For more information, see Working with user devices in your user pool in the *Amazon Cognito Developer Guide*.

- For API details, see AdminListDevices in *Amazon CLI Command Reference*.

`admin-list-groups-for-user`

The following code example shows how to use `admin-list-groups-for-user`.

Amazon CLI

To list groups for a user

This example lists groups for username jane@example.com.

Command:

```
aws cognito-idp admin-list-groups-for-user --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com
```

Output:

```
{
  "Groups": [
      {
          "Description": "Sample group",
          "Precedence": 1,
          "LastModifiedDate": 1548097827.125,
          "RoleArn": "arn:aws:iam::111111111111:role/SampleRole",
          "GroupName": "SampleGroup",
          "UserPoolId": "us-west-2_aaaaaaaaa",
          "CreationDate": 1548097827.125
      }
  ]
}
```

- For API details, see AdminListGroupsForUser in *Amazon CLI Command Reference*.

`admin-list-user-auth-events`

The following code example shows how to use `admin-list-user-auth-events`.

Amazon CLI

To list authorization events for a user

The following `admin-list-user-auth-events` example lists the most recent user activity log event for the user diego.

```
aws cognito-idp admin-list-user-auth-events \
    --user-pool-id us-west-2_ywDJHlIfU \
    --username brcotter+050123 \
    --max-results 1
```

Output:

```
{
    "AuthEvents": [
        {
            "EventId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "EventType": "SignIn",
            "CreationDate": 1726694203.495,
            "EventResponse": "InProgress",
```

```
            "EventRisk": {
                "RiskDecision": "AccountTakeover",
                "RiskLevel": "Medium",
                "CompromisedCredentialsDetected": false
            },
            "ChallengeResponses": [
                {
                    "ChallengeName": "Password",
                    "ChallengeResponse": "Success"
                }
            ],
            "EventContextData": {
                "IpAddress": "192.0.2.1",
                "City": "Seattle",
                "Country": "United States"
            }
        }
    ],
    "NextToken": "a1b2c3d4-5678-90ab-cdef-EXAMPLE22222#2024-09-18T21:16:43.495Z"
}
```

For more information, see Viewing and exporting user event history in the *Amazon Cognito Developer Guide*.

- For API details, see AdminListUserAuthEvents in *Amazon CLI Command Reference*.

`admin-remove-user-from-group`

The following code example shows how to use `admin-remove-user-from-group`.

Amazon CLI

To remove a user from a group

This example removes jane@example.com from SampleGroup.

Command:

```
aws cognito-idp admin-remove-user-from-group --user-pool-id us-west-2_aaaaaaaaa --
username jane@example.com --group-name SampleGroup
```

- For API details, see AdminRemoveUserFromGroup in *Amazon CLI Command Reference*.

`admin-reset-user-password`

The following code example shows how to use `admin-reset-user-password`.

Amazon CLI

To reset a user password

This example resets the password for diego@example.com.

Command:

```
aws cognito-idp admin-reset-user-password --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com
```

- For API details, see AdminResetUserPassword in *Amazon CLI Command Reference*.

`admin-respond-to-auth-challenge`

The following code example shows how to use `admin-respond-to-auth-challenge`.

Amazon CLI

To respond to an authentication challenge

There are many ways to respond to different authentication challenges, depending on your authentication flow, user pool configuration, and user settings. The following `admin-respond-to-auth-challenge` example provides a TOTP MFA code for diego@example.com and completes sign-in. This user pool has device remembering turned on, so the authentication result also returns a new device key.

```
aws cognito-idp admin-respond-to-auth-challenge \
    --user-pool-id us-west-2_EXAMPLE \
    --client-id 1example23456789 \
    --challenge-name SOFTWARE_TOKEN_MFA \
    --challenge-responses USERNAME=diego@example.com,SOFTWARE_TOKEN_MFA_CODE=000000
 \
    --session AYABeExample...
```

Output:

```
{
```

```
    "ChallengeParameters": {},
    "AuthenticationResult": {
        "AccessToken": "eyJra456defEXAMPLE",
        "ExpiresIn": 3600,
        "TokenType": "Bearer",
        "RefreshToken": "eyJra123abcEXAMPLE",
        "IdToken": "eyJra789ghiEXAMPLE",
        "NewDeviceMetadata": {
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceGroupKey": "-ExAmPlE1"
        }
    }
}
```

For more information, see Admin authentication flow in the *Amazon Cognito Developer Guide*.

- For API details, see AdminRespondToAuthChallenge in *Amazon CLI Command Reference*.

`admin-set-user-mfa-preference`

The following code example shows how to use `admin-set-user-mfa-preference`.

Amazon CLI

To set the user MFA preference

This example sets the SMS MFA preference for username diego@example.com.

Command:

```
aws cognito-idp admin-set-user-mfa-preference --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com --sms-mfa-settings Enabled=false,PreferredMfa=false
```

- For API details, see AdminSetUserMfaPreference in *Amazon CLI Command Reference*.

`admin-set-user-password`

The following code example shows how to use `admin-set-user-password`.

Amazon CLI

To set a user password as an admin

The following `admin-set-user-password` example permanently sets the password for diego@example.com.

```
aws cognito-idp admin-set-user-password \
    --user-pool-id us-west-2_EXAMPLE \
    --username diego@example.com \
    --password MyExamplePassword1! \
    --permanent
```

This command produces no output.

For more information, see Passwords, password recovery, and password policies in the *Amazon Cognito Developer Guide*.

- For API details, see AdminSetUserPassword in *Amazon CLI Command Reference*.

`admin-set-user-settings`

The following code example shows how to use `admin-set-user-settings`.

Amazon CLI

To set user settings

This example sets the MFA delivery preference for username diego@example.com to EMAIL.

Command:

```
aws cognito-idp admin-set-user-settings --user-pool-id us-west-2_aaaaaaaaa --
username diego@example.com --mfa-options DeliveryMedium=EMAIL
```

- For API details, see AdminSetUserSettings in *Amazon CLI Command Reference*.

`admin-update-auth-event-feedback`

The following code example shows how to use `admin-update-auth-event-feedback`.

Amazon CLI

To provide feedback for an authorization event

This example sets the feedback value for an authorization event identified by event-id to Valid.

Command:

```
aws cognito-idp admin-update-auth-event-feedback --user-pool-id us-west-2_aaaaaaaaa
 --username diego@example.com --event-id c2c2cf89-c0d3-482d-aba6-99d78a5b0bfe --
feedback-value Valid
```

- For API details, see AdminUpdateAuthEventFeedback in *Amazon CLI Command Reference*.

`admin-update-device-status`

The following code example shows how to use `admin-update-device-status`.

Amazon CLI

To update device status

This example sets the device remembered status for the device identified by device-key to not_remembered.

Command:

```
aws cognito-idp admin-update-device-status --user-pool-id us-west-2_aaaaaaaaa
 --username diego@example.com --device-key xxxx  --device-remembered-
status not_remembered
```

- For API details, see AdminUpdateDeviceStatus in *Amazon CLI Command Reference*.

`admin-update-user-attributes`

The following code example shows how to use `admin-update-user-attributes`.

Amazon CLI

To update user attributes

This example updates a custom user attribute CustomAttr1 for user diego@example.com.

Command:

```
aws cognito-idp admin-update-user-attributes --user-pool-id us-
west-2_aaaaaaaaa --username diego@example.com --user-attributes
 Name="custom:CustomAttr1",Value="Purple"
```

- For API details, see AdminUpdateUserAttributes in *Amazon CLI Command Reference*.

`admin-user-global-sign-out`

The following code example shows how to use `admin-user-global-sign-out`.

Amazon CLI

To sign out a user as an admin

The following `admin-user-global-sign-out` example signs out the user diego@example.com.

```
aws cognito-idp admin-user-global-sign-out \
    --user-pool-id us-west-2_EXAMPLE \
    --username diego@example.com
```

For more information, see Authentication with a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see AdminUserGlobalSignOut in *Amazon CLI Command Reference*.

`associate-software-token`

The following code example shows how to use `associate-software-token`.

Amazon CLI

To generate a secret key for an MFA authenticator app

The following `associate-software-token` example generates a TOTP private key for a user who has signed in and received an access token. The resulting private key can be manually entered into an authenticator app, or applications can render it as a QR code that the user can scan.

```
aws cognito-idp associate-software-token \
```

```
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "SecretCode": "QWERTYUIOP123456EXAMPLE"
}
```

For more information, see TOTP software token MFA in the *Amazon Cognito Developer Guide*.

- For API details, see AssociateSoftwareToken in *Amazon CLI Command Reference*.

`change-password`

The following code example shows how to use `change-password`.

Amazon CLI

To change a password

This example changes a password.

Command:

```
aws cognito-idp change-password --previous-password OldPassword --proposed-
password NewPassword --access-token ACCESS_TOKEN
```

- For API details, see ChangePassword in *Amazon CLI Command Reference*.

`confirm-device`

The following code example shows how to use `confirm-device`.

Amazon CLI

To confirm a user device

The following `confirm-device` example adds a new remembered device for the current user.

```
aws cognito-idp confirm-device \
   --access-token eyJra456defEXAMPLE \
   --device-key us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
```

```
   --device-secret-verifier-
config PasswordVerifier=TXlWZXJpZmllclN0cmluZw,Salt=TXlTUlBTYWx0
```

Output:

```
{
    "UserConfirmationNecessary": false
}
```

For more information, see Working with user devices in your user pool in the *Amazon Cognito Developer Guide*.

- For API details, see ConfirmDevice in *Amazon CLI Command Reference*.

`confirm-forgot-password`

The following code example shows how to use `confirm-forgot-password`.

Amazon CLI

To confirm a forgotten password

This example confirms a forgotten password for username diego@example.com.

Command:

```
aws cognito-idp confirm-forgot-password --client-id 3n4b5urk1ft4fl3mg5e62d9ado --
username=diego@example.com --password PASSWORD --confirmation-code CONF_CODE
```

- For API details, see ConfirmForgotPassword in *Amazon CLI Command Reference*.

`confirm-sign-up`

The following code example shows how to use `confirm-sign-up`.

Amazon CLI

To confirm sign-up

This example confirms sign-up for username diego@example.com.

Command:

```
aws cognito-idp confirm-sign-up --client-id 3n4b5urk1ft4fl3mg5e62d9ado --
username=diego@example.com --confirmation-code CONF_CODE
```

- For API details, see ConfirmSignUp in *Amazon CLI Command Reference*.

`create-group`

The following code example shows how to use `create-group`.

Amazon CLI

To create a group

This example creates a group with a description.

Command:

```
aws cognito-idp create-group --user-pool-id us-west-2_aaaaaaaaa --group-
name MyNewGroup --description "New group."
```

Output:

```
{
  "Group": {
      "GroupName": "MyNewGroup",
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "Description": "New group.",
      "LastModifiedDate": 1548270073.795,
      "CreationDate": 1548270073.795
  }
}
```

To create a group with a role and precedence

This example creates a group with a description. It also includes a role and precedence.

Command:

```
aws cognito-idp create-group --user-pool-id us-west-2_aaaaaaaaa --group-
name MyNewGroupWithRole --description "New group with a role." --role-
arn arn:aws:iam::111111111111:role/MyNewGroupRole --precedence 2
```

Output:

```
{
  "Group": {
      "GroupName": "MyNewGroupWithRole",
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "Description": "New group with a role.",
      "RoleArn": "arn:aws:iam::111111111111:role/MyNewGroupRole",
      "Precedence": 2,
      "LastModifiedDate": 1548270211.761,
      "CreationDate": 1548270211.761
  }
}
```

- For API details, see CreateGroup in *Amazon CLI Command Reference*.

`create-identity-provider`

The following code example shows how to use `create-identity-provider`.

Amazon CLI

Example 1: To create a user pool SAML identity provider (IdP) with a metadata URL

The following `create-identity-provider` example creates a new SAML IdP with metadata from a public URL, attribute mapping, and two identifiers.

```
aws cognito-idp create-identity-provider \
    --user-pool-id us-west-2_EXAMPLE \
    --provider-name MySAML \
    --provider-type SAML \
    --provider-
details IDPInit=true,IDPSignout=true,EncryptedResponses=true,MetadataURL=https://
auth.example.com/sso/saml/metadata,RequestSigningAlgorithm=rsa-sha256 \
    --attribute-mapping email=emailaddress,phone_number=phone,custom:111=department
 \
    --idp-identifiers CorpSAML WestSAML
```

Output:

```
{
```

```
    "IdentityProvider": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "ProviderName": "MySAML",
        "ProviderType": "SAML",
        "ProviderDetails": {
            "ActiveEncryptionCertificate": "MIICvTCCAaEXAMPLE",
            "EncryptedResponses": "true",
            "IDPInit": "true",
            "IDPSignout": "true",
            "MetadataURL": "https://auth.example.com/sso/saml/metadata",
            "RequestSigningAlgorithm": "rsa-sha256",
            "SLORedirectBindingURI": "https://auth.example.com/slo/saml",
            "SSORedirectBindingURI": "https://auth.example.com/sso/saml"
        },
        "AttributeMapping": {
            "custom:111": "department",
            "emailaddress": "email",
            "phone": "phone_number"
        },
        "IdpIdentifiers": [
            "CorpSAML",
            "WestSAML"
        ],
        "LastModifiedDate": 1726853833.977,
        "CreationDate": 1726853833.977
    }
}
```

For more information, see Adding user pool sign-in through a third party in the *Amazon Cognito Developer Guide*.

Example 2: To create a user pool SAML identity provider (IdP) with a metadata file

The following `create-identity-provider` example creates a new SAML IdP with metadata from a file, attribute mapping, and two identifiers. File syntax can differ between operating systems in the `--provider-details` parameter. It's easiest to create a JSON input file for this operation.:

```
aws cognito-idp create-identity-provider \
    --cli-input-json file://.\SAML-identity-provider.json
```

Contents of `SAML-identity-provider.json`:

```
{
    "AttributeMapping": {
        "email" : "idp_email",
        "email_verified" : "idp_email_verified"
    },
    "IdpIdentifiers": [ "platform" ],
    "ProviderDetails": {
        "MetadataFile": "<md:EntityDescriptor xmlns:md=
\"urn:oasis:names:tc:SAML:2.0:metadata\" entityID=\"http://www.example.com/
sso\"><md:IDPSSODescriptor WantAuthnRequestsSigned=\"false\"

            "platform"
        ],
        "LastModifiedDate": 1726855290.731,
        "CreationDate": 1726855290.731
    }
}
```

For more information, see Adding user pool sign-in through a third party in the *Amazon Cognito Developer Guide*.

- For API details, see CreateIdentityProvider in *Amazon CLI Command Reference*.

`create-resource-server`

The following code example shows how to use `create-resource-server`.

Amazon CLI

To create a user pool client

The following `create-resource-server` example creates a new resource server with custom scopes.

```
aws cognito-idp create-resource-server \
    --user-pool-id us-west-2_EXAMPLE \
    --identifier solar-system-data \
    --name "Solar system object tracker" \
    --scopes ScopeName=sunproximity.read,ScopeDescription="Distance in AU from Sol"
 ScopeName=asteroids.add,ScopeDescription="Enter a new asteroid"
```

Output:

```
{
    "ResourceServer": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "Identifier": "solar-system-data",
        "Name": "Solar system object tracker",
        "Scopes": [
            {
                "ScopeName": "sunproximity.read",
                "ScopeDescription": "Distance in AU from Sol"
            },
            {
                "ScopeName": "asteroids.add",
                "ScopeDescription": "Enter a new asteroid"
            }
        ]
    }
}
```

For more information, see Scopes, M2M, and APIs with resource servers in the *Amazon Cognito Developer Guide*.

- For API details, see CreateResourceServer in *Amazon CLI Command Reference*.

`create-user-import-job`

The following code example shows how to use `create-user-import-job`.

Amazon CLI

To create a user import job

This example creates a user import job named MyImportJob.

For more information about importing users, see Importing Users into User Pools From a CSV File.

Command:

```
aws cognito-idp create-user-import-job --user-pool-id us-west-2_aaaaaaaaa --
job-name MyImportJob --cloud-watch-logs-role-arn arn:aws:iam::111111111111:role/
CognitoCloudWatchLogsRole
```

Output:

```
{
  "UserImportJob": {
      "JobName": "MyImportJob",
      "JobId": "import-qQ0DCt2fRh",
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "PreSignedUrl": "PRE_SIGNED_URL",
      "CreationDate": 1548271795.471,
      "Status": "Created",
      "CloudWatchLogsRoleArn": "arn:aws:iam::111111111111:role/
CognitoCloudWatchLogsRole",
      "ImportedUsers": 0,
      "SkippedUsers": 0,
      "FailedUsers": 0
  }
}
```

Upload the .csv file with curl using the pre-signed URL:

Command:

```
curl -v -T "PATH_TO_CSV_FILE" -H "x-amz-server-side-encryption:aws:kms"
 "PRE_SIGNED_URL"
```

- For API details, see CreateUserImportJob in *Amazon CLI Command Reference*.

`create-user-pool-client`

The following code example shows how to use `create-user-pool-client`.

Amazon CLI

To create a user pool client

The following `create-user-pool-client` example creates a new user pool client with a client secret, explicit read and write attributes, sign in with username-password and SRP flows, sign-in with three IdPs, access to a subset of OAuth scopes, PinPoint analytics, and an extended authentication session validity.

```
aws cognito-idp create-user-pool-client \
    --user-pool-id us-west-2_EXAMPLE \
    --client-name MyTestClient \
    --generate-secret \
    --refresh-token-validity 10 \
    --access-token-validity 60 \
    --id-token-validity 60 \
    --token-validity-units AccessToken=minutes,IdToken=minutes,RefreshToken=days \
    --read-attributes email phone_number email_verified phone_number_verified \
    --write-attributes email phone_number \
    --explicit-auth-
flows ALLOW_USER_PASSWORD_AUTH ALLOW_USER_SRP_AUTH ALLOW_REFRESH_TOKEN_AUTH \
    --supported-identity-providers Google Facebook MyOIDC \
    --callback-urls https://www.amazon.com https://example.com http://
localhost:8001 myapp://example \
    --allowed-o-auth-flows code implicit \
    --allowed-o-auth-scopes openid profile aws.cognito.signin.user.admin solar-
system-data/asteroids.add \
    --allowed-o-auth-flows-user-pool-client \
    --analytics-configuration ApplicationArn=arn:aws:mobiletargeting:us-
west-2:767671399759:apps/thisisanexamplepinpointapplicationid,UserDataShared=TRUE \
    --prevent-user-existence-errors ENABLED \
    --enable-token-revocation \
    --enable-propagate-additional-user-context-data \
```

```
    --auth-session-validity 4
```

Output:

```
{
    "UserPoolClient": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "ClientName": "MyTestClient",
        "ClientId": "123abc456defEXAMPLE",
        "ClientSecret": "this1234is5678my91011example1213client1415secret",
        "LastModifiedDate": 1726788459.464,
        "CreationDate": 1726788459.464,

            "code"
        ],
        "AllowedOAuthScopes": [
            "aws.cognito.signin.user.admin",
            "openid",
            "profile",
            "solar-system-data/asteroids.add"
        ],
        "AllowedOAuthFlowsUserPoolClient": true,
        "AnalyticsConfiguration": {
            "ApplicationArn": "arn:aws:mobiletargeting:us-west-2:123456789012:apps/
thisisanexamplepinpointapplicationid",
            "RoleArn": "arn:aws:iam::123456789012:role/aws-service-role/cognito-
idp.amazonaws.com/AWSServiceRoleForAmazonCognitoIdp",
            "UserDataShared": true
        },
        "PreventUserExistenceErrors": "ENABLED",
        "EnableTokenRevocation": true,
        "EnablePropagateAdditionalUserContextData": true,
        "AuthSessionValidity": 4
    }
}
```

For more information, see Application-specific settings with app clients in the *Amazon Cognito Developer Guide*.

- For API details, see CreateUserPoolClient in *Amazon CLI Command Reference*.

`create-user-pool-domain`

The following code example shows how to use `create-user-pool-domain`.

Amazon CLI

Example 1: To create a user pool domain

The following `create-user-pool-domain` example creates a new custom domain.

```
aws cognito-idp create-user-pool-domain \
    --user-pool-id us-west-2_EXAMPLE \
    --domain auth.example.com \
    --custom-domain-config CertificateArn=arn:aws:acm:us-
east-1:123456789012:certificate/a1b2c3d4-5678-90ab-cdef-EXAMPLE22222
```

Output:

```
{
    "CloudFrontDomain": "example1domain.cloudfront.net"
}
```

For more information, see Configuring a user pool domain in the *Amazon Cognito Developer Guide*.

Example 2: To create a user pool domain

The following `create-user-pool-domain` example creates a new domain with a service-owned prefix.

```
aws cognito-idp create-user-pool-domain \
    --user-pool-id us-west-2_EXAMPLE2 \
    --domain mydomainprefix
```

For more information, see Configuring a user pool domain in the *Amazon Cognito Developer Guide*.

- For API details, see CreateUserPoolDomain in *Amazon CLI Command Reference*.

`create-user-pool`

The following code example shows how to use `create-user-pool`.

Amazon CLI

To create a minimally configured user pool

This example creates a user pool named MyUserPool using default values. There are no required attributes and no application clients. MFA and advanced security is disabled.

Command:

```
aws cognito-idp create-user-pool --pool-name MyUserPool
```

Output:

```
{
  "UserPool": {
      "SchemaAttributes": [
          {
              "Name": "sub",
              "StringAttributeConstraints": {

To create a user pool with two required attributes

This example creates a user pool MyUserPool. The pool is configured to accept email as a username attribute. It also sets the email source address to a validated address using Amazon Simple Email Service.

Command:

```
aws cognito-idp create-user-pool --pool-name MyUserPool --username-
attributes "email" --email-configuration=SourceArn="arn:aws:ses:us-
east-1:111111111111:identity/
jane@example.com",ReplyToEmailAddress="jane@example.com"
```

Output:

```
{
    "UserPool": {
        "SchemaAttributes": [
            {
```

}
```

- For API details, see CreateUserPool in *Amazon CLI Command Reference*.

`delete-group`

The following code example shows how to use `delete-group`.

Amazon CLI

To delete a group

This example deletes a group.

Command:

```
aws cognito-idp delete-group --user-pool-id us-west-2_aaaaaaaaa  --group-
name MyGroupName
```

- For API details, see DeleteGroup in *Amazon CLI Command Reference*.

`delete-identity-provider`

The following code example shows how to use `delete-identity-provider`.

Amazon CLI

To delete an identity provider

This example deletes an identity provider.

Command:

```
aws cognito-idp delete-identity-provider --user-pool-id us-west-2_aaaaaaaaa --
provider-name Facebook
```

- For API details, see DeleteIdentityProvider in *Amazon CLI Command Reference*.

`delete-resource-server`

The following code example shows how to use `delete-resource-server`.

Amazon CLI

To delete a resource server

This example deletes a resource server named weather.example.com.

Command:

```
aws cognito-idp delete-resource-server --user-pool-id us-west-2_aaaaaaaaa --
identifier weather.example.com
```

- For API details, see DeleteResourceServer in *Amazon CLI Command Reference*.

`delete-user-attributes`

The following code example shows how to use `delete-user-attributes`.

Amazon CLI

To delete a user attribute

The following `delete-user-attributes` example deletes the custom attribute "custom:attribute" from the currently signed-in user.

```
aws cognito-idp delete-user-attributes \
    --access-token ACCESS_TOKEN \
    --user-attribute-names "custom:department"
```

This command produces no output.

For more information, see Working with user attributes in the *Amazon Cognito Developer Guide*.

- For API details, see DeleteUserAttributes in *Amazon CLI Command Reference*.

`delete-user-pool-client`

The following code example shows how to use `delete-user-pool-client`.

Amazon CLI

To delete a user pool client

This example deletes a user pool client.

Command:

```
aws cognito-idp delete-user-pool-client --user-pool-id us-west-2_aaaaaaaaa --client-id 38fjsnc484p94kpqsnet7mpld0
```

- For API details, see DeleteUserPoolClient in *Amazon CLI Command Reference*.

`delete-user-pool-domain`

The following code example shows how to use `delete-user-pool-domain`.

Amazon CLI

To delete a user pool domain

The following `delete-user-pool-domain` example deletes a user pool domain named `my-domain`

```
aws cognito-idp delete-user-pool-domain \
```

```
    --user-pool-id us-west-2_aaaaaaaaa \
    --domain my-domain
```

- For API details, see DeleteUserPoolDomain in *Amazon CLI Command Reference*.

`delete-user-pool`

The following code example shows how to use `delete-user-pool`.

Amazon CLI

To delete a user pool

This example deletes a user pool using the user pool id, us-west-2_aaaaaaaaa.

Command:

```
aws cognito-idp delete-user-pool --user-pool-id us-west-2_aaaaaaaaa
```

- For API details, see DeleteUserPool in *Amazon CLI Command Reference*.

`delete-user`

The following code example shows how to use `delete-user`.

Amazon CLI

To delete a user

This example deletes a user.

Command:

```
aws cognito-idp delete-user --access-token ACCESS_TOKEN
```

- For API details, see DeleteUser in *Amazon CLI Command Reference*.

`describe-identity-provider`

The following code example shows how to use `describe-identity-provider`.

Amazon CLI

To describe an identity provider

This example describes an identity provider named Facebook.

Command:

```
aws cognito-idp describe-identity-provider --user-pool-id us-west-2_aaaaaaaaa --
provider-name Facebook
```

Output:

```
{
  "IdentityProvider": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "ProviderName": "Facebook",
      "ProviderType": "Facebook",
      "ProviderDetails": {
          "attributes_url": "https://graph.facebook.com/me?fields=",
          "attributes_url_add_attributes": "true",
          "authorize_scopes": myscope",
          "authorize_url": "https://www.facebook.com/v2.9/dialog/oauth",
          "client_id": "11111",
          "client_secret": "11111",
          "token_request_method": "GET",
          "token_url": "https://graph.facebook.com/v2.9/oauth/access_token"
      },
      "AttributeMapping": {
          "username": "id"
      },
      "IdpIdentifiers": [],
      "LastModifiedDate": 1548105901.736,
      "CreationDate": 1548105901.736
  }
}
```

- For API details, see DescribeIdentityProvider in *Amazon CLI Command Reference*.

`describe-resource-server`

The following code example shows how to use `describe-resource-server`.

Amazon CLI

To describe a resource server

This example describes the resource server weather.example.com.

Command:

```
aws cognito-idp describe-resource-server --user-pool-id us-west-2_aaaaaaaaa --
identifier weather.example.com
```

Output:

```
{
  "ResourceServer": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "Identifier": "weather.example.com",
      "Name": "Weather",
      "Scopes": [
          {
              "ScopeName": "weather.update",
              "ScopeDescription": "Update weather forecast"
          },
          {
              "ScopeName": "weather.read",
              "ScopeDescription": "Read weather forecasts"
          },
          {
              "ScopeName": "weather.delete",
              "ScopeDescription": "Delete a weather forecast"
          }
      ]
  }
}
```

- For API details, see DescribeResourceServer in *Amazon CLI Command Reference*.

`describe-risk-configuration`

The following code example shows how to use `describe-risk-configuration`.

Amazon CLI

To describe a risk configuration

This example describes the risk configuration associated with pool us-west-2_aaaaaaaaa.

Command:

```
aws cognito-idp describe-risk-configuration --user-pool-id us-west-2_aaaaaaaaa
```

Output:

```
{
  "RiskConfiguration": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "CompromisedCredentialsRiskConfiguration": {
          "EventFilter": [
              "SIGN_IN",
              "SIGN_UP",
              "PASSWORD_CHANGE"
          ],
          "Actions": {
              "EventAction": "BLOCK"
          }
      },
      "AccountTakeoverRiskConfiguration": {
          "NotifyConfiguration": {
              "From": "diego@example.com",
              "ReplyTo": "diego@example.com",
              "SourceArn": "arn:aws:ses:us-east-1:111111111111:identity/

                "EventAction": "MFA_IF_CONFIGURED"
            }
        }
    }
  }
}
```

- For API details, see DescribeRiskConfiguration in *Amazon CLI Command Reference*.

`describe-user-import-job`

The following code example shows how to use `describe-user-import-job`.

Amazon CLI

To describe a user import job

This example describes a user input job.

For more information about importing users, see Importing Users into User Pools From a CSV File.

Command:

```
aws cognito-idp describe-user-import-job --user-pool-id us-west-2_aaaaaaaaa --job-id import-TZqNQvDRnW
```

Output:

```
{
  "UserImportJob": {
      "JobName": "import-Test1",
      "JobId": "import-TZqNQvDRnW",
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "PreSignedUrl": "PRE_SIGNED URL",
      "CreationDate": 1548271708.512,
      "Status": "Created",
      "CloudWatchLogsRoleArn": "arn:aws:iam::111111111111:role/
CognitoCloudWatchLogsRole",
```

```
        "ImportedUsers": 0,
        "SkippedUsers": 0,
        "FailedUsers": 0
    }
}
```

- For API details, see DescribeUserImportJob in *Amazon CLI Command Reference*.

`describe-user-pool-client`

The following code example shows how to use `describe-user-pool-client`.

Amazon CLI

To describe a user pool client

This example describes a user pool client.

Command:

```
aws cognito-idp describe-user-pool-client --user-pool-id us-west-2_aaaaaaaaa --
client-id 38fjsnc484p94kpqsnet7mpld0
```

Output:

```
{
  "UserPoolClient": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "ClientName": "MyApp",
      "ClientId": "38fjsnc484p94kpqsnet7mpld0",
      "ClientSecret": "CLIENT_SECRET",
      "LastModifiedDate": 1548108676.163,
      "CreationDate": 1548108676.163,
      "RefreshTokenValidity": 30,
      "ReadAttributes": [
          "address",
          "birthdate",
          "custom:CustomAttr1",
          "custom:CustomAttr2",
          "email",
          "email_verified",
          "family_name",
          "gender",
```

```
            "given_name",
            "locale",
            "middle_name",
            "name",
            "nickname",
            "phone_number",
            "phone_number_verified",
            "picture",
            "preferred_username",
            "profile",
            "updated_at",
            "website",
            "zoneinfo"
        ],
        "WriteAttributes": [
            "address",
            "birthdate",
            "custom:CustomAttr1",
            "custom:CustomAttr2",
            "email",
            "family_name",
            "gender",
            "given_name",
            "locale",
            "middle_name",
            "name",
            "nickname",
            "phone_number",
            "picture",

            "updated_at",
            "website",
            "zoneinfo"
        ],
        "ExplicitAuthFlows": [
            "ADMIN_NO_SRP_AUTH",
            "USER_PASSWORD_AUTH"
        ],
        "AllowedOAuthFlowsUserPoolClient": false
    }
}
```

- For API details, see DescribeUserPoolClient in *Amazon CLI Command Reference*.

`describe-user-pool-domain`

The following code example shows how to use `describe-user-pool-domain`.

Amazon CLI

To describe a user pool client

This example describes a user pool domain named my-domain.

Command:

```
aws cognito-idp describe-user-pool-domain --domain my-domain
```

Output:

```
{
  "DomainDescription": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "AWSAccountId": "111111111111",
      "Domain": "my-domain",
      "S3Bucket": "aws-cognito-prod-pdx-assets",
      "CloudFrontDistribution": "aaaaaaaaaaaaa.cloudfront.net",
      "Version": "20190128175402",
      "Status": "ACTIVE",
      "CustomDomainConfig": {}
  }
}
```

- For API details, see DescribeUserPoolDomain in *Amazon CLI Command Reference*.

`describe-user-pool`

The following code example shows how to use `describe-user-pool`.

Amazon CLI

To describe a user pool

The following example describes a user pool with the user pool id us-west-2_EXAMPLE.

```
aws cognito-idp describe-user-pool \
```

```
    --user-pool-id us-west-2_EXAMPLE
```

Output:

```
{
    "UserPool": {
        "Id": "us-west-2_EXAMPLE",
        "Name": "MyUserPool",
        "Policies": {

```

For more information, see Amazon Cognito user pools in the *Amazon Cognito Developer Guide*.

- For API details, see DescribeUserPool in *Amazon CLI Command Reference*.

`forget-device`

The following code example shows how to use `forget-device`.

Amazon CLI

To forget a device

This example forgets device a device.

Command:

```
aws cognito-idp forget-device --device-key us-west-2_abcd_1234-5678
```

- For API details, see ForgetDevice in *Amazon CLI Command Reference*.

`forgot-password`

The following code example shows how to use `forgot-password`.

Amazon CLI

To force a password change

The following `forgot-password` example sends a message to jane@example.com to change their password.

```
aws cognito-idp forgot-password --client-id 38fjsnc484p94kpqsnet7mpld0 --
username jane@example.com
```

Output:

```
{
    "CodeDeliveryDetails": {
        "Destination": "j***@e***.com",
        "DeliveryMedium": "EMAIL",
        "AttributeName": "email"
    }
}
```

- For API details, see ForgotPassword in *Amazon CLI Command Reference*.

`get-csv-header`

The following code example shows how to use `get-csv-header`.

Amazon CLI

To create a csv header

This example creates a csv header.

For more information about importing users, see Importing Users into User Pools From a CSV File.

Command:

```
aws cognito-idp get-csv-header --user-pool-id us-west-2_aaaaaaaaa
```

Output:

```
{
  "UserPoolId": "us-west-2_aaaaaaaaa",
  "CSVHeader": [
      "name",
      "given_name",
      "family_name",
      "middle_name",
      "nickname",
      "preferred_username",
      "profile",
      "picture",
      "website",
      "email",
      "email_verified",
      "gender",
      "birthdate",
      "zoneinfo",
      "locale",
      "phone_number",
      "phone_number_verified",
      "address",
      "updated_at",
      "cognito:mfa_enabled",
      "cognito:username"
```

```
  ]
}
```

... Importing Users into User Pools From a CSV File: https://docs.aws.amazon.com/cognito/latest/developerguide/cognito-user-pools-using-import-tool.html

- For API details, see GetCsvHeader in *Amazon CLI Command Reference*.

`get-device`

The following code example shows how to use `get-device`.

Amazon CLI

To get a device

The following `get-device` example displays one device for currently signed-in user.

```
aws cognito-idp get-device \
    --access-token eyJra456defEXAMPLE \
    --device-key us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
    "Device": {
        "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "DeviceAttributes": [
            {
                "Name": "device_status",
                "Value": "valid"
            },
            {
                "Name": "device_name",
                "Value": "MyDevice"
            },
            {
                "Name": "dev:device_arn",

                "Name": "dev:device_sdk",
                "Value": "aws-sdk"
            }
        ],
        "DeviceCreateDate": 1715100742.022,
        "DeviceLastModifiedDate": 1723233651.167,
        "DeviceLastAuthenticatedDate": 1715100742.0
    }
}
```

For more information, see Working with user devices in your user pool in the *Amazon Cognito Developer Guide*.

- For API details, see GetDevice in *Amazon CLI Command Reference*.

`get-group`

The following code example shows how to use `get-group`.

Amazon CLI

To get information about a group

The following `get-group` example lists the properties of the user group named `MyGroup`. This group has a precedence and an IAM role associated with it.

```
aws cognito-idp get-group \
    --user-pool-id us-west-2_EXAMPLE \
    --group-name MyGroup
```

Output:

```
{
    "Group": {
        "GroupName": "MyGroup",
        "UserPoolId": "us-west-2_EXAMPLE",
        "RoleArn": "arn:aws:iam::123456789012:role/example-cognito-role",
        "Precedence": 7,
        "LastModifiedDate": 1697211218.305,
        "CreationDate": 1611685503.954
    }
}
```

For more information, see Adding groups to a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see GetGroup in *Amazon CLI Command Reference*.

`get-identity-provider-by-identifier`

The following code example shows how to use `get-identity-provider-by-identifier`.

Amazon CLI

To get the configuration of an identity provider from the IdP identifier

The following `get-identity-provider-by-identifier` example returns the configuration of the identity provider with the identifier `mysso`.

```
aws cognito-idp get-identity-provider-by-identifier \
    --user-pool-id us-west-2_EXAMPLE \
    --idp-identifier mysso
```

Output:

```
{
    "IdentityProvider": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "ProviderName": "MYSAML",
        "ProviderType": "SAML",
        "ProviderDetails": {
            "ActiveEncryptionCertificate": "[Certificate contents]",
            "IDPSignout": "false",
            "MetadataURL": "https://auth.example.com/saml/metadata/",
            "SLORedirectBindingURI": "https://auth.example.com/saml/logout/",
```

```
            "SSORedirectBindingURI": "https://auth.example.com/saml/assertion/"
        },
        "AttributeMapping": {
            "email": "email"
        },
        "IdpIdentifiers": [
            "mysso",
            "mysamlsso"
        ],
        "LastModifiedDate": 1705616729.188,
        "CreationDate": 1643734622.919
    }
}
```

For more information, see Third-party IdP sign-in in the *Amazon Cognito Developer Guide*.

- For API details, see GetIdentityProviderByIdentifier in *Amazon CLI Command Reference*.

`get-log-delivery-configuration`

The following code example shows how to use `get-log-delivery-configuration`.

Amazon CLI

To display the log delivery configuration

The following `get-log-delivery-configuration` example displays the log export settings of the requested user pool.

```
aws cognito-idp get-log-delivery-configuration \
    --user-pool-id us-west-2_EXAMPLE
```

Output:

```
{
    "LogDeliveryConfiguration": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "LogConfigurations": [
            {
                "LogLevel": "INFO",
                "EventSource": "userAuthEvents",
                "FirehoseConfiguration": {
```

```
                    "StreamArn": "arn:aws:firehose:us-
west-2:123456789012:deliverystream/my-test-deliverystream"
                }
            },
            {
                "LogLevel": "ERROR",
                "EventSource": "userNotification",
                "CloudWatchLogsConfiguration": {
                    "LogGroupArn": "arn:aws:logs:us-west-2:123456789012:log-
group:my-message-delivery-logs"
                }
            }
        ]
    }
}
```

For more information, see Exporting user pool logs in the *Amazon Cognito Developer Guide*.

- For API details, see GetLogDeliveryConfiguration in *Amazon CLI Command Reference*.

`get-signing-certificate`

The following code example shows how to use `get-signing-certificate`.

Amazon CLI

To display the SAML signing certificate

The following `get-signing-certificate` example displays the SAML 2.0 signing certificate for the request user pool.

```
aws cognito-idp get-signing-certificate \
    --user-pool-id us-west-2_EXAMPLE
```

Output:

```
{
    "Certificate": "[Certificate content]"
}
```

For more information, see SAML signing and encryption in the *Amazon Cognito Developer Guide*.

- For API details, see GetSigningCertificate in *Amazon CLI Command Reference*.

`get-ui-customization`

The following code example shows how to use `get-ui-customization`.

Amazon CLI

To display the classic hosted UI customization settings for an app client

The following `get-ui-customization` example displays the classic hosted UI customization settings for an app client that doesn't inherit settings from the user pool.

```
aws cognito-idp get-ui-customization \
    --user-pool-id us-west-2_EXAMPLE \
    --client-id 1example23456789
```

Output:

```
{
    "UICustomization": {
        "UserPoolId": "us-west-2_EXAMPLE",
        "ClientId": "1example23456789",
        "ImageUrl": "https://example.cloudfront.net/us-
west-2_EXAMPLE/1example23456789/20250115191928/assets/images/image.jpg",
        "CSS": "\n.logo-customizable {\n  max-width: 80%;\n  max-height: 30%;

        "CSSVersion": "20250115191928"
    }
}
```

For more information, see Hosted UI (classic) branding in the *Amazon Cognito Developer Guide*.

- For API details, see GetUiCustomization in *Amazon CLI Command Reference*.

`get-user-attribute-verification-code`

The following code example shows how to use `get-user-attribute-verification-code`.

Amazon CLI

To send an attribute verification code to the current user

The following `get-user-attribute-verification-code` example sends an attribute verification code to the currently signed-in user's email address.

```
aws cognito-idp get-user-attribute-verification-code \
    --access-token eyJra456defEXAMPLE \
    --attribute-name email
```

Output:

```
{
    "CodeDeliveryDetails": {
        "Destination": "a***@e***",
        "DeliveryMedium": "EMAIL",
        "AttributeName": "email"
    }
}
```

For more information, see Signing up and confirming user accounts in the *Amazon Cognito Developer Guide*.

- For API details, see GetUserAttributeVerificationCode in *Amazon CLI Command Reference*.

`get-user-auth-factors`

The following code example shows how to use `get-user-auth-factors`.

Amazon CLI

To list the authentication factors available to the current user

The following `get-user-auth-factors` example lists the available authentication factors for the currently signed-in user.

```
aws cognito-idp get-user-auth-factors \
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "Username": "testuser",
    "ConfiguredUserAuthFactors": [
        "PASSWORD",
        "EMAIL_OTP",
        "SMS_OTP",
        "WEB_AUTHN"
    ]
}
```

For more information, see Authentication in the *Amazon Cognito Developer Guide*.

- For API details, see GetUserAuthFactors in *Amazon CLI Command Reference*.

`get-user-pool-mfa-config`

The following code example shows how to use `get-user-pool-mfa-config`.

Amazon CLI

To display the multi-factor authentication and WebAuthn settings of a user pool

The following `get-user-pool-mfa-config` example displays the MFA and WebAuthn configuration of the requested user pool.

```
aws cognito-idp get-user-pool-mfa-config \
    --user-pool-id us-west-2_EXAMPLE
```

Output:

```
{
    "SmsMfaConfiguration": {
        "SmsAuthenticationMessage": "Your OTP for MFA or sign-in: use {####}.",
        "SmsConfiguration": {
            "SnsCallerArn": "arn:aws:iam::123456789012:role/service-role/my-SMS-
Role",
            "ExternalId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "SnsRegion": "us-west-2"
        }
    },
    "SoftwareTokenMfaConfiguration": {
        "Enabled": true
    },
    "EmailMfaConfiguration": {
        "Message": "Your OTP for MFA or sign-in: use {####}",
        "Subject": "OTP test"
    },
    "MfaConfiguration": "OPTIONAL",
    "WebAuthnConfiguration": {
        "RelyingPartyId": "auth.example.com",
        "UserVerification": "preferred"
    }
}
```

For more information, see Adding MFA in the *Amazon Cognito Developer Guide*.

- For API details, see GetUserPoolMfaConfig in *Amazon CLI Command Reference*.

`get-user`

The following code example shows how to use `get-user`.

Amazon CLI

To get the details of the current user

The following `get-user` example displays the profile of the currently signed-in user.

```
aws cognito-idp get-user \
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "Username": "johndoe",
    "UserAttributes": [
        {
            "Name": "sub",
            "Value": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
        },
        {
            "Name": "identities",
            "Value": "[{\"userId\":\"a1b2c3d4-5678-90ab-cdef-EXAMPLE22222\",
\"providerName\":\"SignInWithApple\",\"providerType\":\"SignInWithApple\",\"issuer
\":null,\"primary\":false,\"dateCreated\":1701125599632}]"
        },
        {
            "Name": "email_verified",
            "Value": "true"
        },
        {
            "Name": "custom:state",
            "Value": "Maine"
        },
        {
            "Name": "name",
            "Value": "John Doe"
        },
        {
            "Name": "phone_number_verified",
            "Value": "true"
        },
        {
            "Name": "phone_number",
            "Value": "+12065551212"
        },
        {
            "Name": "preferred_username",
            "Value": "jamesdoe"
        },
        {
```

```
            "Name": "locale",
            "Value": "EMEA"
        },
        {
            "Name": "email",
            "Value": "jamesdoe@example.com"
        }
    ]
}
```

For more information, see Managing users in the *Amazon Cognito Developer Guide*.

- For API details, see GetUser in *Amazon CLI Command Reference*.

`global-sign-out`

The following code example shows how to use `global-sign-out`.

Amazon CLI

To sign out the current user

The following `global-sign-out` example signs out the current user.

```
aws cognito-idp global-sign-out \
    --access-token eyJra456defEXAMPLE
```

This command produces no output.

For more information, see Managing users in the *Amazon Cognito Developer Guide*.

- For API details, see GlobalSignOut in *Amazon CLI Command Reference*.

`initiate-auth`

The following code example shows how to use `initiate-auth`.

Amazon CLI

To sign in a user

The following `initiate-auth` example signs in a user with the basic username-password flow and no additional challenges.

```
aws cognito-idp initiate-auth \
    --auth-flow USER_PASSWORD_AUTH \
    --client-id 1example23456789 \
    --analytics-metadata AnalyticsEndpointId=d70b2ba36a8c4dc5a04a0451aEXAMPLE \
    --auth-parameters USERNAME=testuser,PASSWORD=[Password] --user-context-
data EncodedData=mycontextdata --client-metadata MyTestKey=MyTestValue
```

Output:

```
{
    "AuthenticationResult": {
        "AccessToken": "eyJra456defEXAMPLE",
        "ExpiresIn": 3600,
        "TokenType": "Bearer",
        "RefreshToken": "eyJra123abcEXAMPLE",
        "IdToken": "eyJra789ghiEXAMPLE",
        "NewDeviceMetadata": {
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceGroupKey": "-v7w9UcY6"
        }
    }
}
```

For more information, see Authentication in the *Amazon Cognito Developer Guide*.

- For API details, see InitiateAuth in *Amazon CLI Command Reference*.

`list-devices`

The following code example shows how to use `list-devices`.

Amazon CLI

To list a user's devices

The following `list-devices` example lists the devices that the current user has registered.

```
aws cognito-idp list-devices \
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "Devices": [
        {
            "DeviceAttributes": [
                {
                    "Name": "device_status",
                    "Value": "valid"
                },
                {
                    "Name": "device_name",
                    "Value": "Dart-device"
                },
                {
                    "Name": "last_ip_used",
                    "Value": "192.0.2.1"
                }
            ],
            "DeviceCreateDate": 1715100742.022,
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceLastAuthenticatedDate": 1715100742.0,
            "DeviceLastModifiedDate": 1723233651.167
        },
        {
            "DeviceAttributes": [
                {
                    "Name": "device_status",
                    "Value": "valid"
                },
                {
                    "Name": "last_ip_used",
                    "Value": "192.0.2.2"
                }
            ],
            "DeviceCreateDate": 1726856147.993,
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE22222",
            "DeviceLastAuthenticatedDate": 1726856147.0,
            "DeviceLastModifiedDate": 1726856147.993
        }
    ]
}
```

For more information, see Working with devices in the *Amazon Cognito Developer Guide*.

- For API details, see ListDevices in *Amazon CLI Command Reference*.

`list-groups`

The following code example shows how to use `list-groups`.

Amazon CLI

To list the groups in a user pool

The following `list-groups` example lists the first two groups in the requested user pool.

```
aws cognito-idp list-groups \
    --user-pool-id us-west-2_EXAMPLE \
    --max-items 2
```

Output:

```
{
    "Groups": [
        {
            "CreationDate": 1681760899.633,
            "Description": "My test group",
            "GroupName": "testgroup",
            "LastModifiedDate": 1681760899.633,
            "Precedence": 1,
            "UserPoolId": "us-west-2_EXAMPLE"
        },
        {
            "CreationDate": 1642632749.051,
            "Description": "Autogenerated group for users who sign in using
 Facebook",
            "GroupName": "us-west-2_EXAMPLE_Facebook",
            "LastModifiedDate": 1642632749.051,
            "UserPoolId": "us-west-2_EXAMPLE"
        }
    ],
    "NextToken": "[Pagination token]"
}
```

For more information, see Adding groups to a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see ListGroups in *Amazon CLI Command Reference*.

`list-identity-providers`

The following code example shows how to use `list-identity-providers`.

Amazon CLI

To list identity providers

The following `list-identity-providers` example lists the first two identity providers in the requested user pool.

```
aws cognito-idp list-identity-providers \
    --user-pool-id us-west-2_EXAMPLE \
    --max-items 2
```

Output:

```
{
    "Providers": [
        {
            "CreationDate": 1619477386.504,
            "LastModifiedDate": 1703798328.142,
            "ProviderName": "Azure",
            "ProviderType": "SAML"
        },
        {
            "CreationDate": 1642698776.175,
            "LastModifiedDate": 1642699086.453,
            "ProviderName": "LoginWithAmazon",
            "ProviderType": "LoginWithAmazon"
        }
    ],
    "NextToken": "[Pagination token]"
}
```

For more information, see Third-party IdP sign-in in the *Amazon Cognito Developer Guide*.

- For API details, see ListIdentityProviders in *Amazon CLI Command Reference*.

`list-resource-servers`

The following code example shows how to use `list-resource-servers`.

Amazon CLI

To list resource servers

The following `list-resource-servers` example lists the first two resource servers in the requested user pool.

```
aws cognito-idp list-resource-servers \
    --user-pool-id us-west-2_EXAMPLE \
    --max-results 2
```

Output:

```
{
    "ResourceServers": [
        {
            "Identifier": "myapi.example.com",
            "Name": "Example API with custom access control scopes",
            "Scopes": [
                {
                    "ScopeDescription": "International customers",
                    "ScopeName": "international.read"
                },
                {
                    "ScopeDescription": "Domestic customers",
                    "ScopeName": "domestic.read"
                }
            ],
            "UserPoolId": "us-west-2_EXAMPLE"
        },
        {
            "Identifier": "myapi2.example.com",
            "Name": "Another example API for access control",
            "Scopes": [
                {

                }
            ],
            "UserPoolId": "us-west-2_EXAMPLE"
        }
    ],
    "NextToken": "[Pagination token]"
```

```
}
```

For more information, see Access control with resource servers in the *Amazon Cognito Developer Guide*.

- For API details, see ListResourceServers in *Amazon CLI Command Reference*.

`list-tags-for-resource`

The following code example shows how to use `list-tags-for-resource`.

Amazon CLI

To list user pool tags

The following `list-tags-for-resource` example lists the tags assigned to the user pool with the requested ARN.

```
aws cognito-idp list-tags-for-resource \
    --resource-arn arn:aws:cognito-idp:us-west-2:123456789012:userpool/us-west-2_EXAMPLE
```

Output:

```
{
    "Tags": {
        "administrator": "Jie",
        "tenant": "ExampleCorp"
    }
}
```

For more information, see Tagging Amazon Cognito resources in the *Amazon Cognito Developer Guide*.

- For API details, see ListTagsForResource in *Amazon CLI Command Reference*.

`list-user-import-jobs`

The following code example shows how to use `list-user-import-jobs`.

Amazon CLI

To list user import jobs and statuses

The following `list-user-import-jobs` example lists first three user import jobs and their details in the requested user pool.

```
aws cognito-idp list-user-import-jobs \
    --user-pool-id us-west-2_EXAMPLE \
    --max-results 3
```

Output:

```
{
    "PaginationToken": "us-west-2_EXAMPLE#import-example3#1667948397084",
    "UserImportJobs": [
        {

        }
    ]
}
```

For more information, see Importing users from a CSV file in the *Amazon Cognito Developer Guide*.

- For API details, see ListUserImportJobs in *Amazon CLI Command Reference*.

`list-user-pool-clients`

The following code example shows how to use `list-user-pool-clients`.

Amazon CLI

To list app clients

The following `list-user-pool-clients` example lists the first three app clients in the requested user pool.

```
aws cognito-idp list-user-pool-clients \
    --user-pool-id us-west-2_EXAMPLE \
    --max-results 3
```

Output:

```
{
    "NextToken": "[Pagination token]",
    "UserPoolClients": [
        {
            "ClientId": "1example23456789",
            "ClientName": "app-client-1",
            "UserPoolId": "us-west-2_EXAMPLE"
        },
        {
            "ClientId": "2example34567890",
            "ClientName": "app-client-2",
            "UserPoolId": "us-west-2_EXAMPLE"
        },
        {
            "ClientId": "3example45678901",
            "ClientName": "app-client-3",
            "UserPoolId": "us-west-2_EXAMPLE"
        }
    ]
}
```

For more information, see App clients in the *Amazon Cognito Developer Guide*.

- For API details, see ListUserPoolClients in *Amazon CLI Command Reference*.

`list-user-pools`

The following code example shows how to use `list-user-pools`.

Amazon CLI

To list user pools

The following `list-user-pools` example lists 3 of the available user pools in the Amazon account of the current CLI credentials.

```
aws cognito-idp list-user-pools \
    --max-results 3
```

Output:

```
{
    "NextToken": "[Pagination token]",
    "UserPools": [
        {
            "CreationDate": 1681502497.741,

    ]
}
```

For more information, see Amazon Cognito user pools in the *Amazon Cognito Developer Guide*.

- For API details, see ListUserPools in *Amazon CLI Command Reference*.

`list-users-in-group`

The following code example shows how to use `list-users-in-group`.

Amazon CLI

To list users in a group

This example lists users in group MyGroup.

Command:

```
aws cognito-idp list-users-in-group --user-pool-id us-west-2_aaaaaaaaa --group-
name MyGroup
```

Output:

```
{
  "Users": [
      {
          "Username": "acf10624-80bb-401a-ac61-607bee2110ec",
          "Attributes": [
```

```
            {
                "Name": "sub",
                "Value": "acf10624-80bb-401a-ac61-607bee2110ec"
            },
            {
                "Name": "custom:CustomAttr1",
                "Value": "New Value!"
            },
            {
                "Name": "email",
                "Value": "jane@example.com"
            }
        ],
        "UserCreateDate": 1548102770.284,
        "UserLastModifiedDate": 1548103204.893,
        "Enabled": true,
        "UserStatus": "CONFIRMED"
    },
    {
        "Username": "22704aa3-fc10-479a-97eb-2af5806bd327",
        "Attributes": [
            {
                "Name": "sub",
                "Value": "22704aa3-fc10-479a-97eb-2af5806bd327"
            },
            {
                "Name": "email_verified",
                "Value": "true"
            },
            {
                "Name": "email",

        "UserStatus": "FORCE_CHANGE_PASSWORD"
    }
  ]
}
```

- For API details, see ListUsersInGroup in *Amazon CLI Command Reference*.

`list-users`

The following code example shows how to use `list-users`.

Amazon CLI

Example 1: To list users with a server-side filter

The following `list-users` example lists 3 users in the requested user pool whose email addresses begin with `testuser`.

```
aws cognito-idp list-users \
    --user-pool-id us-west-2_EXAMPLE \
    --filter email^=\"testuser\" \
    --max-items 3
```

Output:

```
{
    "PaginationToken": "efgh5678EXAMPLE",
    "Users": [
        {
            "Attributes": [
                {
                    "Name": "sub",
                    "Value": "eaad0219-2117-439f-8d46-4db20e59268f"
                },
                {
                    "Name": "email",
                    "Value": "testuser@example.com"
                }
            ],
            "Enabled": true,
            "UserCreateDate": 1682955829.578,
            "UserLastModifiedDate": 1689030181.63,
            "UserStatus": "CONFIRMED",
            "Username": "testuser"
        },
        {
            "Attributes": [
                {
                    "Name": "sub",
                    "Value": "3b994cfd-0b07-4581-be46-3c82f9a70c90"
```

```
                },
                {
                    "Name": "email",
                    "Value": "testuser2@example.com"
                }
            ],
            "Enabled": true,
            "UserCreateDate": 1684427979.201,
            "UserLastModifiedDate": 1684427979.201,
            "UserStatus": "UNCONFIRMED",
            "Username": "testuser2"
        },
        {
            "Attributes": [
                {
                    "Name": "sub",
                    "Value": "5929e0d1-4c34-42d1-9b79-a5ecacfe66f7"
                },
                {
                    "Name": "email",
                    "Value": "testuser3@example.com"
                }
            ],
            "Enabled": true,
            "UserCreateDate": 1684427823.641,
            "UserLastModifiedDate": 1684427823.641,
            "UserStatus": "UNCONFIRMED",
            "Username": "testuser3@example.com"
        }
    ]
}
```

For more information, see Managing and searching for users in the *Amazon Cognito Developer Guide*.

Example 2: To list users with a client-side filter

The following `list-users` example lists the attributes of three users who have an attribute, in this case their email address, that contains the email domain "@example.com". If other attributes contained this string, they would also be displayed. The second user has no attributes that match the query and is excluded from the displayed output, but not from the server response.

```
aws cognito-idp list-users \
    --user-pool-id us-west-2_EXAMPLE \
    --max-items 3
    --query Users\[\*\].Attributes\[\?Value\.contains\(\@\,\'@example.com\'\)\]
```

Output:

```
[
    [
        {
            "Name": "email",
            "Value": "admin@example.com"
        }
    ],
    [],
    [
        {
            "Name": "email",
            "Value": "operator@example.com"
        }
    ]
]
```

For more information, see Managing and searching for users in the *Amazon Cognito Developer Guide*.

- For API details, see ListUsers in *Amazon CLI Command Reference*.

`list-web-authn-credentials`

The following code example shows how to use `list-web-authn-credentials`.

Amazon CLI

To list passkey credentials

The following `list-web-authn-credentials` example lists passkey, or WebAuthn, credentials for the current user. They have one registered device.

```
aws cognito-idp list-web-authn-credentials \
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "Credentials": [
        {
            "AuthenticatorAttachment": "cross-platform",
            "CreatedAt": 1736293876.115,
            "CredentialId": "8LApgk4-lNUFHbhm2w6Und7-
uxcc8coJGsPxiogvHoItc64xWQc3r4CEXAMPLE",
            "FriendlyCredentialName": "Roaming passkey",
            "RelyingPartyId": "auth.example.com"
        }
    ]
}
```

For more information, see Passkey sign-in in the *Amazon Cognito Developer Guide*.

- For API details, see ListWebAuthnCredentials in *Amazon CLI Command Reference*.

`resend-confirmation-code`

The following code example shows how to use `resend-confirmation-code`.

Amazon CLI

To resend a confirmation code

The following `resend-confirmation-code` example sends a confirmation code to the user `jane`.

```
aws cognito-idp resend-confirmation-code \
    --client-id 12a3b456c7de890f11g123hijk \
    --username jane
```

Output:

```
{
    "CodeDeliveryDetails": {
        "Destination": "j***@e***.com",
        "DeliveryMedium": "EMAIL",
        "AttributeName": "email"
```

```
    }
}
```

For more information, see Signing up and confirming user accounts in the *Amazon Cognito Developer Guide*.

- For API details, see ResendConfirmationCode in *Amazon CLI Command Reference*.

`respond-to-auth-challenge`

The following code example shows how to use `respond-to-auth-challenge`.

Amazon CLI

Example 1: To respond to a NEW_PASSWORD_REQUIRED challenge

The following `respond-to-auth-challenge` example responds to a NEW_PASSWORD_REQUIRED challenge that initiate-auth returned. It sets a password for the user `jane@example.com`.

```
aws cognito-idp respond-to-auth-challenge \
    --client-id 1example23456789 \
    --challenge-name NEW_PASSWORD_REQUIRED \
    --challenge-responses USERNAME=jane@example.com,NEW_PASSWORD=[Password] \
    --session AYABeEv5HklEXAMPLE
```

Output:

```
{
    "ChallengeParameters": {},
    "AuthenticationResult": {
        "AccessToken": "ACCESS_TOKEN",
        "ExpiresIn": 3600,
        "TokenType": "Bearer",
        "RefreshToken": "REFRESH_TOKEN",
        "IdToken": "ID_TOKEN",
        "NewDeviceMetadata": {
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceGroupKey": "-wt2ha1Zd"
        }
    }
```

```
}
```

For more information, see Authentication in the *Amazon Cognito Developer Guide*.

Example 2: To respond to a SELECT_MFA_TYPE challenge

The following `respond-to-auth-challenge` example chooses TOTP MFA as the MFA option for the current user. The user was prompted to select an MFA type and will next be prompted to enter their MFA code.

```
aws cognito-idp respond-to-auth-challenge \
    --client-id 1example23456789
    --session AYABeEv5HklEXAMPLE
    --challenge-name SELECT_MFA_TYPE
    --challenge-responses USERNAME=testuser,ANSWER=SOFTWARE_TOKEN_MFA
```

Output:

```
{
    "ChallengeName": "SOFTWARE_TOKEN_MFA",
    "Session": "AYABeEv5HklEXAMPLE",
    "ChallengeParameters": {
        "FRIENDLY_DEVICE_NAME": "transparent"
    }
}
```

For more information, see Adding MFA in the *Amazon Cognito Developer Guide*.

Example 3: To respond to a SOFTWARE_TOKEN_MFA challenge

The following `respond-to-auth-challenge` example provides a TOTP MFA code and completes sign-in.

```
aws cognito-idp respond-to-auth-challenge \
    --client-id 1example23456789 \
    --session AYABeEv5HklEXAMPLE \
    --challenge-name SOFTWARE_TOKEN_MFA \
    --challenge-responses USERNAME=testuser,SOFTWARE_TOKEN_MFA_CODE=123456
```

Output:

```
{
    "AuthenticationResult": {
        "AccessToken": "eyJra456defEXAMPLE",
        "ExpiresIn": 3600,
        "TokenType": "Bearer",
        "RefreshToken": "eyJra123abcEXAMPLE",
        "IdToken": "eyJra789ghiEXAMPLE",
        "NewDeviceMetadata": {
            "DeviceKey": "us-west-2_a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "DeviceGroupKey": "-v7w9UcY6"
        }
    }
}
```

For more information, see Adding MFA in the *Amazon Cognito Developer Guide*.

- For API details, see RespondToAuthChallenge in *Amazon CLI Command Reference*.

`revoke-token`

The following code example shows how to use `revoke-token`.

Amazon CLI

To revoke a refresh token

The following `revoke-token` revokes the requested refresh token and associated access tokens.

```
aws cognito-idp revoke-token \
    --token eyJjd123abcEXAMPLE \
    --client-id 1example23456789
```

This command produces no output.

For more information, see Revoking tokens in the *Amazon Cognito Developer Guide*.

- For API details, see RevokeToken in *Amazon CLI Command Reference*.

`set-log-delivery-configuration`

The following code example shows how to use `set-log-delivery-configuration`.

Amazon CLI

To set up log export from a user pool

The following `set-log-delivery-configuration` example configures the requested user pool with user-notification error logging to a log group and user-authentication info logging to an S3 bucket.

```
aws cognito-idp set-log-delivery-configuration \
    --user-pool-id us-west-2_EXAMPLE \
    --log-
configurations LogLevel=ERROR,EventSource=userNotification,CloudWatchLogsConfiguration={LogG
west-2:123456789012:log-group:cognito-
exported} LogLevel=INFO,EventSource=userAuthEvents,S3Configuration={BucketArn=arn:aws:s3:::a
s3-demo-bucket1}
```

Output:

```
{
   "LogDeliveryConfiguration": {
        "LogConfigurations": [
            {
                "CloudWatchLogsConfiguration": {
                    "LogGroupArn": "arn:aws:logs:us-west-2:123456789012:log-
group:cognito-exported"
                },
                "EventSource": "userNotification",
                "LogLevel": "ERROR"
            },
            {
                "EventSource": "userAuthEvents",
                "LogLevel": "INFO",
                "S3Configuration": {
                    "BucketArn": "arn:aws:s3:::amzn-s3-demo-bucket1"
                }
            }
        ],
        "UserPoolId": "us-west-2_EXAMPLE"
   }
}
```

For more information, see Exporting user pool logs in the *Amazon Cognito Developer Guide*.

- For API details, see SetLogDeliveryConfiguration in *Amazon CLI Command Reference*.

`set-risk-configuration`

The following code example shows how to use `set-risk-configuration`.

Amazon CLI

To set the threat protection risk configuration

The following `set-risk-configuration` example configures threat protection messages and actions, compromised credentials, and IP address exceptions in the requested app client. Because of the complexity of the NotifyConfiguration object, JSON input is a best practice for this command.

```
aws cognito-idp set-risk-configuration \
    --cli-input-json file://set-risk-configuration.json
```

Contents of `set-risk-configuration.json`:

```
{
    "AccountTakeoverRiskConfiguration": {
        "Actions": {
            "HighAction": {
                "EventAction": "MFA_REQUIRED",

```

For more information, see Threat protection in the *Amazon Cognito Developer Guide*.

- For API details, see SetRiskConfiguration in *Amazon CLI Command Reference*.

set-ui-customization

The following code example shows how to use `set-ui-customization`.

Amazon CLI

Example 1: To customize the classic hosted UI for an app client

The following `set-ui-customization` example configures the requested app client with some custom CSS and with the Amazon Cognito logo as the application logo.

```
aws cognito-idp set-ui-customization \
    --user-pool-id us-west-2_ywDJHlIfU \
    --client-id 14pq32c5q2uq2q7keorloqvb23 \
    --css ".logo-customizable {\n\tmax-width: 60%;\n\tmax-height: 30%;\n}\n.banner-
customizable {\n\tpadding: 25px 0px 25px 0px;\n\tbackground-color: lightgray;
\n}\n.label-customizable {\n\tfont-weight: 400;\n}\n.textDescription-customizable
 {\n\tpadding-top: 10px;\n\tpadding-bottom: 10px;\n\tdisplay: block;\n\tfont-
size: 16px;\n}\n.idpDescription-customizable {\n\tpadding-top: 10px;\n\tpadding-
bottom: 10px;\n\tdisplay: block;\n\tfont-size: 16px;\n}\n.legalText-customizable
 {\n\tcolor: #747474;\n\tfont-size: 11px;\n}\n.submitButton-customizable {\n\tfont-
size: 11px;\n\tfont-weight: normal;\n\tmargin: 20px -15px 10px -13px;\n\theight:
 40px;\n\twidth: 108%;\n\tcolor: #fff;\n\tbackground-color: #337ab7;\n\ttext-align:
 center;\n}\n.submitButton-customizable:hover {\n\tcolor: #fff;\n\tbackground-color:
 #286090;\n}\n.errorMessage-customizable {\n\tpadding: 5px;\n\tfont-size: 14px;

    }
}
```

Example 2: To set the default UI customization for all app clients

The following `set-ui-customization` example configures the requested user pool for all app clients that don't have a client-specific configuration. The command applies some custom CSS and with the Amazon Cognito logo as the application logo.

```
aws cognito-idp set-ui-customization \
--user-pool-id us-west-2_ywDJHlIfU \
--client-id ALL \
--css ".logo-customizable {\n\tmax-width: 60%;\n\tmax-height: 30%;\n}\n.banner-
customizable {\n\tpadding: 25px 0px 25px 0px;\n\tbackground-color: lightgray;
\n}\n.label-customizable {\n\tfont-weight: 400;\n}\n.textDescription-customizable
 {\n\tpadding-top: 10px;\n\tpadding-bottom: 10px;\n\tdisplay: block;\n\tfont-
size: 16px;\n}\n.idpDescription-customizable {\n\tpadding-top: 10px;\n\tpadding-
bottom: 10px;\n\tdisplay: block;\n\tfont-size: 16px;\n}\n.legalText-customizable
 {\n\tcolor: #747474;\n\tfont-size: 11px;\n}\n.submitButton-customizable {\n\tfont-
size: 11px;\n\tfont-weight: normal;\n\tmargin: 20px -15px 10px -13px;\n\theight:
 40px;\n\twidth: 108%;\n\tcolor: #fff;\n\tbackground-color: #337ab7;\n\ttext-align:
 center;\n}\n.submitButton-customizable:hover {\n\tcolor: #fff;\n\tbackground-color:
 #286090;\n}\n.errorMessage-customizable {\n\tpadding: 5px;\n\tfont-size: 14px;
\n\twidth: 100%;\n\tbackground: #F5F5F5;\n\tborder: 2px solid #D64958;\n\tcolor:
 #D64958;\n}\n.inputField-customizable {\n\twidth: 100%;\n\theight: 34px;\n\tcolor:
 #555;\n\tbackground-color: #fff;\n\tborder: 1px solid #ccc;\n\tborder-radius:
 0px;\n}\n.inputField-customizable:focus {\n\tborder-color: #66afe9;\n\toutline:
 0;\n}\n.idpButton-customizable {\n\theight: 40px;\n\twidth: 100%;\n\twidth: 100%;
\n\ttext-align: center;\n\tmargin-bottom: 15px;\n\tcolor: #fff;\n\tbackground-
color: #5bc0de;\n\tborder-color: #46b8da;\n}\n.idpButton-customizable:hover {\n

```

For more information, see Hosted UI (classic) branding in the *Amazon Cognito Developer Guide*.

- For API details, see SetUiCustomization in *Amazon CLI Command Reference*.

`set-user-mfa-preference`

The following code example shows how to use `set-user-mfa-preference`.

Amazon CLI

To set a user's MFA preference

The following `set-user-mfa-preference` example configures the current user to use TOTP MFA and disables all other MFA factors.

```
aws cognito-idp set-user-mfa-preference \
    --access-token eyJra456defEXAMPLE \
    --software-token-mfa-settings Enabled=true,PreferredMfa=true \
    --sms-mfa-settings Enabled=false,PreferredMfa=false \
    --email-mfa-settings Enabled=false,PreferredMfa=false
```

This command produces no output.

For more information, see Adding MFA in the *Amazon Cognito Developer Guide*.

- For API details, see SetUserMfaPreference in *Amazon CLI Command Reference*.

`set-user-pool-mfa-config`

The following code example shows how to use `set-user-pool-mfa-config`.

Amazon CLI

To configure user pool MFA and WebAuthn

The following `set-user-pool-mfa-config` example configures the requested user pool with optional MFA with all available MFA methods, and sets the WebAuthn configuration.

```
aws cognito-idp set-user-pool-mfa-config \
    --user-pool-id us-west-2_EXAMPLE \
    --sms-mfa-configuration "SmsAuthenticationMessage=\"Your OTP for MFA or sign-
in: use {####}.\",SmsConfiguration={SnsCallerArn=arn:aws:iam::123456789012:role/
service-role/test-SMS-Role,ExternalId=a1b2c3d4-5678-90ab-cdef-
EXAMPLE11111,SnsRegion=us-west-2}" \
    --software-token-mfa-configuration Enabled=true \
    --email-mfa-configuration "Message=\"Your OTP for MFA or sign-in: use
 {####}\",Subject=\"OTP test\"" \
    --mfa-configuration OPTIONAL \
    --web-authn-
configuration RelyingPartyId=auth.example.com,UserVerification=preferred
```

Output:

```
{
    "EmailMfaConfiguration": {
        "Message": "Your OTP for MFA or sign-in: use {####}",
        "Subject": "OTP test"
    },
    "MfaConfiguration": "OPTIONAL",
    "SmsMfaConfiguration": {
        "SmsAuthenticationMessage": "Your OTP for MFA or sign-in: use {####}.",
        "SmsConfiguration": {
            "ExternalId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
            "SnsCallerArn": "arn:aws:iam::123456789012:role/service-role/test-SMS-
Role",
            "SnsRegion": "us-west-2"
        }
    },
    "SoftwareTokenMfaConfiguration": {
        "Enabled": true
    },
    "WebAuthnConfiguration": {
        "RelyingPartyId": "auth.example.com",
        "UserVerification": "preferred"
    }
}
```

For more information, see Adding MFA and Passkey sign-in in the *Amazon Cognito Developer Guide*.

- For API details, see SetUserPoolMfaConfig in *Amazon CLI Command Reference*.

`set-user-settings`

The following code example shows how to use `set-user-settings`.

Amazon CLI

To set user settings

This example sets the MFA delivery preference to EMAIL.

Command:

```
aws cognito-idp set-user-settings --access-token ACCESS_TOKEN --mfa-
options DeliveryMedium=EMAIL
```

- For API details, see SetUserSettings in *Amazon CLI Command Reference*.

`sign-up`

The following code example shows how to use `sign-up`.

Amazon CLI

To sign up a user

This example signs up jane@example.com.

Command:

```
aws cognito-idp sign-up --client-id 3n4b5urk1ft4fl3mg5e62d9ado --
username jane@example.com --password PASSWORD --user-attributes
 Name="email",Value="jane@example.com" Name="name",Value="Jane"
```

Output:

```
{
  "UserConfirmed": false,
```

```
  "UserSub": "e04d60a6-45dc-441c-a40b-e25a787d4862"
}
```

- For API details, see SignUp in *Amazon CLI Command Reference*.

`start-user-import-job`

The following code example shows how to use `start-user-import-job`.

Amazon CLI

To start an import job

The following `start-user-import-job` example starts the requested import job in the requested user pool.

```
aws cognito-idp start-user-import-job \
    --user-pool-id us-west-2_EXAMPLE \
    --job-id import-mAgUtd8PMm
```

Output:

```
{
    "UserImportJob": {
        "CloudWatchLogsRoleArn": "arn:aws:iam::123456789012:role/example-cloudwatch-
logs-role",
        "CreationDate": 1736442975.904,
        "FailedUsers": 0,
        "ImportedUsers": 0,
        "JobId": "import-mAgUtd8PMm",

    }
}
```

For more information, see Importing users into a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see StartUserImportJob in *Amazon CLI Command Reference*.

`start-web-authn-registration`

The following code example shows how to use `start-web-authn-registration`.

Amazon CLI

To get passkey registration information for a signed-in user

The following `start-web-authn-registration` example generates WebAuthn registration options for the current user.

```
aws cognito-idp start-web-authn-registration \
    --access-token eyJra456defEXAMPLE
```

Output:

```
{
    "CredentialCreationOptions": {
        "authenticatorSelection": {
            "requireResidentKey": true,
            "residentKey": "required",
            "userVerification": "preferred"
        },
        "challenge": "wxvbDicyqQqvF2EXAMPLE",
        "excludeCredentials": [
            {

uxcc8coJGsPxiogvHoItc64xWQc3r4CEXAMPLE",
                "type": "public-key"
            }
        ],
        "pubKeyCredParams": [
            {
                "alg": -7,
                "type": "public-key"
            },
            {
                "alg": -257,
```

```
                "type": "public-key"
            }
        ],
        "rp": {
            "id": "auth.example.com",
            "name": "auth.example.com"
        },
        "timeout": 60000,
        "user": {
            "displayName": "testuser",
            "id": "ZWFhZDAyMTktMjExNy00MzlmLThkNDYtNGRiMjBlNEXAMPLE",
            "name": "testuser"
        }
    }
}
```

For more information, see Passkey sign-in in the *Amazon Cognito Developer Guide*.

- For API details, see StartWebAuthnRegistration in *Amazon CLI Command Reference*.

`stop-user-import-job`

The following code example shows how to use `stop-user-import-job`.

Amazon CLI

To stop an import job

The following `stop-user-import-job` example stops the requested running user import job in the requested user pool.

```
aws cognito-idp stop-user-import-job \
    --user-pool-id us-west-2_EXAMPLE \
    --job-id import-mAgUtd8PMm
```

Output:

```
{
    "UserImportJob": {
        "CloudWatchLogsRoleArn": "arn:aws:iam::123456789012:role/example-cloudwatch-
logs-role",
        "CompletionDate": 1736443496.379,
        "CompletionMessage": "The Import Job was stopped by the developer.",
```

```
        "CreationDate": 1736443471.781,
        "FailedUsers": 0,
        "ImportedUsers": 0,
        "JobId": "import-mAgUtd8PMm",
        "JobName": "Customer import",
        "PreSignedUrl": "https://aws-cognito-idp-user-import-pdx.s3.us-
west-2.amazonaws.com/123456789012/us-west-2_EXAMPLE/import-mAgUtd8PMm?
X-Amz-Security-Token=[token]&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-
Date=20241226T193341Z&X-Amz-SignedHeaders=host%3Bx-amz-server-side-encryption&X-Amz-
Expires=899&X-Amz-Credential=[credential]&X-Amz-Signature=[signature]",
        "SkippedUsers": 0,
        "StartDate": 1736443494.154,
        "Status": "Stopped",
        "UserPoolId": "us-west-2_EXAMPLE"
    }
}
```

For more information, see Importing users into a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see StopUserImportJob in *Amazon CLI Command Reference*.

`tag-resource`

The following code example shows how to use `tag-resource`.

Amazon CLI

To tag a user pool

The following `tag-resource` example applies `administrator` and `department` tags to the requested user pool.

```
aws cognito-idp tag-resource \
    --resource-arn arn:aws:cognito-idp:us-west-2:123456789012:userpool/us-
west-2_EXAMPLE \
    --tags administrator=Jie,tenant=ExampleCorp
```

This command produces no output.

For more information, see Tagging Amazon Cognito resources in the *Amazon Cognito Developer Guide*.

- For API details, see TagResource in *Amazon CLI Command Reference*.

`untag-resource`

The following code example shows how to use `untag-resource`.

Amazon CLI

To remove tags from a user pool

The following `untag-resource` example removes `administrator` and `department` tags from the requested user pool.

```
aws cognito-idp untag-resource \
    --resource-arn arn:aws:cognito-idp:us-west-2:767671399759:userpool/us-west-2_l5cxwdm2K \
    --tag-keys administrator tenant
```

This command produces no output.

For more information, see Tagging Amazon Cognito resources in the *Amazon Cognito Developer Guide*.

- For API details, see UntagResource in *Amazon CLI Command Reference*.

`update-auth-event-feedback`

The following code example shows how to use `update-auth-event-feedback`.

Amazon CLI

To update auth event feedback

This example updates authorization event feedback. It marks the event "Valid".

Command:

```
aws cognito-idp update-auth-event-feedback --user-pool-id us-west-2_aaaaaaaaa --username diego@example.com --event-id EVENT_ID --feedback-token FEEDBACK_TOKEN --feedback-value "Valid"
```

- For API details, see UpdateAuthEventFeedback in *Amazon CLI Command Reference*.

`update-device-status`

The following code example shows how to use `update-device-status`.

Amazon CLI

To update device status

This example updates the status for a device to "not_remembered".

Command:

```
aws cognito-idp update-device-status --access-token ACCESS_TOKEN --device-
key DEVICE_KEY --device-remembered-status "not_remembered"
```

- For API details, see UpdateDeviceStatus in *Amazon CLI Command Reference*.

`update-group`

The following code example shows how to use `update-group`.

Amazon CLI

To update a group

This example updates the description and precedence for MyGroup.

Command:

```
aws cognito-idp update-group --user-pool-id us-west-2_aaaaaaaaa --group-name MyGroup
 --description "New description" --precedence 2
```

Output:

```
{
  "Group": {
      "GroupName": "MyGroup",
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "Description": "New description",
      "RoleArn": "arn:aws:iam::111111111111:role/MyRole",
      "Precedence": 2,
      "LastModifiedDate": 1548800862.812,
```

```
      "CreationDate": 1548097827.125
  }
}
```

- For API details, see UpdateGroup in *Amazon CLI Command Reference*.

`update-identity-provider`

The following code example shows how to use `update-identity-provider`.

Amazon CLI

To update a user pool identity provider

The following `update-identity-provider` example updates the OIDC provider "MyOIDCIdP" in the requested user pool.

```
aws cognito-idp update-identity-provider \
    --cli-input-json file://update-identity-provider.json
```

Contents of `update-identity-provider.json`:

```

For more information, see Configuring a domain in the *Amazon Cognito Developer Guide*.

- For API details, see UpdateIdentityProvider in *Amazon CLI Command Reference*.

update-managed-login-branding

The following code example shows how to use update-managed-login-branding.

Amazon CLI

To update a managed login branding style

The following update-managed-login-branding example updates the requested app client branding style.

```
aws cognito-idp update-managed-login-branding \
    --cli-input-json file://update-managed-login-branding.json
```

Contents of update-managed-login-branding.json:

```

For more information, see Apply branding to managed login pages in the *Amazon Cognito Developer Guide*.

- For API details, see UpdateManagedLoginBranding in *Amazon CLI Command Reference*.

`update-resource-server`

The following code example shows how to use `update-resource-server`.

Amazon CLI

To update a resource server

This example updates the the resource server Weather. It adds a new scope.

Command:

```
aws cognito-idp update-resource-server --user-pool-id us-west-2_aaaaaaaaa
 --identifier weather.example.com --name Weather --scopes
 ScopeName=NewScope,ScopeDescription="New scope description"
```

Output:

```
{
  "ResourceServer": {
      "UserPoolId": "us-west-2_aaaaaaaaa",
      "Identifier": "weather.example.com",
      "Name": "Happy",
      "Scopes": [
          {
              "ScopeName": "NewScope",
              "ScopeDescription": "New scope description"
          }
      ]
  }
}
```

- For API details, see UpdateResourceServer in *Amazon CLI Command Reference*.

`update-user-attributes`

The following code example shows how to use `update-user-attributes`.

Amazon CLI

To update user attributes

This example updates the user attribute "nickname".

Command:

```
aws cognito-idp update-user-attributes --access-token ACCESS_TOKEN --user-attributes
 Name="nickname",Value="Dan"
```

- For API details, see UpdateUserAttributes in *Amazon CLI Command Reference*.

`update-user-pool-client`

The following code example shows how to use `update-user-pool-client`.

Amazon CLI

To update an app client

The following `update-user-pool-client` example updates the configuration of the requested app client.

```
aws cognito-idp update-user-pool-client \
    --user-pool-id us-west-2_EXAMPLE \
    --client-id 1example23456789 \
    --client-name my-test-app \
    --refresh-token-validity 30 \
    --access-token-validity 60 \
    --id-token-validity 60 \
    --token-validity-units AccessToken=minutes,IdToken=minutes,RefreshToken=days \
    --read-
attributes "address" "birthdate" "email" "email_verified" "family_name" "gender" "locale" "m
 \
    --write-
attributes "address" "birthdate" "email" "family_name" "gender" "locale" "middle_name" "name
 \
    --explicit-auth-
flows "ALLOW_ADMIN_USER_PASSWORD_AUTH" "ALLOW_CUSTOM_AUTH" "ALLOW_REFRESH_TOKEN_AUTH" "ALLOW
 \
    --supported-identity-providers "MySAML" "COGNITO" "Google" \
    --callback-urls "https://www.example.com" "https://app2.example.com" \
    --logout-urls "https://auth.example.com/login?
client_id=1example23456789&response_type=code&redirect_uri=https%3A%2F
%2Fwww.example.com" "https://example.com/logout" \
```

```
    --default-redirect-uri "https://www.example.com" \
    --allowed-o-auth-flows "code" "implicit" \
    --allowed-o-auth-scopes "openid" "profile" "aws.cognito.signin.user.admin" \
    --allowed-o-auth-flows-user-pool-client \
    --prevent-user-existence-errors ENABLED \
    --enable-token-revocation \
    --no-enable-propagate-additional-user-context-data \
    --auth-session-validity 3
```

Output:

```
{
    "UserPoolClient": {
        "UserPoolId": "us-west-2_EXAMPLE",

}
```

For more information, see Application-specific settings with app clients in the *Amazon Cognito Developer Guide*.

- For API details, see UpdateUserPoolClient in *Amazon CLI Command Reference*.

`update-user-pool-domain`

The following code example shows how to use `update-user-pool-domain`.

Amazon CLI

To update a custom domain

The following `update-user-pool-domain` example configures the branding version and certificate for the custom domain the requested user pool.

```
aws cognito-idp update-user-pool-domain \
    --user-pool-id ca-central-1_EXAMPLE \
    --domain auth.example.com \
    --managed-login-version 2 \
    --custom-domain-config CertificateArn=arn:aws:acm:us-
east-1:123456789012:certificate/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111
```

Output:

```
{
```

```
    "CloudFrontDomain": "example.cloudfront.net",
    "ManagedLoginVersion": 2
}
```

For more information, see Managed login and Configuring a domain in the *Amazon Cognito Developer Guide*.

- For API details, see UpdateUserPoolDomain in *Amazon CLI Command Reference*.

`update-user-pool`

The following code example shows how to use `update-user-pool`.

Amazon CLI

To update a user pool

The following `update-user-pool` example modifies a user pool with example syntax for each of the available configuration options. To update a user pool, you must specify all previously-configured options or they will reset to a default value.

```
aws cognito-idp update-user-pool --user-pool-id us-west-2_EXAMPLE \
    --policies PasswordPolicy=
\{MinimumLength=6,RequireUppercase=true,RequireLowercase=true,RequireNumbers=true,RequireSym
 \
    --deletion-protection ACTIVE \
    --lambda-config PreSignUp="arn:aws:lambda:us-
west-2:123456789012:function:cognito-test-presignup-
function",PreTokenGeneration="arn:aws:lambda:us-
west-2:123456789012:function:cognito-test-pretoken-function" \
    --auto-verified-attributes "phone_number" "email" \
    --verification-message-template \{\"SmsMessage\":\""Your code is
 {####}"\",\"EmailMessage\":\""Your code is {####}"\",\"EmailSubject\":\""Your
 verification code"\",\"EmailMessageByLink\":\""Click {##here##} to verify
 your email address."\",\"EmailSubjectByLink\":\""Your verification link"\",
\"DefaultEmailOption\":\"CONFIRM_WITH_LINK\"\} \
    --sms-authentication-message "Your code is {####}" \
    --user-attribute-update-settings
 AttributesRequireVerificationBeforeUpdate="email","phone_number" \
    --mfa-configuration "OPTIONAL" \
    --device-
configuration ChallengeRequiredOnNewDevice=true,DeviceOnlyRememberedOnUserPrompt=true
 \
```

```
    --email-configuration SourceArn="arn:aws:ses:us-
west-2:123456789012:identity/admin@example.com",ReplyToEmailAddress="amdin
+noreply@example.com",EmailSendingAccount=DEVELOPER,From="admin@amazon.com",ConfigurationSet
configuration-set" \
    --sms-configuration SnsCallerArn="arn:aws:iam::123456789012:role/service-role/
SNS-SMS-Role",ExternalId="12345",SnsRegion="us-west-2" \
    --admin-create-user-config AllowAdminCreateUserOnly=false,InviteMessageTemplate=
\{SMSMessage=\""Welcome {username}. Your confirmation code is
 {####}"\",EmailMessage=\""Welcome {username}. Your confirmation code is
 {####}"\",EmailSubject=\""Welcome to MyMobileGame"\"\} \
    --user-pool-tags "Function"="MyMobileGame","Developers"="Berlin" \
    --admin-create-user-config AllowAdminCreateUserOnly=false,InviteMessageTemplate=
\{SMSMessage=\""Welcome {username}. Your confirmation code is
 {####}"\",EmailMessage=\""Welcome {username}. Your confirmation code is
 {####}"\",EmailSubject=\""Welcome to MyMobileGame"\"\} \
    --user-pool-add-ons AdvancedSecurityMode="AUDIT" \
    --account-recovery-setting RecoveryMechanisms=
\[\{Priority=1,Name="verified_email"\},\{Priority=2,Name="verified_phone_number"\}\]
```

This command produces no output.

For more information, see Updating user pool configuration in the *Amazon Cognito Developer Guide*.

- For API details, see UpdateUserPool in *Amazon CLI Command Reference*.

`verify-software-token`

The following code example shows how to use `verify-software-token`.

Amazon CLI

To confirm registration of a TOTP authenticator

The following `verify-software-token` example completes TOTP registration for the current user.

```
aws cognito-idp verify-software-token \
    --access-token eyJra456defEXAMPLE \
    --user-code 123456
```

Output:

```
{
    "Status": "SUCCESS"
}
```

For more information, see Adding MFA to a user pool in the *Amazon Cognito Developer Guide*.

- For API details, see VerifySoftwareToken in *Amazon CLI Command Reference*.

`verify-user-attribute`

The following code example shows how to use `verify-user-attribute`.

Amazon CLI

To verify an attribute change

The following `verify-user-attribute` example verifies a change to the current user's email attribute.

```
aws cognito-idp verify-user-attribute \
    --access-token eyJra456defEXAMPLE \
    --attribute-name email \
    --code 123456
```

For more information, see Configuring email or phone verification in the *Amazon Cognito Developer Guide*.

- For API details, see VerifyUserAttribute in *Amazon CLI Command Reference*.

Amazon Comprehend examples using Amazon CLI

The following code examples show you how to perform actions and implement common scenarios by using the Amazon Command Line Interface with Amazon Comprehend.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

- Actions

Actions

`batch-detect-dominant-language`

The following code example shows how to use `batch-detect-dominant-language`.

Amazon CLI

To detect the dominant language of multiple input texts

The following `batch-detect-dominant-language` example analyzes multiple input texts and returns the dominant language of each. The pre-trained models confidence score is also output for each prediction.

```
aws comprehend batch-detect-dominant-language \
    --text-list "Physics is the natural science that involves the study of matter
 and its motion and behavior through space and time, along with related concepts
 such as energy and force."
```

Output:

```
{
    "ResultList": [
        {
            "Index": 0,
            "Languages": [
                {
                    "LanguageCode": "en",
                    "Score": 0.9986501932144165
                }
            ]
        }
    ],
    "ErrorList": []
}
```

For more information, see Dominant Language in the *Amazon Comprehend Developer Guide*.

- For API details, see BatchDetectDominantLanguage in *Amazon CLI Command Reference*.

batch-detect-entities

The following code example shows how to use `batch-detect-entities`.

Amazon CLI

To detect entities from multiple input texts

The following `batch-detect-entities` example analyzes multiple input texts and returns the named entities of each. The pre-trained model's confidence score is also output for each prediction.

```
aws comprehend batch-detect-entities \
    --language-code en \
    --text-list "Dear Jane, Your AnyCompany Financial Services LLC credit card account 1111-XXXX-1111-XXXX has a minimum payment of $24.53 that is due by July 31st." "Please send customer feedback to Sunshine Spa, 123 Main St, Anywhere or to Alice at AnySpa@example.com."
```

Output:

```

`batch-detect-key-phrases`

The following code example shows how to use `batch-detect-key-phrases`.

Amazon CLI

To detect key phrases of multiple text inputs

The following `batch-detect-key-phrases` example analyzes multiple input texts and returns the key noun phrases of each. The pre-trained model's confidence score for each prediction is also output.

```
aws comprehend batch-detect-key-phrases \
    --language-code en \
    --text-list "Hello Zhang Wei, I am John, writing to you about the trip for
 next Saturday." "Dear Jane, Your AnyCompany Financial Services LLC credit card
 account 1111-XXXX-1111-XXXX has a minimum payment of $24.53 that is due by July
 31st." "Please send customer feedback to Sunshine Spa, 123 Main St, Anywhere or to
 Alice at AnySpa@example.com."
```

Output:

```

`batch-detect-targeted-sentiment`

The following code example shows how to use `batch-detect-targeted-sentiment`.

Amazon CLI

To detect the sentiment and each named entity for multiple input texts

The following `batch-detect-targeted-sentiment` example analyzes multiple input texts and returns the named entities along with the prevailing sentiment attached to each entity. The pre-trained model's confidence score is also output for each prediction.

```
aws comprehend batch-detect-targeted-sentiment \
    --language-code en \
    --text-list "That movie was really boring, the original was way more
 entertaining" "The trail is extra beautiful today." "My meal was just okay."
```

Output:

```

`classify-document`

The following code example shows how to use `classify-document`.

Amazon CLI

To classify document with model-specific endpoint

The following `classify-document` example classifies a document with an endpoint of a custom model. The model in this example was trained on a dataset containing sms messages labeled as spam or non-spam, or, "ham".

```
aws comprehend classify-document \
    --endpoint-arn arn:aws:comprehend:us-west-2:111122223333:document-classifier-endpoint/example-classifier-endpoint \
    --text "CONGRATULATIONS! TXT 1235550100 to win $5000"
```

Output:

```
{
    "Classes": [
        {
            "Name": "spam",
            "Score": 0.9998599290847778
        },
        {
            "Name": "ham",
            "Score": 0.00014001205272506922
        }
    ]
}
```

For more information, see Custom Classification in the *Amazon Comprehend Developer Guide*.

`contains-pii-entities`

The following code example shows how to use `contains-pii-entities`.

Amazon CLI

To analyze the input text for the presence of PII information

The following `contains-pii-entities` example analyzes the input text for the presence of personally identifiable information (PII) and returns the labels of identified PII entity types such as name, address, bank account number, or phone number.

```
aws comprehend contains-pii-entities \
    --language-code en \
    --text "Hello Zhang Wei, I am John. Your AnyCompany Financial Services, LLC
 credit card
       account 1111-XXXX-1111-XXXX has a minimum payment of $24.53 that is due by
 July 31st. Based on your autopay settings,
       we will withdraw your payment on the due date from your bank account number
 XXXXXX1111 with the routing number XXXXX0000.
       Customer feedback for Sunshine Spa, 100 Main St, Anywhere. Send comments to
 Alice at AnySpa@example.com."
```

Output:

```
{
    "Labels": [
        {
            "Name": "NAME",
            "Score": 1.0
        },
        {
            "Name": "EMAIL",
            "Score": 1.0
        },
        {
            "Name": "BANK_ACCOUNT_NUMBER",
            "Score": 0.9995794296264648
        },
        {
```

```
            "Name": "BANK_ROUTING",
            "Score": 0.9173126816749573
        },
        {
            "Name": "CREDIT_DEBIT_NUMBER",
            "Score": 1.0
        }
}
```

For more information, see Personally Identifiable Information (PII) in the *Amazon Comprehend Developer Guide*.

- For API details, see ContainsPiiEntities in *Amazon CLI Command Reference*.

`create-dataset`

The following code example shows how to use `create-dataset`.

Amazon CLI

To create a flywheel dataset

The following `create-dataset` example creates a dataset for a flywheel. This dataset will be used as additional training data as specified by the `--dataset-type` tag.

```
aws comprehend create-dataset \
    --flywheel-arn arn:aws:comprehend:us-west-2:111122223333:flywheel/flywheel-entity \
    --dataset-name example-dataset \
    --dataset-type "TRAIN" \
    --input-data-config file://inputConfig.json
```

Contents of `file://inputConfig.json`:

```
{
    "DataFormat": "COMPREHEND_CSV",
    "DocumentClassifierInputDataConfig": {
        "S3Uri": "s3://amzn-s3-demo-bucket/training-data.csv"
    }
}
```

Output:

```
{
    "DatasetArn": "arn:aws:comprehend:us-west-2:111122223333:flywheel/flywheel-
entity/dataset/example-dataset"
}
```

For more information, see Flywheel Overview in *Amazon Comprehend Developer Guide*.

- For API details, see CreateDataset in *Amazon CLI Command Reference*.

`create-document-classifier`

The following code example shows how to use `create-document-classifier`.

Amazon CLI

To create a document classifier to categorize documents

The following `create-document-classifier` example begins the training process for a document classifier model. The training data file, `training.csv`, is located at the `--input-data-config` tag. `training.csv` is a two column document where the labels, or, classifications are provided in the first column and the documents are provided in the second column.

```
aws comprehend create-document-classifier \
    --document-classifier-name example-classifier \
    --data-access-arn arn:aws:comprehend:us-west-2:111122223333:pii-entities-
detection-job/123456abcdeb0e11022f22a11EXAMPLE \
    --input-data-config "S3Uri=s3://amzn-s3-demo-bucket/" \
    --language-code en
```

Output:

```
{
    "DocumentClassifierArn": "arn:aws:comprehend:us-west-2:111122223333:document-
classifier/example-classifier"
}
```

For more information, see Custom Classification in the *Amazon Comprehend Developer Guide*.

- For API details, see CreateDocumentClassifier in *Amazon CLI Command Reference*.

`create-endpoint`

The following code example shows how to use `create-endpoint`.

Amazon CLI

To create an endpoint for a custom model

The following `create-endpoint` example creates an endpoint for synchronous inference for a previously trained custom model.

```
aws comprehend create-endpoint \
    --endpoint-name example-classifier-endpoint-1 \
    --model-arn arn:aws:comprehend:us-west-2:111122223333:document-classifier/
example-classifier \
    --desired-inference-units 1
```

Output:

```
{
    "EndpointArn": "arn:aws:comprehend:us-west-2:111122223333:document-classifier-
endpoint/example-classifier-endpoint-1"
}
```

For more information, see Managing Amazon Comprehend endpoints in the *Amazon Comprehend Developer Guide*.

- For API details, see CreateEndpoint in *Amazon CLI Command Reference*.

`create-entity-recognizer`

The following code example shows how to use `create-entity-recognizer`.

Amazon CLI

To create a custom entity recognizer

The following `create-entity-recognizer` example begins the training process for a custom entity recognizer model. This example uses a CSV file containing training documents, `raw_text.csv`, and a CSV entity list, `entity_list.csv` to train the model. `entity-list.csv` contains the following columns: text and type.

```
aws comprehend create-entity-recognizer \
    --recognizer-name example-entity-recognizer
    --data-access-role-arn arn:aws:iam::111122223333:role/service-role/
AmazonComprehendServiceRole-example-role \
    --input-data-config "EntityTypes=[{Type=DEVICE}],Documents={S3Uri=s3://amzn-s3-
demo-bucket/trainingdata/raw_text.csv},EntityList={S3Uri=s3://amzn-s3-demo-bucket/
trainingdata/entity_list.csv}"
    --language-code en
```

Output:

```
{
    "EntityRecognizerArn": "arn:aws:comprehend:us-west-2:111122223333:example-
entity-recognizer/entityrecognizer1"
}
```

For more information, see Custom entity recognition in the *Amazon Comprehend Developer Guide*.

- For API details, see CreateEntityRecognizer in *Amazon CLI Command Reference*.

`create-flywheel`

The following code example shows how to use `create-flywheel`.

Amazon CLI

To create a flywheel

The following `create-flywheel` example creates a flywheel to orchestrate the ongoing training of either a document classification or entity recognition model. The flywheel in this example is created to manage an existing trained model specified by the `--active-model-arn` tag. When the flywheel is created, a data lake is created at the `--input-data-lake` tag.

```
aws comprehend create-flywheel \
    --flywheel-name example-flywheel \
    --active-model-arn arn:aws:comprehend:us-west-2:111122223333:document-
classifier/example-model/version/1 \
    --data-access-role-arn arn:aws:iam::111122223333:role/service-role/
AmazonComprehendServiceRole-example-role \
    --data-lake-s3-uri "s3://amzn-s3-demo-bucket"
```

Output:

```
{
    "FlywheelArn": "arn:aws:comprehend:us-west-2:111122223333:flywheel/example-
flywheel"
}
```

For more information, see Flywheel Overview in *Amazon Comprehend Developer Guide*.

- For API details, see CreateFlywheel in *Amazon CLI Command Reference*.

`delete-document-classifier`

The following code example shows how to use `delete-document-classifier`.

Amazon CLI

To delete a custom document classifier

The following `delete-document-classifier` example deletes a custom document classifier model.

```
aws comprehend delete-document-classifier \
    --document-classifier-arn arn:aws:comprehend:us-west-2:111122223333:document-
classifier/example-classifier-1
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the *Amazon Comprehend Developer Guide*.

- For API details, see DeleteDocumentClassifier in *Amazon CLI Command Reference*.

`delete-endpoint`

The following code example shows how to use `delete-endpoint`.

Amazon CLI

To delete an endpoint for a custom model

The following `delete-endpoint` example deletes a model-specific endpoint. All endpoints must be deleted in order for the model to be deleted.

```
aws comprehend delete-endpoint \
    --endpoint-arn arn:aws:comprehend:us-west-2:111122223333:document-classifier-endpoint/example-classifier-endpoint-1
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the *Amazon Comprehend Developer Guide*.

- For API details, see DeleteEndpoint in *Amazon CLI Command Reference*.

`delete-entity-recognizer`

The following code example shows how to use `delete-entity-recognizer`.

Amazon CLI

To delete a custom entity recognizer model

The following `delete-entity-recognizer` example deletes a custom entity recognizer model.

```
aws comprehend delete-entity-recognizer \
    --entity-recognizer-arn arn:aws:comprehend:us-west-2:111122223333:entity-recognizer/example-entity-recognizer-1
```

This command produces no output.

For more information, see Managing Amazon Comprehend endpoints in the *Amazon Comprehend Developer Guide*.

- For API details, see DeleteEntityRecognizer in *Amazon CLI Command Reference*.

`delete-flywheel`

The following code example shows how to use `delete-flywheel`.

Amazon CLI

To delete a flywheel

The following `delete-flywheel` example deletes a flywheel. The data lake or the model associated with the flywheel is not deleted.

```
aws comprehend delete-flywheel \
    --flywheel-arn arn:aws:comprehend:us-west-2:111122223333:flywheel/example-flywheel-1
```

This command produces no output.

For more information, see Flywheel overview in the *Amazon Comprehend Developer Guide*.

- For API details, see DeleteFlywheel in *Amazon CLI Command Reference*.

`delete-resource-policy`

The following code example shows how to use `delete-resource-policy`.

Amazon CLI

To delete a resource-based policy

The following `delete-resource-policy` example deletes a resource-based policy from an Amazon Comprehend resource.

```
aws comprehend delete-resource-policy \
    --resource-arn arn:aws:comprehend:us-west-2:111122223333:document-classifier/example-classifier-1/version/1
```

This command produces no output.

For more information, see Copying custom models between Amazon accounts in the *Amazon Comprehend Developer Guide*.

- For API details, see DeleteResourcePolicy in *Amazon CLI Command Reference*.

`describe-dataset`

The following code example shows how to use `describe-dataset`.

Amazon CLI

To describe a flywheel dataset

The following `describe-dataset` example gets the properties of a flywheel dataset.

```
aws comprehend describe-dataset \
    --dataset-arn arn:aws:comprehend:us-west-2:111122223333:flywheel/flywheel-entity/dataset/example-dataset
```

Output:

```
{
    "DatasetProperties": {
        "DatasetArn": "arn:aws:comprehend:us-west-2:111122223333:flywheel/flywheel-entity/dataset/example-dataset",
        "DatasetName": "example-dataset",
        "DatasetType": "TRAIN",
        "DatasetS3Uri": "s3://amzn-s3-demo-bucket/flywheel-entity/schemaVersion=1/12345678A123456Z/datasets/example-dataset/20230616T203710Z/",
        "Status": "CREATING",
        "CreationTime": "2023-06-16T20:37:10.400000+00:00"
    }
}
```

For more information, see Flywheel Overview in *Amazon Comprehend Developer Guide*.

- For API details, see DescribeDataset in *Amazon CLI Command Reference*.

`describe-document-classification-job`

The following code example shows how to use `describe-document-classification-job`.

Amazon CLI

To describe a document classification job

The following `describe-document-classification-job` example gets the properties of an asynchronous document classification job.

```
aws comprehend describe-document-classification-job \
    --job-id 123456abcdeb0e11022f22a11EXAMPLE
```

Output:

```
{
    "DocumentClassificationJobProperties": {
        "JobId": "123456abcdeb0e11022f22a11EXAMPLE",
        "JobArn": "arn:aws:comprehend:us-west-2:111122223333:document-
classification-job/123456abcdeb0e11022f22a11EXAMPLE",
        "JobName": "exampleclassificationjob",
        "JobStatus": "COMPLETED",
        "SubmitTime": "2023-06-14T17:09:51.788000+00:00",
        "EndTime": "2023-06-14T17:15:58.582000+00:00",

west-2:111122223333:document-classifier/mymodel/version/1",
        "InputDataConfig": {
            "S3Uri": "s3://amzn-s3-demo-bucket/jobdata/",
            "InputFormat": "ONE_DOC_PER_LINE"
        },
        "OutputDataConfig": {
            "S3Uri": "s3://amzn-s3-demo-destination-bucket/testfolder/111122223333-
CLN-123456abcdeb0e11022f22a11EXAMPLE/output/output.tar.gz"
        },
        "DataAccessRoleArn": "arn:aws:iam::111122223333:role/service-role/
AmazonComprehendServiceRole-servicerole"
    }
}
```

For more information, see Custom Classification in the *Amazon Comprehend Developer Guide*.

- For API details, see DescribeDocumentClassificationJob in *Amazon CLI Command Reference*.

`describe-document-classifier`

The following code example shows how to use `describe-document-classifier`.

Amazon CLI

To describe a document classifier

The following `describe-document-classifier` example gets the properties of a custom document classifier model.

```
aws comprehend describe-document-classifier \
    --document-classifier-arn arn:aws:comprehend:us-west-2:111122223333:document-
classifier/example-classifier-1
```

Output:

For more information, see Creating and managing custom models in the *Amazon Comprehend Developer Guide*.

- For API details, see DescribeDocumentClassifier in *Amazon CLI Command Reference*.

`describe-dominant-language-detection-job`

The following code example shows how to use `describe-dominant-language-detection-job`.

Amazon CLI

To describe a dominant language detection detection job.

The following `describe-dominant-language-detection-job` example gets the properties of an asynchronous dominant language detection job.

```
aws comprehend describe-dominant-language-detection-job \
    --job-id 123456abcdeb0e11022f22a11EXAMPLE
```

Output:

```
{
    "DominantLanguageDetectionJobProperties": {
        "JobId": "123456abcdeb0e11022f22a11EXAMPLE",

    }
}
```

For more information, see Async analysis for Amazon Comprehend insights in the *Amazon Comprehend Developer Guide*.

- For API details, see DescribeDominantLanguageDetectionJob in *Amazon CLI Command Reference*.

`describe-endpoint`

The following code example shows how to use `describe-endpoint`.

Amazon CLI

To describe a specific endpoint

The following `describe-endpoint` example gets the properties of a model-specific endpoint.

```
aws comprehend describe-endpoint \
    --endpoint-arn arn:aws:comprehend:us-west-2:111122223333:document-classifier-endpoint/example-classifier-endpoint
```

Output:

```
{
    "EndpointProperties": {
        "EndpointArn": "arn:aws:comprehend:us-west-2:111122223333:document-classifier-endpoint/example-classifier-endpoint,
        "Status": "IN_SERVICE",
        "ModelArn": "arn:aws:comprehend:us-west-2:111122223333:document-classifier/exampleclassifier1",

    }
}
```

For more information, see Managing Amazon Comprehend endpoints in the *Amazon Comprehend Developer Guide*.

- For API details, see DescribeEndpoint in *Amazon CLI Command Reference*.

`describe-entities-detection-job`

The following code example shows how to use `describe-entities-detection-job`.

Amazon CLI

To describe an entities detection job

The following `describe-entities-detection-job` example gets the properties of an asynchronous entities detection job.

```
aws comprehend describe-entities-detection-job \
    --job-id 123456abcdeb0e11022f22a11EXAMPLE
```

Output:

```
{
    "EntitiesDetectionJobProperties": {
        "JobId": "123456abcdeb0e11022f22a11EXAMPLE",
        "JobArn": "arn:aws:comprehend:us-west-2:111122223333:entities-detection-

        "InputDataConfig": {
            "S3Uri": "s3://amzn-s3-demo-bucket/AsyncBatchJobs/",
            "InputFormat": "ONE_DOC_PER_LINE"
        },
        "OutputDataConfig": {
            "S3Uri": "s3://amzn-s3-demo-bucket/thefolder/111122223333-
NER-123456abcdeb0e11022f22a11EXAMPLE/output/output.tar.gz"
        },
        "LanguageCode": "en",
        "DataAccessRoleArn": "arn:aws:iam::12345678012:role/service-role/
AmazonComprehendServiceRole-example-role"
    }
}
```

For more information, see Async analysis for Amazon Comprehend insights in the *Amazon Comprehend Developer Guide*.

- For API details, see DescribeEntitiesDetectionJob in *Amazon CLI Command Reference*.

`describe-entity-recognizer`

The following code example shows how to use `describe-entity-recognizer`.

Amazon CLI

To describe an entity recognizer

The following `describe-entity-recognizer` example gets the properties of a custom entity recognizer model.

```
aws comprehend describe-entity-recognizer \
    entity-recognizer-arn arn:aws:comprehend:us-west-2:111122223333:entity-recognizer/business-recongizer-1/version/1
```

Output:

```
{
    "EntityRecognizerProperties": {
        "EntityRecognizerArn": "arn:aws:comprehend:us-west-2:111122223333:entity-recognizer/business-recongizer-1/version/1",
        "LanguageCode": "en",
        "Status": "TRAINED",
        "SubmitTime": "2023-06-14T20:44:59.631000+00:00",
        "EndTime": "2023-06-14T20:59:19.532000+00:00",
        "TrainingStartTime": "2023-06-14T20:48:52.811000+00:00",

`describe-events-detection-job`

The following code example shows how to use `describe-events-detection-job`.

Amazon CLI

To describe an events detection job.

The following `describe-events-detection-job` example gets the properties of an asynchronous events detection job.

```
aws comprehend describe-events-detection-job \
    --job-id 123456abcdeb0e11022f22a11EXAMPLE
```

Output:

```
{
```

```
    "EventsDetectionJobProperties": {
        "JobId": "123456abcdeb0e11022f22a11EXAMPLE",
        "JobArn": "arn:aws:comprehend:us-west-2:111122223333:events-detection-
job/123456abcdeb0e11022f22a11EXAMPLE",

`describe-flywheel-iteration`

The following code example shows how to use `describe-flywheel-iteration`.

Amazon CLI

To describe a flywheel iteration

The following `describe-flywheel-iteration` example gets the properties of a flywheel iteration.

```
aws comprehend describe-flywheel-iteration \
    --flywheel-arn arn:aws:comprehend:us-west-2:111122223333:flywheel/example-flywheel \
    --flywheel-iteration-id 20232222AEXAMPLE
```

Output:

```
{
    "FlywheelIterationProperties": {
        "FlywheelArn": "arn:aws:comprehend:us-west-2:111122223333:flywheel/flywheel-entity",
